Date	

Fill pipe should not be less than 2 in. pipe and should slant toward the tank. It should terminate outside the building at a point not less than 4 feet of any building opening at the same or lower level. Fill terminal should be closed tight and provided with a metal cover designed to prevent tampering.

Illustration I

Typical Underground Tank Installation

Illustration II

Typical Inside Tank Installation

BOILER ROOM AIR REQUIREMENTS

Tight boiler rooms shall have opening of not less than the area in square inches of broiler breeching to admit fresh air for burner operation.

WIRING AND CONTROLS

Wiring diagrams are furnished with each control and due to the many types of heating plants and methods of controlling the operation, a complete wiring diagram for each installation cannot be furnished in this pamphlet. Having the individual control diagrams, a competent electrician can make the proper hook-up. Local wiring codes and National Electrical Code, or Canadian Electrical Code, whichever applies, should be adhered to in all cases. A typical diagram is shown in Chart II.

Chart II

SPECIFICATIONS FOR FUEL (Commercial Standard CS 12-40)

Fuel oil not heavier than No. 2. A minimum flash of 110° F. and a maximum of 230° F. The pour point 20° C. Water and sediment not more than one-tenth of one percent. Distillation Temperature a minimum of 600° F. and a maximum of 675° F. at 90% Point of Recovery. The viscosity of the fuel at Saybolt Universal at 100° F.: Maximum of 45 seconds.

INSTALLATION REQUIREMENTS AND PERFORMANCE TESTS (When CS 75-42 Requirements Must Be Met)

INSTALLATION REQUIREMENTS:

Size—The burner shall be of adequate size for the boiler or furnace and the connected heating load as recorded on the oil burner certificate by the installer.

Certificate—Following installation of the burner, certain test data shall be obtained and recorded by the installer on the oil burner certificate to be placed with each oil burner installation. The

THE INSTALLATION OF THE BURNER SHALL BE IN ACCORDANCE WITH THE REGULATIONS OF AUTHORITIES HAVING JURISDICTION.

HEATING PLANT

Before installing this Oil Burner in a conversion (converting coal firing to oil firing) installation the heating system should be carefully inspected for defects and cleanliness, if proper performance is to be obtained. An oil burner is only a means of supplying heat to the fire box and from there the heating system must absorb and circulate the heat.

The flue passages and heat absorbing surfaces must be clean to assure maximum heat transfer to the furnace or boiler. Soot and fly ash act as insulators retarding the transfer of heat.

All doors, openings and cracks should be cemented air-tight to climinate air infiltration into the heating plant causing heating losses. Inspect smoke pipe and chimney for elimination of leaks and obstructions. Remove damper in smoke pipe and install a mechanical draft adjuster, same size as smoke pipe.

COMBUSTION CHAMBER

The purpose of a combustion chamber is to maintain a high flame temperature by reflecting the heat back into the flame. A high flame temperature assures greater combustion efficiency and lower stack losses. An insulating refractory type combustion chamber is recommended for use with this burner. This type attains maximum temperature rapidly to give the desired high flame temperature.

It is important to select and install the recommended size combustion chamber on a conversion job (See Chart I). The atomized oil must burn in suspension and the flame must not touch the sides or the bottom of the chamber or smoke will result. To eliminate the smoke, excess air will be required, resulting in high stack temperature and lower combustion efficiency.

CHART I

Rating	Nozzle Size	Onamber			Boiler Rating				Warm	B.T.U.	
NO.	Size	Round Dia.	Rectangular W. L.	Nozzle To Floor	Overall Height		s EDR Water	IBR Steam	Net Water	Air Furnace Size	Input

20	1.65 1.75 2.00	14 14 15	12 x 13 12 x 13 13 x 14	5 5 5 1/2	13 13 13 1/2	644 683 780	1031 1092 1250	413 437 500	660 700 800		235,000 245,000 280,000
30	2.50 3.00	17 18	14 x 16 15 x 17	5 1/2 6	14 14 1/2	975 1170	1562 1875	625 750	1000 1200	, ,	350,000 420,000

Install the combustion chamber in the heating plant so the end of the oil burner air tube can be set flush with the inside front wall of the chamber. The combustion chamber bottom should be made of refractory material to a depth of 1 to $1\frac{1}{2}$ inches. After the chamber has been set and oil burner installed on a conversion job we recommend the use of Expanded Mica for fill around the outside of the chamber and the sides of the heater. This is an excellent insulator and will pervent the transfer of heat from the combustion chamber to the lower portion of the heater.

CHIMNEY REQUIREMENTS

The chimney requirements for domestic oil burner installations are the same as used when the heater is coal-fired and in no case should they be smaller than 8 x 12 flue lining. All makers of heating equipment give the size and height of chimneys best suited to their units and when the heater is to be oil-fired these same dimensions should be maintained, as it is very essential that the products of combustion have ample smoke pipe and chimney volume in order that there will be no back draft or pressure in the heating plant. The excess draft can be readily controlled by the use of a barometric damper set into the smoke pipe. This damper shall be the same size as smoke pipe with full opening cut in the smoke pipe. The heater should have from .05 to .15 inches of water (as measured with a reputable draft gage) in the smoke pipe, depending on the size of the heater and amount of oil being used. Domestic installations up to 2½ gallons per hour should have .05 to .08 inches in the smoke pipe and .01 to .03 inches measured over the fire through a small opening in the front of the heater. Manual operated smoke pipe dampers shall be removed or locked in the opening position.

We recommend that the chimney size be as outlined in the catalog of the heater manufacturer and can assume no obligation if this is not carried out and the burner does not operate satisfactorily from lack of chimney draft.

TANKS AND PIPING

Local rules and regulations must be adhered to regarding tank and burner installation. For U.S.A. installations Underwriter's Laboratories Tank Specifications must be used.

If tank is buried outside, the pipe connections to it must be made with swing joints to prevent pipe breakage in case the tank settles. Inside tanks should not be located within 7 feet, horizontally, of any fire or flame.

All Pipe work and fittings must be air-tight and only high grade material used. Pipe lines should be run direct as possible, free of traps, out of the way, and if possible place lines beneath floor. Copper tubing is most desirable wherever possible. On gravity flow from inside tanks $\frac{3}{8}$ in. O.D. tubing is ample size for runs less than 50 feet, longer runs require $\frac{1}{2}$ in. O.D. tubing. On outside underground tanks where a suction lift is present use $\frac{1}{2}$ in. O.D. tubing.

On all installations requiring a suction lift, a return line must be run to properly handle any entrained air in the oil or system. Failure to do so will prevent satisfactory fuel pump operation. (See Fuel Unit Instruction Sheet).

Tank vent should not be less than 11/4 in. pipe size and should slant toward the tank. It should terminate outside the building at a point not less than 2 feet vertically or horizontally from any window or other building opening. Vent should be provided with weatherproof hood and should be sufficiently high to prevent snow and ice obstruction.

test shall cover the following points: CO: in the flue gas by analysis, draft, stack temperature, firing rate, and smoke. (Certificate packed with burner).

TEST DATA REQUIRED ON CERTIFICATE:

- (1) CO: in the flue gas by analysis shall not be less than 8 percent.
- (2) Drast—The drast shall be in accordance with specifications in the manufacturer's installation manual. An automatic drast regulator or its equivalent is required.
- (3) Stack Temperature—The stack temperature shall be measured on the boiler side of automatic draft regulator and not more than 12 inches from the boiler smoke connection. The stack temperature shall be measured at the certified firing rate. If an automatic draft regulator is built into the boiler of furnace such regulator shall be closed when the stack temperature is measured.
- (4) Firing Rate—The firing rate shall be based on the burner manufacturer's recommendation for the existing total connected load. Burner shall be fired at that rate as a minimum, but not to exceed 25 percent additional for the maximum rate.
- (5) Smoke-During the above test, there shall be no visible smoke at the chimney.
- (6) Installation Manual—The burner shall be installed in accordance with manufacturer's manual.

INSTALLATION TEST PROCEDURE:

Equipment—The following equipment shall be available on each oil burner installation before the tests are started:

- (a) Where the oil rate is not indicated on the nozzle tip, a suitable device for determining the rate in terms of gallons per hour fed to the burner shall be used. This may be in the form of a graduated glass vessel. Nozzle tips furnished with this burner are marked.
- (b) A suitable flue-gas analyzer for determining the percentage of CO2 in the flue gases.
- (c) A suitable draft gage, graduated in hundredths of an inch of water.
- (d) A suitable thermometer to indicate the flue-gas temperatures.
- (e) Provision for inserting a thermometer into the flue pipe as follows: Not more than 12 inches from the boiler or furnace outlet, measured on the center line of the flue pipe, there shall be a hole not more than ½ inch in diameter, located at the side of the pipe on the center line so that the thermometer may be inserted horizontally. The thermometer is to be placed so that the sensitive element is one-fourth of the pipe diameter from the near side of the flue pipe. The opening around the thermometer stem shall be sealed to prevent air leakage. The same opening may be used for checking draft and sampling flue gases.

NOTE: Other things being equal, flue-gas temperature may be expected to be higher by some 50° F. if the smoke pipe is insulated. Stack temperature is largely controlled by boiler design. High stack temperatures do not necessarily condemn the burner.

(f) In addition to the above, provision shall be made on the boiler or furnace for inscrting a small tube into the combustion chamber for measuring the draft. The area of the opening shall not exceed that of a ½ inch diameter round hole (¼ inch pipe tap).

TEST PROCEDURE: The test procedure is as follows:

- (a) The burner shall be operated and the fuel rate adjusted to that required for the particular installation.
- (b) The draft then shall be adjusted to meet the burner manufacturer's specifications both over the fire and at the breeching.
- (c) Combustion air adjustments are to be made to give the highest CO² without visible smoke (unburned carbon) at the chimney. If the minimum required percentage of CO² cannot be obtained in the breeching it will be permissible to take CO² over the fire, which will be acceptable. In that event, both CO² readings shall be recorded on the certificate. A considerable difference between the two CO² readings indicate a leak of air into the flue passes of fire box of the boiler.
- (d) Stack temperature shall be recorded after 10 minutes of operation after reaching steaming temperature for steam boilers, or 180° F. water temperature for hot water boilers, or 125° F. bonnet temperature for hot-air heating plants.

READINGS: During the period of operation to permit flue-gas temperatures to reach maximum, periodic readings of draft, CO² and oil rate shall be taken and the average recorded on the certificate. All controls and limiting devices shall be checked for proper operation.

OIL BURNER GENERAL

These burners are furnished in several air delivery combinations to assure maximum combustion efficiency by proper air and oil ratios through the entire range of the burner from 0.60 GPH to 3.00 GPH Incl. for 60 cycle and 0.60 GPH to 2:50 GPH Incl. for 25 and 50 cycle units.

These various air delivery combinations are designated by a rating number which suffixes the model number of the burner. Only two burner parts are effected in covering the entire capacity range of the burner, namely: Air cone and baffle plate. See Chart III for the proper cone and plate diameter for the rating desired.

All burners are shipped with a 33% in. O.D. 4 in 1 multiple steel baffle plate which may be sized to the required diameter as spcified by Chart III for the firing rate in a specific installation. Baffle plate is sheared to provide 3 in., 21/2 in. and 2 in. O.D. diameters with segmented tie-in ribs. These tie-in ribs may be easily broken with pliers. Each ring should be broken off successively beginning with the outer ring until the desired baffle size is attained.

This model burner is furnished in three types, namely: Base Mounted (for conversion installations), Rigid Flange Mounting and Adjustable Flange Mounting. Air tubes are supplied in 6 in., 8 in., 10 in., 15 in., and 23 in. lengths to permit proper installation into the many types of heating plants. When burner is furnished as a part of an oil heating unit the proper type and air tube length will be supplied and may not necessarily conform to the above.

CHARTS III

60 Cycle					25 and 50 Cycle				
Rating No.	Rating Gal. Per Hr.	Air Cone Bore	Baffle Plate Dia.	Rating No.	Rating Gal. Per Hr.	Baffle Plate Dia.	Air Cone Bore

12	From .85 thru 1.25	2 1/4	3	2	From 1.00 thru 1.50	none	2 1/4		
15	From 1.00 thru 1.50	2 1/2	2 1/2	3	From 1.50 thru 2.00	2	3		
20	From 1.50 thru 2.25	3	2	4	From 2.00 thru 2.50	none	3		
30	From 2.25 thru 3.00	3	none						

NOTE: This chart normally covers conversion installations. For some types of oil-fired units the combinations shown do not apply, and in these cases a supplementary page is attached to this manual.

BURNER ADJUSTMENT

Removing Gun Assembly. Disconnect the oil line at the fan housing and remove lock nut on copper tube fitting. Remove transformer hold-down screw in upper left hand corner and swing transformer to right on hinge clips. Gun Assembly can now be removed through this opening.

BURNER NOZZLE

We recommend the use of 80-degree nozzles wherever possible but we realize that there are some boilers that this is not possible in which case other degree nozzles can be used. All nozzles shipped with oil burners will be 80-degree unless otherwise specified before shipping.

Check nozzle size as to conformance to installation requirements. Install nozzle by screwing into hexagon adaptor. In cleaning the nozzle, the rotor slots and orifice should not be touched by any material which will scratch or damage these surfaces. Toothpick or thin piece of wood will suffice. Clean screen with a solvent or hot water.

Nozzle Adaptor: This burner is equipped with a dribble-proof nozzle adaptor which will accomplish intended results only when installed with the stampted word "TOP" in the correct position.

Spacing of Electrodes: The electrodes should be spaced $\frac{1}{8}$ in. apart. They should extend $\frac{1}{8}$ in. beyond the end and $\frac{1}{2}$ in. above the center of the nozzle tip as shown in drawing below.

Gun Assembly Adjustment. The gun assembly can be adjusted in the slot in side of fan housing by loosening screw holding slot cover in position. Nozzle tip should ordinarily be located 5/8 inch behind the front face of the air cone. One-half inch forward adjustment is provided for use on larger rating when necessary.

Air Adjustment. The air intake is located on the left side of the blower housing and consists of two interlocking bands. To adjust, loosen screw in outer band and position band by rotating to the desired opening. Retighten screw after adjustment to assure permanent adjustment.

Sufficient air should be introduced into the fire until flame has a dark orange color. The screws should then be locked in position. After this has been set, check the top of the chimney on the outside. There should be a very slight haze, not smoke, coming out of the same. On a cold stack in extreme cold weather a white haze may come out of the chimney. This is due to the chilling of the gases and will correct itself as the chimney warms up. Any type of automatic fuel being burned in extreme cold weather will bring about the same chimney condition.

FUEL UNIT: See separate instruction sheet packed with burner.

MOTOR: Motor should be oiled at time of installation and twice during each heating season.

CHECKING INSTALLATION

After the installation has been completed and tank filled with oil, the piping should be checked for leaks. It is imperative that any indication of leaks be corrected, as an oil leak will give the house an unpleasant odor.

Adjustments made on the burner from the preceding paragraphs should be rechecked. Positive assurance must be made that the ignition and safety timing are working properly. The thermostat and furnacestat or boiler control should be checked for accuracy. Check the heating plant for leaks.

BURNER RECHECK

It is recommended that each installer make a practice of following up each installation after a period of two or three weeks for a through inspection and check to be sure the controls are properly set and working properly, that the burner is properly adjusted to a good CO² in the flue gases and that there are no oil leaks and that the fuel unit is set at 100 P.S.I. and nozzle cut-off is sharp, and electrodes properly set and are not collecting carbon or oil deposits, and that the nozzle is delivering a finely atomized well-shaped oil spray and is not causing electrode trouble by kicking back on the electrodes when cutting off. This kick-back of a faulty nozzle can be the source of trouble later on if not corrected. All defective nozzles should be discarded and new ones used unless you have proper facilities for reconditioning them.

DIRECTIONS FOR THE OPERATION AND CARE OF

OIL BURNER

Read Instructions Carefully and Hang This Card Near Burner for Future Reference

(A) TO START BURNER:

- 1. Check for oil in the storage tank.
- 2. Fuses in the main switch must be good.
- 3. Have oil burner switch open.
- 4. Set room thermostat about 10 degrees higher than room temperature to make sure the thermostat contacts are made. Limit control must be set high enough to make contact also.
- Oil valve at the tank should be open and the check valve in return line properly installed so oil can return to tank.
- 6. Be sure nozzle of proper size for heater is in the adapter and tightly screwed down, and that the electrodes are properly spaced (See Manual). With heating plant door open, close the burner switch; and if wiring is properly done and all controls properly installed and adjusted, the burner should start. If not, check primary relay first to be sure it is properly set; and if burner does not start, recheck wiring and all controls thoroughly.
- 7. If burner is installed with a single oil line, the fuel unit will have to be purged of the entrapped air in the oil lines and fuel unit before the oil will flow to the nozzle (See fuel unit instruction sheet for this operation). If a return line is used, purging will not be necessary, although this will speed the starting of the burner if done. If this is done, the pump should pick up its oil in less than a minute (which is the setting for the lockout switch in the primary control). If ignition does not take place during this time, check the nozzle and electrodes.

STARTING BURNER AFTER IGNITION FAILURE.

- Do not attempt to restart burner when excess oil has accumulated, when heating unit is full of vapors, or when the combustion chamber is very hot.
- Press reset button on primary control and burner should start. Do not attempt this more than twice. If burner fails to operate call serviceman.
- (B) FUEL OIL SPECIFICATIONS:
- 1. This burner is approved for oil not heavier than No. 2 The commercial standards for this oil are: Flash 110°

minimum or legs!; Maximum 230°F; Pour point 20°F; Water and sediment not more than 0.1%; Distillation temperature 500°F maximum and 575°F maximum at 90% of recovery. Viscosity at 100°F Saybolt Universal of 40 seconds maximum.

DO NOT USE GASOLINE, CRANKCASE OIL, OR ANY OIL CONTAINING GASOLINE.

- (C) LUBRICATION:
- The two oil cups on the oil burner motor should be lubricated every three months with a few drops of good grade light motor oil, No. 10 or 20 S.A.E.
- (D) AT THE END OF THE HEATING SEASON:
- 1. Shut off electric current to burner at oil burner switch.
- If oil strainer has not been cleaned recently, it should be removed and cleaned (consult instructions card furnished with fuel unit).
- 3. Oil storage tank should be kept filled to prevent water vapor from collecting. It is suggested the valve in the suction line be closed and oil burner switch opened. Oil storage tank should be cleaned every 2 or 3 years to remove any sediment or water that has collected in the tank. Your Fuel Oil Dealer has the equipment to do this.
- (E) AT THE START OF THE HEATING SEASON:
- 1. It is advisable to have the Dealer inspect and service your butner for the coming hearing season.
- 2. Heating plant, smoke pipe and chimney should be cleaned and checked for repairs.
- 3. Lubricate burner as directed under "C" above.
- 4. It is advisable to have the entire electrical system inspected before putting the burner into operation after it has been standing idle for the summer months. This should include primary relay, limit control, thermostat (clean dust from contact points), and check the electrodes for carbon and cracks in insulators, and corrosion on all terminals of the electrodes and transformer.
- (F) EMERGENCY STOPS:
- 1. CUT OFF ALL CURRENT TO THE BURNER BY MOVING LEVER ON THE OIL BURNER ELECTRIC SWITCH TO THE "OFF" POSITION.

CAUTION

- Check the gauge in oil storage tank periodically. Keep tank filled.
- Don't attempt to burn garbage or refuse in your heating unit.
- 3. Don't fill storage tank while burner is operating.
- 4. Don't start burner if there is oil or vapor in the heating unit.
- 5. Don't attempt to burn crankcase drainings or crude oil.
- DON'T TAMPER WITH BURNER OR CONTROLS CALL YOUR SERVICEMAN.
