EFFECTS OF HYDROGEN FLUORIDE ON A LUNG TISSUE CULTURE. (Deystviye ftoristogo vodoroda na kul turu legochnoy tkani). Text in Russian. Scientific Research Inst. for Occupational Health and Occupational Diseases, Sverdlovsk (USSR), Flyuroz Ego Profil., Mater. Simp. 1966, p. 94-9. The lung tissue culture from animals exposed to an atmosphere containing hydrogen fluoride was cultivated in a medium consisting of 0.5% lactalbumin, ox serum, and antibiotics. Five months of intoxication of the experimental animals with HF of a 3.0 mg/sq m concentration resulted in intense slow down of cell migration and it completely stopped cell growth and mitotic processes in lung tissue cultures. An 0.5 mg/sq m concentration slowed down growth and mitosis of lung cells to a much lesser degree, but even this concentration, which is the maximum permissible HF concentration in the atmosphere of industrial production plants, did not prove to be harmless for organism. Cultivation of lung tissue is considered a sensitive test suitable for investigations of the threshold concentrations and mechanisms of the effect of some harmful atmospheric substances.

TOXICOLOGICAL CHARACTERISTICS OF FLUORINE DURING ITS SIMULTANEOUS ENTRANCE INTO AN ORGANISM ALONG WITH DRINKING WATER AND INHALED AIR. (Toksikologicheskaya kharakteristika ftora pri odnovremennom postuplenii ego v organizm s pit evoy vodoy i vdykhaemym vozdukhom) Text in Russian. Scientific Research Inst. for Occupational Health and Occupational Diseases, Sverdlovsk (USSR), Flyuroz Ego Profil., Mater. Simp., 1966, p. 157-163. The experimental animals were exposed to an atmosphere containing 0.01 mg/sq m of hydrogen fluoride and to drinking water containing 0.2-1.5 mg/l of fluorine. The inhalation of fluorine in this concentration emphasized toxic effect of fluorine in drinking water. Changes in motoric chronaxie and increase of fluorine content in urea were observed in studied animals. Accumulation of fluorine in the skeleton, teeth, and bone tissue were found, as well as morphological changes in the cortex of main brain and liver. On the basis of the study, the maximum permitted concentration of fluorine in drinking water in inhabited areas near industrial plants emitting fluorine

<xref image="2000WVI7.TIF|V3|2006:09:28:01:33:06.00|122709|0"> image: </xref>

compounds was suggested not to exceed 0.5 mg/l. Since further reduction of fluorine content in drinking water is not biologically expedient, the harmful combined effect of fluorine on an organisms has to be prevented by reduction of its content in the atmosphere. Thus, the study indicates the urgency of solving the problem of purification of industrial effluents containing fluorine.

TOXICOLOGICAL CHARACTERISTICS OF SODIUM FLUORIDE DURING ITS INHALATION INTO AN ORGANISM. (Ktoksikologicheskoy kharakteristike ftoristogo natriya pri ingahatsionnom postuplenii ego v organism). Text in Russian. Scientific Research Inst. for Occupational Health and Occupational Diseases, Sverdlovsk (USSR), Flyuoroz Ego Profit., Mater. Simp., 1966, p. 113-122. 4 refs.

Sodium fluoride has high solubility in biological media. During the chronic intoxication of experimental animals by inhalation of NaF, an 0.03-0.1 mg/sq m concentration had a toxic effect and cause accumulation of fluorine in bone tissue of animals. The toxic effect of a NaF concentration of 0.1 mg/sq m was manifested in retardation of the central nervous system, inhibition of blood cholinesterase and alkaline phosphatase activity, blocking of mercaptan groups in liver, and histomorphologic changes of the large brain, lungs, and liver. In 0.03 mg/sq m of NaF, increases in motoric chronaxie and decreases in blood cholinesterase and alkaline phosphatase activity were observed, but internal organs were not affected. Because of the neutral character of NaF and because of the incomplete absorption of its dust in the course of its entry into an organism through respiration organs, the degree of its toxic effect is much lower than that of analogic concentrations of hydrogen fluoride. The average daily maximum allowed concentration in the atmosphere of easily soluble fluorides should not exceed 0.01 mg/sq m.

TOXICOLOGICAL CHARACTERISTICS OF POORLY SOLUBLE FLUORIDES AND THE EFFECT OF THEIR INHALATION ON AN ORGANISM. (Toksikologicheskaya kharakteristika plokhro rastvorimyykh ftoristykh soley pri ingalatsionnom vozdeystvii na organism). Text in Russian. Scientific Research Inst. for Occupational Health and Occupational Diseases, Sverdlovsk (USSR), Flyuoroz Ego Profil., Mater. Simp., 1966, p. 123-130.

The toxic effect of the inhalation of fluorides, which are poorly soluble in biologic media, on an animal was investigated. The experimental animals were exposed to atmosphere containing finely dispersed aluminum fluoride dust in a 0.03-0.1 mg/sq m concentration for five months. Slight changes were observed in animals motoric chronaxie. Inhibition of blood cholinesterase and alkaline phosphatase and changes in the liver were observed at 0.1 mg/sq m. Fluorine content in urea was increased. The AlF₃ was expelled from the organism mainly through the intestines. The degree of fluorine accumulation in bones was much lower than in the case of hydrogen fluoride or sodium fluoride inhalation. Also all changes observed during AlF₃ inhalation were much weaker than those caused by HF and NaF inhalation. A comparison of the toxic effect of various fluorides shows decreasing toxicity from gaseous HF, to fluorides well soluble in biological media (NaF), to fluorides poorly soluble in biological liquids (like AlF₃). The average daily maximum permissible concentration of the last should be 0.03 mg/sq m.

Florentin, D.

THE DANGER OF CHEMICAL AIR POLLUTION IN CITIES.

THE REMEDIES. (Le danger des pollutions chimiques de 1 air des villes. Les Remedies). Text in French. Ann. Hyg. Pub., Ind. Sociale, 29(11): 209-219, 1951. 13 refs.

The most prominent and dangerous air pollutants are reviewed, starting with sulfur dioxide which is emitted into the air from industrial and domestic ovens where coal, coke, or petroleum type oil is used as fuel. Some chemical and metallurgical factories also emit significant quantities of this gas. An estimate made in 1943 indicates, as a worldwide total, an emission of 37 million tons of sulfur, equivalent to 74 million tons of SO₂. Through the effect of ultraviolet rays, SO₂ is transformed into SO₃, and the latter then to sulfuric acid which has a corrosive effect on masonry. The SO₂ itself is damaging to vegetation, and in greater concentrations, such as 35 to 50 ppm, to the human respiratory organs, particularly when contained in fog formations. Another important pollutant is carbon monoxide, a product of incomplete combustion of carbon. The principal sources are exhaust gases from automotive vehicles, and the emission through chimneys from certain industrial and domestic types of incineration. This gas is particularly dangerous for the human organism, since it combines with the hemoglobin of the blood and thus impedes the transport of oxygen by the blood stream. Carbon dioxide is far less dangerous than CO, but can have ill effects when accumulated in confined spaces due to extended exhalation without renewal of fresh air. Nitric oxides, emanating from some chemical operations, attack metals. Hydrofluoric acid is a very toxic compound. Sources for its emission can be phosphate plants, aluminum works, and iron foundries. Dust in its various forms and compositions can be damaging to the human lung, if the particle size permits penetration into the alveoli.

ACUTE INHALATION TOXICITY OF BERYLLIUM. II. THE ENHANCING EFFECT OF THE INHALATION OF HYDROGEN FLUORIDE VAPOR ON BERYLLIUM

SULFATE POISONING IN ANIMALS. Arch. Ind. Hyg. Occupational Med., 1(4):398-410, 1950. 11 refs.

In a study conducted to determine whether hydrogen fluoride has a potentiating effect on beryllium poisoning by inhalation, 80 albino male rats were exposed for one month in groups of 10 and 20 each to beryllium sulfate mist (9 mg/cu m), to hydrogen fluoride vapor (8 mg/cu m), or to both agents in alternating daily exposures. By the 21st day of exposure, identical mortality rates of 40% had occurred in the group exposed to the two agents alternately and in the group exposed to beryllium sulfate alone. The same two groups were the only groups to show weights lower than preexposure levels. Pulmonary edema was noted only in these two groups and was as marked in rats dying from inhalation of both agents as in those dying from inhalation of beryllium alone. Alternate inhalation of hydrogen fluoride vapors and beryllium sulfate mist led to a 1.3-fold increase in the fluoride content of all hard tissue analyzed over that for animals exposed to hydrogen fluoride alone. These results are a clear demonstration that hydrogen fluoride enhances the poisonous action of beryllium.

Stokinger, Herbert E., Charles J. Spiegl, Robert E. Root, Robert H. Hall, Luville T. Steadman, Catherine A. Stroud, James K. Scott, Frank A. Smith, and Dwight E. Gardner
ACUTE INHALATION TOXICITY OF BERYLLIUM. IV.
BERYLLIUM FLUORIDE AT EXPOSURE CONCENTRATIONS OF ONE AND TEN MILLIGRAMS PER CUBIC METER. Arch. Ind. Hyg. Occupational Med., 8(6):493-S06, Dec. 1953. 23 refs.

Pulmonary lesions were produced in animals exposed to beryllium fluoride mist at concentrations of 10 and 1 mg/cu m. These closely resemble the lung changes resulting from inhalation of beryllium sulfate. Beryllium fluoride is acutely more toxic than beryllium sulfate. Exposure to 1 mg BeF₂/cu m resulted in lung damage in cats, rabbits, and rats comparable in extent and degree to that produced by 10 mg of beryllium sulfate mist/cu m. Macrocytic anemia occurred in dogs and rabbits exposed to 1 mg BeF₂/cu m. The anemia was more severe than that observed after inhalation of beryllium oxide dust or beryllium sulfate mist. Urinary uric acid excretion can possibly serve as an index of the degree of exposure to beryllium. Beryllium tended to accumulate in the lungs, pulmonary lymph nodes, liver, skeleton, and bone marrow of dogs. The deposition rate in the lungs and lymph nodes increased with the duration of exposure. A greater proportion was distributed to the skeleton, liver, spleen, and kidney after inhalation of BeF₂ than occurred with beryllium oxide dust or beryllium sulfate mist in earlier studies. (Author summary modified)

Lindberg, Z. Ya.
EFFECT OF INSTANT MAXIMUM PERMISSIBLE CONCENTRATIONS OF SULFUR DIOXIDE AND HYDROGEN FLUORIDE WHEN SIMULTANEOUSLY PRESENT IN THE ATMOSPHERE. (Razovyye predel no dopustimyye kontsentratsii SO₂ i HF pri ikh sovместnom prisutstvii v atmosfernom vozdukh). Text in Russian. Riga Medical Inst. (USSR) Mater. Dokl. Nauch. Sess. Rizh. Med. Inst., 15th, 1967, p. 42-43. The biological effect of sulfur dioxide and hydrogen fluoride when both are present in the atmosphere at their maximum permissible concentration was studied. First the minimum permissible concentration of impurity sensed by olfactory organs of 17 studied people was determined. In case of most sensitive persons it was 1.6 and .04 mg/cu m SO₂ and HF, respectively. The indices of concentration of each mixture of HF and SO₂ were expressed as sum of fractions of their maximum permissible concentrations when only one is present. The lowest mixture concentration sensed by olfactory organs was a mixture characterizing complete summation of the effect of both components, its index being equal to one. Some atmospheric pollutants cause a change in light sensitivity of an eye, even if its concentration is lower than sensed by olfactory organs. Therefore, the reflex effect of above substances was studied by the adaptometric method. The changes in light sensitivity of the eye were observed for mixtures with a mixture concentration index equal to one. The data obtained indicate the summation of effect of SO₂ and HF when simultaneously present in the atmosphere.

Lindberg, Z. Ya.
EFFECT OF EFFLUENT FROM A SUPERPHOSPHATE PLANT ON WHOLE-BLOOD CHOLINESTERASE ACTIVITY IN ANIMALS EXPOSED UNDER NATURAL CONDITIONS. (Vliyaniye vybrosov superfosfatnogo zavoda na aktivnost tsel'noy krovi u eksperimental'nykh zhivotnykh, eksponirovannykh v natural'nykh usloviyakh). Text in Russian. Aktual. Voprosy Gig. Truda Prof. Patol., Mater. Konf., 1st, 1967, p. 236-238. Experimental animals rabbits and white rats, were kept for five months 1000 from a superphosphate plant at point of max-

imum atmospheric pollution with the wind blowing in that direction from the plant. The effect of emissions inhaled by the animals was studied; animals were fed by fodder grown in an unpolluted area or by fodder grown in the vicinity of the plant. During the observation, the average concentrations of sulfur dioxide, fluorine, sulfuric acid mist, and nitrogen oxides in the atmosphere were 2.8-6.4 times higher than the maximum permissible concentration. The determination of the activity of whole-blood cholinesterase was accepted as a sensitive test in study of effect of toxic substances on animals. The average daily concentrations of the above substances in the atmosphere in the vicinity of the superphosphate plant unfavorably effect organisms specifically, they increase the activity of cholinesterase.

Lindberg, Z. Ya.

EFFECT OF HYDROGEN FLUORIDE AND SULFUR DIOXIDE ON AN ORGANISM WHEN BOTH ARE PRESENT

SIMULTANEOUSLY. (Deystviye ftoristogo vodoroda i sernistogo gaza na organizm pri ikh sovместnom prisutstvii). Text in Russian. Scientific Research Inst. for Occupational Health and Occupational Diseases, Sverdlovsk USSR, Flyuroz Ego Profil., Mater. Symp., 1966, p. 131-138.

Experimental animals located 1000 m from a superphosphate plant were exposed to emissions for five months. The emissions entered the animals both orally and by inhalation. Maximum average fluorine concentration was .15 mg/cu m and sulfur dioxide concentration was .84 mg/cu m. The morphological composition of the blood changed with a decrease in erythrocytes, hemoglobin, sugar, calcium, phosphorous, and cholinesterase activity. Pathological changes in the lungs were also observed. Thus, a safety zone of 1000 m around the production plant is not enough. The combined effects of hydrogen fluoride and SO₂ on humans produced olfactory sensations and changes in the light sensitivity of the eyes. The maximum permissible concentration of the mixture expressed as a sum of fractions of maximum permissible concentrations of HF and SO₂ must not be more than one. White rats were subjected to three months chronic inhalation of HF and SO₂. Changes in motoric chronaxy, cholinesterase activity, and hemoglobin content were observed. Coproporphynn in the area of animals increased. Also, histologic changes in the lungs occurred. The simultaneous presence of HF and SO₂ in their maximum permissible individual concentrations is not permissible. The permissible level should be determined from the sum of their relative concentrations.

TOXICOLOGICAL CHARACTERISTICS OF HYDROGEN FLUORIDE DURING CONTINUOUS INHALATION BY

ANIMALS. (Toksikologicheskaya kharakteristika ftoristogo vodoroda pri kruglosutochnoy ingalatsioynoy zatravke zhivotnykh). Text in Russian. Scientific Research Inst. for Occupational Health and Occupational Diseases, Sverdlovsk (USSR), Flyuroz Ego Profil., Mater. Simp., 1966, p. 105-12.

Hydrogen fluoride a 0.03-0.1 mg/sq m concentration had a toxic effect during a continuous five-month intoxication of ex-

<xref image="2000WVI9.TIF|V3|2006:09:28:01:33:12.00|117997|0"> image: </xref>

perimental animals. It caused changes in functional condition of central nervous system of the animals and changes in their motoric chronaxy. Along with this, the accumulation of fluorine in teeth and bone tissue and development of specific diseases of teeth and bone tissue were observed. Concentration of 0.01 mg/sq m caused only changes in phosphorus-calcium exchange, observed by isotopic indication. This concentration is therefore considered threshold. The average daily maximum permissible HF concentration in the atmosphere of inhabited areas is suggested to be equal to 0.005 mg/sq m.

STUDIES ON THE HEALTH-DAMAGING EFFECT OF THE FLUORINE-POLLUTION OF THE AIR AROUND AN ALUMINUM FACTORY. (A levego fluorszennyezodesenek egeszseguyi hatasa az Inotai Aluminkoho kornyeken vegzett vizsgalatok alapjain). Text in Hungarian. Egeszsegtudomany, vol. 15:74-80, July 1971. 21 refs.

Children in the housing estate Varpalota-Inota were examined for the effects of fluorine pollution from a nearby aluminum foundry. The presence of fluorine in the urine of the children was demonstrated, in some cases at a level usually found in the urine of the foundry workers. In a fluorine-free control area, no fluorine could be demonstrated in urine from children. The hemoglobin level of the children at risk was low. A causal relationship between these findings and the fluorine pollution of air cannot be established because fluorine is only one of the air pollutions around Varpalota-Inota. Further investigations are in progress. (Author abstract modified)

Hall, Robert H., L. T. Steadman, Catherine A. Stroud, James K. Scott, F. A. Smith, and Herbert E. Stokinger

ACUTE TOXICITY OF INHALED BERYLLIUM. IV. STUDIES OF BERYLLIUM FLUORIDE AT CONCENTRATIONS OF 10 AND 1 MG/CU M. Rochester Univ., N. Y., Atomic Energy Project, Atomic Energy Commission Contract W-7401-eng-49, UR-177, 39p., July 17, 1951. 16 refs.

Pulmonary lesions were produced in animals exposed daily to beryllium fluoride mist at concentrations of 10 and 1 mg/cu m. These closely resembled the lung changes resulting from inhalation of beryllium sulfate. BeF₂ was more toxic than beryllium sulfate. Exposure to 1 mg/cu m BeF₂ resulted in lung damage in cats, dogs, rabbits, and rats roughly comparable in extent and degree to that produced by 10 mg/cu m of beryllium sulfate. Hematologic changes, suggestive of the development of macrocytic anemia, occurred in dogs and rabbits exposed to 1 mg/cu m BeF₂. The proportion of mature polymorphonuclear leukocytes decreased in the circulating blood. Beryllium tended to accumulate in the lungs, pulmonary lymph nodes, liver, skeleton, and bone marrow of dogs. The rate of deposition in the lungs and lymph nodes increased with the duration of exposure. Deposition in the skeleton was greater in all four species studied than in any other tissue except the lungs and lymph nodes. The evidence suggests that there are specific differences in the rate and manner in which inhaled BeF₂ is transported from the lungs to other tissues, or excreted in the urine or feces, in the four species studied. A considerably greater proportion was distributed to other tissues after inhalation of BeF₂ than was found in studies of insoluble beryllium oxide and soluble beryllium sulfate mist, possibly because BeF₂ is transported in the blood in the form of a soluble, diffusible complex containing one atom of fluorine/mol of beryllium. (Author summary modified)

THE PROBLEM OF PERMISSIBLE LIMITS OF POTENTIALLY TOXIC SUBSTANCES IN THE WORKING AND GENERAL ENVIRONMENT OF MODERN MAN. (Le probleme des limites admissible* pour les polluants de l'air).

Text in French. *Prod. Probl. Pharm.*, 26(8):530-548, Aug./Sept. 1971. 47 refs.

The effects of exposure to various pollutants on human health are examined to determine maximum allowable concentrations. Immediate and insidious toxic effects and long-range effects, including potential carcinogenicity, are reviewed and correlated with respective dosages to establish toxic tolerances and thresholds. The methodology for evaluating risks and the selection of adequate criteria are discussed. The concept of air quality standards is defined, and maximum allowable concentrations for chlorine, hydrogen chloride, ozone, sulfur dioxide, hydrogen sulfide, ammonia, hydrogen arsenide, n-butyl alcohol, butyl amine, sulfuric acid, chromic acid, zinc oxides, vanadium dusts and smokes, fluorides, beryllium, cadmium oxides, various aromatic hydrocarbons, and other dusts, gases, and vapors are listed. The complexity of urban air pollution, frequent chemical changes of the atmosphere due to certain environmental factors, and socio-economic considerations of applying air standards to general community air pollution are discussed.

THE FLUORESES. THEIR IMPORTANCE IN INDUSTRIAL AND ALIMENTARY HYGIENE. ANALYTICAL METHODS APPLICABLE TO THEIR STUDY. (Les fluoreses. Leur importance en hygiene industrielle et en hygiene alimentaire. Les methodes analytiques applicables a leur etude). Preprint. Paris Univ. (France), Faculty of Pharmacy, Translated from French, 77p.

A lexicological study of fluorine derivatives is presented. The principal compounds which pose an effect to health are indicated, as well as their distribution in nature and their principal industrial uses. Symptoms of exposure to the fluorine derivations are described, including acute and chronic intoxication. Analytical reactions of the fluorine ion are presented. Elimination of fluorosis is discussed.

GUIDES FOR SHORT-TERM EXPOSURES OF THE PUBLIC TO AIR POLLUTANTS. III. GUIDE FOR GASEOUS HYDROGEN FLUORIDE. National Academy of Sciences, National Research Council, Washington, D. C., Committee on Toxicology, Air Pollution Control Office Contract CPA 70-57, 15p., Aug. 1971. 16 refs. NTIS: PB 203465

The primary effect of acute exposure to gaseous hydrogen fluoride in concentrations above a few mg/cu m is irritation of the skin, eyes, and respiratory passages. In addition, localized tissue damage may occur as a result of the corrosive nature of this compound at concentrations above the recommended limits. Exposure to concentrations higher than 10 mg/cu m may lead to pulmonary edema and respiratory distress. This may be accompanied by gastroenteritis, with nausea, vomiting, abdominal burning, diarrhea, and collapse. Exposure to lethal concentrations produces muscular weakness and tremors, clonic convulsions, a drop in blood pressure, and moderate cyanosis; and death may result from sudden respiratory or cardiac arrest. Toxicity studies with animals are cited, as well as reported case of HF poisoning from accidental exposures in

<xref image="2000WVIA.TIF|V3|2006:09:28:01:33:16.00|117929|0"> image: </xref>

industrial environments. Plants are more susceptible to damage from gaseous HF than are animals, although among plant species there is a wide variation in tolerance. Cattle, sheep, and goats that feed on fluoride-contaminated forage may sicken and die from chronic fluoride poisoning, fluorosis. Atmospheric concentrations of HF are indicated, as well as the basis for setting limits for short-term and emergency exposure of the public to HF. Sources and physical-chemical properties of HF are cited.

35670

Sadilova, M. S., T. S. Egorova, and V. L. Vishnevskiy
REFLEX REACTIONS OF AN ORGANISM UNDER THE EFFECT OF HF, NaF AND AlF_3 . (Nekotoryye reflektornyye reaktsii organizma pri deystvii HF, NaF i AlF_3). Text in Russian. *Flyuoroz Ego Profil.*, Mater. Simp., 1966, p. 100-104. 2 refs.

The effect of hydrogen fluoride and its salts in the atmosphere on the sensitivity of the human eye was studied using an adaptometer. Participants in the experiment were placed in a completely darkened room. After 15 minutes of adaptation to darkness, air containing various concentrations of HF or its salts was introduced into the room. A diaphragm over the light spot kept open until noticed by the subject. Results are expressed in optical density. An increased sensitivity of eye to light was observed in the presence of studied materials in following concentrations: .03 mg/cu m HF, .05 mg/cu m NaF, and .3 mg/cu m AlF_3 . Thus, the maximum permissible concentrations recommended are, for HF, .02 mg/cu m; for NaF, .03 mg/cu m, and for AlF_3 , .2 mg/cu m.

36411

EFFECT OF HYDROGEN FLUORIDE ON INTEGRAL INDICES OF THE CONDITION OF ANIMALS. (Vliyaniye ftoristogo vodoroda na integral nyye pokazateli sostoyaniya organizma zhivotnykh). Text in Russian. Scientific Research Inst. for Occupational Health and Occupational Diseases, Sverdlovsk (USSR), *Flyuoroz Ego Profil.*, Mater. Simp., 1966, p. 81-89. The effect of hydrogen fluoride inhalation on the organism of white rats was studied during their exposure to HF atmosphere in a .1-3.0 mg/cu m concentration for five months for six hours daily. The composition of the peripheral blood of the animals was slightly effected by HF. In all studied cases, the tendency towards decrease in hemoglobin content was observed. The condition of central nervous system under HF inhalation was studied by method of conditioned reflexes and by chronaxymetry. It revealed the prevalence of inhibition of reflexes in the cortex of the large brain and disruption of motoric chronaxy.

Masironi, Roberto
TRACE ELEMENTS AND CARDIOVASCULAR DISEASES. *Bull. World Health Organ.* (Geneva), vol. 40:305-312, 1969. 82 refs. (Presented at the IAEA Panel Meeting on Activation Analysis in the Study of Mineral Element Metabolism in Man, Teheran, Iran, June 1968.) The relationship between trace elements and cardiovascular diseases was reviewed. The trace element that is studied most extensively in relation to cardiovascular diseases is cadmium, which appears to play a number of detrimental roles, particularly in relation to arterial hypertension. Further investigations are needed to ascertain whether this element really plays a role and to establish what mechanism is involved. Zinc concentrations in the air are reported to correlate strongly with death rates from hypertension and atherosclerosis, as cadmium does. Manganese also seems to play a role in atherosclerosis: it prevents the development of experimental atherosclerosis in rabbits and has a beneficial effect on lipid metabolism in

atherosclerotic patients. Another trace element that appears to exert a beneficial effect on atherosclerosis is chromium. Experiments in rats show that chromium deficiency is associated with a high prevalence of aortic plaques whereas a lifetime administration of this metal in trace amounts prevents the formation of atheromatous lesions, decreases the blood cholesterol level, and prolongs the life-span of the animals. The relationship of cobalt is not clear. Arsenic may cause myocardial necrosis both in animals and man. Vanadium reduces the cholesterol level in plasma and in the aorta of rabbits and in healthy humans. The rapid increase of nickel in the blood may perhaps be used as a diagnostic indicator of recent myocardial infarction. Silicon plays a functional role since it protects the elastic state of the artery walls and maintains the intima impermeable to lipid infiltration. Selenium, copper, and fluorine were also discussed.

Salazar, Antonio Ruiz and Alejandro Castanedo
PATHOLOGY IN PETROLEUM INDUSTRY. (Patologia de la Industria del Petroleo). Text in Spanish. Med. Deporte Trab., 18(128):S60-S81, 624-641, 647, 1953. 29 refs. (Presented at the Medicina del Trabajo, Congreso Americano, 11th, San Pablo, Brazil.)

Massive hydrogen sulfide poisoning was manifested in a workers camp situated in the vicinity of a natural gas refining plant in Poza Rica, Mexico. The raw natural gas contains 4.39% H₂S. Due to unusual meteorological conditions (temperature inversion), the H₂S from the refinery exhaust fumes did not dissipate in the upper atmospheric layers; accordingly, it contaminated the area and resulted in 330 cases of H₂S poisoning. Twenty-five patients died almost immediately and 45 others required hospitalization for 2-15 days; the others recovered following emergency treatment. The patients presented respiratory, circulatory, digestive, urinary, and central nervous system disorders. Histopathological examination (at autopsy) revealed alterations in the kidneys, liver, and lungs. In the alkylation department of a petroleum refinery there were 16 accidents due to contact with hydrofluoric acid (HF), nine instances of poisoning due to inhalation of HF, and one case of allergy to HF. Of 574 cases of lung tuberculosis in the Mexican petroleum industry, 117 were refinery workers, 121 were office workers, while the others were auxiliary personnel and oil field workers; however, the incidence of tuberculosis among petroleum industry workers does not seem to be higher than in the general Mexican population. Occupational pathology in the petroleum industry is reviewed extensively.

National Academy of Sciences - National Research Council,
Washington, D. C., Committee on Biologic Effects of
Atmospheric Pollutants
FLUORIDES. Washington, D. C., National Academy of
Sciences, 1971. 295p. 751 refs.

Severe effects of airborne fluoride on man, such as crippling fluorosis, have so far been observed only from long-term occupational exposures. Osteosclerosis, as evidenced by increased density to x-rays, may be associated with a concentration of about 6000 ppm of fluoride in bone. Analysis of urinary fluoride is recommended as a means of monitoring populations

<xref image="2000WVIB.TIF|V3|2006:09:28:01:33:18.00|116990|0"> image: </xref>

for possible excessive exposures to fluoride. The current threshold limit value for fluorine gas is 0.1 ppm v/v; for hydrogen fluoride, 3.0 ppm; and for particulate fluoride, 2.5 mg/cu m. Environmental sources and forms of fluoride are considered, as well as the fate and transformations of fluoride, its environmental analysis, and general aspects of its effects on living systems. In addition to human health effects, the effects of fluoride on vegetation and animals are considered. Recommendations for future research are made.

Sadilowa, M. S. and L. N. Jelmtschnych
EXPERIMENTAL TOXICOLOGIC VALUES FOR THE HYGIENIC ASSESSMENT OF LOW CONCENTRATIONS OF INORGANIC FLUORINE COMPOUNDS IN THE AIR. (Toxikologische Experimentalwerte zur hygienischen Einschätzung geringer Konzentration anorganischer Fluorverbindungen in der Luft). Text in German. Z. Ges. Hyg. Ihre Grenzgebiete (Berlin), 13(10):741-745, 1967. 3 refs.

The toxicity of fluorine compounds was investigated to determine maximum allowable concentrations. The severity of the toxic effects of different fluorine compounds depends on the concentration and solubility in the biological media. For biological aggressiveness, fluorine gases rank first, followed closely by fluorides, and then by hardly soluble fluorine salts. Unique and daily average maximum allowable concentrations were, therefore, established, respectively, at 0.02 and 0.005 mg/cu m for gaseous fluorine compounds, 0.03 and 0.01 mg/cu m for fluorides, and 0.2 and 0.03 mg/cu m for the hardly soluble salts.

Gerdes, R. A.
THE INFLUENCE OF ATMOSPHERIC HYDROGEN FLUORIDE ON THE FREQUENCY OF SEX-LINKED RECESSIVE LETHALS AND STERILITY IN DROSOPHILA MELANOGASTER. Fluoride, 4(1):25-29, Jan. 1971. 8 refs. (Presented at the Conference of the International Society of Fluoride Research, Annual, 3rd, Vienna, Austria, March 22-25, 1970.)

The influence of hydrogen fluoride as an atmospheric contaminant was investigated in the Oregon-r strain of *Drosophila melanogaster*. Two principle parameters of mutagenicity were used: sex-linked recessive lethals and sterility. The flies were exposed in fumigation chambers to 1.3, 2.9, or 4.3 ppm HF for three or six weeks. Sex-linked recessive mutation frequency increased at each level of sublethal concentration. The frequencies of sterility in both males and females increased with increased treatment level and treatment period. Genetic differences were observed in the response of the progeny of treated flies. The sex-linked recessive lethals indicated an effect on a specific chromosome; the increased sterility levels resulted from a broad effect on the genome as a whole. (Author abstract modified)

Steinegger, S.
HISTOLOGY OF CHIZZOLA MUCULAE. Fluoride, 5(1): 14-17, Jan. 1972. 4 refs.

In recent years, skin lesions resembling traumatic suffusions have occurred in epidemic proportion in two Italian cities located near aluminum and other fluoride-emitting factories: Chizzola and Bolzano. Morphologically, the lesions are round or oval in shape. They have reddish-brown color when they originate but change to a bluish-brown prior to their disappearance. As determined by skin biopsies on three children with characteristic maculae, pericapillary lymphocytic infiltration and proliferation of endothelial cells of capillaries are the principle pathological features of the lesions. These features suggest a toxic inflammatory process.

Balazova, G.

LONG TERM EFFECT OF FLUORIDE EMISSION UPON CHILDREN. Fluoride, 4(2):85-88, April 1971. 4 refs. (Presented at the International Society of Fluoride Research Conference, Annual, 3rd, Vienna, Austria, March 22-25, 1970.)

Five years after an aluminum smelter began operation, an 8-year study was initiated of the health status of 6- to 14-year-old children living in close proximity to the smelter. In the study area, the daily fluoride intake averaged 1.4 mg from food, 0.4-0.7 mg from air, and 0.1-31 mg/1 from water. In a control area, the daily F(-) intake from food was 0.8 mg. and that from air was negligible. No evidence of skeletal fluorosis was found in the exposed children. Nevertheless, the average hemoglobin decreased and the F(-) content of teeth, nails, hair, and urine increased in the children. In teeth, fluoride levels averaged 45.02 mg/100 g (450 ppm) of the original weight compared to 15.71 mg in controls. Nail fluoride levels were 20.9 mg/100 g (209 ppm) for the exposed children versus 14.3 mg/100 g (143 ppm) for the controls. The F(-) content of hair in the affected area averaged 1.6 mg/100 g (16 ppm) compared to 0.75 mg/100 g (7.5 ppm) in the control area. Urinary fluoride values were 0.8 ppm and 0.4 ppm, respectively for the exposed children and the controls. In the smelter area, the urinary excretion of F(-) was lower in the 12-14 age group than in children aged 6-11.

THE EFFECTS OF A PROLONGED INDUSTRIAL ATMOSPHERIC POLLUTION FROM FLUORINE ON CHILDREN S ORGANISM. (Der langfristige Einfluss von Fluoremissionen auf den Kinderorganismus). Text in German. Med. Lavoro (Milan), 62(4):202-207, April, 1971. 11 refs.

The effect of fluorine emissions from an aluminum factory on the health of children living near the plant was investigated after 8 yrs of plant operation. The absorption of fluorine through food and in the air was examined. The theoretical daily intake of fluorine should be 1.4 mg food and 0.4-0.7 mg from air; in the control zone, the absorption in food was 0.9 mg/day and was practically insignificant in air. The fluorine content of drinkable water in both the control and exposed areas was 0.1-0.3 mg/1. Although no signs of fluorosis detected, the fluorine content of teeth, nails, hair and urine of the children exposed to plant emissions was higher than that of controls. The average values for the exposed and control groups, respectively, were 45.02 and 15.7 mg/100 g in the teeth; 20.9 and 14.3 mg/100 g in the nails; 1.6 and 0.7 mg/100 g in the hair; and 0.8 and 0.4 mg/1 in the urine.

G. EFFECTS-HUMAN HEALTH

301

tions which revealed a radiation hazard in the fluorspar mines located in the area. Environmental surveys for determinations of dust and radiation concentrations were conducted as well as epidemiological studies of community and occupational mortality. Although free silica content was high in certain instances, the general degree of dustiness at the time of the survey was not alarming. Average dust concentrations were above the threshold limit value at seven underground and two surface locations. Average fluoride concentrations were well below the limit at each of the localities sampled. High relative concentrations of radon and radon daughters were determined in the working places. The environmental survey data and results of epidemiological studies are tabulated. Exposure to radon was pinpointed as the most important site-potentiating and cancer-inducing factor.

37795

FLUORIDE INTOXICATION IN HUMANS. Fluoride Quart. Repts., 4(3): 102-108, July 1971. 40 refs.

Fluoride enters the human system through ingestion with food and water, less through inhalation, and to an even more limited extent through the skin. In a nonfluoridated area, the estimated F(-) intake through food is 0.03-0.5 mg/day. In a fluoridated community, the daily intake by healthy indoor workers is 3/5 mg. Acute poisoning occurs following excessive inhalation or ingestion of F(-) compounds. The acute phase is of significance in evaluating health effects due to air and water pollution, since the acute abdominal pains associated with it are not uncommon during the chronic stage of the disease, probably due to temporary consumption of extraordinarily contaminated food or water. Chronic intoxication can be classified according to its major causes as follows: hydrofluorosis due to drinking water; industrial fluorosis; neighborhood fluorosis, which occurs in populations near F(-)-emitting industries; and alimentary fluorosis due to fluoride-containing food. The clinical picture of F(-) poisoning varies considerably from person to person because of wide differences in F(-) uptake, storage, and excretion. The dental and skeletal changes on which physicians usually depend for the diagnosis of chronic intoxication are not obligatory features of the disease.

EFFECT OF AIR POLLUTION CAUSED BY FLUORIDES ON HUMAN BODIES. (Fukkabutsu ni yoru taikiosen no jintai iii oyobosu eikyo ni (suite). Text in Japanese. Nippon Kosshu Eisei Zasshi (Japan. J. Public Health), 1S(10):428, 1971.

At the Naoetsu coastal factory area, an aluminum refinery with an annual product of about 150,000 tons has been in operation since May, 1963. The results of mass medical examinations conducted for the inhabitants of over 40 yrs old who had been living in the area within 1 km from this refinery for more than 5 yrs (Naoetsu area-708, Kubiki area-444, and control area-93, amounting to 1245 in total) are briefly reported here. For the investigation, examinations of subjective symptoms, general medical and dental examinations, respiratory function tests, and urine tests were conducted in Nov. 1970, and in March 1971, tests for basal metabolic rate, bone examinations by X-ray, electrocardiography and functional tests of blood and enzymes were carried out. The amount of urinary F was 0.574 ppm on the average in 62 people of controlled group, and with a screening standard of 1.2 ppm, the number of high excretors became 107; and it was significantly high in contaminated area. Proliferation or calcification of bone was also evident, but there was no areal difference, and there was no osteosclerosis nor spotted teeth. Findings in chest X-ray tests revealed a high rate of pulmonary fibrosis.

NOXIOUS EFFECTS OF Air POLLUTION. (Efectele Nocive ale impurificarii aerului). Text in Romanian. In: Protectia atmosferei impotriva impurificarii cu pulberi si gaze. Bucharest, Romania, Editura Technica, 1969, Chapt. 7-9, p. 130-183.

The mechanism of interaction between air pollutants and the respiratory tract is analyzed. Aerosols are categorized into toxic and nontoxic species and the indirect damaging of the latter as carriers for toxic substances is pointed out. The action of lead, fluorine, arsenic, beryllium, Manganese, and carcinogenic compounds is reviewed among the toxic aerosols. Included are discussions on the action of carbon monoxide, sulfur dioxide, nitrogen oxides, chlorine, hydrogen sulfide, and oxidant gases on the animal and plant organism. Reference is made to air pollution dwelling in metropolitan areas such as London, Los Angeles, or New York. Data illustrating morbidity and mortality due to chronic exposure to polluted environments are included. Discussions on economic damage from air pollution due to construction and other material deterioration are presented. The effect of air pollution on meteorology and solar radiation is also discussed.

Corn, Morton

DOSE TO THE RESPIRATORY TRACT FROM PERSONAL, OCCUPATIONAL AND COMMUNITY AIR POLLUTANTS.

Environ. Letters, 1(1):29-39, Jan. 1971. 8 refs. (Presented at the Pennsylvania Tuberculosis and Health Society, Annual Meeting, 78th, Pittsburgh, Pa., April 29, 1970.)

The doses (concentration-time) to the respiratory tract by urban, occupational and personal pollutants were calculated by assuming the pollutant concentrations in air equivalent to air quality standards, threshold limit values, and reported cigarette smoke concentrations, respectively. Urban pollution includes carbon monoxide, nitrogen oxides, lead, hydrocarbons, smoke, ash, sulfur dioxide, sulfuric acid, fluorine, beryllium, cadmium oxides, zinc oxides, pollens, allergens, and particulate matter from automotive, domestic, industrial, and natural sources; occupational pollution consists of dusts, fumes, gases, organic dusts, and radioactive particles within industries. The most severe challenge by a large margin was that posed to the pack-a-day cigarette smoker. Assumptions and results of calculations are presented. (Author abstract modified)

A STUDY ON THE EFFECTS OF Air POLLUTION DUE TO FLUORIDES ON HUMANS IN THE VICINITY OF MANUFACTURING FACTORY (1).

(Arumi kojo shuhen ni okeru fukukabutsu ni yoru taikiosen no seitai ni oyobosu eikyo ni kansuru chosa kenkyu (1)). Text in Japanese. Kankyo Hoken Reporto (Environ. Health Rept.), no 8:41-51 Jan. 1972.

Effects of fluorides on human and the results of epidemiological studies carried out in Japan, were described. Schoolchildren living near an aluminum factory in Japan were tested as to subjective symptoms, mottled teeth, lung ventilation, x-ray examination of the bones, and fluorine concentration in urine. The incidence of malaise was remarkably higher in schoolchildren from a polluted area. Many schoolchildren of the polluted

<xref image="2000WVID.TIF|V3|2006:09:28:01:33:26.00|123336|0"> image: </xref>

area showed mottled teeth and osteosclerosis of the knee joint. The amount of fluorine taken into body/day was investigated in fifty 30-60-year-old residents living around the same factory. A fanning area within 500 m under the lee of the main wind was determined as a polluted area, and the other farming area over 6 km from the factory was determined as the control. Investigated items were staple foods intake and fluorine intake from them, fluorine intake from subsidiary foods, fluorine intake from drinking water, and excretion of fluorine in urine. Intake of fluorine from staple foods was significantly higher in residents of the polluted area, and its mean value was 2.89 ppm, 40% higher than that of the control. Fluorine taken from the air and the water by residents of the polluted area was suspected to be 0.1 mg higher/day than that by residents of the control area. Fluorine in urine was higher in residents of the polluted area, but the relationship between the intake and excretion of fluorine was not clarified.

THE FOG DISASTER IN THE MEUSE VALLEY, 1930: A FLUORINE INTOXICATION. J. Ind. Hyg. Toxicol., 19(3):126-137, March 1937. 47 refs. (Presented at the Danish Society for Internal Medicine, Oct. 30, 1936.)

The fog disaster which occurred in the Meuse Valley near Liege, Belgium, early in December 1930, involved several thousand cases of sickness and 60 deaths. An analysis of the details of the disaster gives circumstantial evidence that the malady was acute fluorine intoxication. Of the 27 factories in the region, fifteen are industrial branches which either use raw products containing fluorine (superphosphate works, zinc works) or add fluorine compounds to the raw materials (steel works, iron foundries, glass works), involving the possibility of passing gaseous fluorine compounds into the chimney smoke. Special climatic and topographic conditions played an important role in the development of the disaster. A survey of acute and chronic fluorine intoxication is included. (Author summary modified)

Martin, A. Edmund

POLLUTION. ITS EFFECT ON HEALTH. Ind. Process Heat., 1970:17-18, Nov. 1970.

The impact of environmental pollution on human health is reviewed. The predominant hazard to health is tobacco smoke. Second to this come pollution of the atmosphere by smoke, soot, grit, ash, hydrocarbons, carbon oxides, sulfur oxides, nitrogen oxides, fluorides, ammonium salts, and other trace elements and the potential hazard of contamination of drinking water and foods. Studies and health statistics have established a relationship between air pollution, smoking, and various respiratory diseases, including lung cancer and chronic bronchitis. The need for research in these fields and for pollution control techniques is apparent.

Cristiani, H.

IS THERE FLUOROSIS OR FLUORINE CACHEXIA IN HUMANS? (Existe-t-il chez l'homme une fluorose ou cachexie fluorique?). Text in French. Presse Med. (Paris), no. 53:833-834, July 13, 1926.

Problems of possible fluorosis and fluorine cachexia in humans are discussed. The amounts of fluorine entering the human organism under normal conditions are not capable of producing intoxication. Acute poisonings are of an accidental character. Fluorine-containing products are, however, massively used as pesticides and preservative agents in different foodstuffs. Such fluorine may cause poisonings. The amount of fluorine entering the human organism (0.13-1.3 mg/kg) is too low to cause acute poisoning, but it can produce poisoning after a long period of time, the length of which has not yet

been clarified. Very small doses are capable of causing lethal cachexia, which makes investigations, into the possible dangers necessary. According to an investigation, doses of about 2 eg/kg lead to lethal cachexia in animals. Due to the intense milk consumption, infants are most affected by fluorine hazards. Measures should be taken to prevent the abuse of fluorine compounds as preservatives.

EXPERIMENTAL FLUORINE CACHEXIA: CHRONIC ACTION OF SODIUM FLUOROSILICATE IN SMALL DOSES.
(La cachexie fluorique experimentale: effets chroniques de petites doses de fluosilicate de soude). Text in French. Compt. Rend. Soc. Biol. (Paris), 1925:946-948, 1925.

The chronic action of small doses of sodium fluorosilicate was studied on two groups of guinea pigs. The feed was powdered with two different doses of fine sodium fluorosilicate, in both cases. In the first group of 13 animals, treated with doses of 2 g, deaths occurred, on an average, 35 days after the experiment started, with maximum and minimum of 64 and 9 days, respectively. The same symptoms were observed in all animals (loss of weight, cachexia, bulbous lesions). Special symptoms occurred a few days before death in some cases (stiffening of the spinal column, respiration troubles, tremors, and convulsions). The second group of 10 animals was exposed to 1/10 of the above dose. Death occurred, on an average, after 149 days, the maximum and minimum being 553 and 41 days. The cachexia was preceded by loss of weight. Similar symptoms and results were obtained with fluorine contaminated feed collected near aluminum plants.

39810

Cristiani, H. and R. Gautier
THE ACTION OF ALKALINE FLUORIDES ON ANIMALS.
(Action des fluorides alcalins sur les animaux). Text in French. Compt. Rend. Soc. Biol. (Paris), 1925:1276-1277, 1925. 1 ref. Tests were carried out with sodium and ammonium fluoride powder introduced in the feed of guinea pigs. Sodium fluoride was applied in doses of 2 g/cage of two animals. Deaths occurred, on an average, 54 days after the start of the treatment, with maximum and minimum of 86 and 22 days, respectively. The average weight of the animals increased at the beginning and dropped sharply in the cachexia period. Similar results were obtained with another group of 10 animals, treated in the same manner with ammonium fluoride. Deaths occurred, on an average, on the 58th day of the treatment, the maximum and minimum being 74 and 41 days, respectively. The symptoms observed were the same as in the case of sodium fluoride. Treatments with sodium fluorosilicate led to similar results.

303

Tests were carried out to determine, separately for each material investigated, the time required for different doses to cause death in guinea pigs. Daily sodium fluoride doses corresponding approximately to 1/10 of the dose caused cachexia which led to death after 2-3 mo, while doses of 1/50 of lethal dose were tolerated fairly well over more than 10 mo, and even the gain in weight was normal. Two animals treated with 1/20 of the lethal dose died after 118 and 98 days, respectively. Feeding experiments with fluorine contaminated feed revealed cachexia appearing during the second or third year.

Dunning, James M.

EFFECTS ON ORAL STRUCTURES FROM AIR POLLU-

TION. Interdepartmental Committee on Air Pollution, Washington, D. C., Air Pollut., Proc. U. S. Tech. Conf., Washington, D. C., 1950, p. 503-506. (May 3-5, Louis C. McCabe, ed.)

Forty-two etiologic agents have been recorded as producing effects on oral structures, 18 of these agents are dusts and 12 are gases. Some of the agents cause physical damage such as staining or abrasion of the teeth, including copper, nickel, iron, chromium, coal dust, bone, celluloid, sawdust, flour, and tobacco. Chemical damage usually associated with some disease process may result from the heavy metals, fluorine, phosphorus, ionizing radiation, and sugar. Arsenic, chromium, phosphorus, and ionizing radiation produce syndromes characterized chiefly by soft tissue and alveolar necrosis. Bismuth, lead, and mercury greatly aggravate periodontal disease and usually produce gingival discoloration as well. Carbohydrate dust produces adherent plaques on the surfaces of teeth leading in time to dental caries. Most of these agents produce far greater effects upon already diseased oral structures than upon healthy ones.

Cristiani, H. and P. Chausse

LATEST OBSERVATIONS ON CHRONIC POISONINGS WITH VERY SMALL SODIUM FLUOROSILICATE DOSES.

(Nouvelles observations sur l'intoxication chronique par de tres petites doses de fluosilicate de sodium). Text in French. Compt. Rend. Soc. Biol. (Paris), 1927:843-844, 1927.

Experiments carried out on guinea pigs with very small doses of sodium fluorosilicate are described. Amounts corresponding (o about one-tenth of a lethal dose (0.50 g/kg body weight), admixed to food, caused death on the average after 18 days, without any signs of cachexia. Weight loss was 20%. Doses corresponding to 1/35 the lethal dose caused death after 51 days treatment, while 1/50 to 1/60 the lethal dose killed one animal after 233 days. That animal showed symptoms of fluorine cachexia and a weight loss of 40%. Thus, even small doses of sodium fluorosilicate were found to be much more toxic than sodium fluoride.

39931

Cristiani, H. and P. Chausse

LATEST OBSERVATIONS ON THE TIME REQUIRED FOR FLUORINE CACHEXIA TO APPEAR IN GUINEA PIGS FOLLOWING INGESTION OF DIFFERENT FLUORINE SALTS.

(Nouvelles experiences sur le temps necessaire a l'apparition de la cachexie fluorique chez les cobayes a la suite d'ingestion de divers sels de fluor). Text in French. Compt Rend. Soc. Biol. (Paris), 1926:15-16.

Tests carried out on guinea pigs with different daily doses of various fluorine salts to determine the time required for lethal fluorine cachexia to appear are described. Alkaline fluorine salts in doses corresponding to 1/10 and 1/30 the lethal dose (0.50 g/kg body weight) caused death after 18 and 44 days, respectively. Animals treated with 1/35 the lethal dose (0.7 eg/day) of sodium fluoride died after 70 days (minimum 67, maximum 74 days), showing symptoms of fluorine cachexia.

The same dose of sodium fluorosilicate caused death after 51 days (minimum 40, maximum 63 days). The data suggest that the time required for fluorine cachexia to appear increases with reduced doses. Feeding tests with very small doses (hay slightly contaminated with fluorine-containing dust) produced cachexia after 1 -2 yrs.

FLUORIDES AS AIR POLLUTANTS. PREVENTIVE TECHNOLOGY. POLLUTION IN ALUMINUM METALLUR-

GY. (Fukkabutsu ni yoru taiki osen boshi gijutsu no genjo to tenbo). Text in Japanese. Kinzoku (Metals) (Tokyo), 41(1):122-125, Jan. 1971. 9 refs.

Fluorine in the air easily reacts to dust, soot, and other inorganic matter. It is easily adsorbed by flue gas and reacts to vapor in the air to form hydrogen fluoride. Even the smallest amount of fluorides give a considerable damage to plants such as pine, iris, and gladioli. Furthermore, fluorides are accumulated in the plant leaves in polluted areas, and cause chronic fluoride poisoning of silkworms, cattle, and other animals that feed on such plants. The effects of fluorides in the air to human health is not severe if the content is on the order of the present 0.75 mg. However, fluoride can accumulate by consumption of agricultural produce grown in the areas that are polluted. There is a considerable amount of fluoride in rice and vegetables. Accumulation of fluoride taken over along period of time can cause chronic poisoning such as streaked teeth or hardening of bones. In the past, mass poisoning occurred in the area where natural ground water contained more than 1 ppm of fluorine or in crystal mines. Streaked teeth appear only when a child takes in a large dosage of fluorine daily between his infancy and 8 years old. Taking the same dosage after maturation does not cause streaked teeth. However hardening of bones will occur. Various methods of treating fluoride containing gas are reviewed. Spray tower, venturi scrubber, water jet scrubber, packed tower, and floating bed scrubber are compared. The most efficient are venturi scrubber and floating bed scrubber; but the operation is extremely costly.

DEATH CAUSE DURING THE FOG CATASTROPHY OF

THE MEUSE VALLEY. (Die Todesursache bei der Nebelkatas-trophe im Maastal). Text in German. Archiv Gewerbepathol Gewerbehyg., vol 7:117-125, 1936. 10 refs.

The 1930 fog catastrophe in the Meuse Valley is described and an attempt is made to determine the cause of the massive deaths which occurred. The meteorological conditions favored the formation of fog. An inversion at an altitude of 70-80 m and the vertical equilibrium led to persistent smog. The symptoms of irritation of respiratory organs, cough, and dyspnea, indicated local effects. Autopsies revealed congestion and diffuse reddening of mucous membranes in the trachea and bronchus, partial loss of the epithelium, alveolar edemas, and hemorrhagic foci. The death cause was undoubtedly severe pollution due to industrial gases, vapors, and aerosols accumulated in excessively high concentration. While the official statement which made the combustion products of coal sulfur chiefly responsible holds true, the massive deaths cannot be

<xref image="2000WVIF.TIF|V3|2006:09:28:01:33:32.00|120394|0"> image: </xref>

satisfactorily explained from the inhalation of sulfur dioxide and trioxide and sulfuric acid bound in aerosols. Eye irritation was not frequent, and even the specific odor of sulfur dioxide was not present. Heart and circulation troubles in many cases indicated the high probability of the presence of other, resorptive toxic substances in the air. In view of the exceptionally high death toll in villages in the area of a plant emitting hydrofluoric acid at a daily rate of more than 2000 cu m, poisoning due to the inhalation of fluorine compounds may be regarded as most probable.

 CHEMICAL AND PHYSICAL CHARACTERISTICS AND
 BIOLOGICAL EFFECTS OF EFFLUENTS FROM AN ALU-
 MINUM PLANT. (Contribute allo studio delle caratteristiche
 chimico-fisiche e degli effetti biologici degli effluenti di una fab-
 brica di alluminio). Text in Italian. Med. Lavoro (Milan),
 61(2):69-101, Feb. 1970.

In 1932, three years after the Mori aluminum plant at Chizzola in the Italian province of Trento went into operation, school children observed round skin spots of a bluish color. By 1937, 786 such cases (the vast majority were children and women) were examined at the local clinic. No symptoms of fluorosis nor an elevated fluorine level in urine were observed. Bioptic examination of the cutaneous lesions revealed a great variety of different manifestations among them congestion of the deep dermo-hypodermic blood vessels, perivascular edema, and diapedesis of neutrophilic granulocytes. After 1937, the phenomenon disappeared only to reappear again in July 1965. At Ziar and Hronom in Czechoslovakia another aluminum plant emitting times the amount of fluorine did not produce this phenomenon, even though fluorosis there was frequent. Also the Rheinfelden aluminum plant in Germany whose fluorine emission is 23 times that of the Mori plant did not produce the above phenomenon. To relate the appearance of the skin spots to fluorine emissions, dust from the Mori electrofilter was fed and injected subcutaneously to rats, mice, guinea pigs, and rabbits and the biological effects were studied by examining their capillary fragility. None of the anatomical, pathological, and biochemical parameters determined showed any difference between experimental and control animals. Thus, in the absence of any other explanation the phenomenon must be ascribed to the toxic or toxic-allergic effect of hydrofluoric acid and fluorides. Chemical analysis of the dust disclosed the presence of many elements in trace quantities, none of which could be relevant to the phenomenon.

STUDIES ON EFFECTS OF AIR POLLUTION DUE TO
 FLUORIDES ON HUMAN BODIES IN NEIGHBOURING
 AREA OF ALUMINIUM MANUFACTURING FACTORY. (H).

(Arumi kojo shuhen ni okeru fukkabutsu niyoru taikiosen no
 jintai ni oyobosu eikyo ni kansuru kenkyu. (II)). Text in
 Japanese. Kankyo Hoken Reporto (Environ. Health Rept.),
 no.8:53-64, Jan. 1972.

The effects of fluorides on human health were investigated. Residents over 40 years old in a polluted area within 1 km from an aluminum factory in Naoetsu City and residents in a control area were examined on the basis of questionnaires concerning subjective symptoms, general physico-chemical examination, and for those who required closer examination, thyroid gland function tests, X-ray examinations of the bones, electrocardiogram, hematological examinations, and enzymatic function tests. The fluorine content in urine was significantly higher at the 0.5% level in the polluted area. The incidence of residents with 1.2 ppm of fluorine in urine tended to be high in the polluted area, but this was not statistically significant. Sub-

jective symptoms, e.g., chronic bronchitis symptoms, exercise limitations and pains of the joints were recognized in the polluted area with high incidence. Closer examination did not determine any significant difference between the polluted and the control areas. Typical symptoms of chronic fluorosis, i.e., osteosclerosis and mottled teeth, were not established. However, proliferation or calcification of the bones was recognized regardless of area, sex, or age. Pulmonary fibrosis was observed in 65% of all subjects, with a higher incidence among residents near the factory. Thyroid gland function, the counts of erythrocytes and white blood cells, hemoglobin amount, and the values of GOT, GPT, and alkaline phosphatase did not establish any difference according to area or age.

Higgins, E. Arnold, Vincent Fiorca, A. A. Thomas, and Harvey V. Davis

ACUTE TOXICITY OF BRIEF EXPOSURES TO HF, HCL, NO₂, AND HCN WITH AND WITHOUT CO. Fire Technol., 8(2):120-130, May 1972. 13 refs.

Ten rats and 15 mice per group were exposed to a series of atmospheric concentrations of each test material to determine LC-50 (lethal concentration for 50% of the test animals). The animals were exposed in a dynamic flow system using a standard Rochester chamber modified to present the animals with a precisely timed 5-minute inhalation challenge. The animals were observed closely for 7 days following exposure in order to include among the observations any delayed deaths due to pulmonary edema. Hydrogen fluoride produced pulmonary edema of varying degrees of severity in most of the exposed animals. Delayed deaths were routinely seen with this compound in exposures below the LC-50 level of 18,200 ppm in exposed rats, with peak mortality occurring about 24 hr after exposure. Exposure of rats to hydrogen chloride resulted in LC-50 values of 40,989 ppm. The 5-minute toxicity from HCl was much less predictable than from HF. The 5-minute LC-50 value for nitrogen dioxide was 831 ppm for the rats. In hydrogen cyanide exposures, all deaths occurred during the exposure period or within 20 min after exposure. The LC-50 value for rats exposed to HCN was 503 ppm. Carbon monoxide concentrations not hazardous to life did not enhance the toxic effect of the four substances tested.

Sadilova, M. S., K. P. Selyankina, and O. K. Shturkina

EXPERIMENTAL STUDIES ON THE EFFECT OF HYDROGEN FLUORIDE ON THE CENTRAL NERVOUS SYSTEM. Hyg. Sanit. (English translation from Russian of: Gigenia i Sanit.), vol. 30:155-160, May 1965. 1 ret.

On an experimental unit, which dosed the desired concentrations of hydrogen fluoride, the threshold volume of smell was determined and that of the reflex action of the substance on the functional state of the cerebral cortex by means of adaptationometry. Both of these threshold values were at level on 0.03 mg/cu m. An all day round poisoning of albino rats for a period of 5 mo with HF at a concentration of 0.10 and 0.03 mg/cu m produced statistically significant functional changes in the central nervous system as revealed by the method of conditioned reflexes and chronaximetry. The neurohistological examinations, made at the end of the poisoning period in the area of motor and sensory analyzers, revealed lesions of the

305

interneural connections and nervous cells in the animals exposed to the action of HF at a concentration of 0.10 mg/cu m. The HF at a concentration of 0.01 mg/cu m produced no changes judging by both of the test studied. Taking into account the cumulative properties of fluorine, the maximum single and the average concentration of HF in the atmospheric air should not exceed 0.01 mg/cu m.

COMBINED EFFECT OF HYDROGEN FLUORIDE AND SULFUR DIOXIDE ON THE BODY OF MAN AND ANIMALS.

In: American Institute of Crop Ecology Survey Of USSR Air Pollution Literature. A Second Compilation of Technical Reports on the Biological Effects and the Public Health Aspects of Atmospheric Pollutants. M. Y. Nuttonson (ed.), Vol. 11, Silver Spring, Md., American Institute of Crop Ecology, 1972, p. 14-23. Translated from Russian. (Also: Izv. Akad. Med. Naiik SSR, vol. 11:32-43, 1968.) NTIS: PB 209478

Experiments on the effects of sulfur dioxide and hydrogen fluoride alone and in combination on the olfactory threshold and on light sensitivity of the eye under dark adaptation conditions determined a complete summation of the effects of each substance. In rats that inhaled a mixture of 0.01 mg/cu m HF and 0.25 mg/cu m SO₂ (inactive concentration of the mixture for short-term inhalation) and in rats exposed to a mixture of HF and SO₂ at the level of maximum permissible concentrations (0.01 mg/cu m for HF and 0.15 mg/cu m for SO₂), changes in the ratio of chronaxia of the antagonist muscles were significant. A histological examination of the organs of the animals showed significant changes in the lungs in the form of a thickening of the alveolar septa, areas of interstitial pneumonia, and emphysema. The combined presence of SO₂ and HF in the air of populated areas at the level of the existing mean daily maximum permissible concentrations for each substance, therefore, is inadmissible.

NEW DATA FOR THE VALIDATION OF THE MEAN DAILY

MAXIMUM PERMISSIBLE CONCENTRATION OF

HYDROGEN FLUORIDE IN ATMOSPHERIC AIR. In: Amer-

ican Institute of Crop Ecology Survey of USSR Air Pollution Literature. A Second Compilation of Technical Reports on the Biological Effects and the Public Health Aspects of Atmospheric Pollutants. M. Y. Nuttonson (ed.), Vol. 11, Silver Spring, Md., American Institute of Crop Ecology, 1972, p. 24-32. Translated from Russian. (Also: Izv. Akad. Med. Nauk SSSR, vol. 11:5-15, 1968.) NTIS: PB 209478

The effects of hydrogen fluoride on the human organism were investigated to validate the basis for a standard maximum allowable concentration. Certain problems of the mechanism of the action of fluoride ions and the phosphorus-potassium metabolism using isotopic tracing were also studied. Two month old female rats were subjected to five-month continuous exposures to 0.10, 0.03, and 0.01 mg/cu m HF. Concentrations of 0.10 and 0.03 mg/cu m caused inhibition in the central nervous system, decreased the activity of a number of enzymes, impaired the phosphorus-calcium metabolism, and caused the accumulation of fluorine in the body and damage to the internal organs and bone tissue. The effects of the 0.01 mg/cu m were changes in the phosphorus metabolism only (inhibition of alkaline blood phosphatase and a delayed inclusion of radiophosphorus in bone tissue, liver, and blood at the end of the five-month exposure). A reduction in the mean daily maximum permissible concentration of hydrogen fluoride in the air of populated areas from 0.01 to 0.005 mg/cu m is suggested.

SANITARY EVALUATION OF FLUORIDES READILY
SOLUBLE IN BIOLOGICAL MEDIA. In: American Institute of
Crop Ecology Survey of USSR Air Pollution Literature. A
Second Compilation of Technical Reports on the Biological Ef-
fects and the Public Health Aspects of Atmospheric Pollutants.
M. Y. Nuttonson (ed.), Vol. 11, Silver Spring, Md., American
Institute of Crop Ecology, 1972, p. 33-41. Translated from Rus-
sian. (Also: Izv. Akad. Med. Nauk SSSR, vol. 11:16-26, 1968.)
NTIS: PB 209478

The biological effects of fluoride salts, the solubility of dif-
ferent fluorides in biological media, and toxic thresholds of
readily soluble fluorides were examined to establish a basis for
a standard maximum allowable concentration. The highest
solubility was displayed by sodium fluoride. Experimental data
permitted the assumption that the NaF retained in the body
dissolves completely in certain biological fluids. Aluminum
fluoride, cryolite, and calcium fluoride will not dissolve
completely in biological fluids and therefore may have a lesser
toxic effect than hydrogen fluoride or OaF. Light sensitivity of
the eye among subjects exposed to concentrations of 0.07
mg/cu m increased; 0.05 mg/cu m concentration affected one
person only. Chronic continuous exposure of rats over the
course of five months to NaF concentrations of 0.10 and 0.03
jg/cu m determined a generally toxic effect and caused the ac-
cumulation of fluorine in the bone tissue. The extent of the
changes was dependent upon the NaF concentration in the air.
Because of the neutral properties of NaF dust and its in-
complete absorption in the body after penetration through the
respiratory organs, its toxic influence is less than that of
similar hydrogen fluoride concentrations. The highest single
NaF concentration in the air of populated areas should not ex-
ceed 0.03 mg/cu m, and the mean daily concentration should
not exceed 0.01 mg/cu m.

Sadilova, M. S.
BIOLOGICAL EFFECT OF POORLY SOLUBLE
FLUORIDES. In: American Institute of Crop Ecology Survey of
USSR Air Pollution Literature. A Second Compilation of
Technical Reports on the Biological Effects and the Public
Health Aspects of Atmospheric Pollutants. M. Y. Nuttonson
(ed.), Vol. 11, Silver Spring, Md., American Institute of Crop
Ecology, 1972, p. 42-47. Translated from Russian. (Also: Izv.
Akad. Med. Nauk SSSR, vol. 11:26-32, 1968.) NTIS: PB 209478

The biological effects of poorly soluble fluorides were studied
to establish a basis for a standard maximum allowable concen-
tration. Aluminum fluoride, a typical representative of poorly
soluble fluorides, was selected for the study. The experiments
were carried out with a condensation aerosol of AlF₃ at a
sublimation temperature of about 700 C. An AlF₃ concentra-
tion of 0.3 mg/cu m caused a reliable increase of the light sen-
sitivity of the eye in all the subjects. Chronic continuous expo-
sure of two month old white female rats over the course of
five months to concentrations of 0.10 and 0.03 mg/cu m
established a slight but statistically reliable prolongation of the
chronaxies of extensors. The heavier concentration inhibited
the activity of the blood cholinesterase. On the whole, expo-
sure to both concentrations had only a slight toxic effect. In
the atmosphere the highest single maximum permissible con-
centration of fluorides sparingly soluble in biological media is
recommended at the level of 0.2 mg/cu m, with the mean daily
value at 0.03 mg/cu m.

MATERIAL FOR STANDARDIZATION OF THE MAXIMUM

PERMISSIBLE CONCENTRATION OF HYDROGEN

FLUORIDE IN THE AIR OF POPULATED AREAS. In: Amer-

ican Institute of Crop Ecology Survey of USSR Air Pollution Literature. A Second Compilation of Technical Reports on the Biological Effects and the Public Health Aspects of Atmospheric Pollutants. M. Y. Nuttonson (ed.), Vol. 11, Silver Spring, Md., American Institute of Crop Ecology, 1972, p. 48-60. Translated from Russian. (Also: Izv. Akad. Med. Nauk SSSR, vol. 10:186-201, 1961.) NTIS: PB 209478

The influence of varying concentrations of hydrogen fluoride on human subjects and on rats was studied and threshold levels were determined to establish a basis for a standard maximum allowable concentration. For the majority of subjects, the minimum olfactory perceptible concentration was 0.03 mg/cu m. In order to determine the effect of HF on the central nervous system via the receptors of the upper respiratory tract, the change in light sensitivity of the eye of three persons with normal vision was studied and determined the threshold concentration at 0.03 mg/cu m. Chronic continuous exposure of white female rats to 0.10 and 0.03 mg/cu m HF caused a number of disturbances in the animals, including the phenomena of inhibition in the central nervous system. A 0.10 mg/cu m concentration caused irreversible destructive changes in the nerve cells; changes in the phosphorus-calcium metabolism; accumulation of fluorine in the bone system; and histopathological changes in the teeth, bone system, and viscera. The 0.01 mg/cu m concentration caused no change in the experimental animals. The highest single concentration of HF, therefore, should not exceed 0.02 mg/cu m, and the mean daily concentration should not exceed 0.01 mg/cu m.

DISHARMONY IN THE ENVIRONMENT. DANGERS OF

THE CHEMICAL ERA. (Dysharmonie de l'environnement.

Dangers de l'Ere Chimique). Text in French. *Protectio Vitae*, 14(3):113-117, 1971. 10 refs.

Health aspects of food additives, household chemicals, and air pollution as well as general principles of the prevention of hazards, are reviewed. Various air pollutants, such as small particles, gases, and vapors may penetrate into the alveoli, cause local damages, and also enter the blood circulation. The major danger involved in air pollutants is long-term toxicity. The chief sources of carbon monoxide are firings and automobiles. Exhaust gas may contain 2.5-7% of CO. Sulfur dioxide plays an important role in the formation of acid smog. Nitrogen oxides are present in automobile exhausts, and nitrogen dioxide is necessary for smog formation. Exhaust gases contain unburnt hydrocarbons, and aromatic polycyclic hydrocarbons, such as benzo(a)pyrene, were detected in soot. Specific emissions from different industries are fluorine compounds, mineral dusts of various compositions, and odorous substances, e.g., mercaptan and amine derivatives. High concentrations due to unfavorable meteorological conditions or synergistic effects can result in acute toxic symptoms, while chronic toxicity may manifest itself as chronic bronchitis due to sulfur dioxide or fluorosis due to fluorine compounds. Increased incidence of bronchial cancer which may be caused by soot was observed in urban areas.

Goldstein, Gerald

BIOCHEMICAL INDICATORS OF ENVIRONMENTAL POLLU-

LUTION. Preprint Oak Ridge National Lab., Tenn., Analytical

Biochemistry Group, 39p., 1972. 176 refs.

Several studies related to the concept of biochemical indicators as monitors of environmental quality are reviewed. Several kinds of tissues and organs are potentially useful as indicators including plant tissues, various animal tissues, and

blood. One study done with plant tissues showed that exposure to Peroxyacetyl nitrate, ozone, and fluorides inhibits the biosynthesis of cellulose due to the inactivation of phosphoglucosyltransferase and cellulose synthetase. By studying various enzymes in fish, it is possible to determine the effects of pesticides and toxic metals. A dietary level of 5 ppm of DDT reduced the activity of glucose-6-phosphate dehydrogenase in rats. Guinea pigs were exposed to 15 ppm of nitrogen dioxide continuously for 10 weeks, and lung, liver, spleen, and kidney tissues subsequently examined. Lactic dehydrogenase and aldolase levels were elevated in most tissues. This indicates that chronic inhalation of air pollutants can cause alterations in tissue enzyme activity levels which can be detected and used as sensitive indicators. The measurement of cholinesterase activity in human blood plasma and erythrocytes can be used as an indicator of exposure to organophosphorus and carbamate pesticides. A decrease in the gamma-aminolevulinic acid dehydrase level may indicate exposure to lead. Nitrogen dioxide has been tested against mouse liver and rabbit and rat lung cell cultures. In the first case, increased cell mortality was observed and in the latter, a reduced oxygen consumption reflecting reduced cellular metabolism. Sulfur dioxide inhibits the growth of mouse liver cells and damages human lymphocytes in culture. Ozone inhibits the growth of human strain L cells. Peroxyacetyl nitrate inactivates isocitric dehydrogenase, glucose-6-phosphate dehydrogenase, and malic dehydrogenase within a few minutes. Ozone inactivates papain and glyceraldehyde-3-phosphate dehydrogenase. Atmospheric SO₂ and O₃ inactivate acetylcholinesterase.

POLLUTION AND TOXIC AND HAZARDOUS SUBSTANCES.

GENERAL THEORY. (Kogai to doku kikenbutsu soronhen).

Text in Japanese. Tokyo, Sankyo Shuppan, 1971, 240p. 76 refs.

Pollution, toxic and hazardous substances are discussed. Poisons are discussed, including acute and chronic poisoning, the effects in bodies, and the chemical structure. Air pollution problems are described in terms of sulfur dioxide, carbon monoxide, chlorine and chlorides, bromine, fluorine and fluorides, hydrogen sulfide, nitrogen oxides, ozone, hydrocarbons, particulates, soots, and radioactive substances. Soil pollution, river pollution, sea pollution, fires, and explosions are mentioned. Tables of plant damage by air pollution, threshold values of various pollutants in drinking water, and a list of poisonous, combustible, and explosive compounds are included.

ETIOLOGIC FACTORS IN CHRONIC BRONCHITIS AND

PULMONARY EMPHYSEMA. (Les facteurs etiologiques dans

la bronchite chronique et l'emphyseme pulmonaire). Text in

French. Rev. Med. (Tirgu-Mures), 11(37):2175-2176, 2178-2179,

Oct. 1970.

<xref image="2000WVII.TIF|V3|2006:09:28:01:33:42.00|114924|0"> image: </xref>

Exogenous and endogenous factors in chronic bronchitis and pulmonary emphysema are reviewed. Several factors overlap in their actions which makes it difficult to assess their respective contributions. Air pollution, primarily due to dust, soot, sulfur dioxide, nitrogen oxides, fluorine compounds, and oxidants, as well as smoking, particularly nicotine, are the most important exogenous factors in chronic bronchitis and emphysema, while air pollution in occupational environment plays a minor role. Air pollutants cause irritation and hypersecretion of the mucous membranes, and reduce the resistance against microbial attacks. These exogenous factors are all the more dangerous when they combine with endogenous factors having produced constitutional predisposition. Such endogenous factors are age and sex, infections of the respiratory tract, allergies, genetic factors, hereditary immunity deficiency, mucoviscidosis, or alpha-1-antitrypsin deficit. The frequency of both chronic bronchitis and emphysema, higher for males than for females, increased with age. Infections of the respiratory tract facilitate the germination of germs in the subglottic tract, and the extension of lesions to the bronchioles or the parenchyma. Asthma is accompanied by bronchial hypersecretion in several cases, which may result in the combination of asthma with chronic bronchitis. Diverse genetic affections are accompanied by bronchial hypersecretion of chronic infection of the bronchi, or, less often, by emphysema.

SOME MEDICAL CONSIDERATIONS REGARDING AT-

MOSPHERIC FLUORIDES. HSMHA (Health Serv. Ment.

Health Adm.) Health Rep., 86(8):752-758, Aug. 1971. 28 refs.

In assessing margins of safety and possible toxic hazards from fluorides, it is necessary to consider the body's total intake of fluoride from all sources. The total intake will be derived in part from the diet, drinking water, and the atmosphere. The fluoride content of some individual foods is indicated, and the hazards to man from industrial fluorides are discussed. Air pollution by fluorides is considered, including man's fluoride intake from polluted air. The occurrence of fluorosis in cattle in the vicinity of factories emitting fluorides suggests a possibility of increased fluoride intakes in man arising from the contamination of food grown in these areas. Experiments indicate that man's consumption of vegetables grown in such areas would not present a hazard to health, but in exceptional cases a grossly excessive consumption of heavily contaminated vegetables might lead to a slight increase in dental fluorosis in children. Such fluorosis, however, is unlikely, though experience from certain other countries indicated that where atmospheric pollution from fluorides is higher, signs of dental fluorosis may be found. Where necessary, a realistic assessment of the margin of safety or of the existence of a fluoride hazard may be obtained by adequate monitoring of pollution in the vicinity of any factory. STUDIES ON THE HEALTH-DAMAGING EFFECT OF THE

FLUORINE-POLLUTION OF THE AIR AROUND AN ALU-

MINIUM FOUNDRY. (A levego fluorszennyezodesenek egesz-

segugyi hatasa az inotai aluminiumpkoho kornyeken vegzett viz-

sgalatok alapjain). Text in Hungarian. Egeszsegtudomany, vol. 15:74-80, 1971. 21 refs.

In the housing estate Varpalota-Inota, Hungary, where the air proved to be contaminated with fluorine, 227 children were examined. Fluorine was found in the urine of the children and in some cases at a level usually found in the urine of foundry workers. In a control area, where the air was free from fluorine, no fluorine was found in the children's urine. The hemoglobin level in the children at risk was low. In spite of

these facts, a causal relationship between the fluorine pollution of the air and the levels of fluorine found in the urine was not established because fluorine is only one of the air pollutants around Varpalota-Inota. (Author abstract modified)

Largent, Edward J.

INTRODUCTION. In: Fluorosis. The Health Aspects of Fluorine Compounds. Columbus, Ohio State Univ. Press, 1961, p. 1-2.

Fluorine is the most electronegative of all elements and one of the most violently reactive substances known to man. Since 1931, when fluoride was identified as the unique substance present in water that had caused mottled dental enamel in man, researchers throughout the world have been reporting on the osseous effects of fluorides, most frequently in cases of occupational exposure. A number of lawsuits alleging damage from fluorides were filed in 1944, stimulating greater interest in the investigation of the biological effects of fluorides.

44590

Largent, Edward J.

SKELETAL FLUOROSIS IN MAN. In: Fluorosis. The Health Aspects of Fluorine Compounds. Columbus, Ohio State Univ. Press, 1961, Chapt. 2, p. 8-21.

The results of various investigations into the health effects of fluorides in man, through occupational exposure and through water supply are summarized. The investigations reported were carried out between 1931 and 1949 in Copenhagen, North Africa, India, Argentina, South Africa, China, Scotland, and Texas and Oklahoma. The findings of these studies are examined concerning the establishment of a relationship between osseous deposition of fluoride and other observed disorders, such as hypertrophic bone changes and ligamentous calcification. Fluoride-induced bone changes that have been clearly demonstrated in man include increased radiopacity and hyperostoses in the forearm and leg, principally in the interosseous membranes. Ankylosing spondylitis or pokerback, or any other disabling change in the skeletal structures, have not been shown to have been caused in part or entirely by fluoride deposition. The changes seen clinically or radiologically in suspected cases of fluorosis are not pathogenomonic of that condition. For example, increased osseous density is observed in several bone diseases, and both calcification of ligaments and ankylosing spondylitis occur in other arthritic disorders. Moderate or advanced fluoride osteosclerosis may be suspected on the basis of demonstrated characteristic roentgenographic changes in the bones. Corroborative evidence as follows should be required in any case: proven absorption of fluoride amounting to 10 to 15 mg/day, or urine concentrations averaging more than 8 mg/l over a period of more than 5 years.

44593

Largent, Edward J.

CHRONIC FLUORIDE INTOXICATION IN ANIMALS. In: Fluorosis. The Health Aspects of Fluorine Compounds. Columbus, Ohio State Univ. Press, 1961, Chapt. 8, p. 74-89.

The dental effects in animals, as in man, are the first detectable response to exposure to relatively small amounts of fluoride. In the rat, bleaching of the orange colored enamel of

<xref image="2000WVIJ.TIF|V3|2006:09:28:01:33:46.00|120800|0"> image: </xref>

the incisors is first detected as alternate white and orange bands. The striation of the enamel has been detected in some incisors when fluoride was added to food in amounts as small as 7 ppm. Fluoride may effect the enamel of most animals only if it is fed prior to the eruption of the permanent teeth. At levels of ingestion somewhat above that required to cause mild dental fluorosis, the next most sensitive physiological response appears to be a reduction in the amounts of food eaten. At progressively higher levels, reduction in calf production, milk production, general condition, cachexia, organ degeneration, and death, appear in that order. Considerable experimental work has been done on the lower animals for the purpose of examining the mechanisms of skeletal storage of fluoride and fluoride excretion. At the highest tolerable levels of fluoride in food, the bones of animals will accumulate relatively large amounts of fluoride. Apparently, however, there is an upper limit of osseous deposition; fluoride in the ash of animal bones has rarely exceeded 3%, or 30,000 ppm. The average urinary fluoride limit, associated with earliest detectable skeletal abnormalities in cattle and sheep, is in excess of 40 ppm, the abnormalities appearing after one to two years of exposure.

44594

Largent, Edward J.

ACUTE FLUORIDE POISONING IN ANIMALS. In: Fluorosis.

The Health Aspects of Fluorine Compounds. Columbus, Ohio State Univ. Press, 1961, Chapt. 9, p. 90-93.

Hydrofluoric acid is very corrosive and may produce serious local injury to the skin, cornea, and mucous membrane whenever it comes in contact with these tissues. Inhalation of elemental fluorine and of fluorides in sufficient concentrations has been fatal to animals. Exposures for periods of three hours at a concentration of 200 ppm, as well as briefer exposures at higher concentrations, were invariably fatal to exposed rabbits, guinea pigs, rats, and mice. At a level of 100 ppm, repeated exposure of these four species over a period of seven hours produced an over-all mortality of 60%. Severe damage to the respiratory tract was the only pathological change that developed consistently as a result of these fatal inhalations. Estimates of the minimum lethal dose for the soluble salts fall in the range of 45 to 90 mg/kg, expressed as fluoride ion when given orally to animals. The estimates for the lethal dose for dogs has been placed as low as 23 mg/kg. Signs of acute poisoning by ingestion are weakness, stupor, salivation, vomiting, thirst, convulsions, spasms, diarrhea, and increase in the frequency and depth of respiration, followed by paralysis. Albuminuria has also been observed and high concentrations of fluoride were found to have been excreted in the urine and in the saliva. Damageto tissues, caused by single massive doses or by repeated large doses of fluorides, is especially prominent in the gastrointestinal tract. Acute inflammation, hyperemia, swelling, bleeding, and epithelial degeneration have been reported. Acute fluoride poisoning has been reported to cause a sudden decrease in the numbers of formed elements in the blood, an inhibition of glycolysis, and a decrease in the concentration of calcium ions in the plasma. It is believed that the use of sodium fluoride for elimination of parasites in swine can be safely conducted without producing fatal acute poisoning.

Largent, Edward J.

FLUORIDES AND OCCUPATIONAL HEALTH. In: Fluorosis.

The Health Aspects of Fluorine Compounds. Columbus, Ohio State Univ. Press, 1961, Chapt. 12, p. 109-123.

Industrial uses of fluorides include processing of nuclear fuels and the manufacture of polymers, octane gasoline, plastic materials, fluorocarbon acids, oils, greases, Pharmaceuticals, and nerve gas. In the form of cryolite, fluorides are used in large amounts each year in the manufacture of aluminum. The

steel making industry depends heavily on fluorspar. The industrial activities in which rock phosphate is used probably liberate the greatest total amounts of fluoride. Sizeable quantities are also encountered in the following industries: glass, magnesium founding, cleaning of steel castings, welding, soldering, ceramic products, and in the disinfection of equipment in breweries. The responses of workmen to occupational exposure to fluorides are discussed with regard to the effects of fluorides on the skin, effects on the respiratory tract, absorption and excretion of fluorides, and osseous deposition of fluorides and changes in radiopacity. Inside industrial plants the level of fluoride in the air should not be allowed to exceed 3 ppm, expressed as HF, or to exceed 2.5 mg/cu m, expressed as particulate fluoride in air. If fluoride exposures are controlled so that no workman repeatedly excretes fluoride at a level as high as 8 mg/l of urine, there is very little likelihood that any ill effects will result from exposure, although a slight increase in osseous radiopacity may, in rare instances, develop after many years of occupational exposure.

Ruiz Salazar, Antonio and Alejandro Castanedo
PATHOLOGICAL CONDITIONS CONNECTED WITH THE
OIL INDUSTRY. (Patologia de la industria del petrolic). Text
in Spanish. Med. deporte trab., 18(128):560-581, 624-641, 674,
1953. 30 refs.

Petroleum processing plant-induced pathology is reviewed. Toxicology is analyzed in terms of effects produced by oil impurities (hydrogen sulfide), ingredients applied for the improvement of fuels (hydrofluoric acid and tetraethyl lead), and by the petroleum hydrocarbons themselves. Petroleum distillation generates air pollutants such as ethane, propane, and butane. But most of the petroleum products are considered to be non-toxic. Gasoline cracking, however, produces toxic non-saturated compounds. Reference is made to an accident which occurred in 1922 under atmospheric inversion conditions in a settlement close to the A.G.W.I. processing plant. Fatalities were attributed to the action of carbon dioxide and/or H₂S. Another air pollution accident which occurred in 1950, due to the deterioration of an emission control unit, is attributed to the large amounts of H₂S in the air. The accident caused 22 deaths and more than 300 poisoning episodes. Autopsies revealed the lungs to be the most affected organ under the circumstances. Victims with tetraethyl lead poisoning were found with brain and lung congestion, and minor inflammation of the other internal organs. Chronic TEL poisoning is characterized by asthenia, anemia, arterial hypotension, and loss of weight. Hydrofluoric acid is described in terms of acute effects due to its high respiratory tract irritation activity. Dermatoses are the most diffused diseases due to chronic exposure to petroleum. The petroleum industry has no causal connection with tuberculosis. The pathology of chronic exposure to the petroleum industry requires systematic studies in order to provide the appropriate control measures.

G. EFFECTS-HUMAN HEALTH

309

English translation from Russian of: *Gigiena i Sanit.*), 35(8): 184-187, Aug. 1970. (Includes discussion by Gabovich, R. D. in *Hyg. Sanit.* (English translation from Russian of: *Gigiena i Sanit.*), 36(5):270-272, May 1971.) NTIS: TT 70-50048/3 and TT 71-50122/2

To assess the various routes of entry of fluorine into the body a series of experiments on albino rats was carried out lasting for 5 months: using water containing fluorine at a concentration of 1.0- 1.5 mg/l; 24-hr inhalation poisoning of animals with low concentrations (0.1, 0.03, and 0.01 mg/cu m); and simultaneous action of fluorine contained in water at concentrations of 1.0-1.5 mg/l and that inhaled at a concentration of 0.01 mg/cu m. A study of functional, biochemical and morphological changes developed proved nonorganic fluorides, entering the body through the respiratory organs, to be much more toxic than the equivalent quantities of fluorine, introduced into the body with water. In the case of long-term inhalation of air with an admixture of small concentrations of fluorides, the primary changes developed in the body at an optimal content of fluorine of 1.0 mg/l. This fact points to the necessity of using highly effective means of decontamination of industrial fluorine discharges into the atmosphere. A critique by a scientist not involved in these particular experiments points to several uncontrolled variables in the methods employed. It is further suggested that on the basis of observations on three groups of human volunteers, there is no significant difference in the effects on man of fluorides between peroral and respiratory administration. (Author summary modified)

THE TOXICITY OF EMISSIONS FROM HEATED REFRACTORY HIGH POLYMER COMPOUNDS. (NO. 3). (*Tainetsusei kobunshi kagobutsu no kanetsu ni yoru seiseibutsu no dokusei ni (suite.) (sono 3).* Text in Japanese. *Sangyo Igaku (Jap. J. Ind. Health)*, 14(4):130-131, July 1972.

The toxicity of emissions from heated teflon was investigated. In 10 minutes, 0.72 g of polyfluoroethylenepropylene (PFEP) heated at over 500 C vanished; mice exposed to the emissions all died in the same period of time. More than 150 ppm of hydrogen fluoride gas was detected. At 350 C, only 3% of the sample PFEP vanished; mice exposed to emissions showed light symptoms of poisoning, e.g., difficulty of breathing and decrease in body weights. Mice exposed to emissions from polytetrafluoroethylene heated at 400 C died in 48 hours. When a filter which reduced more than half of the fluorides in the emission was used, only slight decreases of body weights were noted.

Truhaut, Rene
DANGERS OF THE CHEMICAL AGE. (*Dangers de l'ere chimique*). Text in French. *Chim Ind., Genie Chun.*, 105(3):239-249, Feb. 1972. 10 refs. (Presented at a Conference in the Centre de Perfectionnement Technique.)

The necessity of understanding the dangers of the chemical age is emphasized; examples of toxic risks in different fields are provided; and the main principles of prevention of these dangers are discussed. Toxicity may take the form of acute, sub-acute, short-term, and long-term intoxication. Particular attention should be paid to exposure to poisons possessing cumulative properties. Various toxic substances such as lead, cadmium, mercury, and fluorides have different forms of absorption and excretion. Human and environmental factors likely to have a qualitative or quantitative effect on toxicity and on the conditions under which it reveals itself are considered. There are risks in using chemicals in medical treatment. The presence of Pharmaceuticals in the home is not always safe, especially in the case of unusual response of certain organisms

to medicines. Fatalities have occurred due to overdosage or erroneous labelling. Workers are more exposed to chemical agents both in industry and agriculture (pesticides). Another major risk is posed by deliberate or accidental addition of chemical agents to foodstuffs and water. The general population is exposed to air pollution in the form of carbon monoxide, hydrogen sulfide, nitrogen oxides, and hydrocarbons. Other risks are related to the use of chemicals in cosmetics and household products. These risks can be minimized by setting purity standards for chemicals, labeling the development of toxic pathology or poison-treatment centers, and the establishment of concerning admissible limits for pollution in working atmospheres or urban air.

Oelschlaeger, Walter

THE EFFECT OF POLLUTANT EMISSIONS ON DOMESTIC

ANIMALS. (Inunissionen und Hire Wirkung auf landwirtschaftliche Nutztiere). Text in German. Umweltforschung, no. 58:26-29, 1971. (Presented at the Hohenheim University Umweltforschung Seminar, 1971.)

General problems of the effects on livestock of various pollutant emissions are reviewed. Livestock damage is mostly due to the ingestion of forage contaminated with toxic substances such as arsenic, chromium, cadmium, molybdenum, copper, fluorine, and lead. Fluorine emission-generated livestock damages in Germany have abated for the last years as a result of the implementation of strict emission standards. Though lead concentrations in plants near highways, especially within the nearest 100-meter strip, are essentially above average, the consumption of such forage by livestock is usually occasional, and hence no damage should be feared. Lack of appetite, diarrhea, loss of weight, sometimes infertility, and reduced milk yield in cows are the nonspecific symptoms of poisoning in livestock. The meat from such animals is usually fit for consumption, while milk lead concentrations may be sometimes too high to be acceptable.

THE EFFECT ON THE HUMAN BODY BY FLUORIDE AIR

POLLUTION. (Fukkabutsu ni yoru taikiosen no junta! no oyobosu eikyo). Text in Japanese. Nippon Kosshu Eisei Zasshi (Japan. J. Public Health), 19(10):425, Oct. 1972. (Presented at the Japan Society of Public Health, General Meeting, 31st, Sapporo, Japan, Oct. 25-27, 1972.)

Subjects were 1210 children aged between 3 and 15 and 1147 subjects out of 1210 who were living in an area within 1 km of an aluminium refinery factory; 63 were chosen for comparison. The average fluoride content in urine of the subjects of the comparison group was 0.180 ppm and the subjects of the polluted area showed a remarkably high value of fluoride. As a result of the second examination, curvature of the ulna, early choosing of epiphysia line were found 9.3% of subjects, pulmonary fibrosis was found 4.1% of subjects, bronchitis was 9.7% and asthma was 3.2%. Twenty-four subjects were hynoplastic dental enamel.

RELATION BETWEEN AIR POLLUTION DUE TO FLUORIDE AND SWELLING OF THE THYROID GLAND IN KITAKATA CITY (FUKUSHIMA PREFECTURE). (Fukkabut-su niyoru kankyoosen to kojosen shucho). Text in Japanese. Nippon Koshu Eisei Zasshi (Japan. J. Public Health), 19(10):426, Oct. 1972. (Presented at the Japan Society of Public Health, General Meeting, 31st, Sapporo, Japan, Oct. 25-27, 1972.)

There is an aluminum refinery factory in Kitakata. This city was divided into several sections. The area nearest to the factory was the most polluted area (fluoride content in air was 173.6 ± 24.2 kg/sq m/mo). Subjects were primary school children of this polluted area. The result was that 193 children out of 339 showed symptoms of swelling of the thyroid gland. But this result doesn't mean the mutual relation between air pollution due to fluoride and swelling of the thyroid gland because even in an area which was not polluted by fluoride, there sometimes were examples of swelling of the thyroid gland. More examinations on this subject are required.

Borsdorf, Wolfgang

DAMAGE OF FLUORINE-INDICATOR PLANTS IN THE WILD FLORA. Wiss. Z. Tech. Univ. Dresden, 11(3), 1962. (Presented at the International Research Congress of Forest Experts in Smoke Damage, 3rd, Tharandt, Germany, May 24-27, 1961.) Translated from German. 2p.

In an area of central Germany which has a high concentration of fluorine-containing exhaust gases, the wild flora and some cultivated plants were examined in order to determine their adequacy as indicators for fluorine damage. Three years of observations resulted in a list of 59 kinds of plants, subsequently divided into four sensitivity groups on the basis of macroscopic damage such as necrosis of the edges of the leaves. In general, the gramineae and Polygonaceae seemed to be sensitive, while the Labiales, composites papilionacea crucifers, and Umbelifera were very resistant. The amount of damage was also influenced by topographic and meteorological factors.

INDUSTRIAL TOXICOLOGY PART II: TOXIC GASES. (Industrietoxikologie II: Toxische Gase). Text in German. In: Arbeitswissenschaftliche Lehrbriefe. Rept. 14/15/16, p. 87-97, 1971 (?).

General lexicological description is given of the most common industrial toxic gases. Gases such as fluorine, chlorine, bromine, and their compounds, as well as phosgene, sulfur dioxide, nitrogen oxides, and ammonia have predominantly irritating effects, while others, such as carbon monoxide, carbon dioxide, acetylene, ethylene oxide, metal carbonyls, hydrocyanic acid, hydrogen sulfide, and hydrogen selenide interfere with metabolic processes. Pulmonary edema, fibrosis, bronchopneumonia, and ocular conjunctivitis are the symptoms of fluorine and hydrofluoric acid. Phosgene, decomposing into hydrochloric acid and CO, damages certain organs, the central nervous system, and interferes with enzymatic processes. Sulfur dioxide causes irritation of the respiratory tract, cough, vomiting, and pulmonary edema. Nitrogen oxides irritate moist mucosa, and cause pulmonary edema, dyspnea, vomiting, asthenia, unconsciousness, and possibly death or pulmonary complications. Ammonia represents a strong irritant for the mucosa, particularly of the eyes. Carbon monoxide, blocking hemoglobin, causes headache at carboxyhemoglobin contents above 25%, and psychic damages at contents of 30-50%, 75-80% concentration is lethal. Damages to the cardiovascular and vegetative nervous systems, and impaired vision and hearing due to chronic poisoning, have been observed. High concentrations of carbon dioxide cause

headache, dizziness, asthenia, and damage to the central nervous system. Nausea, vomiting, and narcosis are the basic symptoms of poisonings with ethylene oxide. Hydrogen sulfide and hydrogen selenide irritate moist mucosa, damage enzyme systems, and may cause sudden death. Hydrocyanic acid interferes with the oxygen metabolism in the cells.

Takizawa, Y., I. Ogima, Y. Watanabe, S. Kuroda, and T. Oshina

THE EFFECT OF AIR POLLUTION DUE TO FLUORIDE ON THE HUMAN BODY - THE THIRD REPORT. (Alumi kojo shuhen ni okeru fukkabutsu ni yoru taiki osen no jintai ni oyobosu eikyo ni tsuite - dai sanpo). Text in Japanese. Kankyo Hoken Reporto (Environ. Health Rept.), no. 16:59-71, Dec. 1972.

A group of 1210 infants, children, and 1147 students aged between 3 and 15 living within 1 km of a factory which produced fluorides (A group) and 63 subjects for comparison (B group) were studied. The first examination studied subjective symptoms and teeth. The fluorine content in urine was 0.181 ppm in A group and 0.391 or 0.408 ppm in B group; this value was higher in boys than in girls. The most frequent subjective symptoms which the subjects complained of were respiratory symptoms especially cough and phlegm. Dysodontiasis or insufficiency of calcification were observed 20.2% of A group. The second examination was done on the subjects who had fluorine in the urine over a 0.42 ppm concentration and who showed other symptoms and on the subjects whose fluorine content was under 0.42 ppm but who showed the symptom of dysodontiasis. The average fluorine content in the urine was 0.358 and 0.204 ppm, respectively; these values were less than the content of the first examination because this examination was done before a meal.

48637

Takizawa, Y., I. Ogima, Y. Watanabe, S. Kuroda, and T. Oshina

THE EFFECT OF AIR POLLUTION DUE TO FLUORIDE ON THE HUMAN BODY - THE FOURTH REPORT. (Alumi kojo shuhen ni okeru fukkabutsu ni yoru taiki osen no jintai ni oyobosu eikyo ni tsuite - dai yonpo). Text in Japanese. Kankyo Hoken Reporto (Environ. Health Rept.), no. 17:69-89, Dec. 1972.

A third examination was made of 74 children and infants who showed symptoms of pulmonary fibrosis, who were diagnosed as bronchitis or asthma patients, or who showed dysodontiasis. The fluorine content in the urine of boys (38 cases) was 0.500 ppm and that of 34 girls was 0.484 ppm. The highest value was 1.5 ppm of a girl, and four cases were over 1.0 ppm. As a result of a dental examination, a mild insufficiency of calcification was observed 10 cases and moderate one in six cases. The respiratory diseases were not observed. As a result of a heart examination, myocardosis was found in two cases and enlargement of cardiac ventricle in one case.

48693

CAN FLUORIDE CAUSE LUNG CANCER? Fluoride, 5(4):169-171, Oct. 1972. 14 refs.

The possible carcinogenic role of the fluoride ion is discussed, and studies on fluoride emissions in relation to lung cancer are summarized. The results of the studies are necessarily limited, but cannot be discounted. Even if fluorides are not solely responsible for the development of lung cancer, in conjunction with other carcinogens they might act as a synergist. Fluoride is also a constituent of asbestos, a recognized carcinogenic agent, at levels of the order of 70-579 ppm.

Cecilioni, V. A.

LUNG CANCER IN A STEEL CITY. ITS POSSIBLE RELATION TO FLUORIDE EMISSIONS. Fluoride, 5(4):172-181, Oct. 1972. 21 refs. (Presented at the International Society for Fluoride Research, Annual Conference, 4th, Hague, Netherlands, Oct. 24-27, 1971.)

The epidemiology of 300 deaths from primary lung cancer in the industrial steel city of Hamilton, Ontario was studied. A breakdown of the city into zones revealed three different rates directly related to the proximity to the main industrial area, with a high of 65 per 100,000 population in the northeast end close to the steel mills, a low of 12 in the most distant section, and 23 in the intermediate zone. A marked rise in steel production and a corresponding increase in the use of fluorspar flux occurred during the same period (1966-68). Characteristic fluoride damage to vegetation was established, especially in the northeast section. Analyses of vegetation, dust, and human bones determined high levels of content of fluoride, sulfur, and silica. (Author summary modified)

EPIDEMIOLOGICAL STUDIES OF FLUORIDES EFFECTS

ON THE HUMAN BODY, 2ND REPORT. (Fukkabutsu no jintai ni oyobosu eikyo no ekigaku-teki kenkyu, Dai-2-ho). Text in Japanese. Kankyo Hoken Reporto. (Environ. Health Kept.), no. 13:69-80, Sept. 1972. 1 ref.

A complete and detailed report is presented on the findings of the third examinations of the 15 patients who were screened by two previous health examinations of 1152 people living 1 km from a chemical factory in Niigata Prefecture. Examinations were given to find out their awareness of symptoms, general clinical diagnoses, dental conditions, basic metabolism, cardiogram, hematological conditions, enzyme functions, fluoride content in their urine, and the chest and bone x-ray results. The total discovery rate of all the examinees was 7.5%. Most people had some form of complaints such as coughing and gagging (69.2%), sputum (69.2%), rhinitis (61.5%), wheezing (53.8%); these symptoms worsened in southerly winds (42.2%). Other common symptoms were exhaustion, toothache, palpitation, and skin damage. All 15 patients originally had more than 1.2 ppm F content in their urine, but in this third test, only three had more than 1.2 ppm, and the average was 0.853 ppm. The chest X-ray showed that 10 persons had the shadows of lung fibrosis. Other X-ray findings were abnormality of the hip bone on six persons and a suspicion of the same on one person; irregularities on other parts such as the knees, pelvic bones, elbows, and hands were recognized on several patients. Altogether, 84.6% of the patients (11 persons) showed some form of abnormality in their bone formation. The general clinical test showed that 10 persons had high blood pressure, seven had chronic bronchitis, and two had bronchial asthma and skin disease.

ACUTE INHALATION AND DERMAL APPLICATION
SCREENING STUDIES OF 2,4,6-TRIFLUORO-SYM-
TRIAZINE AND 2,4,6-TRIS(TRIFLUOROMETHYL)-SYM-
TRIAZINE. Am. Ind. Hyg. Assoc. J., 33(6):382-388, June 1972.
7 refs.

Screening studies of the effects of acute inhalation of 2,4,6-trifluoro-sym-triazine ((FCN)₃ - known as cyanuric fluoride) and of 2,4,6-tris(trifluoromethyl)-sym-triazine ((CF₃CN)₃) on male albino rats are reported. Values for LC₅₀ of 3 ppm for cyanuric fluoride and 1400 ppm for 2,4,6-tris(trifluoromethyl)-sym-triazine were found. Acute dermal application studies of the same two chemicals on rabbits are also reported. The lethal dose 50 values of 100 microliters/kg of body weight for cyanuric fluoride and more than 1000 microliters/kg of body weight for (CF₃CN)₃ were established. The cyanuric fluoride was particularly insidious because of its high skin permeability. Data on human response to either chemical is not well documented and therefore is quite subjective. Small quantities as low as about 1 to 5 ppm of cyanuric fluoride can be detected from its pungent odor before other body senses respond. At higher levels, burning of the eyes and breathing discomfort are readily apparent. The properties of cyanuric fluoride and (CF₃CN)₃, and data on the effects of both chemicals on the trachea, lungs, liver, spleen, and kidneys of rats are given.

THE CHANGES OF THYROID OF CHILDREN IN
FLUORIDE-POLLUTED AREAS. (Fukkabutsu ni yoru kankyo
osen to kojosen shucho). Text in Japanese. Japan Society of Air
Pollution, Proc. Symp. Japan Soc. Air Pollut., 13th, 1972, p.
201. (Nov. 7-9, Paper 156.)
The pollution from an aluminum refining factory has been investigated for several years. In this report, air pollution by fluorides between Jan. and Dec. 1971 and thyroid gland swelling were examined. Fluoride content in the air was sampled with the rain water collected in deposit gauges. Children of two elementary schools were given health and dental examinations, and the frequency of the swelling of the thyroid and maculosa teeth were studied. There were some occurrences that could suggest the effects of fluoride pollution. But there were instances of swelling of the thyroid and maculosa teeth in unpolluted areas also, and the examples were too few to relate the instances with the fluoride pollution.

PROBLEMS INVOLVED IN THE PREVENTION OF
FLUORINE AND FLUORINE COMPOUNDS-GENERATED
HAZARDS. (Analyse des problemes de protection poses par le
fluor et les composés fluores). Text in French. Centre d Etudes
Nucleaires, Fontenay-aux-Roses (France), Dept. de Protection,
54p., June 1971. 81 refs. NTIS: CEABIB200
General problems of the hazards involved in and the effects
on man, animals, and plants of fluorine and its compounds, as
well as the possible sources of fluorine emissions with special
regard to fission fuel processing and nuclear engineering are
<xref image="2000WVIN.TIF|V3|2006:09:28:01:34:02.00|116799|0"> image: </xref>

reviewed. Fluorine and its compounds, either ingested or inhaled, are carried by the blood to different organs such as the kidney, and are eliminated relatively rapidly in urine. Gastrointestinal, cardiac, and renal damages, pulmonary edema, convulsions, and irritation of the respiratory tract are typical symptoms of acute fluorine poisoning. Fluorosis due to chronic exposure to fluorine and its compounds manifests itself in bone and tooth damage, gastrointestinal troubles, and asthma. Unlike cattle, humans are relatively insensitive to fluorine intake. *Colchicum autumnale*, *Lilium* sp. cultivar, *Iris germanica* and *Vitis vinifera* L. are among the most fluorine-sensitive plant species. Physical and chemical properties, as well as metabolic mechanisms of various fluorine compounds are described.

ON THE FLUORIDE BODY BURDEN OF RESIDENTS LIVING IN FLUORIDE POLLUTED AREAS. (Taiki-chu fukkabusu ni yoru kankyo osen chiku jumin no seitai osen ni (suite). Text in Japanese. Japan Society of Air Pollution, Proc. Syntp. Japan Soc. Air Pollut., 13th, 1972, p. 199. (Nov. 7-9, Paper 154.)

The fluorine pollution of the living body checked by the urine test is discussed. When a solution of fluoride is taken orally, an increase of fluorine content in the plasma is noted in 15 min, and the index reaches a peak in 30 min, then drastically reduces. Approximately 15% of orally taken fluorine is excreted in the urine in 1 hour, 25% in 2 hours, 43% in 3 hours, and more than 50% of the consumed fluorine is excreted in 12 hours. When examining the in-vivo effects of fluorine by urine samples, spot sampling is not enough, but continuous tests are necessary. According to the 24-hour samplings of people living in a fluorine polluted area, in more than 1 l of urine averages of 2.05 plus or minus 0.30 mg/person of F for 13 men, and 1.77 plus or minus 0.43 mg of F for 17 women were excreted. A similar test was given to people in an unpolluted area, and averages of 0.79 plus or minus 0.07 mg/person for nine men and 0.73 plus or minus 0.07 mg for 13 women were excreted in 24 hr. The difference was conjectured to be the amount of fluorine residues in the agricultural produce gathered from the environment. The results of an examination of teeth fluorosis in a polluted area is briefly mentioned.

Ordonez, Blanca Raquel
THE EFFECTS OF AIR POLLUTION ON HUMAN HEALTH. (Los efectos de la contaminación atmosferica en la salud del hombre). Text in Spanish. Salud Publica Mexico, 14(2):209-216, March-April 1972. 38 refs. (Presented at the National Security Congress, Mexican Hygiene and Security Association, Nov. 1971.)
Effects of air pollution on human health are reviewed and illustrated by the famous accidents which occurred in London, the Meuse Valley, in the U. S., and in Japan. Meteorological (humidity, temperature inversion, solar radiation), geographical, and biological factors enhancing the damaging effects of air pollution on whole populations are discussed. Pollutants are divided into irritant and absorption agents according to their action target. Irritant pollutants can be divided into reducing (sulfur dioxide and dust particles) and oxidizing agents such as ozone and nitrogen oxides. Agents acting upon absorption include carbon monoxide, lead, 3,4-benzopyrene, polynuclear hydrocarbons, and fluorides. The action of SO₂ and dust particles on the respiratory tract is strongly interrelated, and the effect of the former is catalyzed by the latter. Both effects are enhanced by atmospheric humidity since respiratory symptoms appear to be more severe under fog conditions. Epidemiology data indicate that chronic bronchitis patients are even more

susceptible to the above and to oxidizing agents. Carbon monoxide effects include formation of carboxyhemoglobin interfering with tissue respiration processes. Inhalation of larger CO amounts may cause death upon failure of the central nervous system. People suffering from heart disease or severe anemia are most susceptible to CO. Lead interferes with the hemoglobin synthesis processes and causes kidney and liver damage, fertility impairment, and mental retardation in children. Benzo(a)pyrene is known to be carcinogenic in laboratory animals and in occupationally exposed workers; however, no correlation between benzo(a)pyrene, emitted by automotive vehicles and lung cancer could be established. The lack of studies relating pollution and health hazards in Mexico is emphasized.

50161

Kuehnert, M.

EMISSIONS AND THEIR IMPORTANCE FOR CATTLE

BREEDING AND HUMAN HEALTH. (Immissionen und ihre Bedeutung fuer die Tierproduktion und die menschliche Gesundheit). Text in German. Z. Ges. Hyg. Ihre Grenzgebiete (Berlin), 19(2):89-98, Feb. 1973. 28 refs. (Presented at the Gemeinschaftstagung der Gesellschaft Allgemeine und Kommunalc Hygiene der DDR undder Wissenschaftlichen Gesellschaft fuer veterinarmedi/Jn der DDR, May 8-15, 1972.)

The effects of fluorine, carbon monoxide, metals such as lead, mercury, and arsenic, and hydrocarbons on cattle and man are reviewed, and data on maximum allowable emission concentrations for these substances in the U. S. are listed. In the German Democratic Republic the emission regulations of June 28, 1968 include maximum allowable emission concentrations for various pollutants, e.g., lead 0.0007 mg/cu m (24 hour value); fluorine 0.01 mg/cu m, sulfur dioxide 0.15 mg/cu m, and oxides of nitrogen 0.1 mg/cu m. Fluorine injuries of a chronic nature were witnessed in East Germany. In young cattle the following F concentrations were measured, lower jaw bone (ash) 2700 ppm, ribs up to 3500 ppm. Retarded growth and lower milk production were also noticed. The lead contamination of cattle in the Mannsfeld and Freiberg areas is mainly due to automobile exhausts. In Poland the arsenic emission in the vicinity of a power plant fired with coal was measured to be 1 t/day. A maximum concentration of 69 micrograms As/cu m was repeatedly measured. Within a radius of 30 km an extensive bee kill was noticed. The government gives the problem of air pollution exposure of humans and cattle great attention. In the centers of the chemical industry such as Bitterfeld, Leuna, and Buna, the development of processes producing a low amount of pollutants is given high priority in the 5 year-plan. The SO₂ and dust emission will be reduced by the erection of a new power plant serving the chemical industry in Bitterfeld operated with natural gas. Electrostatic precipitators are used to reduce pollution from the Buna power plant.

G. EFFECTS-HUMAN HEALTH

313

The measurements of sulfur dioxide, suspended particulates, soot, fluoride, automotive exhaust gases, fluoride ion, nitric oxide, nitrogen dioxide, and hydrogen fluoride, for Niigata Prefecture are presented. The fluoride and sulfur content in 426 samplings of cedar leaves are compared. The leaves from the most damaged areas showed significant differences of F content by age; the greatest amount was found in new leaves, followed by 1 year leaves, 2-year leaves, and dead leaves. But in the areas with slight damages, there was no significant difference in the age of leaves and the amount; slightly higher F content was found in dead leaves. The fluoride ion content in urine was measured from the samplings of 958 children in polluted areas and 61 children in non-polluted areas. The total average in non-polluted areas was 0.17 ppm, and that of the polluted area was 0.43 ppm. The average of the infants in the polluted areas was 0.38 ppm, elementary schoolchildren 0.41 ppm, and junior high school pupils 0.38 ppm.

EFFECTS OF FLUORIDE FROM ALUMINUM REFINING

MANUFACTURE IN MAN-NAOETSU LITTORAL INDUSTRI-

AL AREAS. (Niigata-ken Naoetsu rinkai kogyo chitai ni okeru fusso ni yoru jintai eikyo ni tsuite). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 9(4):339-346, April 1973. 21 refs.

The chronic effects of fluoride pollution on the human health were examined thoroughly in the Naoetsu Coastal Industrial Area, near Mitsubishi Chemical Plants. Examinations were given on the general health, teeth, respiratory system, and urine on the primary level, and on the secondary level, blood, basic metabolism, cardiograph, and X-ray images were examined. The tests were started in Nov. 1970 and completed before Aug. 1972. The adult urine in two polluted areas had averages of 0.813 ppm and 0.759 ppm, and in control area 0.574 ppm. Among children, the averages were 0.391 and 0.408 ppm in polluted areas, and 0.180 ppm in the control area. The significant difference was greater among children than among adults. The frequency of incomplete or irregular enamel formation of teeth among children (3-15 yr) was 198/982 in polluted areas (20.2%), and 11/61 (18.0%) in the control area. For the examination of mottled teeth, all the malformation of enamel layers suspected of other factors than pollution were eliminated. Ten mottled teeth of a light degree and six advanced cases were recognized among 198 children with irregular enamel formation. There were five slight cases of mottled teeth in the control area. The ratio of cavities on permanent teeth was 69% in polluted areas and 82% in non-polluted area. The X-ray tests showed that 11 among 57 adults (19.3%) had abnormal bone formation. Symptoms like chronic bronchitis were complained of by 44 in polluted areas (5.2%) and one in nonpolluted area (1.6%). Some ventilation function impairment and lung infections were noted.

Tsuji, Yoshito

STUDIES ON THE TOXICITY OF FLUORIDE UNDER SOME

ENVIRONMENTAL POLLUTIONS. (Fukkabutsu ni yoru chiiki

osen to seitai). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 9(4):324-330, April 1973. 62 refs.

The relationship between fluoride and teeth, such as cases of mottled teeth, prevention of decay, and bone formation are discussed. Normally, mottled teeth are formed as a result of consumption of water containing 0.3-0.8 ppm F. However, air pollution containing F has produced some mottled teeth cases in the Kita area of Fukushima prefecture, where the Showa Electric Aluminum Plant is located. When F is taken into the body over a long period of time, the bone structure changes as well as the teeth, and fluorosis occurs. The amount of fluoride causing osteosclerosis or osteoporosis is about 5.9 ppm 11.78

ppm. A large quantity of F interferes with the normal growth of children, whereas a small amount seems to enhance the growth. Children with third degree mottled teeth were small, but those with first degree were rather tall. In the Kita area, the atmospheric F content is 3-5 ppm within 2 km of the Showa Aluminum Plant, and F in the settling particles is 100-230 kg/sq km/mo. The control area 4-7 km from the pollution source has about 1/10th the F content in both atmosphere and settling particles. The average height of the children was slightly greater in the polluted area, and the growth rate per year was also greater in the same area. However, an X-ray examination of the right arm revealed that there was a slight delay of maturity of bones in the fifth and sixth graders. Among the junior high school pupils, the maturity of hand bones was slightly faster among the children from polluted areas.

THE NORMAL URINE EXCRETION OF LEAD, CADMIUM,
MERCURY, AND FLUORIDE. (Ippan kenkojin no nyochu-en,
kadominmu, suigin, fusso no haiset.su ni tsuite). Text in
Japanese. Japan Society of Industrial Hygiene, p. 188-189, 1973.
(Presented at the Japan Society of Industrial Hygiene, Annual
Meeting, 46th, April 1973, Paper 305.)
Urine from 400 healthy residents in the metropolitan Tokyo
area was analyzed for content of lead, cadmium, mercury, and
fluorine. The Pb content was compared to that in urine from
occupational workers exposed to an atmosphere containing
different concentrations of Pb. The urine of healthy persons
contained 6.94 + or - 4.18 micrograms Pb/l, 0.82 + or - 0.62
micrograms/Cd/l, 10.37 + or - 8.21 micrograms Hg/l and 0.50
+ or - 0.29 micrograms F/l. The Pb content in urine from wor-
kers exposed to 0.01-0.03 mg/Pb/cu m was 14-17 micrograms/l,
from those exposed to 0.05-0.10 mg Pb/cu m was 30-60 micro-
grams/cu m, and from those exposed to 0.17-1.67 mg/cu m of
lead was 75-95 micrograms/cu m.

<xref image="2000WVIP.TIF|V3|2006:09:28:01:34:10.00|121410|0"> image: </xref>

The contribution of fluorine compounds to the general problem of air pollution and the physiological effect of fluorine pollutants on vegetation, man, and animals are examined. The outward symptoms of fluorine poisoning in plants are generally a typical necrosis of the tips and edges of leaves and eventual destruction of the assimilating apparatus, depending on intensity of exposure. The toxicology of the fluorine ion with respect to human beings and animals is connected primarily with changes in the body disposition of calcium and iodine. The external disease symptoms in animals include thickening and formation of nodes on long leg bones, ribs, and joints, leading to lameness; lack of appetite; stiffness. The human organism is more susceptible to fluorine poisoning than animal organisms; the toxic effects in humans are manifested as fluorosis. Emission sources and types of exposure are examined.

Suzuki, Takeo

ENVIRONMENTAL HEALTH. (Kankyo Hoken). Text in Japanese. Koshu Eisei Joho (Public Health Inform.), 3(5):27-35, May 1973. 2 refs.

The recent environmental problems, problems presently increasing in importance, the effects of environment on the human being, and WHO's environmental health projects are discussed. One of the increasing problems is the traceable amount of heavy metal in suspended particulates its relationship with cancer and high blood pressure. The metals which in excessive quantities cause cancer include iron, copper, manganese, magnesium, molybdenum, and zinc; traceable metal carcinogens are nickel, cadmium, and chromium. Those that are conjectured to be carcinogens but have not been proven are cobalt and lead; the role of selenium as a carcinogen is still unclear. The known traceable metals which have bad effects on cardiac and vascular functions are manganese, chromium, vanadium, cobalt, zinc, fluorine, selenium silicon, copper, cadmium, and arsenic. According to the recommendations of WHO, new criteria must be set for nitrogen oxides, polychlorinated biphenyls, nitrite, nitrate, nitrosoamine, manganese, noise, ultrasonic waves, tritium, krypton, and a few other compounds.

TOXICITY OF WEAKLY SOLUBLE FLUORIDES INTRODUCED BY INHALATION ROUTE. (K voprosu o toksichnosti plokho rastvorimykh ftoridov pri ingalyatsionnom vozdeystvii). Text in Russian. Gigiena i Sanit., no. 4:14-16, 1973. 2 refs.

The chronic toxicity of the weakly soluble fluoride cryolite was studied in albino rats that inhaled 3.1 and 0.5 mg/cu m concentrations of this substance for 6 hr a day over 5 months. Concentrations of 3 and 1 mg/cu m produced both general and specific toxic effects on the organism, with manifestations such as disturbances in motor chronaxy, tendency of decreased blood cholinesterase activity, reduced vitamin C level in the adrenal glands, inhibition of carbohydrate metabolism, increased fluorine concentration in the urine, accumulation of fluorine in teeth and bones, edema of the mucous membranes of the respiratory tract, eosinophilic leukocyte infiltration of the lung tissue with focal hemorrhages, granular dystrophy of the liver and kidney cells, inflammation of the gastrointestinal tract, and corrugation of brain cells. Cryolite at a concentration of 0.5 mg/cu m was ineffective, and this level may be recommended as the maximum permissible concentration of weakly soluble fluorides in the air of industrial premises.

AN ATTEMPT TO EVALUATE EXPOSURE TO FLUORIDES BASED UPON FLUORIDE LEVELS IN HAIR. Fluoride,

4(2):98-100, April 1971.

The relationship between fluoride exposure and fluoride levels in hair was investigated using three groups of subjects. Group one constituted the control group and were residents of an area with no exposure to fluoride. Group two were residents in an area where the drinking water contained 1.2 mg F/l. Group three consisted of welders with occupational exposure to fluorides. Based on tests of all three groups, a direct relationship between the fluoride levels in hair and their concentration in air and drinking water was determined.

ADSORPTIVE CHARACTERISTICS OF DUSTS AND FUMES

- THEIR POSSIBLE ROLES IN TISSUE REACTIONS. Cin-

cinnati Univ., Ohio, Inst. of Industrial Health, Thesis (Ph.D.), Ann Arbor, Mich., Univ. Microfilms, Inc., 1962, 93p. 55 refs.

The role of adsorptive properties in the interactions of particles with tissues and the causation of fibrotic processes was investigated with respect to the adsorptive characteristics of dusts and fumes. Globulins in varying concentrations were subjected to adsorption upon a series of dusts. The value of a constant was determined as an index of strength of the adsorptive bonds for 14 different dusts, including forms of silica (quartz, cristobalite, and silica gel), charcoal, graphite, kaolin, emery, Georgia clay, asbestos, beryllium oxide, ferric oxide, calcium fluoride, and mixtures of dusts and fumes collected from an electrometallurgical plant. The dusts known to be less active in eliciting the production of fibrous tissue were at either end of the spectrum, i.e., had either very weak or very strong bonds. Those known to be active in fibrotic processes were in the middle. The selectivity of the adsorptive sites for certain properties was also investigated. All dusts adsorbed selectively certain groups of proteins, but the differences were not correlated with the biological activity. (Author summary modified)

URINARY FLUORIDE ELIMINATION AND FLUORINE

DEPOSITION IN BONES AND TEETH OF THE RATS

AFTER INHALATION. Fluoride, 6(3):151-154, July 1973.

Urinary fluoride elimination and fluoride deposition in bones and teeth of rats after inhalation was studied. Rats in the experiment inhaled fluoride in concentrations of 9.4-11.7 micrograms/l of air for a period of 5 mo. The animals were divided into four groups, three exposed and one control. The first group was exposed 90 hr, the second 180 hr, and the third 270 hr to hydrogen fluoride in the inhalation chamber. After inhalation, rapid absorption of fluoride in the organism took place. This was indicated by increased elimination of fluorides in the urine, the occurrence of characteristic changes in the dental enamel, and elevation of fluoride in bones and teeth, without radiographic changes. The changes following inhalation are the same as those for oral administration. Fluoride absorbed by the lung was eliminated rapidly from the organism; the amount present in the urine depended upon the duration of the exposure. About 1/3 of the inhaled fluoride was eliminated in the urine. Fluoride deposition in bones and teeth increased regardless of the duration of intoxication. No increase in fragility of the bones was noted in relation to their fluoride content. (Author abstract)

Prival, Michael J. and Farley Fisher

FLUORIDES IN THE AIR. *Environment*, 15(3):25-32, April 1973. 61 refs.

Fluoride is released into the air in large quantities by aluminum reduction plants, phosphate processors, steel mills, coal burning operations, brick and tile manufacturers, and various less significant sources. It can cause adverse effects when ingested by domestic animals or absorbed by plants. Fluoride air pollution can adversely effect human health. Fluorides are released into air in both a gaseous state as hydrogen fluoride and silicon tetrafluoride and in solid particles. Nationwide control of airborne fluorides is needed. The simultaneous control of levels of fluoride in the air and levels in sensitive plants, in food, and in forage should all be included in any set of standards. Permissible concentrations should be determined by field studies in areas where fluoride pollution is a problem. Improvement in occupational health standards for hydrogen fluoride and other airborne fluorides is needed. Any devices used to control emissions of fluoride from polluting industries can, and should, be designed to minimize exposure of the people who work within industry. Monitoring of fluorides is mentioned.

Hackel, R. and J. Reichert

ON THE DEMONSTRATION OF SILICOFLUORIDE

POISONINGS. (Zum Nachweis von Silicofluoride-Vergiftung).
Beitr. Gerichtl. Med., vol. 29:421-424, 1972. 4 refs. Translated

from German, 7p.

Silicofluoride poisoning was chemically demonstrated by analyzing body organs containing lethal doses of zinc fluoride ($ZnSiF_6$) for zinc. The Zn content was determined by measurement of atomic absorption after destruction of the organic material and this concentration was significantly higher than normal standards. The zinc silicofluoride intoxication was easily diagnosed in connection with the positive fluoride analysis of the stomach. Normal values for mg of Zn/100 g in blood are 0.880, in liver 5.717, and in kidneys 4.225. In the case of zinc silicofluoride poisoning, the values were 76.659 for blood, 10.575 for liver, and 11.075 for kidneys. Fluoride and silicofluoride values were calculated from the Zn values and are expressed in mg/100 g. In blood, the values for Zn are 76.659, for fluoride 133.675, and for $ZnSiF_6$ 243.270. In urine the values are 0.375, 0.769, 1.190; in the stomach the values are 274.325, 478.359, 870.546; in liver the values are 10.575, 18.440, 33.559; in kidneys the values are 11.075, 19.312, 35.146. The determination of the metallic cation is an effective chemical demonstration of silicofluoride poisoning.

SUPPRESSIVE ACTIVITY BY FLUORIDE ON THE INDUCTION OF CHROMOSOME ABERRATIONS IN HUMAN CELLS WITH ALKYLATING AGENTS IN VITRO. *Mutat. Res.*, 19(3):369-371, Sept. 1973. 11 refs.

Sodium fluoride was investigated in combination with three alkylating agents in human cells in vitro to determine if fluoride inhibits the induction of chromosome breaks. The mutagens used were 2,5-bis-(methoxyethoxy)-3,6-bis-ethyleneimino-p-benzoquinone (A139), 2,3,5-tris-ethyleneimino-p-benzoquinone (trenimon), and 2,3,5,6-tetraethyleneimino-p-benzoquinone (TEB). Sodium fluoride alone had no effect on the chromosomes. The ethyleneimines induced typical chromatid aberrations whose frequencies were lowered in the combination series with NaF. The suppressive effect of fluoride was especially clearcut with the chromatid translocations (RB prime). Considerable amounts of triradials were only seen with TEB. This aberration type was also lessened in the combination series, showing a frequency of 0.04 per cell with TEB

alone and 0.01 with TEB and NaF. The frequencies of achromatic lesions were lowered or not changed at all in the combination series. Fluoride had a strong antimutagenic effect on the aberration induction with polyfunctional alkylating agents.

Schorn, Gert

MANKIND THREATENED BY SLOW DEATH. (Wir leben mit dem schleichenden Tod). Text in German. Deut. Apoth.-Z., 111(2):46-49, Jan. 1971.

Global problems of environmental pollution are outlined, and criticism is given of the ignorance and one-sided profit-mindedness displayed in environmental issues. The steady increase in the atmospheric carbon dioxide concentration, a result of ever-increasing energy demands, high carbon monoxide and sulfur dioxide levels, occurring especially in urban agglomerations with heavy traffic and in industrial areas, as well as the ubiquitous presence of lead and fluorine in the atmosphere are among the serious environmental hazards. Health, plant, and material damages due to CO, SO₂, and nitrogen oxides are described. The hazards of lead residue are in its ability to accumulate in the human organism and to pass the placental barrier. Lead is activated during pregnancy, and it interfered with the synthesis of desoxyribonucleic acid, sexual functions, and spermiogenesis. Adequate technical solutions are now available for the control of vehicle exhaust CO emissions.

NEW OBSERVATIONS ON CFFLZZOLA MACULAE. Proc. Int. Clean Air Congr., 3rd, Duesseldorf, West Germany, 1973, p. A63-A67. 12 refs.

Epidemiological findings are reviewed for four groups of individuals from widely separated geographical areas where outbreaks of skin lesions (maculae) occurred. Fluoride exposure either by industrial air pollution or by presence in the drinking water or vegetation was common to all outbreak areas. The skin lesions are round or oval maculae of one to two cm in diameter and not sharply delineated. They are painless upon digital pressure and remain unchanged upon diascopy. Color upon first appearance is pinkish-brown which turns to a darker red brown after five to seven days before gradual fading. There is no break of the skin, nor are the lesions raised above the surface. The limbs and to a lesser extent the trunk are the parts mainly affected. Histological specimens have shown mild pericapillary infiltrations with lymphocytes, neutrophils, and mast cells involving the upper layer of the chorium. Laboratory studies showed eight of 22 cases exhibiting an elevation of alkaline phosphatase. Attempts to reproduce the lesions experimentally in mice and rats have failed thus far, and this fact combined with a higher incidence of lesions among children and women suggests that certain factors in addition to fluoride intake are involved.

EXPERIMENTAL EXPOSURE OF GOATS TO ENVIRONMENTAL POLLUTION BY FLUORIDES IN THE AIR, PART

I: OUTLINE OF THE EXPERIMENT. (Taiki chu fukkabutsu

no kankyo osen ni yoru yagi no bakuro jikken -dai lop- jikken

<xref image="2000WVIR.TIF|V3|2006:09:28:01:34:18.00|119178|0"> image: </xref>

gaiyo). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 8(3):418, Oct. 1973. (Presented at the Japan. Society for Air Pollution, Annual Meeting, Fukushima, Japan, 14th, Nov. 6-8, 1973.)

Goats are bred in fluorine-polluted fields to determine the effects of air and environmental pollution. Experimental goats were bred in fields 0.1 km and 0.5 km away from an aluminum refinery. The average concentrations of hydrogen fluoride in the air were 0.9-2.6 ppm and 0.5-0.6 ppb. The goats are fed 21.8-42.6 ppm F2 in dried herbs and 3-7 ppm F2 in bran and potatoes. Control goats are pastured 4-6 km from the factory in a non-polluted area and fed 5-9.9 ppm F2. Monthly analysis shows F2 contents in the blood 4-6 times greater in the experimental goats, and 5-7 times greater in the urine. The F2 in the feed is more influential than the F2 in the air.

Takizawa, Y.

ON THE INFLUENCES OF FLUORIDES ON HUMAN BODY.

(Fukkabutsu no jintai ni oyobosu eikyo ni (suite). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 8(3):421, Oct. 1973. (Presented at the Japan. Society for Air Pollution, Annual Meeting, 14th, Fukushima, Japan, Nov. 6-8, 1973.)

An epidemiological investigation was conducted on the total population residing within 1 km of an aluminum refinery. Fluorine content in the urine, subjective symptoms, percussion, stethoscopy, dental health, respiratory function, hematology, alkaline phosphatase, basal metabolism, ECG, chest and bone x-rays, and urinalysis were considered. The investigations on persons older than 40 and children between 3 and 15 show the following: fluoride ion concentration was higher in the polluted area for both age groups, macular teeth appeared 2 times as frequently in the polluted area, the frequency of caries in permanent teeth was 69% in the polluted areas, anomalies of bone development in children were more frequent in the polluted areas, respiratory complaints were more frequent in the polluted areas and chronic bronchitis morbidity was high, diffuse shadows on the lungs were found in the polluted areas, and deposition of Al was less than 10 micron in all respiratory systems,

Sato, Y., H. Tsunoda, and N. Konno

EXPERIMENTAL EXPOSURE OF GOATS TO ENVIRONMENTAL POLLUTION BY FLUORIDES IN THE AIR, PART HI: ON THE TRANSPLACENTAL PASSAGE OF

FLUORIDES. (Taikichu fukkabutsu no kankyo osen ni yoru yagi no bakuro hikken -dau 3po- fukkabutsu no taiban tsuka ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 8(3):420, Oct. 1973. (Presented at the Japan. Society for Air Pollution, Annual Meeting, 14th, Fukushima, Japan, Nov. 6-8, 1973.)

The fluorine content of the blood of a mother goat bred in fluoride-polluted air was determined and compared to the F2 levels in the hard and soft tissues of her kids directly after birth. The F2 levels in the serum of one mother goat fluctuated widely between 0.05-0.6 ppm in a year, but the other experimental goat had a more stable level of 0.05-0.15 ppm. The average F2 content was higher before, rather than during, pregnancy. The distribution of F2 in the kids concentrated in the aorta and the spleen from the soft tissues, and in the ribs, vertebrae, and bones (excluding teeth), from the hard tissues. A correlation between the F2 contents of the mother's serum and the F2 contents in the kid's body, especially in the hard tissues, was recognized.

EXPERIMENTAL EXPOSURE OF GOATS TO ENVIRONMENTAL POLLUTION BY FLUORIDES IN THE AIR, PART

II: RESULTS OF CLINICAL EXAMINATIONS FOR ONE YEAR. (Taiki chu fukkabutsu no kankyo osen ni yoru yagi no bakuro jikken -dai 2ho- ichinenkan no rinsho kensa seiseki). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 8(3):419, Oct. 1973. (Presented at the Japan. Society for Air Pollution, Annual Meeting, 14th, Fukushima, Japan, Nov. 6-8, 1973.)

A comparison of the rate of weight increase and blood chemistry in goats bred in fluorine-polluted and control areas is given. No difference of the rate of body weight increase, nor any difference in tissue appearance or palpitation is noted. Hematocrit percentage, hemoglobin, total protein, albumin, glucose, bilirubin, TTT, ZTT, GOT, GTP, Alkaline-phosphatase, LDH, LAP, cholesterol, BUN, nutrition, liver function, and enzyme activity were similar for the experimental and control goats for the first year.

Ronzani, E.

ON THE EFFECT OF INHALATIONS OF IRRITANT INDUSTRIAL GASES ON THE PROTECTIVE ABILITIES OF THE SYSTEM WITH RESPECT TO INFECTIOUS DISEASES.

(Ueber den Einfluss der Einatmungen von reizenden Gasen der Industrie!! auf die Schutzkräfte des Organismus gegenueber den infektiiven Krankheiten). Arch. Hyg. Bakteriologie (Munich), vol. 70:217-233, 1909. Translated from German, 20p.

Rabbits, guinea pigs and doves were exposed to hydrofluoric acid gas for extended periods of time at concentrations of 0.01%, following preliminary examinations at higher levels with other animals of the same kind, in order to examine the overall effects of the gas as well as the effects of its inhalation on immunological mechanisms. Autopsies, histological examinations, and serum tests were performed subsequent to exposure. The extended inhalations were found to cause death in a significant number of animals with symptoms of catarrhal bronchopneumonitis, interstitial pneumonitis, and marasmus. Animals which survived experienced severe lesions of the lungs, severe anemia, and weight loss up to 23.2%. Experimental animals also produced considerably less agglutinating substances than control animals; and among animals immunized for typhus, those exposed to inhalations showed a sharp decrease in the production of specific antibodies. Bacteriocidal studies using *B. prodigiosi* showed considerable weakening of the lungs capability to destroy such microorganisms in the face of Hf inhalation.

Nishimura, H.

TETATOGENIC SUBSTANCES. Intern. Chem. Eng., 13(4):774-780, Oct. 1973. (Also: Iden (Heredity), 26(5):19-22, 1972.) The toxic effects of various substances on human beings are discussed. Fetuses are highly susceptible to toxic and mutagenic effects from external causes. The origin, nature, and detection of disturbances in fetuses are mentioned. Several cities with high air pollutant concentrations had higher infant death rates and higher rates of deformed infants and stillbirths. Poisonous heavy metal and inorganic compounds include mercury, lead, sodium selenite, fluorine, and arsenic. Pesticides such as DDT and PCB (polychlorinated biphenyls) also have harmful effects. Mercury and PCB have contaminated rice, fish, and shellfish, foods which mainly constitute the diet of Japanese. Miscellaneous organic compounds such as PCB, detergents, and organic solvents have also affected infants and fetuses. Artificial sweeteners such as cyclamates and sodium glutamate affected laboratory animals.

SKEV-RESORPTIVE EFFECT OF HYDROGEN FLUORIDE FUMES. (Kozhno-rezorbktivnoye deistvie parov ftoristogo vodoroda). Text in Russian. Gigiena Truda i Prof. Zabolevaniya, no. 1:31-33, 1974. 9 refs.

The repeat action of hydrogen fluoride in concentrations of 38.6 an/ 72 mg/cu m on the respiratory organs and skin of rats caused marked resorptive effects in both cases. Fluorine accumulated in the organism, and specific biochemical changes occurred in the carbohydrate, mineral metabolism, and the redox processes. The degree and nature of pathological alterations were similar in an isolated action of gaseous HF both via the skin said the organs of respiration. Possible penetration of fluorine into the organism in ionic form via the skin occurred.

Tsuji, Yoshito

AIR POLLUTION AND HUMAN HEALTH. (Taiki osen to ken-ko). Text in Japanese. Fukushima Igaku Zasshi (Fukushima Med. J.), 22(5-6): 159-160, Dec. 1973. (Presented at the Fukushima Medical Association, Annual Meeting, 94th, Nov. 11, 1973.)

Influences of air pollution on the human body generally appear as epidemiological increases of non-specific disturbances of pulmonary functions resulting from interactions between the pollutant, the environment, and the host. Initial effects are eye and respiratory system irritations, followed by increases in airway resistance and mucus secretion, and they end in acute and chronic diseases such as bronchitis and emphysema. Air pollution increases discomfort experienced in chronic diseases. The known effects of specific pollutants are described, with special attention given to suspended dusts and fluorine compounds.

60625

INDIVIDUAL COMPONENTS OF AIR POLLUTION. (Die einzelnen Komponenten der Luftverunreinigung). Text in German. Bull. Eidgenoess. Gesundheitsamtes, Beilage B, no. 6:324-343, Dec. 1973.

The individual components of air pollution, such as sulfur dioxide, panaculate matter, 3,4-benzo(a)pyrene, lead, fluorine compounds, carbon monoxide, and smog, as well as their effects on the human and organisms and on plants are described.

The increase of the total SO₂ emission between 1960 and 1970 were relatively moderate despite the strong increase in the fuel consumption, while an increase by about 40% until 1980 is expected unless adequate measures such as (fuel and flue gas desulfurization) are introduced. Domestic heating-generated SO₂ is especially remarkable due to the low chimneys. Particulate matter, especially respirable dust and soot, are hazardous because they can penetrate to the lower respiratory tract, and may contain other pollutants, such as SO₂. Benzo(a)pyrene concentrations of 2-15 micrograms/1000 cu m were measured in Basel and Zurich. Carbon monoxide, emitted mostly by automobiles, causes no subjective symptoms of poisoning as long as its concentration is below 60 cu cm/cu m, corresponding to COHb values below 10%. The rate of resorption of atmospheric lead is estimated at 30-40%. The lead concentration in Zurich increased from 1.5 microgram/cu m in 1949 to 1.9 micrograms/cu m in 1973. Photochemical smog and fluorine compounds have strong irritative effect on the human organism and on plants.

60748

Grieser, N.

HYDROFLUORIC ACID. (Fluorwasserstoff). In: Medizinisches Institut fuer Lufthygiene und Silikoseforschung Jahresbericht 1971. Text in German. Duesseldorf, Michael Tritsch Verlag, 1972, p. 69-89. 77 refs.

Studies on the mechanism of action, resorption, elimination, and the acute, subacute and chronic effects of hydrofluoric acid in the human and animal organisms are reviewed. Fluorine can enter the human and animal organism enterally, pulmonally, or percutaneously. The resorption after enteral uptake is strongly dependent on the solubility of the fluorine compounds. Very rapid diffusion of fluorine in tissues and body fluids was observed. Chlorine is eliminated from the organism mainly by the kidneys, while residual fluorine is incorporated in bones from which it may again enter the blood. Cumulation of fluorine in soft tissues was not evidenced. Fluorides inhibit numerous enzymatic processes due to the formation of fluorine-containing enzyme antagonists, and through binding the metallic cofactors of the enzymes. Retardation of the proliferation and destruction of bone cells, and gelatin-like degeneration of the bone marrow due to fluorine were observed. Pathologic changes of bones are possible at fluorine concentrations of 3000 to 5900 ppm. Changes in the metabolism in organs and bones, anorexia, cachexia, diarrhea, lesions of the renal tissues, and exostoses may occur in subacute poisoning by fluorine. Acute poisonings are characterized by such symptoms as changes in the enzymatic processes, especially in calcium and glucose metabolism, muscular fibrillation, clonicotonic spasms, hyperpnea, lachrymation, salivation, intensified intestinal tonus, gastroenteritis, and necrosis of the myocardium. The maximum allowable workplace concentration of hydrofluoric acid in West Germany is set at 2 mg/cu m.

BALNEOLOGY AND CLIMATOLOGY). (Dai 37kai Nippon Onsen Kiko Butsuri Igakukai Sokai, Tokubetsu koen; Kankyo osen to kenko). Text in Japanese. Nippon Onsen Kiko Butsuri Igakkai Zasshi, (J. Japan. Assoc. Phys. Med., Balneol. Climatol.), 36(1.2):34-36, Oct. 1972.

The air pollutants sulfur dioxide, nitrogen oxides (mainly nitrogen dioxide), carbon monoxide, lead, hydrogen fluoride, cadmium, vanadium, ozone oxidants, aldehyde, peroxyacetyl nitrates, and smoke are discussed. Better indices of air pollution than SO₂, CO, and dust {the currently used indices) are needed. The effects of air pollution on humans, especially the elderly, infants, and the sick, are reviewed. The relationships between environmental pollution and Minamata and Itai-Itai disease are discussed. Bathing in, drinking and inhalation of hot-spring water is suggested as a possibly beneficial practice.

61467

Makino, S. and A. Miyamoto
AIR POLLUTION AND ALLERGY. (Taiki osen to arerugi). Text in Japanese. Jibi Inkoka (Otolaryngol.), 45(10):701-712, Oct. 1973, 36 refs.

The relationship between air pollution and respiratory diseases such as allergies and asthma is reviewed. Epidemiological studies reveal that air pollution tends to induce respiratory symptoms in older persons with allergic dispositions and asthma. Sulfur dioxide and photochemical oxidant levels have been implicated in the onset of asthmatic fits. Other offenders, existing as gases, dusts, and aerosols, include carbon monoxide, sulfur oxides, nitrogen oxides, hydrocarbons, metal powders, pesticides, fluorides, asbestos, radioactive substances, and natural pollutants such as pollen and fungal spores. Experimental animal studies are described. Airway hypersensitivity is discussed in relation to the effect of chemical mediators, allergens, and housedusts. Although air pollution is known to aggravate allergies at the levels of stimulation of airway mucosa, constriction of bronchus, accentuation of airway hypersensitivity, stimulation of antibody production, and increase of airway infection, it is still not known whether it is a causal factor.

Hodge, Harold C. and Frank A. Smith
FLUORIDES. In: Metallic Contaminants and Human Health. D. H. K. Lee (ed.), New York, Academic, 1972, Chapt. 7, p. 163-187. 31 refs.

In an overall review of fluorides, the health hazards and air-borne distribution of the compounds are discussed. The literature reports the concentrations of airborne fluoride in individual samples range from traces to maximal values of approximately 8 mg/cu m, averages range from 0.12 to 3.4 mg/cu m. Urinary fluoride excretions range from 1-5 mg/11. Analyses of the ambient atmospheres normally present over a number of Lf. S. cities show fluoride concentrations ranging between 0.01 microgram/cu m and 3.9 micrograms/cu m. Fluoride absorption has not been measured, but assuming a volume of 20 cu m is inhaled per 24 hr with 100% retention, the maximal dose would be 0.004-0.04 mg daily. In a heavily polluted area, the intake of the average man would be about 0.04 mg. Such amounts constitute negligible contributions to the total daily intake of fluoride from food and water, about 0.5-1.5 mg.

Oshina, T., R. Sugai, H. Sato, and K. Kaneda
RESULTS OF THE ENVIRONMENTAL POLLUTION INVESTIGATION ON FLUORIDES IN THE SURROUNDING OF AN ALUMINUM REFINERY - INVESTIGATION OF FLUORINE POLLUTION OF DIETS. (Arumi seiren kojo shuhen no fukkabutsu no kankyo osen chosa - sesshu shokuhin no osen chosa). Text in Japanese. Nippon Kosho Eisei Zasshi (Japan. J. Public Health), 20(10)Special Suppl.): 1p., Oct. 1973. (Presented at the Japan Society of Public Health, Annual Meet-

ing, 32nd, Hiroshima, Japan, Oct. 1973. Paper 561.)
By the investigation of daily diets of inhabitants of the area surrounding an aluminum refinery, the intake of fluorine was estimated to obtain the fundamental information concerning indirect effects of fluorine to human body. Differences of fluorine in urine between areas, ages, and sexes in the districts where the effects of air pollution of fluorine had been recognized were considered. The aerial content of fluorine in the neighboring zone of the refinery averaged 381 micrograms/LTP sq cm/mo from May 1972 to Feb. 1973. The ingested fluorine in the neighboring zone was 1.57-2.33 times larger than that of the control area, in the surrounding zone 1.33-2.13 times larger, and both are significantly larger in adult females and children of both sexes. The fluorine content of urine in the people of the neighboring zone and the surrounding zone of the refinery were respectively, 1.29-1.92 and 1.30-2.13 times larger in the people in the control area. The ratio of fluorine in urine to retained fluorine averaged 0.635 in adults and 0.476 in children, the ratio in adults to the ratio in children being 1:0.75. There is apparently a difference of fluorine metabolism in age.

62596

Balazova, G. and V. Lipkova
EVALUATION OF SOME HEALTH PARAMETERS IN CHILDREN IN THE VICINITY OF AN ALUMINUM FACTORY.
Fluoride, 7(2):88-93, April 1974. 4 refs.

The health status of 6-14-year old children was investigated with special regard to the hematological indices and the content of fluorine compounds in urine and hair. The children have been living in a settlement in the environs of the aluminum factory in operation for 20 yr. In the first years of the operation of the factory, examinations of children showed evidence of potential hazard, induced by the influence of the factory on the environment. Certain sanitary measures were designed and implemented: a portion of the population was translocated; precautions were taken regarding consumption of crops grown in the polluted area; and regular visits to clinically suitable recreational areas were organized every year for children. After 10 yr the medical examinations were repeated. The values obtained were related to the concentration of fluorine compounds in the air and compared with the results obtained from a group of children of the same age during the first years of the operation of the factory. There was a clear and total improvement of the studied indices. Their values approach the values of the control group of children from non-exposed areas. (Author summary modified)

319

Prefecture. The concentration of hydrogen fluoride in the air at a point 0.5 Km from the refinery averages 0.6-1.4 ppb, and is less than 4 ppb at the highest. The animals were fed with weeds and vegetables grown there as well as with bran in the winter season. The fluoride content in the blood of the mother goats increased proportionately with the fluoride content of the feed. An increase of the fluoride content of the mother goat's blood increased retention of fluorides in the body of newborns, especially in the hard tissues. Airborne fluoride can be transferred via polluted feeds from the mother to her offspring.

FURTHER OBSERVATIONS ON CANCER IN A STEEL CITY. Fluoride, 7(3):153-165, July 1974. 9 refs. (Presented at the Conference of I.S.F.R., 5th, Annual, April 8-11, 1973.) The incidence of cancer in the steel city of Hamilton (Ontario) was investigated during 1969-1970. The death rate from cancer in Hamilton was higher than in the less industrialized city of Ottawa. The highest rate (65 per 100,000) occurred in the proximity of the steel mills, compared with the death rates (23 and 12 per 100,000) farther distant. Continuous monitoring in the industrial area disclosed that the levels of carbon monoxide, fluoride, lead, nitrogen oxides, sulfur dioxide, and suspended particulates increased to 15 times above the average of the province of Ontario. In 1971-1972 the atmospheric fluoride levels were up to 20 times higher than the average value for Ontario as a whole which is 40 mgm F/100 sq cm/30 days. Admission records at two large Hamilton Hospitals showed a close correlation between respiratory disease and the daily pollution index. (Author abstract modified)

ON THE JOINT ACTION OF COMPOUNDS OF MANGANESE AND FLUORINE ON THE BODY. (K voprosu o kombinirovannom dcystvii na organizm soyedineniy margantsa i ftora). Text in Russian. Gigiena i Sanit., no. 7:21-25, 1974. 6 refs.

The joint action of low concentrations of manganese dioxide and hydrofluoric acid in the air, a combination usually occurring during welding operations, was studied in albino rats and compared with the action of the individual components. The respective concentrations corresponded to the maximum allowable values or were 50% lower, 0.28 and 0.16 mg/cu m for MnO₂, and 0.56 and 0.22 mg/cu m for HF. The animals were exposed for 2.5 to 3 hrs daily for 16 weeks. The joint action of MnO₂ and HF on the animal organism was different from that of the individual compounds and potentiation as well as attenuation of the effects of the individual compounds were observed. Statistically significant differences from groups exposed to either MnO₂ or HF were observed in such changes as increase of the relative weight of the lung, increased stain retention by spleen and adrenal tissues, reduction of the serum alkaline phosphatase activity, increase in the serum SH group level, and prolongation of the chronaxia. Also, premature damage of the dental enamel was observed. The maximum allowable MnO₂ and HF concentrations in their joint action should be set at a level close to their respective MAC values, i.e., 0.15 mg/cu m for MnO₂, and 0.25 mg/cu m for HF.

Marier, J. R. and Dyson Rose

ENVIRONMENTAL FLUORIDE. National Research Council of Canada, Ottawa (Canada), Pub-12,226, 1971 (?), 39p. 168 refs. A review is presented on fluoride contamination of the environment. Topics covered include: the occurrence of fluoride in the soil, water, air, vegetation, terrestrial mammals, wildlife, ocean water, seafood, and man; sources and sinks of

fluoride pollution; fluoride contamination of vegetation; the effects of fluoride on animals; and the effects of fluoride on man, including sources and doses, analysis and diagnosis, toxic effects, and intake of highly toxic organofluorides. Airborne fluoride is of two types, gaseous and particulate, each of which can contain components differing in solubility. Fluoride released as particulate matter tends to deposit as fallout in the general downwind vicinity of fluoride emitting source. Depending on the type of industrial operation, a factory-stack effluent is estimated to contain from 3.6-15,600 mg/Fl, with the gaseous phase representing anywhere from 0.7-96%. Skeletal fluorosis is the most common toxic effect of fluoride exposure, though other disorders such as anemia and symptoms involving the skin, eyes, gastrointestinal tract, and nervous system are also reported.

DAMAGES TO ANIMALS BY INDUSTRIAL EMISSIONS.

(Schaedigung der Tierwelt durch Industrie und Technik). Text in German. Deut. Tieraerztl. Wochenschr., 39(22):340-345, May 1931. 25 refs.

Damages and health hazards due to air pollutant emissions and other environmental pollutants in connection with industrial activity are surveyed. Sulfur dioxide, arsenic trioxide, and lead, emitted by ore smelters, can cause damage to plants and animals either directly or by ingestion of contaminated plants. Sulfur dioxide causes reduction of the magnesium, phosphoric acid, and calcium levels in plants, and osteomalacia due to depletion of the calcium reserves in animals. Arsenic is responsible for colic, emesis, fatty generation in the liver, cachexia, eczema, and overall asthenia in cattle. Lead, accumulating in the liver, bones, kidneys, spinal cord, intestines, and muscles, causes gastric troubles and convulsions in acute poisoning, and general depression, abortion, colic, muscular pains, epilepsy, and pareses in chronic poisoning. Fluorine compounds, and especially hydrofluoric acid, as emitted by fertilizer plants, affect the bones due to the mobilization and depletion of calcium.

STUDIES ON AIR POLLUTION BY FLUORIDE. PART XH:
THE NORMAL VALUE OF FLUORIDE CONCENTRATION

IN SERUM. (Fukkabutsu ni yoru taiki o sen ni kansuru kenkyu (dai 12 ho) kesseichu fusso nodo no tsujochi ni tsuite). Text in Japanese. Nippon Koshu Eisei Zasshi (Japan. J. Public Health), 21(10):323, Oct. 1974. (Presented at the Japanese Society of Public Health Annual Meeting, 33rd, Fukushima, Japan, Oct. 16-18, 1974, Paper 437.)

The fluorine concentration in serum was studied as an index for biological load of fluorides. Trace concentrations of fluorine in the sera of the population in a non-polluted area appeared in 55% of the men and 77% of the women; 99% of the values were less than 0.02 ppm fluorine. The frequency of people with more than 0.05 ppm of fluorine was a little higher in the mountainous parts of the non-polluted area. There were no cases of persons with a serum fluorine concentration of more than 0.05 ppm near the aluminum refinery in a polluted area which had an aerial fluorine concentration of around 1 ppb; however, 25% of the rural persons near the refinery showed serum fluorine concentrations of more than 0.05 ppm.

HEALTH EFFECTS AND RECOMMENDATIONS FOR AIR-

BORNE FLUORIDES (FINAL REPORT). Proj. 10.006, Rept.

IEEQ 74-23, 65p., June 1973. 99 refs. NTIS: PB 233845

Airborne fluorides are injurious to corn, sorghum, tomatoes, soybeans, gladioli, and a variety of other plants. The human health effects of exposure to excessive concentrations of airborne fluorides include acute effects such as severe eye and nose irritation and skin injury, and chronic effects such as osteosclerosis. Based on these two considerations, phytotoxicity and human toxicity, the Environmental Health Resource Center supports a standard for airborne fluorides of 0.7 micrograms/cu m based on a 24-hour average. This standard applies to airborne fluorides in both gaseous and particulate forms and is based on one atmosphere of pressure and 25 C. The chronic and acute effects of fluorides upon which this recommendation is based are reviewed. (Author abstract modified)

COMBINED BIOLOGICAL ACTION OF CHEMICAL COM-

POUNDS AND PHYSICAL FACTORS OF THE ENVIRON-

MENT. (Kombinirovannoye biologicheskoye deystviye

khimicheskikh soyedineniy, khimicheskikh i fizicheskikh fak-

torov vneshey sredy). Text in Russian. Zh. Vses. Khim.

Obshchestva, Im DI Mendeleeva, 19(2): 164-169, 1974. 84 refs.

Studies on the combined action of chemical compounds and physical factors of the environment on the organism are reviewed. Summation, potentiation, antagonism, or independent action may occur during the simultaneous action of different toxic and irritating substances, including air pollutants. The simultaneous presence in the atmosphere of nitrogen dioxide, ozone, and unsaturated hydrocarbons results in the formation of highly irritative peroxides, epoxides, and aldehydes, while NO₂ forms practically harmless ammonium nitrate with ammonia. Extraneous substances present in the organism may increase or decrease the toxicity of other extraneous substances by inhibiting or activating enzymes responsible for the metabolism of the latter. Carbon monoxide and carbon tetrachloride inhibit the microsomal enzymes. Accelerated development of poisoning, and increased susceptibility of the organism to toxic substances were observed at high temperatures. High humidity increases the irritative effect of nitrogen oxides and hydrogen sulfide and the toxicity of fluorine compounds and certain petroleum products while alleviating the course of poisoning by gasoline. The effect of CO and carbon tetrachloride is intensified by strong muscular stress. The development of hypoxia due to CO, carbon tetrachloride, benzene, and gasoline is facilitated by reduced barometric pressure. Loud noise intensifies the effect of CO, boric acid aerosol, and cracking gas, while vibration potentiated the effect of fluorine, lead, cobalt dust, and quartz dust. Hypoxia-inducing substances, such as CO and sodium nitrite antagonize ionizing radiation.

THE FLUORINE IN BONES AND TEETH OF RABBITS

WHICH WERE EXPOSED UNDER NATURAL CONDITIONS.

(Der Fluorgehalt in Knochen und Zaehnen von Kaninchen, die unter natuerlichen Bedingungen exponiert wurden). Text in German. Z. Ges. Hyg. Dire Grenzgebiete (Berlin), 20(9):591-592, 1974. 11 refs.

In Dimitroffgrad, Bulgaria 1500 m from a fluorine emitting chemical combine, 15 rabbits were exposed to the fluorine polluted air for determination of the influence on the fluorine content in bones and teeth. For determination of fluorine in biological material, a modified ion exchange method by Nilsen was used. An aluminum eriochrome zyanine complex was

photometrically determined by the method of Kateswarlu. For elimination of possible errors, the fluorine content was calculated in relation to the mineralized ash residue rather than to the mass of dry substance. The results show a clearly higher fluorine content in those rabbits exposed to fluorine polluted air. The measured concentrations were 96.7 mg% F in the bones of the exposed animals vs. 75.2 mg% F in the bones of the control group. In teeth the measured concentrations were 242.1 and 209.2 mg% F. Since the fluorine content in drinking water in Dimitroffgrad is negligible, the higher F concentrations are clearly attributable to atmospheric pollution from the chemical combine.

Nakaya, S., S. Sakurai, Y. Suzuki, K. Itai, and F. Tsunoda
ON THE QUANTITATIVE DETERMINATION OF
FLUORINE IN URINE BY ION ELECTRODE. (Ion denkyoku
ni yoru nyochu fusso teiryoho ni tsuite). Text in Japanese. San-
gyo Igaku (Jap. J. Ind. Health), 16(4):498, Sept. 1974.
(Presented at the Tohoku Lecture Meeting, 32nd, Yamagata,
Japan, July 20, 1974.)

The fluorine content of urine collected over a 24-hour period can be used as a biological indicator of exposure to fluorine compounds in the air. Several conditions of pre-treatment and preservation of the urine specimen were examined. The stability of 10 ml aliquots kept in closely stoppered vials was better than the 2000 ml sample kept in a stoppered bottle, considering time and temperature. One hundred percent fluorine was shown after 3 weeks. The standard deviation after keeping for 3 weeks at 0 C and 24 C was very small compared to 40 C. Fluorine contents were quantified by the ion-electrode method.

Ueda, K.
STUDIES AND COUNTERMEASURES FOR DISEASES DUE
TO ENVIRONMENTAL POLLUTION. (Kogaibyō no kenkyū to
taisaku). Text in Japanese. Karada no Kagaku (Pop. Med.), no.
61:67-73, Jan. 1975.

Recent cases of health disturbances of epidemiological proportions are to environmental pollution caused by an error of industry or administration are described. Health disturbance symptoms due to air pollutants such as sulfur oxides, nitrogen oxides, carbon monoxide, photochemical smog, lead, fluorides, cadmium, vanadium, benzopyrene, asbestos, and other carcinogenic substances were described. Countermeasures such as the establishment of environmental standards for each pollutant and total air quality are described. Regulation of sulfur oxides has good prospects, but that of nitrogen oxides has many problems. Evaluation of the analytical value of a pollutant must be considered in relation to other values of materials. The new law which necessitates the evaluation of any new substance to be introduced in commerce will greatly contribute to environmental health.

refs. (Presented at the Air Pollution Medical Research Conference, 1974 (?).)

A tabulation of the health effects of specific air pollutants on children is presented based on a literature review of more than 100 investigations prior to 1970. Clinical and laboratory findings as well as the pollutant source are summarized for the following substances: fluorine, lead, arsenic, asbestos, silicates fatty acids, carbon monoxide, chloroprene, sulfur dioxide, hydrogen sulfide, carbon disulfide, hydrocarbons, sulfuric acid, and particulate matter. A brief review of epidemiological findings associated with major air pollution episodes is also presented.

ESTIMATE OF THE HEALTH HAZARD OF THYPOPULATION BY FLUORIDE IMMISSIONS. (Die Abschaetzung des gesundheitlichen Risikos der Bevoelkerung durch Fluorid-Immissionen). Text in German. Oeffentl. Gesundheitswesen (Stuttgart), 37(1):32-36, 1975. 17 refs.

A review of foreign literature on the effects of fluorine emissions on man (adults and children) and animals is given. Mainly the effects of hydrogen fluoride, sodium fluoride, aluminum trifluoride, and Na_3AlF_6 are discussed. The Verein Deutsche Ingenieure guideline issued in Sept. 1974 has set the following maximum allowable immission concentrations in micrograms F/cu m: hydrogen fluoride 50, aluminum fluoride, sodium fluoride and cryolithe 100, and calcium fluoride 200 over a period of 1 yr.

Berry, Wade L. and Arthur Wallace

TRACE ELEMENTS IN THE ENVIRONMENT - THEIR ROLE AND POTENTIAL TOXICITY AS RELATED TO FOS-SIL FUELS - A PRELIMINARY STUDY. California Univ., Los Angeles, Lab. of Nuclear Medicine and Radiation Biology, Atomic Energy Commission Contract AT (04-1) GEN 12, Rept. UCLA 12-946, 72p., Jan. 1974. 134 refs.

The nature, occurrence, and effects of trace elements in the environment are reviewed along with the identification of probable hazards of trace element emissions to the environment, particularly as a result of fossil fuel power generation. The ecology of trace elements is very delicately balanced, and small additions of some trace elements from polluting sources can significantly alter an existing ecosystem. The pathways and rates of movement of trace elements between each component of any soil-water-plant-animal system are not well defined. Generally, the lower the concentration of a trace element in nature, the higher is its toxicity. Trace elements such as cadmium and mercury are known to occur in fossil fuels in somewhat higher concentrations than elsewhere, were making the study of their emission a matter of urgency. Elements such as zinc, copper, and cobalt which are essential for life at low concentrations can be toxic at higher concentrations. The trace element composition of fossil fuels is extremely variable, resulting in a great uncertainty regarding potential toxicity problems. The fate of volatile trace elements released from fossil fuels upon combustion is largely unknown, adding further to the uncertainty. This volatile group includes: antimony, arsenic, beryllium, bromine, cadmium, fluorine, gallium, mercury, and selenium; excluding antimony, bromine, and gallium, these pose a serious hazard to man. The nonvolatile trace elements of significant abundance in fossil fuels include: boron, chromium, cobalt, copper, iodine, lead, lithium, manganese, nickel, vanadium, and zinc. These afford a lesser, but still significant, hazard. Boron is certain to present soil-plant problems whenever coal ash is applied to soil.

TOXIC HAZARDS RESEARCH UNIT ANNUAL TECHNICAL

REPORT: 1973 (FINAL REPORT). California Univ. at Irvine, Dayton, Ohio, Overlook Branch, Aerospace Medical Research Lab. Contract F33615-73-C-4059, Proj. 6302, Task 01, Work Unit 63020113, AMRL-TR-73-83, 170p., Aug. 1973. 38 refs. NTIS, DDC: AD-771 025

The activities of the Toxic Hazards Research Unit for the period June 1972-May 1973 are reviewed. Acute inhalation toxicity experiments were conducted on rats with mixtures of carbon monoxide and hydrogen cyanide. Acute toxicity tests on inhaled HCN for 5-minute exposures conducted in combination with CO did not show any increased toxic response at carboxyhemoglobin levels of 25% saturation. Emergency Exposure Limits (EEL) were validated for chlorine pentafluoride and 24-hour EEL of 1 ppm is proposed for monomethylhydrazine. A series of chronic inhalation toxicity studies were conducted with hydrazine, methylhydrazine, and coal tar aerosols. Oral percutaneous toxicity evaluations were conducted (to determine LD-50 values for mixed creosols, allyl isothiocyanate, methyl isothiocyanate, methyl isocyanate, ortho-nitroaniline, ethyl chloracetate, and phenyl isocyanate. (Author abstract modified)

THE PROBLEM OF AGE SENSITIVITY OF THE BODY TO

FLUORINE IONS IN THE AIR. (K voprosu o vozrastnoy chuvstvitel'nosti organizma k ionu ftora v vozdukh). Text in Russian. Gigiena i Sanit., no. 12:33-36, Dec. 1974. 4 refs.

The age-dependent sensitivity of the organism to inhaled fluorine was studied in rats. The animals were most susceptible to fluorine at the age of 1.2 to 3.9 mo and again at the age of 11.6-23.6 mo. In the first case, damage of the dental enamel, and lesions of the respiratory tract were most pronounced, while in the second age bracket animals were affected by lesions of the bones, lungs, and upper respiratory tract. Proliferation in the interalveolar septa, atrophy and focal edema of the bronchial mucosa, and hyperplasia of the peribronchial tissue were found on autopsy. The above age brackets correspond to those of 1-14 yr and 26-55 yr in humans.

French, Jean G.
EPIDEMIOLOGY AND CLINICAL MANIFESTATIONS OF DISEASE ASSOCIATED WITH EXPOSURE TO EMISSIONS FROM COAL AND OIL SHALE UTILIZATION. Preprint, Cincinnati Univ., Ohio, Dept. of Environmental Health, National Inst. of Environmental Health Sciences, and the National Inst. for Occupational Safety and Health, 21p., 1975. 33 refs. (Presented at the Workshop on the Health Effects of Coal and Oil Shale Mining, Conversion and Utilization, Cincinnati, Ohio, Jan. 25, 1975.)

The epidemiological and clinical implications of exposure to emissions from increased coal and oil shale utilization are discussed. Combustion products considered include: sulfur dioxide, sulfates, sulfuric acid aerosol, nitrogen oxides, nitrates, polynuclear hydrocarbons, carbon monoxide, aldehydes, and various toxic trace elements (beryllium, fluorine, arsenic, selenium, cadmium, mercury, and lead) found in fly ash. Epidemiological studies indicate that prolonged exposure to nitrogen dioxide levels of 117-205 micrograms/cu m can contribute to increased prevalence of chronic bronchitis, acute lower respiratory disease, and diminished pulmonary function. Associations between asthma attacks and levels of suspended nitrates and sulfates also exist. Human chamber studies indicate that ozone in the presence of SO₂ is more irritating than ozone alone. Animal studies demonstrate high toxicities for sulfuric acid mists and various sulfate compounds which are products of the atmospheric transformation of SO₂. Purified polycyclic compounds produce tumors of the tracheobroncholar tree or lung parenchyma when absorbed on particles and delivered below the larynx. The increased processing of oil shale appears to offer even greater potential than coal combustion for increasing levels of hydrocarbons, nitrogen oxides, and photochemical oxidants.

Dorst, Jean
THE ACTION OF POLLUTION ON THE BIOLOGICAL EQUILIBRIUM AND ON HUMANS. (Actions des pollutions sur les equilibres biologiques et sur l'homme). Text in French. Bull. Tech Inf., no. 262:655-658, 1971.

The effects of environmental pollution on the equilibrium of the ecosystem and on the human organism are discussed. Air pollution, especially particulates, sulfur dioxide, nitrogen oxides, carbon monoxide, and hydrocarbons, may cause chronic bronchitis, emphysema, cardiovascular disorders, and lung cancer. Fluorine and SO₂ cause plant necrosis. Certain air pollutants exert synergistic effects with other pollutants and generate smog under the influence of solar radiation.

74369

Shizuoka Prefectural Office (Japan)
STATUS OF DAMAGES DUE TO ENVIRONMENTAL POLLUTION. SEC 1 STATUS OF HEALTH INJURIES IN FUJI DISTRICT AND ITS COUNTERMEASURES. SEC. 2. STATUS OF AGRICULTURAL CROP DAMAGE. (Kogai ni yoru higai no jokyo. Dai 1-setsu. Fuji chiiki no kenkohigai no genkyo to taisaku. Dai 2-setsu. Nosakumotsu higai no jokyo to taisaku). Text in Japanese. In: Shizuoka Prefectural Environmental Nuisance White Paper, p. 254-260, 1974.

The rapid expansion of paper factories in the Fuji district of Shizuoka Prefecture resulted in increased air pollution leading to health injuries such as chronic bronchitis. The number of officially recognized air pollution patients was 360 by the end

of March 1973 and 469 by the end of March 1974, including seven mortalities. The percentage of chronic bronchitis, bronchial asthma, asthmatic bronchitis, and pulmonary emphysema cases were, respectively, 6.4, 85.1, 5.5, and 3.0%. The number of such patients outside the appointed jurisdiction was 173 by the end of March 1974. Patients younger than 14 and older than 60 yr accounted for 78% of the total cases. Countermeasures included medical compensation. Agricultural crop damage was due to photochemical smog (covering 12,000 hectares) acidic rainfall, and hydrogen fluoride emissions from an aluminum refinery.

74380

Nakaya, S., S. Sakurai, K. Itai, Y. Suzuki, and F. Tsunoda
ON THE SIGNIFICANCE OF URINARY FLUORINE CON-
CENTRATION AS AN INDICATOR OF EXPOSURE TO
FLUORIDES. (Fukka butsu bakuro shihvo to shite no nyochu
fusso nodo no igi ni (suite). Text in Japanese. Taiki Osen Ken-
kyu J. Japan. Soc. Air Pollution), 9(2):346, Nov. 1974.
(Presented at the Japan Society of Air Pollution, National Meet-
ing, 15th, Paper 201.)

The behavior of urinary fluorine upon long-term urine storage was investigated. When the pH of urine changes from 5-6 to 9 (2-3 mo storage at 30 C; 2-liter sample of 24-hour urine collection in polyethylene jar), because of ammonia fermentation, most of the fluorine precipitates as calcium fluoride. Thus, fluorine analysis by the direct ion electrode method would give erroneous results for total fluorine content. Storage of the 2-liter samples at 0 C maintained the pH at 6, and fluoride precipitation was not marked at the end of 2-3 mo. Storage of urine in 10-milliliter polyethylene test tubes at 0, 20, 40 C, for a 3-week period, did not result in any significant reduction in values of average fluorine content, upon analysis by the direct ion electrode method. The steam distillation method for fluorine analysis results in values 1.5 times those obtained from direct ion electrode analysis.

RECENT TREND IN THE RESEARCH ON HUMAN HEALTH
EFFECTS OF AIR POLLUTION. (Saikin no taikiosen ni kansu-
ru igakuteki kenkyu no doko). Text in Japanese. Iwate Igaku
Zasshi (J. Iwate Med. Assoc.), 26(5):516-522, Oct. 1974. 42 refs.
The present state of air pollution in Japan is outlined with respect to the major air pollutants; and the health effects of sulfur dioxide reviewed in relation to the amendment of the air quality standard from 0.06 to 0.04 ppm daily average value. The additive health effects of SO₂ and nitrogen dioxide are also described. Long-term exposure to NO₂ at low concentrations causes hyperplastic foci due to the proliferation of bronchiolar epithelial cells, suggesting a relationship between NO₂ in air and lung tumorigenesis. The effects of suspended particulates and carbon monoxide and differences between symptoms resulting from Japanese photochemical oxidants versus those in Los Angeles are described along with proposed criteria. The accumulation of airborne fluorides in agricultural crops is compared to its minute concentration in air.

Tsuji, Yoshito

ENVIRONMENTAL POLLUTION BY FLUORIDE AND ITS INFLUENCE ON THE HUMAN BODY. (Fukkabutsu ni yoni kankyo o sen to seitai eikyo). Text in Japanese. Supplement, Nippon Koshu Eisei Zasshi (Japanese J. Public Health), 21(10):73-74, Oct. 1974. (Presented at the Japanese Society of Public Health, Annual Meeting, 33rd, Fukushima, Japan, Oct. 16-18, 1974.)

The cumulative effects of fluorine on the human body are disclosed. The incidence of fluorosis (mottled teeth) increases sharply as a cumulative effect of fluorine concentrations above 1.0-1.5 ppm in the drinking water. In Japan, the threshold fluorine concentrations seem to be 0.5-0.6 ppm, although mottled teeth have occurred at fluorine concentrations of 0.3-0.4 ppm in drinking water. Prevention of tooth decay by fluoridation (1 ppm) of drinking water is considered safe, and is practiced in the United States. Low amounts of fluorine cause osteosclerosis, while large amounts cause softening of the bones. Schoolchildren with 3rd degree (heavily) mottled teeth were small in height, while those with 1st degree mottling were somewhat taller than average. In Katakata, schoolchildren from areas of high fluoride pollution had a higher incidence of goiter, but an increase in growth with trace amounts of fluorine was also observed. Fairly rapid excretion of fluorine from the body in urine was found in studies conducted on workers from Showa Denko, Kitakata. In experiments conducted at this school with tadpoles and fertilized sea urchin eggs, the presence of 5 ppm sodium fluoride resulted in faster emergence of frog forelegs and a higher percentage of formation of normal spines on sea urchins than in the absence of sodium fluoride. At fluoride concentrations above 25 ppm, deformed sea urchins with no skeletal structures were observed.

ON THE EFFECTS OF ENVIRONMENTAL POLLUTION BY AIRBORNE FLUORIDES ON EXPERIMENTAL GOATS (IV). RESULTS OF 2-YEAR CLINICAL EXAMINATIONS.

(Taikichu fukkabutsu no kankyo o sen ni yoru yagi no bakuro jikken (Dai-4-ho). 2-Nenkan no rinsho kensa seiseki). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution) 9(2):347, Nov. 1974. (Presented at the Japan Society of Air Pollution, National Meeting, 15th, Paper 202.)

The biological effects of atmospheric fluoride pollution were investigated with seven goats raised for 2 yr (1972-1974) in an area exposed to pollution from an aluminum refinery. A control group of 4 goats was raised in a non-polluted area during the same time. Average fluorine content of pasture grasses in the pollution area was 30 ppm, 4 times as high as that in the control area. The monthly average atmospheric hydrogen fluoride concentrations during the 2 yr ranged from 0.4-1.4 micrograms/cu m. The average monthly serum fluorine concentrations in the exposed goats varied from 0.1 ppm to 0.4 ppm. The average monthly urinary fluorine concentrations for exposed goats ranged from 7 ppm to about 15 ppm. Control goats had a steady serum fluorine level of about 0.05 ppm, and urinary fluorine concentrations between 0-4 ppm. Blood tests were also taken for hematocrit; hemoglobin, protein, cholesterol, BUN, ZTT, GOT, Al-P. In general, no significant variations were found between plots for exposed and control goats, although exposed goats had higher levels of GOT, and the plots did not coincide well for cholesterol concentrations.

ON THE EFFECTS OF ENVIRONMENTAL POLLUTION BY AIRBORNE FLUORIDES ON EXPERIMENTAL GOATS (V). PLACENTAL TRANSMISSION OF FLUORIDE (CON-

TINUED). (Taikichu fukkabutsu no kankyo osen ni yoru yagi no bukuro jikken (Dai-5-ho). Fukkabutsu no taiban tsukasei (Zoku-ho)). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 9(2):348, Nov. 1974. (Presented at the Japan Society of Air Pollution, National Meeting, 15th, Paper 203.)

Studies were made with goats on the correlation of fluorine concentrations in maternal serum with fluorine concentrations in placenta and offspring. Goats were divided into three groups: one control, and two pollution-exposed. Offspring were jugulated after birth, and amounts of fluorine in serum, tissues, organs, and various skeletal structures were determined. Fluorine concentrations in maternal serum ranged from 0.043-0.065 ppm for the control groups, and 0.098-0.292 ppm for the exposed groups. In the offspring, serum fluoride concentrations ranged from 0.010-0.016 ppm for the control group, and 0.018-0.031 ppm for the exposed groups. Placental fluorine concentrations (2.2-4.5 ppm) were higher than maternal and offspring serum fluorine concentrations, but no significant differences were found among the three groups. In all three groups, highest and lowest fluorine accumulations were found in the same types of tissues, organs, and skeletal structures. In tissues and organs, fluorine contents were highest in the aorta (5.1-5.5 ppm) and spleen (5.4-7.9 ppm), and lowest in the brain (0.48-1.75 ppm) was muscle (0.72-1.15 ppm). In skeletal structures, fluorine content was lowest in molars (73.9-259 ppm), and highest in rib (149-569 ppm) and vertebra (152-545 ppm).

Tsunoda, F., E. Aizawa, S. Sakurai, H. Kunita, and K. Sasaki
ON THE BODY POLLUTION OF INHABITANTS IN ENVIRONMENTALLY POLLUTED AREAS BY FLUORIDES IN

AIR. (Taikichi fukkabutsu ni yoru kankyoosen chiku jimin no seitaiosen ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 7(2):199, Nov. 1972.

According to the urinalysis of 13 male and 17 female inhabitants living in an area environmentally polluted by fluorine from whom more than 1 liter of urine in a day were obtained, the average content of fluorine was 2.02 mg (S.D. of 0.30 mg) and 1.77 mg (S.D. of 0.43 mg), respectively. The data obtained on the urinalysis of 9 male and 13 female inhabitants living in an area not polluted by fluorine was 0.79 mg (S.D. of 0.07 mg) and 0.73 mg (S.D. of 0.07 mg). The above difference of fluorine in urea is due to the difference of the amount of fluorine on agricultural products on which fluoride in air is deposited. The average fluorine content of urine of peoples who showed spotted teeth due to excessive intake of fluoride was 1.20 (S.D. of 0.12) mg (19 males 20 - 49 yr old), 1.50 (S.D. of 0.2) mg (10 males 50-69 yr old), 1.20 (S.D. of 0.12) mg (17 females 20-49 yr old) and 1.13 (S.D. of 0.08) mg (15 females 50-69 yr old). Considering the fact that orally taken fluorine was excreted more than 50% within 12 hr, urinalysis of fluorine was a very effective indicator of fluorine pollution.

PORPHYRINS, POWER, AND POLLUTION. Ann. N. Y. Acad. Sci., vol. 244:685-694, April 15, 1975. 37 refs. (Presented at the Biological Role of Porphyrins and Related Structures Conference, Oct. 23-26, 1973.)

The involvement of porphyrinic materials with pollution processes is discussed. Many of the anion pollutants, such as
<xref image="2000WVIZ.TIF|V3|2006:09:28:01:34:50.00|125030|0"> image: </xref>

cyanide and fluoride, and many of the gas pollutants, such as carbon monoxide and the nitrogen oxides, have the central iron of hemoproteins as their primary target. Many forms of heavy metal poisoning arise due to interference of these metals with the roles or biosyntheses of porphyrins. The metalloporphyrins are sensitive simple colorimetric detectors of pollutants as carbon monoxide, nitrogen oxides, cyanides, fluorides, and strong oxidants. Hemoproteins are primary targets for nitrite pollution and iron porphyrins catalyze a number different types of nitrogen oxide interactions that are of significance in areas of pollution and health.

Takizawa, Y. and I. Nakamura
EFFECTS OF CALCIUM FLUORIDE ON RESPIRATORY SYSTEM. (CaF no kokyuki-kei ni oyobosu eikyo). Text in Japanese. Nippon Koshu Eisei Zasshi (Japan. J. Public Health), 22(10):400, Oct. 1975.

Wistar adult female rats were exposed to calcium fluoride dust at 27(?) /cu m, 4 hr/day for 10 and 30 days. Rats were sacrificed 24 hours after the last exposure of each day. The findings were: (1) fluorine in exposed rat s urine increased to 2.3 times as high as in the control group after 15 days of exposure, (2) fluorine in the rat s serum became about 2.5 times as high as the control; however, this was not dependent on length of exposure, suggesting a small accumulation of fluorine in serum, (3) fluorine in the lung was notably higher, followed by spleen, liver, heart and kidney in the order, (4) fluorine in femurs and incisors tended to increase with exposure, histologically, in rats exposed for 10 days (5) edema in bronchiolar mucous epithelium and intramucosal epithelium, infiltration of neutrocytes, appearance of plasmocytes in the mucosal proper layer, smoothing of mucosal epithelium, lling of the alveolar epithelium, and fall-out of alveolar epithelium and phagocytes into the alveolar cavity were observed, in rats exposed for 30 days, (6) disappearance of the edema and the filtration, increase of appearance of plasmocytes and of smoothing of the mucosal epithelium, swelling of the alveolar epithelium, increase of fall-out of alveolar epithelium and phagocytes into the alveolar cavity, stagnation of acidphile substances in the alveoli, agglomeration of plasmocytes around small vessels, and increase of cells on alveolar septa without fibrous thickening and glassy membrane were also observed.

79623

Nakamura, I. and Y. Takizawa
EFFECTS OF FLUORIDES ON RESPIRATORY SYSTEM OF RAT. (Rat kokyukikei ni oyobosu fukkabutsu no eikyo). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):479, Nov. 1975.

Groups of adult female Wistar rats were exposed by inhalation to sodium fluoride at 13 mg/cu m and to calcium fluoride at 25 mg/cu m for 4 hr/day for, respectively, 10 days and 10 and 30 days. All the rats were sacrificed for 24 hours after the last exposure. The fluorine content of the urine of rats exposed to NaF increased rapidly, and that of CaF₂ rats showed slower increase; the former at 10 days of exposure was 3.5 times higher than the latter. The fluorine concentration in serum was about 6 times higher in the NaF group than in the CaF₂ group after one day of exposure; however, the absolute concentration 24 hours of the last exposure was about the same as that of the unexposed control. The fluorine concentration in the lung of rats exposed to CaF₂ was higher than those in other organs and showed increase with exposure time, in contrast to that of the group exposed to NaF. The fluorine content of the femur of the rats exposed to NaF was significantly higher than that in the control group. Pathological findings include swelling of alveolar epithelium, reinforced omission of the alveovacuolar phagocyte, stagnation of acidphilic substances in the alveoli, aggregation of plasma cells around small vessels and proliferation of cells in the pulmonal septum, without,

however, fibrous thickening or formation of hyaline membrane. These findings suggest species differences of fluorides in metabolism in the body.

STUDIES ON AIR POLLUTION DUE TO FLUORIDES PART
16. ON THE FLUORINE CONTENT IN URINE AND SERUM
OF INHABITANTS AROUND PHOSPHATE FERTILIZER
FACTORIES. (Fukkabutsu ni yoni taikiosen ni kansuru kenkyu
Part 16. Rin-hiryo kojo shuhen chiku jumin no nyochu kesseichu
fusso nodo ni tsuite). Text in Japanese. Nippon Kosshu Eisei
Zasshi (Japan. J. Public Health), 22(10):399, Oct. 1975.
The fluorine content in urine and blood serum of men and
women living in the area of phosphatic fertilizer plants for
more than five years, and of primary school boys in the 5th
and 6th years of classes was determined. The area studied was
within a radius of 1 km from a fused phosphatic fertilizer fac-
tory and within 2 km (to the SE), 2 km (to the NW) and 7.5
km (to the W) from a superphosphate factory. The fluorine
content of urine and serum was higher as distance from the
factory decreased; however, there were no data showing
health impairment due to fluorine.

ON THE DYNAMIC STATE OF IONS AND THE RELATING
ENZYME ACTIVITY IN FLUORINE-POISONED RATS. (Fus-
so-chudoku rat ni okeru ion-dotai to sono kanken koso kassei ni
tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air
Pollution), 10(4):516, Nov. 1975.
The effects of airborne fluorides deposited on pastures and
taken by domesticated animals is of interest. Sodium fluoride
was p.o. administered to male Wistar rats at a rate of 2.3 mg
fluorine/100 g body weight, and the effects were observed.
The concentration of fluoride ion in the blood reached its max-
imum, 2.2 ppm, after 30 min of administration, then decreased
slowly to 0.2 ppm after 15 hours. Urinary fluoride was highest
during the first day of tests, with a conspicuous increase of
urinary phosphate ion. Magnesium ion showed a small increase
and calcium ion showed a small decrease in the urine. Serum
alkaline phosphatase activity showed an increase; however,
acidic phosphatase activity and renal-alkaline and renal-acidic
phosphatase activity showed a decrease. The ATPase in renal
cortex activity increase with administration of sodium fluoride
and sodium chloride, compared to the control group. How-
ever, the activity in rats administered sodium fluoride was in-
hibited when compared to that in rats administered sodium
chloride.

POLLUTION BY FLUORINE. (L'inquinamento da fluoro). Text in Italian. *Med. Lavoro* (Milan), 64(3-4): 132-142, March-April 1973. 36 refs.

Fluorine pollution is caused by the discharge of gas, liquid, and solid effluents from industries using fluorine compounds which are extremely stable, and by substances contaminated by fluorine. Chronic intoxication of organisms is related to the liberation of soluble ionic F, which is absorbed in the digestive tract: insoluble compounds are significantly less harmful. Acute intoxication centers in the respiratory tract and is expressed, in the case of inorganic compounds, by severe lesions of the lung cells, and in the case of organic compounds, by major pulmonary clearance with a high Ostwald coefficient. In general, damaging effects on biological structures manifest themselves as multiple and diffuse lesions of an abiotrophic type and an irreversible nature. It affects the growth of vegetation and the fertility of animals, in which it produces considerable deformities; skeletal deformations have already been observed in children from Japanese industrial areas.

NORMAL VALUES OF FLUORIDE FROM A DEFINED REGION OF THE HUMAN ILIAC CREST. *Int. Arch. Occup. Environ. Health*, 35(3): 233-244, 1975. 32 refs.

Normal fluoride concentrations in the human iliac crest were determined by analysis of bone ash from 100 cadavers of both sexes. The bone samples were taken from exactly the same skeletal location to allow for direct comparison with samples derived by bioptical methods from living subjects. The analysis was carried out on samples of dried bone ash with an ion sensitive electrode. Statistical analysis of the results indicates a positive linear relationship between fluoride content and age.

Mazliak, P.

PHYSICO-CHEMICAL FACTORS OF THE PENETRATION OF TOXIC SUBSTANCES. (Facteurs physico-chimiques de la penetration des toxiques). Text in French. *Ann. Nutr. Aliment*, 28(4):277-296, 1974. 10 refs.

The physicochemical factors involved in the penetration of toxic substances into cells were studied on a model. The penetration of a foreign substance into the cell is determined by such factors as the chemical nature of the cell membrane, the cytoplasm, and the foreign substance, and by the molecular organization of the membrane and of the cytoplasm. The central hydrophobic zone of the cell membrane plays the major role in the penetration of the toxic substance, as the passage through the hydrophilic outer zone and the passage from the central lipophilic zone into the aqueous medium of the cytoplasm are fairly easy. Halogens, gaseous halogenides, gaseous sulfur and nitrogen compounds, compounds of phosphorus and arsenic, carbon oxides, carbon sulfides, gaseous hydrogen, cyanide, hydrocarbons, acetone, methylene chloride, dichloroethylene, trichloroethylene, toluene and its derivatives penetrate through the cell membrane by simple diffusion. The penetration of solid fluorides, fluorosilicates, mer-

cury, copper, lead, and chromium involved active transport or a diffusion mechanism implying a bond with the membrane proteins.

Newman, James R.

ANIMAL INDICATORS OF AIR POLLUTION. Inst. of Environmental Sciences, Mt. Prospect, 111., Inst. Environ. Sci. Energy Environ., Annu. Meet., 21st, Anaheim, Calif., 1975, p. 152-154. 5 refs. (April 13-16.)

An analysis of the feasibility of using animals as biological indicators of air pollution is presented. Most animals found to be potential biological indicators are fairly common in the environment, and all are easily sampled. Some groups like domestic animals and zoo animals are particularly easy to monitor; game animals which represent more natural conditions are also easy to monitor. The four best responses of biological indicators used for providing specific information on specific pollutants are: physiological changes observed at autopsy or during histological examination, residue accumulation, changes in blood chemistry and physiology, and changes in the morphology or appearance of the animal. Air pollutants can be generally classified in terms of being permanent accumulators, temporary accumulators, and non-accumulators. A list of possible biological indicators of air pollution is provided and includes the following air pollutants: carbon monoxide, fluoride, hydrogen sulfide, nitrogen dioxide, sulfur dioxide, arsenic, lead, molybdenum, participates, photochemical oxidants, selenium, and vanadium.

EXPOSURE EXPERIMENTS OF GOATS TO ENVIRONMENTAL POLLUTION DUE TO FLUORINE IN AIR PART VII.

FLUORINE CONTENT OF ITS TISSUES. (Taikichu fukkabut-su no kankyoosen ni yoru yaqi no bakuro jikken Part 7. Soshiki no fusso ganyuryo). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):481, Nov. 1975.

Goats were reared in an area where the concentration of hydrogen fluoride in the air was 0.5-1.0 ppb, and their 7th thoracic vertebra, the central part of the rib, the ilium, and the muscles of the haunch were analyzed for fluorine by an ion electrode method. The fluorine content of the thoracic vertebra and rib was 545-570 ppm just after birth, four times greater than for the control group, and it increased markedly with time, reaching in 3 months the level which the control group attained in 3 years. After 3 years, the fluorine content became 8000 and 6000-7000 ppm in the thoracic vertebra and in the rib and ilium, respectively, 3.6-4.3 times that of the control. In the muscles, on the contrary, the fluorine content remained at about 1.0 ppm for 3 years, showing no difference with the control. The pollution of goats by fluorine is probably via polluted pasturage rather than inhalation.

THREE YEAR STUDY OF HEALTH EXAMINATION AT IWANABE FROM 1970, MAINLY ON THE EFFECTS OF FLUORIDE. Text in Japanese. Ehime Kenritsu Byoin Gakkai Kaishi (Ehime J. Med.), 12(2):66-71, Nov. 1974. 6 refs.

Partial damage to rice plants probably due to fluorides from an aluminum electrolysis factory in Niihama, followed by findings of abnormally high amounts of fluorine in rice plants and grain led to medical examinations and measurement of fluorides in 1970. Control measures at the factory led to a decrease in the concentration of hydrogen fluoride in the air, from 7-8 ppb in March 1969 to 0.4 ppb in March 1972. The plant damage was most apparent on gladiolus and pine trees. The amount of fluorine in daily urine varied by family and age, suggesting that inhaled air is not the important factor. On the other hand, the inhabitants complain of sticking in the throat and tiredness of the legs, although these complaints are decreasing with time. The problem of fluorine pollution has been settled by the efforts of industry and mass migration of inhabitants from the area.

FLUOROSIS. A POLLUTION SOURCE YET IGNORED:

FLUOROSIS HAZARDS IN SAVOY. (La fluorose. Une source de pollution encore meconnue: les ravages du fluor en Savoie). Text in French. Contours Med. (Paris), 97(16):2755-2756, 2759-2760, 1975. 29 refs.

Effects of air pollution due to fluorine and its compounds on plants, animals, and humans are reviewed. In high concentrations, fluorine is harmful for plants, especially for fruit trees and conifera. Fluorine is hazardous for insects, including honey-bees, and especially for herbivorous animals. It causes cachexia, osteomalacia, and spontaneous bone fractures in cattle. Industrial emissions are hazardous for humans, causing osteopetrosis after a long latency period, especially in the pelvis region. Osteopetrosis in an aluminum factory worker is reported; sudden elimination of the fluorine and normalization of the bones occurred 10 yr after cessation of the exposure.

Tsunoda, F.

EFFECTS OF FLUORINE COMPOUNDS ON MAN, AS AIR

POLLUTANTS AND IN WORK PLACES. (Shokuba to taikiosenbutsu to shite no fukkabutsu no ningen e no eikyo). Text in Japanese. Rodo no Kagaku (Dig. Sci. Labor), 31(4):10-16, April 1976. 12 refs.

Human injury by fluorine compounds in air has been experienced far more than 40 years in factories, but fluorine compounds as air pollutants were first recognized as a toxicant to plants and animal feed crops. Two cases of fluorine intoxication, one in a work place and the other affecting the general population directly in air and via other environmental routes are described. The primary health disturbance by inhalation of fluorine compounds involves the face, nose and eyes; no injury was found by inhalation at less than 10 ppb. The accumulation of fluorine from air to plants has been an important problem. The human intake of fluorine via several routes is illustrated. Chronic symptoms include macular teeth and osteosclerosis; dose-response relationships are known for the symptoms of both. Urinalysis of fluorine is described, emphasizing the accumulation of fluorine from the air in vegetables.

Yoshikawa, H.

INTOXICATION BY FLUORIDES. (Fukkabutsu chudoku).

Text in Japanese. Rodo no Kagaku (Dig. Sci. Labor), 31(4):4-9, April 1976.

General problems of fluorides in ecological systems and of the toxicity of fluorides are outlined. The natural background con-

centration of fluorine in air is 0.01-3.9 microgram/cu m and that in drinking water is from trace to 10 ppm, in most cases less than 0.1 ppm. The fluorine compounds to which workers are exposed include molecular fluorine, hydrogen fluoride, and several metal fluorides. The toxicity of inorganic fluorine compounds is stressed, including gaseous fluorine, hydrogen fluoride, silicon tetrafluoride, boron trifluoride and oxygen difluoride. The health hazard of fluorine compounds is described in detail for inhalation and absorption from skin by contact with fluoride particles in air. Chronic intoxication due to fluorine compounds, fluorosis, is described in detail.

Tanizawa, Y.

EFFECTS OF FLUORINE COMPOUNDS ON MAN, AS AIR

POLLUTANTS. (Taikiosen butsu to shite no fukkabutsu no ningen e no eikyo). Text in Japanese. Rodo No Kagaku (Dig. Sci. Labor), 31(4):17-21, April 1976. 1 ref.

Air pollution due to fluorine compounds has accompanied the increase of aluminum and phosphate fertilizer production. While plant damage due to airborne fluorine compounds has been widely publicized, human injury has not. Refrigerants, plastics, drugs and missile propellants are sources. In Japan the ambient fluorine concentration is 0.1 -0.5 microgram F/cu m in larger cities and 0.1-0.3 microgram F/cu m in smaller cities. Epidemiological information on the effects of airborne fluorine compounds on humans is given, including results of medical examinations. Urinary fluorine, the frequency of macular teeth, the frequency of complaints of cough, sputum, and stridor, cases of osteosclerosis and of ECG findings, and thyroidal function disturbance, all of which indicate the degree of human injury due to fluorine, are described. The route of fluorine intake into the human body and the relationship of respiratory diseases such as chronic bronchitis, asthmatic bronchitis, bronchial asthma, and pulmonary emphysema to ambient fluorides around an aluminum refinery are described in detail.

Monturiol, J. M., J. Artalejo, J. Garrido, and J. Ruiz Zubero
SURVEY METHOD FOR CHRONIC BRONCHITIS. RESULTS
OF A PILOT STUDY IN THREE DIFFERENT POPULATION

GROUPS. (Metodologia de las encuestas sobre la bronquitis cronica. Resultados de una encuesta piloto en tres grupos de poblacion). Text in Spanish. Rev. Enf. Torax, 23(80-89):81-108, 1974. 13 refs.

The results of a survey on the incidence and causes of chronic bronchitis (CB) carried out during 1972 and 1973 by means of a questionnaire submitted to 7806 subjects (59% men and 1810 women) chosen from three different segments of the population (5634 employees of Standard Electrica of Madrid; 609 persons from various districts of Guadalajara; 1563 inhabitants of six agricultural villages from the Madrid region) are reported. The CB found in 1006 (12.86%) of the subjects was attributed to cigarette smoking (75.15% of the men and 10% of the women were smokers), and to socioeconomic conditions or cold climate. Environmental pollution at the existing levels did not influence the appearance of CB, as exemplified in the vil-

<xref image="2000WVJ2.TIF|V3|2006:09:28:01:35:02.00|117175|0"> image: </xref>

G. EFFECTS-HUMAN HEALTH

327

lages of the Madrid region (308/1563 subjects with CBj with clean air but a high number of smokers among the men (76.19%), cold winters and the lowest average salaries of the three groups sampled. Occupational air pollution, however, is considered a high risk factor, especially when associated with cigarette smoking. Of 860 workers at Standard Electrica (SE) subjected to occupational exposure to air pollution for one year or more, 207 (24%) developed CB; 402 were exposed to dust (emery, wood, etc.), 330 to irritating chemical smoke or gases from electrolytic baths (chromium, cyanides, trichlorethylene, cadmium, nickel, fluorine, carbon monoxide and carbon dioxide, welding fumes, varnish naphtha and synthetic or cellulose dyes, 128 were exposed to various types of occupational air pollution for at least one year before being hired by SE; 661 were cigarette smokers. Of 2656 SE workers not exposed to air pollution risks, only 290 (10.9%) developed CB; 2029 were smokers. A national survey using the British Medical Council - type questionnaire is recommended by the authors.

84233

Gylseth, Bjorn and Jorgen Jahr
SOME HYGIENIC ASPECTS OF WORKING IN ALUMINUM
REDUCTION POTROOMS WITH SPECIAL REFERENCE TO
THE USE OF ALUMINA FROM THE DRY- CLEANING
PROCESS OF SODERBERG POT-GASES. Staub, Reinhaltung
Luft, 35(12):43-49, 1975. 6 refs.

An increase in subjective symptoms such as irritation of the mucous membranes, headache, and nausea was registered by the workers in an aluminum reduction plant when the alumina from a dry-regaining construction (secondary alumina) was used. There was a statistically significant difference between the working conditions in the potrooms using the secondary alumina. The difference was related to airborne dust as well as gaseous and particulate fluorides. The content of potential carcinogenic polynuclear aromatic hydrocarbons (PAH) in the secondary alumina and in some airborne dust samples was determined by gas chromatography in the cyclohexane soluble fraction of these samples.

Pilet, P. E. and M. Bejaoui
INTERACTIONS BETWEEN FLUORIDE, CALCIUM AND
MAGNESIUM ON THE O₂ UPTAKE BY TISSUES CULTIVATED IN VITRO. (Interactions entre le fluor, le calcium et le magnésium sur l'absorption de l'oxygène par des tissus cultivés in vitro). Text in French. Biochem. Physiol. Pflanzen, 168(5/6):483-491, 1975. 30 refs.

The combined and separate effects of calcium (++) , magnesium (++) , and fluorine (-) concentrations on young *Rubus hispidus* L. neofortis. Exposure to Ca(++) stimulated absorption of oxygen up to a .00125 M concentration of calcium chloride; Mg(++) , however, was an inhibitor; the O₂ absorption value remained the same for all Mg(++) concentrations used. Both Ca(++) and Mg(++) will reduce the inhibiting action of F(-) on O₂ absorption. Thus, they protect the tissues against F(-) more effectively as their concentrations increase and that of F(-) decreases. When Ca(++) and Mg(++) are simultaneously present and F(-) is absent, O₂ absorption is stimulated. Low concentrations of F(-) will not prevent O₂ absorption from being stimulated by Ca(++) and Mg(++) together at a .00125 M concentration. This concentration, however, as well as higher concentrations will not inhibit high rates of F(-).

Antweiler, H.
EFFECT AND LIMITS OF GASEOUS AIR POLLUTANTS.
(Einwirkung und Grenzwerte gasförmiger Luftverunreinigungen). Text in German. Oeffentl. Gesundheitswesen (Stuttgart), 37(9):513-519, 1975.

The most important groups of noxious gases and vapors, the type and mechanism of their effect on man, and limits to prevent health damage are reviewed. Four different groups were differentiated: (1) irritants, (2) asphyxiators, (3) anesthetics and narcotics, and (4) systemic gases effective subsequent to resorption. Among those in group (1) were aldehydes, ammonia, hydrogen chloride, hydrogen fluoride, sulfur dioxide, and sulfur trioxide, all of which attack the upper respiratory tract; and halides and ozone that attack the lungs. The terminal pulmonary region (alveoli) was the target of phosgene and nitrogen dioxide. Group (2), carbon dioxide, helium, methane, ethane, nitrogen, and nitrous oxide, disturb oxygenation of the tissues, and diluted atmospheric oxygen. Others, such as carbon monoxide, nitrobenzene, hydrogen cyanide and hydrogen sulfide disrupt O₂-transport or tissue oxygenation. The gases in group (3), acetylene, ethylene, propane, acetone, and alcohols, had a depressant effect on the CNS. Systematically effective gases in group (4), halogenated hydrocarbons, benzene, phenol, carbon disulfide and methanol, act on visceral organs, hematopoiesis and the CNS. Problems of industrial toxicology relating to operations in more or less enclosed industrial spaces, involve the whole spectrum of noxious gases and vapors because of their acute danger, due to accidents, or their health damage attributable to long-term exposure. The situation of atmospheric pollution by virtually innumerable substances, among them numerous gases and vapors, was different since only a relatively small number of the latter occurred at health-threatening concentrations. Smog catastrophes have recently occurred in various locations all over the globe, the result of inverted climatic conditions and the absence of air flow. Gases, vapors and floating particles from industrial and residential sources near ground level caused the death of people with chronic bronchitis and emphysema.

Tsunoda, F.

EFFECTS OF FLUORIDES IN THE AIR ON HUMAN BODY.

(Taiki-chu no fukkabutsu ni yoru jintai eikvo). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):210-214, Nov. 1975.

Although a dose-response relationship was established for the more than 130 million persons drinking potable water with added fluorine (around 1 ppm), the effects of fluorides in air on the human body could not be simply evaluated by such a dose-response relationship because of the accumulated pollution on agricultural crops. It is necessary first to measure the fluorine in fluorine-polluted food crops. Experiments with humans given a standard diet for 5 days, then a diet from crops grown in a fluorine polluted area for 2 days, and then standard diets again for 3 days were conducted. The fluorine intake was 1.6-2.1 mg/day from the standard diet and 7.5-8.2 mg/day from polluted crops. From analysis of feces and urine of animals it was determined that accumulation of fluorine is conspicuous only in hard tissue (5000 ppm and 3000 - 4000 ppm in the dried fat of cows and sheep respectively after 3 years: 4 times that of control animals). Human absorption and excretion of sodium fluoride was measured. Slight irritation of mucosa and skin and a decrease of pulmonary ventilatory function was found epidemiologically; however, the result of long-term exposure

<xref image="2000WVJ3.TIF|V3|2006:09:28:01:35:06.00|122169|0"> image: </xref>

to concentrations of less than 10 ppb was not known. The average content of fluorine in the urine of Japanese males is 0.69 plus or minus 0.58 mg/day.

STUDIES ON Affi POLLUTION DUE TO FLUORIDES. PART
18. ON THE NORMAL CONCENTRATION OF FLUORINE
IN JAPANESE BONES. (Fakkabutsu ni yoru taikiosen ni kansu-
ru kenkyu. Part 18. Nihonjinno kotsu-chu fusso nodo no sei-
jo chi ni tsuite). Text in Japanese. Nippon Eiseigaku Zasshi (Japan
J. Hyg.), 31(1):175, April 1976.

Reports that high accumulations of fluorine have occurred in the hard tissues of goats grown under conditions of air pollution from fluoride suggested the possibility of evaluation of physiological pollutions and of diagnosis of osteosclerosis due to fluorine by analyzing the fluorine. The fluorine content of Japanese skeletons was taken as a standard. Fluorine was distributed relatively evenly in all bones. In persons older than 60 yr, the ash base fluorine content differed a little by position; however, in general, it was higher in men than in women, 1250-1500 and 850-1250 ppm, respectively. With age (older than 30), fluorine content showed a slowly increasing tendency.

RESPONSE OF SOME PATHOGENIC FUNGI TO SODIUM

FLUORIDE. *Mycologia* 57, (2) 216-21, Apr. 1965.

Growth rate of the 7 fungus isolates investigated was affected when sodium fluoride was incorporated in the substrate. Minimum concentrations required to inhibit growth varied greatly among species ranging from as low as 0.0005 M for *Pythium debaryanum* to as high as 0.01 M for *Verticillium albo-atrum* and *Helminthosporium sativum*. Growth rates of *Alternaria*, *Botrytis* and *Colletotrichum* species were suppressed when the fungi were grown at 0.005 M NaF and higher. Since the rate of growth was considered far more meaningful with regard to pathogenicity, radial growth measurements comprised the bulk of the study. Stimulation of the growth rate of some fungus species at certain concentrations of NaF was also evidenced. Growth of both *Botrytis* and *Colletotrichum* species was accelerated by NaF concentrations of 0.001 M. Spore production of *B. cinerea* was markedly inhibited at higher NaF concentrations. Such an effect could be particularly significant under field conditions if it occurred. Sporulation of other species was not sufficient for the possible effects of NaF to be definite. The response of fungi to NaF in all instances was most pronounced near the optimal temperature for growth of the species in question. This relation of temperature to growth response may be associated with the rate of the NaF uptake. The more rapid growth at optimal temperatures would cause a more rapid relative uptake of fluorides during a shorter period of time causing a higher fluoride buildup. It is the fluoride in the cell which is most significant; not the concentration to which the cells are exposed.

THE DISPOSITION OF ATMOSPHERIC FLUORIDES BY

VEGETATION (FINAL REPT.). Stanford Research Inst., South

Pasadena, Southern California Labs., Apr. 1963. 28 pp.

Alfalfa, orchard grass, chard, endive, spinach, and romaine lettuce were grown in sand culture and fumigated with hydrogen fluoride in the atmosphere at concentrations primarily undf 1.0 microgram/cu m. The fumigations were continuous for periods as long as 4 months. Under the conditions of the experiments, no significant effects of the fluorides were found on the growth of aboveground portions of the plants as long as the leaves did not develop any markings ascribable to the fluorides. The results indicated that the growth of the roots may have been suppressed slightly by the fumigations. Additional studies are needed to verify this result. Analysis of plant organs and tissues indicated that the fluorides were taken in by the leaves or chlorophyll-bearing tissue (stems of alfalfa) and translocated to the leaf extremities. No evidence of downward translocation was found. (Author)

EFFECTS OF FLUORIDE ON THE VIRULENCE OF TOBAC-

CO MOSAIC VIRUS IN VITRO. *Utah Acad. Arts Sci. Proc.*,

43, May 18, 1966. 4 pp.

This study was begun to determine if any relationship existed between fluoride concentrations in plant foliage and the activity of viruses. Initially, it was of primary concern to develop a technique to detect the possible influence of fluoride levels below those causing visible symptoms on the infectivity of tobacco mosaic virus. In vitro studies were conducted in order to minimize the variance of results. Numerous research modifications were investigated to increase and quantify the number of lesions thereby increasing the reliability of the bioassay test as well as provide a basis for evaluating possible effects of fluoride on virus pathogenicity. Some of the questions in developing this bioassay technique were: Could fluoride be introduced into the leaves, the tissues kept viable,

and the virus inoculation carried out? Another important question was: Is the fluoride contributing to the increase in lesion count or are other stress conditions of the technique primary contributions? Despite the many variables encountered which affected lesion development, fluoride content of the leaves also appeared to be a factor where tobacco mosaic virus was concerned. At least this was the case under laboratory conditions where the variability could be minimized. Under field conditions where virulence would be influenced by so many more factors, the effect of fluoride may prove to be negligible or not detectable. Even where close control of variation was maintained under in vitro conditions, results were not completely consistent. On the whole though, the slight stimulation of virus activity at foliar fluoride levels of 200 to 300 ppm appeared significant. The suppression of lesion development at higher fluoride levels was far more striking and proved to be statistically significant. (Author)

H. M. Benedict, J. M. Ross, and R. H. Wade
SOME RESPONSE OF VEGETATION TO ATMOSPHERIC
FLUORIDES (FINAL REPT.). J. Air Pollution Control Assoc.
15(6):253-255, June 1965.

A study was made of the effects of environmental conditions on fluoride uptake from the atmosphere and of internal fluoride on cell wall permeability. The significant results obtained indicated that alfalfa plants fumigated with hydrogen fluoride at night accumulated fluoride about as rapidly as plants fumigated during the day for the first three days. However, most of the fluoride accumulated at night could be washed off the plants, indicating it was adsorbed on the surface rather than taken into the plants. After three days, the plants fumigated during the day showed a much more rapid accumulation of fluoride than those fumigated at night. When the roots of plants are maintained in water cultures at 30 C, the uptake of atmospheric fluoride by the tops was much less than when the roots were held at 20 C even though the air temperature surrounding the tops of the plants was identical. The

<xref image="2000WVJ5.TIF|V3|2006:09:28:01:35:10.00|103915|0"> image: </xref>

results suggest that additional studies on temperature effect on fluoride uptake by vegetation would be a fruitful field of investigation. Preliminary results indicate that the cell walls of plant tissues which have absorbed fluoride from the atmosphere have an increased permeability to solutes, based on electrical resistance of water extracts. Again, further study is needed to verify this point. (Authors' abstract)

SOME CHEMICAL AND PHYSICAL CHARACTERISTICS
OF FLUORIDE COMPOUNDS AFTER CONCENTRATION
BY PLANTS IN LEAVES (FINAL REPT.). Stanford Research
Inst., South Pasadena, Southern California Labs. Apr. 1963. 16
pp.

Plants of orchard grass, alfalfa, and romaine lettuce which had been exposed to atmospheric fluorides were dried, or frozen and then dried, then extracted with various solvents. The solvents were applied either singly, followed by water, or in successive series, ending or beginning with water. The micrograms of fluoride recovered by each solvent and remaining undissolved in the residue were determined and expressed as such or expressed as parts per million of the dry weight of the original material. The results show that: (1) Freezing the tissues increases the ease with which fluorides are extracted by the various solvents, especially water; (2) The greatest proportion of the fluorides are extracted by water whether preceded or followed by organic solvents; (3) Of the organic solvents used, the petroleum ether extracted the most fluoride from the plants, but the ratio of the amount thus extracted to the amount extracted by water was similar to the ratio obtained when pure potassium fluoride was extracted by these solvents; (4) The actual amount of fluoride unextracted by the various solvents is approximately the same for fumigated and control plants; and (5) The proportion of fluorides extracted by water is much greater from the fumigated plants than from the control plants. From all of these studies it is concluded that practically all of the fluorides absorbed as hydrogen fluoride by plants from the atmosphere is retained in living cells in a water-soluble, presumably inorganic form, although small quantities of organic fluorides appear to be present. M. D. Thomas
GAS DAMAGE TO PLANTS. Ann. Rev. Plant Physiol. 2, 293-
322, 1951.

A detailed review is given of gas damage to plants with references containing important bibliographies. Investigations on the effects on vegetation of sulfur dioxide, other sulfur-containing gases, halogens and hydrogen halides, nitrogen oxides, ammonia, mercury vapor, and carbon compounds are cited and results discussed. Phytotoxicities of the different gases seem to depend on (a) absorbability, which is related to water solubility and reactivity with the tissues; (b) acidity or alkalinity; (c) oxidation or reduction reactions; (d) hormonal properties; and (e) toxicity of the element itself. Carbon monoxide, hydrogen cyanide and hydrogen sulfide are of comparatively low toxicity. Greater toxicity is evidenced by chlorine and sulfur dioxide due to their rapid oxidizing or reducing properties. The even greater toxicity of fluorine and iodine compounds is due to their rapid absorption and inherent toxicity as elements in themselves.

FLUORIDE ACCUMULATION AND GROWTH OF PLANTS EXPOSED TO PARTICULATE CRYOLITE IN THE ATMOSPHERE. Contrib. Boyce Thompson Inst. Vol. 23(1):1-12, Mar. 1965.

The effects of air-borne particulate cryolite on the fluoride accumulation and growth of gladiolus, Milo maize, corn, tomato, and alfalfa were studied in a series of experiments using exposure periods of 9 to 49 days and atmospheric fluoride concentrations of 1.2 to 15 microgram cubic meter. Exposure to cryolite resulted in 2- to 50-fold increases in the fluoride level of foliage depending upon the duration of exposure, the atmospheric fluoride level, and the species or variety of plant. Except for a small increase in tip burn over plants exposed to ambient air in gladiolus, exposure to cryolite produced no visible injury and there was no effect of cryolite on growth or yield. A comparison of the effects of an Alconox-EDTA wash and position in the leaf on tissue fluoride levels in gladiolus exposed to HF and cryolite indicates that the relative inactivity of cryolite results from an inability of the accumulated fluoride to penetrate the leaf in a form that is physiologically effective. EFFECTS OF FLUORINE COMPOUNDS ON VEGETATION, WITH SPECIAL REFERENCE TO SWEET CORN. J. Air Pollution Control Assoc. 14, (12) 503-8, Dec. 1964. (Presented at the 57th Annual Meeting, Air Pollution Control Association, Houston, Tex., June 21-25, 1964.)

Since 1951 many fumigation experiments have been carried out with different species and varieties of plants, including field corn and sweet corn. Results for gladiolus and Milo maize have been summarized, but only brief mention has been made of results obtained with corn. This report summarizes some of the earlier results obtained with sweet corn, used alone or in comparative tests with field corn in unreplicated experiments and the results of replicated fumigation experiments with Marcross sweet corn (*Zea mays* L.) and lamb's-quarters (*Chenopodium album* L.) carried out in 1963. AIR QUALITY CRITERIA AND STANDARDS FOR AGRICULTURE. J. Air Pollution Control Assoc., 18(10):476-480, Oct. 1965. (Presented at the 58th Annual Meeting, Air Pollution Control Association, Toronto, Canada, June 20-24, 1965)

Air pollution damage to crops is not only important for the damage it causes agriculture but because vegetation damage is a harbinger of air pollution problems affecting man and his well-being. Some of the effects of varying dosages of ethylene, fluoride, ozone, PAN, and sulfur oxides on plants and animals are given. Knowledge of the response of certain plants and animals to specific air pollutants permits the establishment of air quality standards for certain of these pollutants. The importance of environmental conditions on host responses to these several toxicants is also presented to illustrate the need of stipulating environmental conditions as well as toxicant dosages when establishing air quality criteria and standards for the protection of the agricultural resource.

THE EFFECTS OF HYDROGEN FLUORIDE AND WOUNDING ON RESPIRATORY ENZYMES IN SOYBEAN LEAVES. Intern. J. Air Water Pollution (London) Vol. 10, 169-181, 1966. Soybeans were cultured in Hoagland's solution and fumigated with hydrogen fluoride (ca 100 ppb). After 24, 96 and 144 hr of fumigation, the enzyme activities of cytochrome oxidase, peroxidase, catalase, polyphenol oxidase, ascorbic acid oxidase and glucose-6-phosphate dehydrogenase were assayed in leaves from fumigated and control plants. The total oxygen uptake after each time of treatment was measured. The effect of mechanically wounding the tissue on the above enzymes was determined by rubbing with carborundum. Glucose-6-phosphate dehydrogenase activity from fumigated leaves showed an average increase of 5 to 22 times that of the control. Cytochrome oxidase, peroxidase and catalase activities were markedly stimulated by fluoride fumigation period. Ascorbic acid oxidase was stimulated at the initial state, then showed a steady decrease in activity. In vitro tests revealed that ascorbic acid oxidase and peroxidase were very sensitive to fluoride ions. Polyphenol oxidase was only slightly inhibited by 10 to the minus 2M KF solution. Cytochrome oxidase and catalase were not affected by KF up to 10 to the minus 2M. Total respiration throughout the treatment period showed an accelerated rate. All enzymes studied were stimulated by wounding. The effect of HF on respiration and specific enzymes is discussed in terms of direct effects and injury. (Author abstract)

SOME EFFECTS OF ATMOSPHERIC FLUORIDE ON PLANT METABOLISM. J. Air Pollution Control Assoc. 14(11):465-468, Nov. 1964. (Presented at the 85th Annual Meet-

ing, Air Pollution Control Association, Houston, Tex., June 21-25, 1964.)

Leaves of Tendergreen bean plants exposed to atmospheric fluoride concentrations in the range 1.7 to 7.6 cubic meter showed increased levels of enolase activity and decreased levels of pyruvate and α -ketoglutarate. Phosphoenolpyruvate carboxylase activity and oxalacetate were not affected. The leaves of Milo maize plants exposed to 5.0 cubic F meter showed increased levels of enolase and pyruvate kinase activity and a decreased level of pyruvate. Oxalacetate and α -ketoglutarate levels were not affected. Catalase activity was increased, then decreased by HF fumigation. The changes induced by HF were greatest six to 10 days after the start of fumigation and disappeared or decreased in magnitude during the post-fumigation period. (Author abstract)

EFFECTS OF INORGANIC FLUORIDES ON ANIMALS. J. Air Pollution Control Assoc., 14(11):461-464, Nov. 1964. (Presented at the 57th Annual Meeting, Air Pollution Control Association, Houston, Tex., June 21-24, 1964.)

Fluoride toxicity in cattle can result from the ingestion of forage contaminated by various industrial processes. The disease is recognizable through its effects on the developing bones and teeth, by chemical analysis of urine and tissues and in advanced stages by definite physiologic disturbances. Definite effects on the well-being of cattle have been found to be associated with levels of fluoride in the compact bone in excess of 5,500 ppm, and marginal bones of from 4,500-5,500 ppm. The concentration of fluoride on forage which would be needed to produce these concentrations in the skeleton would depend on a large number of factors. Air quality standards based on atmospheric fluoride levels do not seem feasible as a means of protecting livestock from possible damage. It does however appear that guidelines based on atmospheric fluoride levels or urinary fluoride content might serve to protect livestock in a community and be acceptable to fluoride emitting industries. SEMI-AUTOMATED ANALYSIS OF FLUORIDE IN BIOLOGICAL MATERIALS. J. Air Pollution Control Assoc. 15(5):222-225, May 1965.

A semi-automated method for determination of fluorine in biological materials has been developed incorporating the Technicon AutoAnalyzer. One-half gram of dried, ground plant material is ashed, alkali-fused, diluted with water, and the suspension is pumped, along with H₂SO₄, at controlled rates, into the hot revolving glass helix of a digester unit. As the acid-digest mixture passes through the heated coil, volatile fluoride and water vapor are evolved. The volatile fluoride and water vapor are pulled from the helix under reduced pressure through a tube which projects into the helix. The tube, in turn, is connected to a water-jacketed condenser and then to an impinger where the sample is continuously mixed. An aliquot of the impinger liquid is being constantly withdrawn. This sam-

<xref image="2000WVJ7.TIF|V3|2006:09:28:01:35:16.00|117126|0"> image: </xref>

pie is then air-segmented and mixed with a reagent containing alizarin complexone, pH 4 acetate buffer, lanthanum nitrate, acetone, and water. The sample-reagent combination passes through 4 full-length mixing coils where color development takes place. Upon reacting with fluoride, the wine-red alizarin complexone-La(III) reagent forms a lilac blue fluorine complex. The solution is pumped from the mixing coils through the tubular flow cell of the colorimeter. The absorbance of the solution is measured at 624 millimicrons, and the signal is transmitted to a recorder where the results are plotted on absorbency paper. The absorbance at the apex of the peak is proportional to the amount of fluoride in the sample between the range of 2.5-80 micrograms F. Samples are analyzed at a rate of 12 per hour. Results compare favorably with those obtained by Willard-Winter distillation. Recent studies indicate that the F content of plant tissues can be estimated without prior ashing and fusion. EFFECT OF MINERAL NUTRITION ON THE GROWTH
AND HF SENSITIVITY OF GLADIOLUS. Contrib. Boyce
Thompson Inst., Vol. 23:295-299, 1966.

The response of a given plant species to atmospheric fluorides can be affected by many factors. Some of these factors reside in the plant and others in the plant's environment. The availability of mineral nutrients may be one of the environmental factors affecting the HF sensitivity of the plant. In beans (*Phaseolus vulgaris* L.) exposed to acute HF fumigations, foliar fluorosis symptoms were found only in plants grown on a nitrate deficient medium although the tissue fluoride levels were equal to or less than those of plants grown in other nutrient media and exposed to the same HF concentrations. The oxygen uptake of bean seedlings and the effect of HF fumigation upon it are altered by N, P, K, Ca, or Fe deficiency. In other studies, however, nutrient excess, as well as nutrient deficiency of N, P, or Ca, was associated with decreased fluoride accumulation and injury in HF-fumigated tomatoes. These apparent contradictions as to the effect of nutrient stress may be due to apparent contradictions as to the effect of nutrient stress may be due to the use of different fumigation regimes, different experimental procedures, and plants of different species and ages. Experiments are reported which were carried out to provide more information on the relationship of nutrient stress to HF sensitivity and the nature of factors that may determine this relationship. J. L. Shupe, M. L. Miner, and D. A. Greenwood
CLINICAL AND PATHOLOGICAL ASPECTS OF FLUORINE
TOXICOSIS IN CATTLE. Ann. N.Y. Acad. Sci. 3, 618-37, Apr.
24, 1964. Also published in J. Oral Therap. Pharmacol.
2(4):315, Jan. 1966.

Continued ingestion by cattle of forage containing fluorides at a toxic level, coupled with the cumulative action of fluorine in the animal body may cause chronic fluorine toxicosis. This has become an important toxicologic problem in some areas of the United States and other countries. Airborne contamination of vegetation, soil, and water in feeding sections near certain fluoride-emitting industries makes the occurrence of such illness in cattle a part of the overall air pollution problem as well. Clinical and pathological data, developed from long-range experiments in Utah, correlated with extensive field and necropsy studies, are presented and analyzed in this paper. The experiments, previously reported in detail, had four objectives: (1) determination of how much fluorine could be tolerated when fed with a normal grain mixture to dairy animals from 3 months to 7 1/2 years in age; (2) influence on the cow's body processes of various levels of fluorine through a life span; (3) comparison of toxicities of various types of fluorides; and (4) study and evaluation of the use of alleviators in preventing fluorosis. Effects on the teeth, bones (especially

ribs), urine, milk production, hair and skin, soft tissues, blood, placental transfer, and reproduction are discussed. The authors concluded that: "The diagnosis, prevention, and control of fluorosis in livestock can be achieved, but only when the complexity of the disease is realized and the pathogenesis, symptomatology, and lesions are properly correlated, interpreted, and evaluated.'

M. Threshow

EVALUATION OF VEGETATION INJURY AS AN AIR POLLUTION CRITERION. J. Air Pollution Control Assoc. 15, (6) 266-9, June 1965.

Foliar markings on vegetation have proven a highly sensitive criterion for the presence of many air pollutants; proper evaluation of such effects can serve as a valuable and inexpensive tool for delineating an air pollution condition. Injury symptoms from fluoride, sulfur dioxide, photochemical oxidants and other pollutants have been described and can be recognized by experienced observers. Several factors must be considered in appraising injury. These include a knowledge of the relative sensitivity of plant species to various pollutants, the syndrome of injury on a number of plants and species, and distribution and geographic relation of affected plants to the suspected source. Background information on cultural, environmental, disease and insect conditions which might be responsible for, or modify, foliar markings or chronic effects in question must also be understood. For some pollutants a chemical analysis of foliage and air may prove helpful. When these factors are studied, the presence, distribution and magnitude of an air pollution situation can be evaluated, thus providing a sensitive criterion of air quality. AIR POLLUTION IMPACTS TO SOME IMPORTANT SPECIES OF PINE. J. Air Pollution Control Assoc., 16(2):63-65, Feb. 1966.

In the past, many species of pine have been severely damaged by acute forms of air pollution associated with ore smelting. More recently, damage to ponderosa pine in the State of Washington has been associated with atmospheric fluoride, and this species in particular has also suffered smog damage in southern California. In the East, white pine has been declining in the vicinity of certain soft-coal-burning power plants, and in one case downwind from an oil-burning power plant; also, throughout the East, an atmospheric oxidant of unknown source has caused a type of needle blight on white pine. Trash burners and city dump combustion have led to the killing of certain pine species, leaving other intermixed pine species unharmed. Localized damage to white pine from automobile exhaust has been observed. Differences in the susceptibility of neighboring trees of the same species to a given air pollutant have been observed repeatedly. (Author abstract)

THE ACCUMULATION OF FLUORINE BY PLANTS. J. Air

Pollution Control Assoc. 16 (8) 412-417, Aug. 1966.

The accumulation and distribution of fluorine in plant leaves and the response of plants to concentrations of atmospheric fluoride similar to those in urban or industrial areas were studied. Chlorosis, necrosis, or growth suppression of leaves of sensitive plants may be induced by extended exposure to atmospheric fluoride concentrations of 0.6 microgram/cubic meter. In other air pollutants higher concentrations are required for injury to occur. The results indicate that at least 3 factors determining the response of plants to atmospheric F are the location of F. surface O_i interior, translocation of F to tips and margins, and the degree of interchange of F between the interior and exterior of a leaf.

SITE OF FLUORIDE ACCUMULATION IN NAVEL ORANGE

LEAVES. Plant Physiol. 41, (2) 211-3, Feb. 1966

Fluoride-polluted navel orange leaves, *Citrus sinensis* (Linn.) Osbeck, were fractionated into the subcellular components in hexane carbon tetrachloride mixtures having various densities. Fluoride was determined at each fraction. Analyses were also made for the subcellular distribution of chlorophyll, nitrogen, and DNA to assess the extent of cross-contamination of each component. The fraction containing cell wall, nuclei, and partly broken cells apparently contained a major amount of fluoride. However, if allowance was made for the cross-contamination of chloroplast and chloroplast fragments, the fraction of chloroplasts was found to be the site of the highest fluoride accumulation. When each particulate component was washed with water after drying, the combined washings contained more than 50% of the total fluoride of the isolated fractions. The usual method of fluoride accumulation from the fraction of chloroplasts to that of the supernatant. (Author summary)

DISTINCTIVE EFFECTS OF ROOT VERSUS LEAF

ACQUIRED FLUORIDES. Proc. Florida State Hort. Soc. 77,

516-7, 1964. (Meeting was held in Miami, Fla., Nov. 3-6, 1964.)

In connection with studies of the effects of fluoride air pollution on plant growth, the question arises as to whether soil-borne fluorides may contribute significantly to the fluoride content of plants and thus add to the toxicity of airborne fluorides. After extensive research, MacIntire and others concluded that with normal agricultural soils of low acidity, fluoride uptake by the roots does not occur to any significant degree. The experiments to be reported were carried out to determine the applicability of these conclusions to Florida conditions and to determine whether the effects of soil fluorides could be distinguished from those of atmospheric fluorides.

(COMPARISON OF THE ACTIONS OF SULPHUR DIOXIDE
AND FLUORINE COMPOUNDS ON SOME PLANTS.) Action
Comparee de l' Anhydride Sulfureux et des Derive Fluores Stir
Quelques Vegetaux. Proc. (Part I) Intern. Clean Air Cong., Lon-
don, 1966. (Paper VI/5. pp. 173-3.
Sulphur dioxide and fluorine compounds are well-known pol-
luting agents. In many industrial areas in France they are the
cause of appreciable damage to the surrounding vegetation.
The appearance and the morphology of the burns vary accord-
ing to the polluting agent involved; moreover, the climatic con-
ditions have a preponderating influence on the extent of the
damage observed. The absorption rates of the two polluting
agents have been studied and there is an important difference
between the two gaseous pollutants. After having been ab-
sorbed, sulphur dioxide and the fluorine compounds behave
differently in the plant. This may be explained by the fact that
sulphur is a normal metabolite of the plant, whereas the
fluorine ion is irrelevant to it and does not therefore take part
in any normal metabolic process. It accumulates in certain
definite parts where it could cause necroses when a certain
level has been overstepped. (Author abstract)

(THE ACTION OF GASEOUS FLUORINE COMPOUNDS ON
FOREST SPECIES.) Action des Fluorures Gazeux Sur les
Espèces Forestières. Proc. (Part I) Intern. Clean Air Cong., Lon-
don, 1966. (Paper VI/13). pp. 193-6.
Very close study of vegetation makes it possible to reduce a
pollution by examining only the canker or burning which this
examination shows occurs on the vegetation around the sta-
tion- herbaceous flowers, shrubs and trees. The time at which
such a programme should start must be judiciously decided.
The possibility of proceeding with sampling and analysis of
leaves or (pine) needles remains. It appears that in the USA
the tendency is to establish a single pollution by chemical anal-
<xref image="2000WVJ9.TIF|V3|2006:09:28:01:35:22.00|110635|0"> image: </xref>

ysis of the air which, incidentally, does not provide information on the damage caused to plants and animals. In the USSR, on the contrary, Dr. Izmerov takes examination of vegetations as the basis for determining air quality. The author thinks that this latest type of study requires sustained attention, and sense of observation, extensive knowledge of vegetable biology, and of the kinds of attack to which various vegetable forms are liable. It makes it possible to place diagnosis of pollution-by fluorine (compounds) on firm basis. (Author abstract)

RESPONSE OF TOMATO FRUITING TO HYDROGEN FLUORIDE AS INFLUENCED BY CALCIUM NUTRITION. J.

Air Pollution Control Assoc. 16, (10) 541-4, Oct. 1966.

An investigation of the response of tomato fruiting to atmospheric HF and the influence of calcium nutrition is described. Two varieties of tomatoes grown at 40-200 ppm. calcium were continuously fumigated with HF throughout flowering and fruit development. Fluoride injury to the tomato foliage was most severe at the lowest calcium level. Treatment with HF about 3 micrograms g.F/cu m produced some injury to tomato foliage but had no apparent effect on fruiting. The relationship between fluoride injury and calcium nutrition suggests interference with calcium metabolism as a mechanism of fluoride injury to plants.

THE TOTAL EFFECT OF AIR POLLUTANTS ON BEARING CITRUS. Preprint. 1965.

The three field installations of plastic covered greenhouse established over bearing lemon and orange trees will be continued for one, two and three years, respectively, until five years of data are obtained at each installation on the effects of air pollutants on fruit yield, leaf drop, fruit quality and storage stability of fruit. More refined measurements of the more basic responses of the trees, apparent photosynthesis, respiration and transpiration will be made and correlated with the occurrence of specific pollutants in the air. The way in which oxidants cause increased leaf drop will be studied. The effects of very low levels of fluoride on trees will be investigated to find out whether or not there may be a significant stimulation of the above mentioned responses, especially fruit yield. The effect of nitrogen dioxide will be examined in the fractions of one part per million range. Interrelationships between the presence of air pollutants and beneficial or deleterious insects will be examined. An attempt will be made to determine threshold levels of pollutants below which no injury occurs to plants. A concerted effort will be made to overcome the excessive fruit abortion of navel oranges by the application of antioxidants. Results of some of the studies in the following categories are reported: photosynthesis; fruit yield, transpiration; leaf carbohydrate levels; anthrone reducing carbohydrates in citrus leaves; leaf drop. METABOLISM OF 2-(C-14)-FLUOROACETATE BY HIGHER PLANTS. Preprint. 1965.

In recent years several plants have been shown to have the capacity to biosynthesize fluoro-organic compounds from inorganic fluorides. Several species of *Dichapetalum* have been shown to be somewhat toxic to animals and to induce increased levels of citric acid in kidney and brain tissues of mammals, a condition induced by fluoracetate poisoning. The experiments described in this paper were carried out to study the metabolism of 2-14C-fluoroacetate in seedlings of *Acacia*,

peanut, castor bean, and Pinto bean, the synthesis of fluoroacetate from NaF in Acacia, and to develop analytical methods for microgram amounts of fluoroacetate and other fluoro-organic compounds.

THE ACCUMULATION OF FLUOROACETATE AND
FLUOROCITRATE IN FORAGE CROPS COLLECTED NEAR
A PHOSPHATE PLANT. Atmos. Environ., Vol. 2, p. 187-190,
1968. 10 refs.

Plants were collected from an area high in atmospheric fluoride. Animals grazing on this area showed severe fluoride injury. Analyses of plants indicated accumulation of fluorocitrate and fluoroacetate at concentrations of 896 micrograms and 179 micrograms per gram leaf dry wt. The presence of these compounds was established by chromatographic techniques, inhibition of aconitase and i.r. spectral analysis. (Authors' abstract)

G. Seidman
EFFECTS OF AIR POLLUTION ON PLANTS. African Violet
Mag. 18, (3) 44-7, Mar. 1965

The first indication of an air pollution problem is often the injury that appears on comparatively sensitive vegetation. Some plants are more resistant than others to a given phytotoxicant. Plant injury from air pollution is caused primarily by the major gaseous pollutants (sulfur dioxide, fluoride gases, ethylene, and the components of the photochemical smog complex) and is produced in various ways in urban or industrial areas. These major pollutants and several of the minor pollutants are discussed in this paper.

G. Tendron
EFFECTS OF AIR POLLUTION ON ANIMALS AND
PLANTS. European Conf. on Air Pollution, Strasbourg, 1964.
pp. 25-69.

There is no doubt as to the effects of air pollution on plants and animals, particularly in the case of a few specific and very dangerous pollutants which are emitted in considerable quantities. In certain regions of Europe, life depends on immediate steps being taken to protect flora and fauna. There is no doubt that they will need to be mainly of a technical nature. It is a matter of reducing the discharge of polluted waste and attenuating, if not completely eliminating, the dangers involved. The necessary technical research must be organised in such a way as to cover all the different aspects of animal and plant life, the safety of which is indissolubly bound up with that of human life. In the Netherlands, a team of workers succeeded in arresting the devastation of horticultural crops by fluorine emissions thanks to the use, during the period of growth, of a raw material which when processed did not give off toxic fumes. In France, the Association for the Prevention of Air Pollution has set up a study group known as the 'Committee for studying the effects of air pollution on cultivated plants and animals' to standardise working methods throughout the country. Mention should also be made of the Norwegian and

<xref image="2000WVJA.TIF|V3|2006:09:28:01:35:24.00|112768|0"> image: </xref>

British studies of the preventive effects of various fluorine alleviators and the research being done in the Federal Republic of Germany on the stimulation of plant nutrition by industrial emissions, as well as on countering the effects of such emissions by the addition of fertilisers. These few achievements show the importance of rational organisation and cooperation in research.

EFFECT OF FLUORINE ON NUCLEIC ACIDS AND
GROWTH IN GERMINATING CORN SEEDLING ROOTS.
Physiol. Plantarum 19, 911-8, 1966.

Corn seeds were treated with 0.01 M sodium fluoride for various time periods. The treated seeds were germinated and grown until the seedling roots reached a standard size of 12 plus/minus 3 mm. Analyses were made for RNA and DNA contents of 3-mm seedling root tips. Determinations also were made for growth rate, rate of cell elongation, cell multiplication, and tissue maturity of 12-mm roots. RNA contents of 3-mm root tips were found to be directly proportional to the growth rates of the entire seedling root of corn seeds treated with sodium fluoride for various periods of time. The RNA content was reduced on a cell basis and was independent of the root tip cell number. The amount of DNA was not related to the growth rate of the intact seedling roots. Since fluoride reduced the number of mitotic multiplication not more than about 40 per cent of the control figures, it was likely that fluoride inhibited DNA synthesis during the interphase of the mitotic cycle. Growth by cell multiplication was inhibited more than that by cell elongation in the sample treated with fluoride for a shorter period. The two types of growth, however, showed a similar level of growth reduction in the sample treated with fluoride for a longer period. Fluoride seemed to reduce the rates of cellular elongation and value in these tissues under present experimental conditions. Fluoride also induced maturity in the seedling roots in proportion to the periods of fluoride treatment. (Author abstract)

M.D. Thomas

EFFECTS OF AIR POLLUTION ON PLANTS. World Health Organ. Monograph Ser. 46 (Air Pollution), 1961. pp. 233-78. The literature on the effects of air pollution on plants has been reviewed with special reference to those pollutants that present major problems - viz., SO₂, HF, London type smog, and Los Angeles type smog. The others, which are definitely of minor importance, are referred to more briefly. SO₂ has long been recognized as an air pollutant because it arises from the combustion of nearly all fuels, especially coal, and from the roasting of sulfide ores. It is phytotoxic in concentrations above 0.1 x 0.2 p.p.m., depending on the length of exposure. Below about 0.4 p.p.m., the gas tends to be oxidized in the cells as rapidly as it is absorbed, and interference with functions such as photosynthesis is slight. Toxic concentrations of sulfate are finally accumulated. Chronic rather than acute injury, if any, is generally manifested with these small concentrations. Above about 0.4 p.p.m., acute injury occurs more frequently, owing to the reducing properties of sulfate in the cells. Temporary interference with photosynthesis or 'invisible injury' can occur to some extent, but these concentrations cause acute injury if maintained for more than short periods, and recovery is rapid when the fumigation is stopped. HF behaves somewhat similarly to SO₂, except that with a few species of plants it is effective in causing lesions and interfering with photosynthesis in concentrations 2 or 3 orders of magnitude smaller than in the case of SO₂. With most species it is up to 10 times as effective as SO₂. Fluoride accumulated in the cells in sublethal amounts interferes with photosynthesis as does sulfite, but whereas the latter is deactivated by simple

oxidation to sulfate, the former must be removed by translocation, volatilization, or some obscure chemical reaction, which makes much slower the recovery of the plant functions after HF fumigation. There appears to be a concentration of HF for each species below which 'invisible injury' does not occur. The Los Angeles type smog is fairly well understood as to its mode of formation and its phytotoxic effects, but the actual compounds that cause these effects are still unknown. The smog causes characteristic leaf lesions which are quite different from those produced by other pollutants, including ozone, which may be a constituent of the smog. It also causes some 'invisible' injury. Visible damage to crops in Southern and Northern California was estimated at over \$5 000 000 and \$1 100 000 respectively, annually, in 1956. AN AIR POLLUTION PHYTOTRON (A CONTROLLED ENVIRONMENT FACILITY FOR STUDIES INTO THE EFFECTS OF AIR POLLUTANTS ON VEGETATION). J. Air

Pollution control Assoc. 11, (10) 470-6, Oct. 1961. (Presented at the 54th Annual Meeting, Air Pollution Control Association, New York City, June 11-15, 1961.)

The facilities described have been used in the study of the influence of atmospheric fluoride pollution on plant response. The design concepts and resultant equipment are equally applicable to similar plant studies using other atmospheric pollutants. Only relatively minor changes in the atmosphere-producing equipment would be required. So-called field conditions cannot be produced in a phytotron chamber since the objective is one of a completely controlled plant environment. However, numerous parameters such as (a) stem elongation and diameter, (b) leaf size and development, (c) chlorophyll, sugar, carbohydrate, and enzyme content, and (d) respiration and photosynthetic rates, etc., readily respond to all phases of the plant environment and thus introduce difficulties in separating the response to these variables from that of the air pollutant. Thus the availability of such an air pollution phytotron promises to eliminate much of the present uncertainty involved in relating physiological and biochemical measurements with air pollution.

EFFECT OF AQUEOUS FLUORIDE SOLUTIONS ON RESPIRATION OF INTACT BUSH BEAN SEEDLINGS. I. INHIBITION AND STIMULATION OF OXYGEN UPTAKE. Am.

J. Botany 47, (5) 339-45, May 1960.

<xref image="2000WVJB.TIF|V3|2006:09:28:01:35:28.00|120272|0"> image: </xref>

Intact bush bean seedlings were infiltrated with 1×10 to the minus 1, 1×10 to the minus 2, 1×10 to the minus 3, and 1×10 to the minus 4 M fluoride. A linear relationship was found to exist between the fluoride concentrations of the infiltrating solutions and tissue fluoride. The higher fluoride concentrations inhibited oxygen uptake, whereas lower fluoride concentrations accelerated oxygen uptake. Both inhibition and acceleration of oxygen uptake by fluoride were modified by light, CO₂, and presence or absence of chlorophyll. (Author abstract)

EFFECT OF ATMOSPHERIC FLUORIDE ON RESPIRATION

OF BUSH BEANS. *Botan. Gaz.* 121, (4) 223-7, June 1960.

The oxygen uptake in bush-bean plants is accelerated when the plants are exposed to atmospheric fluoride at concentration levels below those inducing visible foliar symptoms of fluorosis. Under the environmental conditions used in this experiment, fluoride uptake of bean plants given a 24-hour fumigation just prior to the day of sampling was relatively constant from the eighth to the twentieth days of growth. Similar plants fumigated continuously from planting until harvest showed steadily increasing amounts of tissue fluoride because of the greater duration of exposure. Under the 24-hour fumigation the daily rate of fluoride accumulation tended to increase until after the plants had emerged and then remained relatively constant; under continuous fumigation the rate tended to increase throughout. (Author summary)

'INVISIBLE INJURY' OF BUSH BEANS BY ATMOSPHERIC

AND AQUEOUS FLUORIDES. *Intern. J. Air Water Pollution*

3, (4) 231-48, 1960. (Presented at the Annual Meeting, American Society of Plant Physiologists, San Diego, Calif., June 17, 1959.)

Bush beans, *Phaseolus vulgaris* var. *humilis*, when subjected to either gaseous fluoride or solutions containing fluoride, have abnormal oxygen uptake when compared with similar plants not subjected to fluoride. Plants given gaseous fluoride for 24 hours prior to harvest consistently had greater oxygen uptake than their control counterparts. Plants given continuous fluoride from time of germination had, with the exception of a short period around the fifth day, greater oxygen uptake than their control plants. Between the fourth and sixth days, continuously fumigated plants had a lower oxygen uptake than the unfumigated control plants. There appeared to be little difference in respiration patterns between gaseous fluoride-mediated respiration and aqueous fluoride-mediated respiration. This physiological disturbance induced by fluoride which has been demonstrated is considered to be an example of 'invisible injury', by classical definition. (Author abstract)

DAMAGE TO VEGETATION FROM POLLUTED AT-

MOSPHERES. *J. Air Pollution Control Assoc.* 8, 9-15, May

1958. (Presented at the 22nd Midyear Meeting, American Petroleum Inst. Division of Refining, Philadelphia, Pa., May 14, 1957.)

Damage to vegetation from polluted atmospheres has been recognized for more than a century. Early interest in air pollution centered largely on smoke and fumes from industrial wastes, particularly those of chemical manufacture, smelting, ceramic production, and coal and petroleum combustion effluents. Vegetation damage has increased with industrialization and urban development. Whereas the principal plant toxicants recognized several decades ago were sulfur dioxide and fluorine, in the last decade a new group of airborne phytotoxicants has been described and identified as oxidants. The principal source of these oxidants is believed to be photolysis reaction products of auto exhaust. Atmospheric contaminants responsible for damage to vegetation may be described as particulates - such as dusts and acid aerosols - and gases - such as sulfur dioxide, halogens, oxidized organics, ozone, nitrogen dioxide, hydrogen sulfide, ammonia, and carbon monoxide. Of these diverse pollutants, gases generally cause more damage to plants than do particulates.

J. T. M'adleton A. O. Paulus

THE IDENTIFICATION AND DISTRIBUTION OF AIR POLLUTANTS THROUGH PLANT RESPONSE. A.M.A. Arch. Ind. Health 14, 526-32, Dec. 1956. (Taken from a paper presented at the 17th Annual Meeting, American Industrial Hygiene Association, Philadelphia, Pa., Apr. 23-27, 1956.)

This paper presents an annual summary of monthly tabulations showing plant damage occurring in 12 of 51 counties. Regional tabulations show that plant damage is limited to the San Francisco Bay area and the coastal plain of southern California. The areas reporting plant damage are those of greatest population density. The toxicants responsible for plant damage are recognized in decreasing order of importance as oxidized hydrocarbons, ethylene and fluorides. Sulfur dioxide is of unusual occurrence and its distribution usually associated with specific industrial wastes. It is generally believed that ozone is present in the urban areas of Los Angeles and San Francisco and responsible for a significant part of the total atmospheric pollution. The wide-spread distribution of ethylene and smog, or reaction products from the oxidation of hydrocarbons, emphasizes the need for regional, research and abatement programs.

DIFFERENTIATING NEEDLE BLIGHTS OF WHITE PINE IN

THE INTERPRETATION OF FUME DAMAGE. Intern. J. Air

Water Pollution 4(1/2): 101-105, 1961. (Presented at 3rd National Air Pollution Seminar, New Orleans, La., Mar. 23, 1960.)

Because of chronic blighting of the foliage of white pine in recent years in east Tennessee, the U.S. Forest Service and TVA have renewed investigation of the white pine blight complex. The eastern white pine is subject to an unusually large assortment of maladies, which could be and have been confused with fume damage. It has proven to be difficult to assess the possible role of air pollution in such cases unless one can clearly differentiate the symptoms of fume damage from those of other troubles that so often occur in the same areas. White pine eastern and western are regarded sensitive to such pollutants as sulfur dioxide and fluoride. One of the primary objectives has been to learn how to distinguish and separate the needle troubles occurring on white pine in the southeast that can now be attributed to a pathogen. Three that can be recognized as distinct entities are discussed in this paper: Emergence tipburn, post-emergence acute tipburn, and post-emergence chronic tipburn.

Merrill, Malcolm H.

RECEPTOR EFFECTS OF AIR POLLUTION. American

Meteorological Society, Boston, Mass., Committee on Air Pollution, Interdisciplinary Conf. Atmos. Pollut., Santa Barbara, Calif., 1959, p. 1-6. W refs. (June.)

Some harmful effects of air pollutants on man and plants are described. There is a positive relationship between air pollution and emphysema and bronchitis. The lung function of patients with emphysema improves considerably when these patients are taken out of polluted air and placed from one to two days in a room with air passed through activated charcoal filters. Most of California plant damage is caused by a group of

airborne contaminants which include ethylene, fluorides, oxidized, hydrocarbons, ozone, and sulfur dioxide. All can be identified by plant response. Ethylene is derived from chemical manufacturing processes and motor vehicle traffic. It causes poor leaf formation in some flowers, leaf irregularities and poor flower formation in others. Failure of carnation blossoms to open, flower drop in snapdragons, and withering and drying of petals of some types of orchids are attributed to the toxicity of ethylene. Prune, apricot, and peach trees are especially susceptible and can be damaged by hydrogen fluoride in concentration as low as 0.02 to 0.05 ppm. This is a problem of special concern to agriculture in the vicinity of a certain number of operations in which fluorides are emitted to the atmosphere.

N. R. Benson

FLUORIDE INJURY OR SOFT SUTURE AND SPLITTING

OF PEACHES. Proc. Am. Soc. Hort. Sci. 74, 184-98, Dec. 1959.

A serious disorder of peaches in which the fruit prematurely develops soft red flesh along the suture toward the apex occurred in an area (near Wenatchee, Washington) having fluoride polluted air. The symptoms were reproduced experimentally by spraying fluoride on the trees and also by subjecting the trees to an atmosphere containing water-scrubbed fumes from heated cryolite. The condition was shown to be recognizably different from fruit symptoms resulting from 2,4-D or 2,4,5-T. In the polluted area, trees sprayed with lime or calcium chloride produced normal fruit. The period of retarded growth (pit hardening) was the time when lime sprays were most effective in preventing the damage. It is concluded that there is a causal relationship between the soft suture disorder and the fluoride pollution of the air. (Author summary)

03873

I. A. Leone, E. G. Brennan, R. H. Daines W. R. Robbins

SOME EFFECTS OF FLUORINE ON PEACH, TOMATO,
AND BUCKWHEAT WHEN ABSORBED THROUGH THE
ROOTS. Soil Sci., 66, 259-266, Dec. 1948.

The specific objectives of this experiment were to ascertain:

(a) amounts of fluorine required in the substrate to produce visible injury in the plant when sodium fluoride is absorbed through the roots; (b) the length of time required for the plant to show external symptoms of fluorine injury; (c) characteristic pattern of injury produced on plant foliage as a result of fluorine absorption through the roots; and (d) the relation between the amount of fluorine in the substrate and that accumulated in the plant tissue. Concentrations of 200 and 400 p.p.m. of fluorine in the nutrient solution caused the death of peach, tomato, and buckwheat plants in a short time. At a concentration of 100 p.p.m. fluorine, peach and buckwheat were severely injured in 3 days, whereas tomato required a considerably longer time, 18 days, for symptoms to appear. At concentrations of 10, 25, and 50 p.p.m. fluorine, peach and buckwheat were moderately injured within 13 days, whereas tomato required as long as 48 days for symptoms to appear. At a concentration of 10 p.p.m. fluorine, peach leaves showed injury, but neither tomato nor buckwheat showed any foliage damage. Where actively growing plants were involved, injury

<xref image="2000WVJD.TIF|V3|2006:09:28:01:35:34.00|116450|0"> image: </xref>

first appeared on the tips of the younger leaves, then extended along the leaf margin and finally inward toward the midrib. In each case the injury appeared as a scorching of the affected areas; however, when injury symptoms appeared on peaches approaching the dormant stage, the youngest fully expanded leaves first showed injury in the form of marginal scorching. At the highest fluorine concentrations, necrosis was preceded by a general wilting of the plant, probably as a result of root injury. The injury in this case progressed from the petioles and veins outward through the leaf blades. Here again there was a bleaching of the original brown color to a buff color with time. In all three plant species, fluorine accumulation in the tissues varied with the amount of fluorine in the nutrient substrate, increasing as the fluorine concentration was increased. In every case the amount of fluorine in the leaves greatly exceeded that of the stems.

THE EFFECTS OF HYDROGEN FLUORIDE GAS ON SEVEN

CITRUS VARIETIES. Proc. Am. Soc. Hort. Sci. 75, 236-43, 1960.

The fumigation experiment, discussed in this paper was designed to determine the effects of exposure to HF gas on growth, fluoride accumulation, and development of toxicity symptoms by 7 varieties of citrus. Trees were divided into two duplicate groups, each containing four trees of a given variety. One group was placed in a greenhouse fumigation chamber receiving air containing 10-12 ppb F as HF. The other group was placed in the duplicate control chamber which received clean, filtered air. The method of analysis for determining fluorine content of plant material was a modification of the Willard-Winter distillation procedure. Accurately rating the varieties as to their relative sensitivity is somewhat difficult, however, because of the wide variations in type as well as degree of response. If degree of chlorosis were the sole criterion, the two lemon varieties would be considered the most sensitive. On the other hand, the Valencia and navel orange would be rated more sensitive than the lemons if gross growth response (linear growth, trunk diameters, and weight of tops) were the criteria used. An unexpected but significant result of these studies was the apparent evidence of so-called 'hidden injury', that is, decreased vigor and growth (growth defined here as gain in dry weight) disproportionate to the amount of leaf areas rendered photosynthetically inactive due to necrosis. This type of injury is almost impossible to diagnose in the field because it can only be recognized when one has a healthy, vigorous tree which has received fluoride-free air for comparison. Actually, the injury was not entirely 'hidden' because it was accompanied by a considerable degree of chlorosis. Unfortunately, as was pointed out previously, the chlorosis patterns varied considerably with variety, and to some extent from leaf to leaf within any given variety. This, of course, makes visual diagnosis extremely difficult and requires chemical analysis to establish the presence of toxic concentrations of fluoride in the foliage.

H. E. Stokinger

EFFECT OF AIR POLLUTANTS ON WILDLIFE. Conn. Mcd.

27, (8) 487-92, Aug. 1963.

A review of information derived from both field and laboratory investigations of the effects of air pollutants on terrestrial animals indicates that (1) of all known air pollutants, economic poisons pose the greatest current threat to the health of wildlife. (2) Inorganic substances, (certain heavy metals and fluorides), account for limited and local injury to wildlife based on known effects on domestic animals. (3) The hazard to wildlife is chiefly from ingestion of the 'fallout' of the air pollutant. (4) Relative species susceptibility to specific air pol-

lutants is far from clear, but it would appear that the mammals are considerably more susceptible than birds. (5) Laboratory studies have revealed three rather general phenomena associated with exposure to air pollutants: a. Synergism, the exalted or potentiated toxic effect of combination of certain air pollutants: its converse, antagonism, in which the summated toxicity is either far less than predicted or nonexistent, b. Tolerance and cross tolerance to pulmonary edema-producing agents, c. The immunochemical response.

SORPTION OF FLUORINE BY CITRUS FOLIAGE FROM
EQUIVALENT SOLUTIONS OF HF, NaF, NH₄F AND
H₂SiF₆. Proc. Am. Soc. Hort. Sci. 76, 215-9, 1960.

Individual young navel orange trees were sprayed five times at two week intervals with .0004, .001, .01 and .01 N solutions of HF, NaF, NH₄F and H₂SiF₆. CaF₂ was also applied at the lowest concentration. Except at the lowest concentration, more fluoride was sorbed by citrus leaves sprayed with NaF and HF than by those sprayed with NH₄F and H₂SiF₆. The average increments in foliar fluoride content per spraying were approximately 1.5 ppm with .0004 N solutions, 5 ppm at the .001 N level, 12 ppm at the .01 N level and 90 ppm with 0.1 N spray solutions. Differences in ion size rather than degree of ionization are suggested as being responsible for the observed differences in the amounts of fluoride sorbed by citrus leaves from equivalent solutions of the various fluoride compounds. THE EFFECT OF FLUORIDES ON MILO MAIZE
(SORGHUM SP.). Contrib. Boyce Thompson Inst. 22, (4) 175-
206, Dec. 1963.

Since 1951 more than 150 species and varieties of plants have been exposed to controlled dosages of fluorides in the air or soil. Gladiolus sp. and Milo maize (Sorghum sp.) were among the species most sensitive to volatile, such as hydrofluoric acid (HF) and fluosilicic acid (H₂SiF₆). Results for gladiolus have been summarized for the period 1951 to 1960. Snow Princess and Elizabeth the Queen gladiolus were used as indicator species in many of the experiments with Milo maize in order to compare the known differential response of the two gladiolus varieties to fluorides with the response of Milo maize. This report summarizes the results of investigations carried out during the years 1953 to 1961 relating to the effects of fluorides on the growth and development of several varieties of Sorghum spp.

RESULTS OF TEN YEAR'S WORK (1951-1960) ON THE EFFECT
OF FLUORIDES ON GLADIOLUS. Contrib. Boyce
Thompson Inst. 21, (5) 303-44, Mar. 1962.

Results of the effects of fluorine (F) compounds on the growth and development of Gladiolus sp. are summarized for a period covering the decade 1951 to 1960. Tip burn and accumulation of F in control and hydrofluoric acid (HF) fumigated plants varied considerably with the variety of gladiolus, cultural site,
<xref image="2000WVJE.TIF|V3|2006:09:28:01:35:36.00|119255|0"> image: </xref>

age of plant, and age of leaf. Control plants in the area where experimental fumigations with fluorides were carried out had more tip burn and accumulated more F than plants 0.5 to 1.3 miles distant. Gladiolus in the 5- to 7- leaf stage exhibited more tip burn and accumulated more F than plants in the 3-leaf stage. Middle-aged leaves generally exhibited the most tip burn, but the older leaves accumulated more F than the younger leaves. In general, the more resistant varieties accumulated the most F and susceptible varieties the least amount, irrespective of the flower color of the variety. Tip burn and accumulation of F were greater at higher concentrations of HF. Increase in tip burn was correlated with dosage up to 2 to 4 times the threshold level. The dosage-response curve for moderately resistant Elizabeth the Queen was significantly flatter than for the susceptible Snow Princess variety. There was a highly significant regression of tip burn on F content of leaves in both varieties. There was no relation between susceptibility and number and location of stomate. At levels of HF up to about 2 parts per billion (ppb.) of air, which caused 5 to 8 cm. of tip burn, there was no significant effect on dry weight of tops or corm yield in the varieties Snow Princess and Elizabeth the Queen, but the production of flower spikes was significantly less in this series of experiments. There was no close correlation between length of tip burn and size of corm produced by the same plant. Within one week after exposure to HF, Snow Princess had lost up to 40 to 50 per cent of the F from aboveground parts of the plant, while control plants gained in F. Elizabeth the Queen lost little (av. 10 per cent) or no F. (Authors' summary)

DISTRIBUTION STUDIES OF RADIOACTIVE FLUORINE-18
AND STABLE FLUORINE-19 IN TOMATO PLANTS. Contrib.
Boyce Thompson Inst. 20, (5) 331-48, Mar. 1960.
A study of distribution and site of accumulation of fluorine in tomato plants was carried out using NaF-18, HF-18, NaF-19, and HF-19 applied as solutions through roots and cut vascular systems, and in gaseous form to the aerial parts. In order of decreasing concentration, the gross distribution of fluorine applied as NaF-19 through the soil was: roots, lower leaves, upper leaves, and stems. Regardless of the path of entrance of the fluorine into the plant, it was possible to wash up to 68 percent of the fluorine from the leaves with distilled water and up to 83 percent with water containing a detergent. Distribution based on autoradiograms showed that most accumulation of fluorine-18 applied as JF-18 to tomato plants was at the tips and margins of leaflets and in the glands along the stem. Little fluorine-18 was found in the stems and petioles. In short-term or long-term experiments up to 80 per cent of the fluorine-18 or fluorine-19 of the leaves applied as HF was found in the stripped epidermis of *Sedum spectabile* Boreau. Distribution of fluorine-19 applied as HF-19 to tomato leaves after long-term accumulation was, in order of decreasing concentration: cell walls, chloroplasts, soluble proteins, mitochondria, and microsomes. With short-term accumulation of fluorine-18 applied as HF-18 the order was: soluble proteins, chloroplasts, cell walls, and mitochondria. The fluorine in the chloroplasts was associated mainly with the proteinaceous substances since little or no fluorine-19 was found in the pigments and lipids. (Author summary)

A METHOD OF FUMIGATING PLANTS WITH
HYDROFLUORIC OR HYDROFLUOSILICIC ACID USING
ATOMIZATION AND THERMAL ACTION. Contrib. Boyce
Thompson Inst. 18, (1) 17-20, Dec. 1954.
Equipment and procedures are described for producing nearly constant concentrations of hydrofluosilicic acid (H₂SJF6) and

hydrofluoric acid (HF) in fumigation cabinets ranging from less than one to several hundred parts per billion. The method makes use of diluted solutions (0.01 to 1 percent) of commercial preparations of these acids which are atomized by an air pressure of 10 to 12 lb. per sq. in. through a modified No. 15 De Vilbiss atomizer and are then passed through a low-temperature, electrically-heated tube where they are changed to the gaseous state before delivery to the air stream entering the fumigation cabinets. All equipment is of simple construction, relatively inexpensive, and has no moving parts. (Author summary)

EFFECTS OF ATMOSPHERIC FLUORIDE ON METABOLIC

CONSTITUENTS OF TOMATO AND BEAN LEAVES. Con-

trib. Boyce Thompson Inst. 21, (4) 215-31, Dec. 1961.

Time-course experiments were run in order to determine the effect of continuous 24-hour fumigation with hydrogen fluoride (12.4 p.p.b. v/v and 1.3 p.p.b. v/v) on the dry weight, fluoride content, and levels of free amino acids and amides, non-volatile organic acids, free sugars, ribo(RNA) and deoxyribonucleic (DNA) acids, and chlorophylls a and b in leaf tissues of Bonny Best tomato and Tendergreen bean plants. The high level of hydrogen fluoride used (12.4 p.p.b. v/v) was selected to induce maximum biochemical effects with a minimum amount of injury. Thus, no attempt was made to duplicate natural field conditions. During fumigation plants were harvested at 3-day intervals for 9 days. This was followed by a recovery period during which plants were again harvested at the same intervals. In general, it was found that during fumigation at 12.4 p.p.b. v/v there was a reduced growth of tomato leaves, although this trend was reversed by the end of the recovery period. In beans there was a small but consistent reduction in yield of leaves.

SUSCEPTIBILITY OF PLANTS TO HYDROFLUORIC ACID

AND SULFUR DIOXIDE GASES. Contrib. Boyce Thompson

Inst. 18, (6) 263-89, Mar. 1956.

The effects of hydrofluoric acid (HF) and sulfur dioxide (SO₂) gases were determined and compared on 49 species of plants.

At given concentrations and periods of exposure some species of plants were susceptible to HF but resistant to SO₂, and some species susceptible to SO₂ were resistant to HF. A few species were equally susceptible to both gases, and some were equally resistant. In tests with HF alone, concentrations of the gas ranged from less than 1 to 100 parts per billion (10 to the 9th power), by volume, and periods of exposure were usually six to eight days. The concentration for SO₂ gas ranged from 0.2 to 1.1 part per million (10 to the 6th power), and the time periods for exposure to the gas were two to eight hours. Special equipment and methods were developed for fumigating plants in the field and in greenhouses. Stomatal counts for upper and lower epidermis of leaves showed no relation between the number of stomata per unit leaf area and relative susceptibility to either gas. All species of plants grown in pots or under field conditions stored fluorine. A few like dogwood (*Cornus florida* L.), *Deutzia* sp., *Gifblaar* (*Dichapetalum cymosum* Hook.), and *Camellia* sp. accumulated abnormally

<xref image="2000WVJF.TIF|V3|2006:09:28:01:35:40.00|125514|0"> image: </xref>

large amounts of fluorine in the leaves. There was considerable difference in rate of absorption by different species when the plants were fumigated, and different parts of the plant absorbed different amounts of fluoride. These results should serve as an aid in diagnosing symptoms of vegetation around industrial areas. (Author summary)

CAN FLUORINE DAMAGE TO PLANTS BE ESTABLISHED BY ANALYZING THEIR ASH. Staub (English Translation) 26, (12) 29-31, Dec. 1966. Ger (Tr.)

The following precepts were obtained regarding the relationship of fluorine plant damage and the correlation to the analysis of their ash: No conclusions can be drawn from the established fluorine content of the plant ash in regard to the state of the plants, since the fluorine content of healthy and atrophied leaves is frequently identical at the same time. The content of total fluoride is not a specific, characteristic magnitude of the vegetation, but varies with location. It is, therefore, not possible to establish reference magnitudes for use as normal values. Data on fluorine content are dependent upon the dry mass of the material being analyzed. The investigation revealed the following: Damage to plants due to the effect of fluorine compounds cannot be proved by analysis of plant ash. The fluorine content determined does not give any information as to the condition and development of the plant. The fluorine content is independent of the age of the leaves.

DIAGNOSIS OF FLUOROSIS IN CATTLE. Publication of the 4th International Meeting, World Society for Buiatrik, Zurich, Switzerland, Aug. 4-9, 1966, 17p. 18 refs.

Structural and physiological processes of animals that ingest fluorine are governed by a number of factors: (1) level or amount of fluoride ingested, (2) duration of ingestion-time, (3) type and solubility of fluoride ingested, (4) age of animal at time of ingestion, (5) level of nutrition, (6) stress factors, and (8) individual biological response. Prevention and control of fluorosis in livestock can be achieved, but only when the complexity of the disease is realized and the pathogenesis, symptomatology, and lesions are properly correlated, interpreted, and evaluated. By computations, the data show that by taking into account the amount of fluorine in the rib and the tooth classification, 95 per cent ($r^2=0.950$) of the variability can be accounted for. In other words, the tooth classification and the amount of fluorine in the ribs can be used to predict the extent of fluorosis with a high degree of accuracy. Other examples of multiple correlation formulas are shown. A comprehensive guide was developed to facilitate diagnosing and evaluating fluorosis. The data in the Table are based on short-and long-term controlled experiments, clinical examinations of more than 70,000 animals in endemic fluorosis areas and 519 detailed necropsy findings of animals of different ages evidencing various degrees of fluorosis. EFFECT OF FLUORIDES ON HEMATOPOIETIC SYSTEM, LIVER AND THYROID GLAND IN CATTLE. J. Am. Med. Assoc., 192(1):26-32, April 5, 1965.

Thirty-two holstein-friesian heifers, divided into groups and fed 10, 25, 50 and 100 ppm sodium fluoride for approximately 7 1/2 years, were studied to determine the effect of fluoride on the hematopoietic system, liver, and thyroid gland. The composite and individual results of numerous detailed blood studies, identical to those used in evaluating the hematopoietic system in man, established that fluoride, fed daily in concentrations up to 100 ppm for more than seven years, (1) does not

show gross, histological, or functional effects on the thyroid gland or liver; (2) does not produce significant changes in the serum calcium, phosphorus, or numerous other blood chemistries studied; (3) had a minimal blood effect in the form of a slightly higher total eosinophil count and a lower level of serum folic acid activity in the 100 ppm group; (4) does not produce anemia or detectable abnormalities of the bone marrow or otherwise affect the hematopoietic system. (Author abstract)

SIMILARITY BETWEEN LEAF MARKINGS CAUSED BY
AIR POLLUTANTS AND OTHER AGENTS: I-MOISTURE
STRESS AND FLUORIDE EXPRESSION. Proc. Utah Acad.
Sci., 41, (Part 1) 49-52, 1964.

The similarities and differences between the toxic effects of fluorides and moisture stress are described. Since fluoride generally causes a characteristic type of necrosis on certain plant species, there is a tendency to ascribe injury of this type to fluoride even though the species in question may be extremely resistant to fluoride. It is therefore necessary to be familiar with the response of each species to fluoride before making a diagnosis. Several guides are listed for distinguishing the cause of leaf necrosis.

EFFECT OF PROLONGED EXPOSURE TO FLUORIDE ON
THE ASH, FLUORIDE, CITRATE, AND CRYSTALLINITY
OF BOVINE BONE. Am. J. Vet. Res. 25, (109) 1595-7, Nov.
1964.

Heifers 3 to 4 months old were allotted to 4 groups at the beginning of the experiment and were given rations containing 12, 27, 49, or 93 p.p.m. of fluoride for over 7 years. The metatarsal bones were examined for ash, fluoride, and citrate, and for crystallinity of the apatite structure. At the termination of the experiment, the fluoride concentration of the ash of the metatarsal bones had increased from 0.10% in group 1 to 1.04% in group 4 without any significant change in the percentage of the bone ash. The citrate content, expressed on an ash basis, had decreased from 1.2% to about 0.9% with a concomitant increase in crystallinity. The data obtained on bovine bone corroborated previous findings in the rat and man on the interrelation of fluoride, citrate, and the crystallinity of bone apatite.

ALKALINE BONE PHOSPHATASE ACTIVITY AS RELATED
TO FLUORIDE INGESTION BY DAIRY CATTLE. Am. J. Vet.
Res. 23, (92) 24-31, Jan. 1962.

Alkaline phosphatase prepared from bone and studied in vitro in relation to the effect of fluoride was relatively insensitive to fluoride. Concentrations of fluoride in excess of .01 M were required for inhibition. Experiments with dairy heifers and cows indicated a close correlation between fluoride ingested, fluoride content of the bone, osseous abnormalities, and alkaline bone phosphatase activity. Fluorosis occurred in heifers-

<xref image="2000WVJG.TIF|V3|2006:09:28:01:35:42.00|114856|0"> image: </xref>

fed rations containing 66 and 68 p.p.m. of fluoride in contaminated hay and NaF, respectively, for a period of 20 months. Additions of about 69 p.p.m. of CaF₂ to the rations for 20 months caused no detrimental effect to the dairy animals. In an experiment lasting seven years and 108 days, dairy cattle were fed rations containing 12, 27, 49, and 93 p.p.m. of sodium fluoride. When the rations contained 49 or 93 p.p.m. of NaF, osseous abnormalities, excessively high accumulation of fluoride in the bone, and significant increases in alkaline bone phosphatase activity occurred. Results indicated that alkaline bone phosphatase activity was related to abnormal bone formation. (Author summary)

EFFECTS OF FLUORINE ON DAIRY CATTLE, in.
DIGESTION AND METABOLISM TRAILS. J. Animal bSsci.
23, (2) 537-46, May 1964.

Thirty-two female Holstein cattle were divided into two replications by weight and assigned to 16 treatments in a factorially designed experiment. The four levels of fluorine used were 10, 28, 55, and 109 ppm on a moisture-free hay basis; computed according to dry matter intakes, the fluorine levels were 12, 27, 49, and 93 ppm. bStwo quantities, 1.0 or 3.0%, of a Ca-P mineral mixture were incorporated in a pelleted grain concentrate. Two or four pounds of the concentrate were fed during the first two metabolism trials. During the last three trials the concentrate levels were raised to 0.75 or 1.0 lb. daily per pound of milk fat produced weekly. Five digestion and metabolism trials were conducted, two before and three after the animals began to lactate. The higher quantities of concentrate tended to result in higher energy intakes and higher amounts of absorbed energy as measured by digestible and metabolizable energy. The high concentrate level did not result in significantly less fluorine retention. Likewise, the higher level of Ca-P mineral did not reduce body retention of fluorine. The results of this experiment indicate that during a 7-year period of the life of a dairy animal, the tolerance level of fluorine as sodium fluoride is between 28 and 55 ppm on a day hay basis or between 27 and 49 ppm on a total dry feed basis.

J. L. Shupe, M. L. Miner, L. E. Harris, and D. A. Greenwood
RELATIVE EFFECTS OF FEEDING HAY ATMOSPHERICALLY CONTAMINATED BY FLUORIDE RESIDUE, NORMAL HAY PLUS CALCIUM FLUORIDE, AND NORMAL HAY PLUS SODIUM FLUORIDE TO DAIRY HEIFERS. Am.
J. Vet. Res. 23, (95) 777-87, July 1962.

Sixteen dairy heifers were allotted to four groups on the basis of weight. The 4 heifers within each group were allotted at random to the following treatments: (1) low F hay (10 p.p.m. F), (2) high F hay (62 p.p.m. F), (3) low F hay plus CaF₂ (69 p.p.m. F), and (4) low F hay plus NaF (68 p.p.m. F). In addition to the hay, each animal was fed 2 lb. of grain daily. The heifers were fed for 588 days. From the data the following conclusions can be drawn: 1) The contaminated high F hay, containing fluoride emitted from a steel plant in Utah County, was as toxic as sodium fluoride; 2) Calcium fluoride proved less toxic than either the fluoride residue on the contaminated hay or the sodium fluoride; 3) Dental fluorosis can be related to the amount and type of fluoride compound ingested and can be correlated with total body reactive fluorotic processes; 4) Unequivocal bone changes were present in the animals that consumed sodium fluoride rations and hay atmospherically contaminated with fluoride; 5) From a given animal, different bones and different anatomical areas of a specific bone varied in the amounts of fluorine retained; 6) Fluoride treatments had no adverse effect upon the soft tissues of the body; and 7)

Fluorine apparently did not influence feed utilization as measured by digestibility and balance trials. (Author summary)

THE EFFECT OF FLUORINE ON DAIRY CATTLE. V. FLUORINE IN THE URINE AS AN ESTIMATOR OF FLUORINE INTAKE. Am. J. Vet. Res. 24, (9) 300-6, Mar. 1963.

Thirty-two Holstein-Friesian cows were fed four levels of fluorine, two levels of calcium-phosphorus mineral, and two levels of a concentrate mix from about 3 months to 7.5 years of age. Two digestion and balance trials were conducted before calving and three after the animals started to lactate. In addition, after the cows were on trail for 7 years and 52 days, urine was collected approximately every 1.5 hours and composited for each 3-hour interval over a 24-hour period. During these and previous studies, it was found that urine samples should be taken in the morning for best results and that, when possible, samples of urine should be obtained from several cows and the results pooled to give a reliable index of the fluorine consumed. The determination of the fluorine:creatinine ratio was found to have merit as a means of adjusting for differences in urine volumes. A correlation was found to exist among concentration of fluorine in the urine, amount of fluorine in dry matter consumed, and length of time that fluorine is ingested. By determining parts per million (p.p.m.) of fluorine in the urine and combining this with a knowledge of the length of time the animals had ingested fluorine, the p.p.m. of fluorine in the ingested dry matter could be estimated. Taken alone, however, this measurement was an inadequate criterion for a definite diagnosis of fluorosis in cattle. (Author summary)

E. E. Stoddard, L. E. Harris, G. Q. Bateman, J. L. Shupe, and D. A. Greenwood

EFFECTS OF FLUORINE ON DAIRY CATTLE. I. GROWTH AND FEED CONSUMPTION. J. Dairy Sci. 46, (10) 1094-102, Oct. 1963.

Thirty-two Holstein females on experiment from about three to four months until about 7.5 yr of age were fed diets involving four levels of fluorine, two levels of concentrate mix, and two levels of a calcium-phosphorus mineral. Fluorine intake averaged 10, 28, 55, and 109 ppm on a hay basis or 12, 27, 49, and 93 ppm on a total dry matter basis. Average calculated levels of fluorine in milligram per kilogram of body weight were 0.30, 0.64, 1.17, and 2.08, respectively, for the four groups, with some variation associated with periods of growth and lactation. The two levels of concentrate were 2 and 4 lb daily during nonlactating periods and 0.75 and 1.0 lb daily for each 1.0 lb of milk fat produced weekly during lactation. Mineral treatments included 1 and 3% of a calcium-phosphorus mineral in the concentrate mix. Fluorine was maintained at designated levels by adding sodium fluoride to the concentrate mix. Animals on the highest fluorine level ingested less hay and total dry matter than those on the other fluorine levels, but did not exhibit a significantly lower body weight gain during the 23, 112-day periods of the trial. No significant effects were noted on increase in height at withers. The kilograms of feed per kilogram of body weight gain was not affected by

<xref image="2000WVJH.TIF|V3|2006:09:28:01:35:46.00|125415|0"> image: </xref>

treatments in the five prelactation periods. Hay refusals were not affected by treatment. It was observed that no single criterion was as effective in evaluating effects of fluoride ingestion as was an evaluation of all effects together. (Author summary)

P. H. Phillips

THE DEVELOPMENT OF CHRONIC FLUORINE TOXICOSIS AND ITS EFFECT ON CATTLE. Proc. Natl. Air Pollution Symp., 2nd, Pasadena, Calif., 1952. pp. 117-21.

A progress report is presented of the experiment on fluorosis at the University of Wisconsin, in which the effect of the ingestion of a soluble fluoride was studied. The abrupt addition of 50 p.p.m. of sodium fluoride to the ration of young dairy cows failed to affect their appetite, failed to produce diarrhea, and failed to reduce milk production significantly. Urinary fluoride measurement is a qualitative measurement which indicated elevated fluorine ingestion, but a single sample analysis is too variable to be quantitative, although it may be considered roughly quantitative. Typical criteria of fluorosis have not been produced in these young dairy cows by the inclusion of as much as 50 p.p.m. of sodium fluoride-borne fluorine in the diet during the first twelve months' period. Exposure to 50 p.p.m. of added dietary fluorine (sodium fluoride) failed to reduce milk production in the first year of experiment.

FLUOROSIS IN CATTLE. Utah State Univ., Logan, Agricultural Experiment Station. (Special Rept. No. 17.) 1964. 36 pp. Investigations of fluorosis in dairy females were conducted by Utah State University personnel in an effort to achieve the following overall objectives: 1. To determine the influence of different levels of fluoride intake on feed consumption and utilization, growth, milk production, and reproduction when the animals started ingesting the fluorides at 3 to 4 months of age. 2. To determine relative effects of ingestion of different types of fluorides, including sodium fluoride, calcium fluoride, and fluoride as a residue on hay; and of exposure to a fluoride-contaminated atmosphere. 3. To determine the effects of fluoride ingestion on tissue structure and on metabolic processes such as dentition, bone formation, organ functions, and enzyme activities. 4. To determine whether elevated intake levels of aluminum, calcium, phosphorus, and grain would reduce effects of fluoride ingestion. 5. To determine fluoride ingestion tolerance levels. In addition, the overall objectives were broadened in potential applicability by annual surveys of selected animals in the endemic fluorosis area. Evaluations of clinical findings from these surveys were correlated with vegetative analyses when possible, and with detailed necropsy studies of selected field cases of both dairy and beef animals of different ages that evidenced varying degrees of fluorosis. This information then was correlated with the data from the controlled experiments.

THE EFFECTS OF ATMOSPHERIC FLUORIDE ON
GLADIOLUS GROWTH, FLOWERING AND CORM
PRODUCTION. Proc. Am. Soc. Hort. Sci. 88, 631-4, 1966.

The effects of hydrofluoric acid gas on growth, flowering and corm production of gladiolus, associated with variable degrees of visible damage to foliage, were studied under controlled greenhouse conditions. Plants with leaf injuries approximating 10, 20, and 30 percent of the total leaf area were compared with control plants grown in F-free air. Flower size and weight and number of florets per spike were reduced as the severity of F injury increased. Corm size and weight were reduced in direct proportion to the extent of leaf injury. Total top weight (leaves and flowers) was inversely related to leaf injury. The variety Snow Princess was more severely affected than Elizabeth the Queen. (Author abstract)

Barley, E. F., Nichols, C. W. and Middleton, J. T.
IDENTIFICATION OF AIR POLLUTION DAMAGE TO
AGRICULTURAL CROPS. (AIR POLLUTION RESEARCH
REVEALS CHEMICAL TOXICANTS INJURING VEGETA-
TION IN POPULOUS AREAS OF CALIFORNIA.) Calif. Dep.
Agri. Bull., 55(1):11 19, 1966.

The subject of this paper is the damage air pollution does to the plants that feed us, clothe us and please our aesthetic sense. This damage is considerable. Estimates of visible damage to agricultural crops amount annually to about \$8 million in California and approximately \$18 million along the Atlantic seaboard. Damage to vegetation has increased with industrialization and urban development. Several decades ago sulfur dioxide and fluorine were recognized as the principal plant toxicants. These two gases continue to be very important but within the last 20 years a new group of toxicants has been identified. These are products of atmospheric photochemical reactions between hydrocarbons and nitrogen oxides. The principal products of these reactions are ozone and the peroxyacyl nitrates (PANs). The distribution of plant damage in California shows that it occurs only in recognized geographical areas which, in each instance, are located within airsheds. Because damage to plants is often the first indication of air pollution, it is important that the surveillance of pollution damage to agriculture be continued. Such information will help communities, in their planning, to take cognizance of the relationship between the air resource and the community needs for commercial and industrial development, energy production, fuel usage and transportation, agriculture, and forest and recreation land. The air contaminants responsible for damage may be either particulate or gaseous in nature. The greatest amount of damage to animals and vegetation is usually caused by gaseous air contaminants which directly injure plants and indirectly injure animals by the toxic effects produced after the animal has consumed contaminated forage and food supplements.

BIOCHEMICAL STUDIES ON THE EFFECT OF FLUORIDE ON HIGHER PLANTS, I. METABOLISM OF CARBOHYDRATES, ORGANIC ACIDS AND AMINO ACIDS. Biochem. J. 88, 505-9, 1963.

The metabolic changes in carbohydrates, organic acids and amino acids that accompanied the development of necrosis resulting from atmospheric fluoride fumigation were studied. Soya bean plants were placed in fumigation chambers when 6-8 in. tall. Treatments consisted of fumigations with air which was contaminated with 0.00006 p.p.m. of HF (control), and with 0.03 p.p.m. of HF in air. The leaves were harvested after 3-5 days of fumigation, depending on when marginal burning first became evident. Fluoride-fumigated leaves contained more reducing sugars and less sucrose than the normal leaves. This result suggested inhibition of sucrose synthesis by fluoride. Necrotic leaves contained increased total concentrations of organic acids, which were mostly attributable to malic acid, malonic acid and citric acid. The greater increase in malic acid relative to that of citric acid was the reverse of results observed in chlorotic tissue. Necrotic leaves contained enhanced amounts of free amino acids. The greatest increase occurred in the concentration of asparagine and might be related to the increased respiratory rate of necrotic leaves. The accumulation of organic acids and amino acids in leaves during fluoride fumigation was evidenced by a lowered respiratory quotient.

BIOCHEMICAL STUDIES ON THE EFFECT OF FLUORIDE ON HIGHER PLANTS. 3. THE EFFECT OF FLUORIDE ON DARK CARBON DIOXIDE FIXATION. Biochem. J. 88, 517-22, 1963.

This investigation was initiated to determine whether the accumulation of organic acids and amino acids in fluoride-necrotic leaves was due to the increased rate of dark CO₂ fixation, and how fluoride might affect the carboxylating enzyme systems. Soya beans were grown and fumigated with HF. At the end of fumigation, one control plant and one fumigated plant that showed slight necrotic symptoms were put into a 6 l. desiccator. After the introduction of ¹⁴CO₂, the desiccator was kept air-tight and in complete darkness for 4 hr. At the end of the dark ¹⁴CO₂ fixation, leaves from each plant were cut off and analyzed for radioactive organic acids and amino acids, ethanol-insoluble nitrogen and soluble protein, and, phosphoenolpyruvate-carboxylase activity. Necrotic leaves had a higher rate of dark CO₂ fixation than control leaves both in vivo and in vitro. Results suggested that the accumulation of organic acids and amino acids in necrotic leaves resulted from an increased rate of dark CO₂ fixation. The possible role of fluoride in stimulating the carboxylation and its implication to necrosis are discussed.

FLUORIDES AND OTHER CHEMICAL AIR POLLUTANTS AFFECTING ANIMALS. In: Agriculture and the Quality of Our Environment. Brady, N. C. (ed.), American Association for the Advancement of Science, Washington, D. C. AAAS-Pub-85, p. 91-95, 1967. 11 refs. (Presented at the 133rd Meeting, American Association for the Advancement of Science, Washington, D. C., 1966.)

A review of air pollution problems involving animals is presented. One pattern of procedures useful in investigating and controlling the effects of chemical air pollution upon animals was developed during United States and British studies of effects of fluoride effluents upon cattle. Generally the effluents collected upon the surfaces of vegetation and exerted

their effects only after ingestion by animals. The investigational procedures included methods of detecting pollutant effects upon animals, diagnosis and evaluation of effects, consideration of pollutant sources, and pollutant control as related to animal well-being. All procedures depended on research with laboratory and farm animals.

AIR POLLUTANTS. Lasca Leaves. 15 (1), 7-18 (Jan. 1965).

After years of careful study, some of the components of smog have been sorted out. The more important ones, their effects on vegetation, and a list of sensitive and resistant plants are discussed. The components are peroxyacetyl nitrate, ozone, ethylene, hydrogen fluoride, sulfur dioxide and aerosols.

EASTERN WHITE PINE-EVERGREEN MONITOR OF AIR

POLLUTION. Preprint. (Presented at the Second National Conference on Air Pollution, Washington, D.C., Dec. 12-14, 1966.)

Six hundred healthy, 2-year-old seedlings were potted and taken to Morgan County, Tenn., where they were installed near a power plant known to be the sulfur dioxide source. After a year of exposure, 106 of the trees had died, either from handling, air pollution damage, or both. Those surviving included 183 that were free of damage and 106 that were only slightly injured. These were presumed resistant to sulfur dioxide and were taken to the Alabama test area for exposure to fluorides. The remaining 202 trees showed serious damage, so they were returned to the recovery area in North Carolina. After a year of exposure in Alabama, 157 injured trees were again removed and sent to North Carolina for recovery. The remaining 26 seedlings still appeared healthy, and they were presumed to be resistant to both sulfur dioxide and fluorides. The healthy trees were moved to Beltsville, Md., where they are still under exposure to oxidants produced by heavy motor traffic. Although, the exposure period is not over, and final figures may be different, 13 trees have been injured and 13 still appear healthy. It is hoped that seedlings from seed of superior trees will be inherently resistant to damage from sulfur dioxide, fluorides, oxidants, and other airborne toxicants. On the other hand, susceptible trees that recover in the clean air in North Carolina may make excellent assay plants because of their demonstrated sensitivity to oxidants at Beltsville. The results of these tests indicate there is enough genetic variation in a large eastern white pine population to provide biological indicators for specific toxicants.

SOME EFFECTS OF HYDROGEN FLUORIDE ON THE INTERNAL STRUCTURE OF PBVUS PONDEROSA NEEDLES.

Proc. Natl. Air Pollution Symp., 3rd, Pasadena, Calif. 164-76 (1955)

Pinus ponderosa trees were submitted to fumigations of 0.5, 1.5, 5.0, and 10.0 p.p.b. hydrogen fluoride. Samples were taken and comparisons made of microscopic cross-sections of injured and uninjured (control) needles. Observations of fu-
<xref image="2000WVJJ.TIF|V3|2006:09:28:01:35:52.00|116790|0"> image: </xref>

migated needles yielded the following results. Over-all needle damage was in the form of browning of the needle apexes, which gradually progressed basipetally. Inward collapse of the interior needle surfaces was observed in all needles showing macroscopic injury. Microscopic changes in the green needle tissue, presumably due to fluoride, were observed only in the tissue immediately adjacent to macroscopically browned areas and were of an intermediate type. The epidermis, hypodermis, and xylem tissues exhibited the least injury of the tissues studied. The phloem and xylem parenchyma enlarged greatly. Extreme needle damage showed the phloem to be collapsed against the xylem tissue. (Author summary modified)

A FIELD INVESTIGATION OF FLUOROSIS IN CATTLE. J.

Air Pollution Control Assoc. 14(5):139-148, May 1964.

(Presented at the 56th Annual Meeting, Air Pollution Control Association, Detroit, Mich., June 9-13, 1963.)

A comparison has been made of the results of a detailed field investigation of the effects of fluoride on cattle with research results from controlled feeding experiments. Specifically, the comparison was made on the basis of the fluoride content in the feed, the fluoride content of the ribs, the fluoride content of the urine, and the fluoride effect on incisor practical field study, it has been shown that fluorosis in cattle might be expected within a two-mile distance of these industrial plants. At this distance, the following conditions were determined: (1) The forage contained more than 40 to 50 ppm F- approximately two mg F/kg of body weight per day; (2) The fluoride content of the rib exceeded 4000 ppm; (3) The fluoride content of the urine exceeded 15 ppm; and (4) Almost 50% of the incisor teeth examined were marked with excessive mottling. Correlation of the results of a field experiment with the results of controlled feeding experiments was excellent. With these comparison data, we have shown that it is possible to delineate herds or areas in which damaging or non-damaging effects of fluoride might be expected. (Authors' summary, modified)

SOME EFFECTS OF HYDROGEN FLUORIDE GAS ON

BEARING NAVEL ORANGE TREES. Proc. Am Soc. Hort. Sci.

76, 208-14, 1960.

The experiment reported in this paper was designed to study the effects of several years of continuous exposure to 1-5 ppb HF on growth, fruiting, toxicity symptoms, and fluoride accumulation by young orange trees. Eight 1-year old field grown Washington navel orange trees were used in the study. In March, 1957, after approximately 5 months of continuous exposure to 3 to 5 ppb HF, the trees began to show effects of the fluoride treatment. In late May and early June, a considerable amount of chlorosis and some necrosis, principally at the tips of nearly mature leaves, appeared on the trees exposed to the fluoride gas. There was some chlorotic foliage on control trees, but the extent and severity of chlorosis on fumigated trees were markedly greater. Although the chlorosis patterns varied somewhat, they resembled manganese deficiency symptoms on citrus. Some of the symptoms resembled the type of injury commonly associated with excess boron. After 13 months of continuous treatment, comparison with control trees indicated significant reductions in trunk diameter, height of tree, crown volume and average leaf size. The data indicate that the navel orange is sensitive to low concentrations (2 to 3 ppb) of HF in the air. The fluoride-induced chlorosis observed in this experiment would be almost impossible to diagnose under field conditions without laboratory analysis of leaf tissue. The most pronounced effect of HF on growth was a 25 to 35 per cent reduction in average leaf size.

PLANT RESPONSE TO POLLUTED AIR. Calif. Agr. 10 (8), 9-10 (Aug. 1956).

Field observations and controlled fumigation experiments have shown that plants differ in their response to atmospheric contamination by ethylene, herbicides, fluorides, sulfur dioxide, and smog, or oxidized hydrocarbons. Controlled experiments have also shown that plant response to air pollution varies with species and variety of plant, age of plant tissue, soil fertility levels, soil moisture, air temperatures during the pre-fumigation growth period, and presence of certain agricultural chemicals on leaves. Plants also vary in their susceptibility to sulfur dioxide, with alfalfa, barley, and cotton damaged at comparatively low levels, and citrus, corn, celery, and melons damaged at much higher levels. Field observations show that young leaves are seldom marked during periods of aggravated air pollution. The young, unexpanded leaves are typically uninjured; the mature, expanded leaves are severely injured; and the old, somewhat chlorotic leaves are rarely damaged. In grasses, where the youngest tissue is at the base of the leaf, injury first occurs at the tip, grading off in intensity of injury toward the base of the leaf. Old chlorotic leaves on grasses are seldom injured. Several groups of chemical compounds are capable of preventing injury to plants caused by oxidized hydrocarbon fumigations when the chemicals are applied to the lower surface of leaves. These chemicals belong to the dithiocarbamate, benzothiazole, and thiuram sulfide groups, and have been used extensively as agricultural fungicides for the control of many fungus diseases. Two of the best chemicals for this purpose are zineb?zinc ethylenebisdithiocarbamate? and thiram?tetramethyl thiuramdisulfide. The degree of protection is directly related to the amount of active ingredient contained in the spray or dust preparations. Protection is achieved only when the underside of leaves are adequately covered. Both groups of chemicals when properly applied to laboratory test plants protect leaves from damage from both ozone and ozonated hexene. Pinto bean leaves dusted with zineb in the laboratory and exposed to naturally polluted air near Los Angeles were protected from serious injury.

Ordin, L. and B. P. Skoe

INHIBITION OF METABOLISM IN AVENA COLEOPTILE TISSUE BY FLUORIDE. Plant Physiol., 38(4):41fr421, July 1963. (Presented at the American Society of Plant Physiologists Annual Meeting, Corvallis, Oreg., Aug. 30, 1962.)

Following treatment of Avena coleoptile sections with 0.01 N NaF for 6 hrs, an 80% inhibition of growth in the presence of 0.05 M glucose and 2.9 times 10 to the minus fifth molar indoleacetic acid ensued, followed by partial recovery in fluoride-free solutions. Studies of glucose utilization in the absence of indoleacetic acid showed the absorption of uniformly labeled C14 glucose was barely affected but inhibition of incorporation of C14 into cellulose and the glucose components of the aqueous and acid-soluble wall fractions was particularly notable. Possible causes of an apparent effect of 0.01 N NaF pretreatment for 6.5 to 7 hrs on respiratory pathways, detected by the use of specifically labeled glucose, <xref image="2000WVJK.TIF|V3|2006:09:28:01:35:56.00|125516|0"> image: </xref>

are discussed. At lower levels of inhibition of growth, the effect of catabolism disappeared but certain effects on the cell wall were still apparent. Interference with metabolism of specific components of the wall including cellulose is considered to be a factor in fluoride inhibition of growth. (Author summary)

STUDY OF PHYTASE AND FLUORIDE EFFECTS IN GERMINATING CORN SEEDS. *Cereal Chem.*, 44 (2), 129-42 (Mar. 1967).

Some properties of phytase enzyme were studied using the 1700 x g fraction of endosperm-scutellar tissue homogenate of 4-day old corn seedlings. The highest total enzyme activity was located in the fraction at 1700 X g, while the supernatant at 20,000 X g was found to be the location of the highest specific enzyme activity. The enzyme resisted high temperature (up to 50 degrees), was activated by calcium chloride (0.01 M), and was inhibited significantly by sodium fluoride ranging from 10 to 0.05 mM. A rapid decomposition of phytin content was correlated with steady rises of phytase activity and inorganic phosphate in the endospennscutellar tissues of germinating corn seedlings. Fluoride, however, prevented the dephosphorylation of phytin compound in the tissues and retarded the rate of seedling root growth during germination. There occurs continuous turn over between inorganic phosphorus and nucleotides in RNA metabolism. It is assumed that the limited supply of phytin-originated orthophosphate may be possibly one of the factors, which influences the growth rate of corn seedling roots.

BOVINE FLUOROSIS FROM SOIL AND WATER SOURCES.

Tennessee Univ., Agr. Expt. Sta. Bull. 347 (Sept. 1962). 50 pp.

The effects upon cattle of soil-borne and water-borne fluorine (F), level of nutrition, and aluminum sulfate were studied. Records were kept on (1) cow weights and gains; (2) reproduction and calf gains; (3) F concentrations in cow and calf bones; (4) urinary F concentrations; (5) changes in teeth; and (6) general health. Nine treatments in replicate with each of the eighteen lots containing five Hereford cows and heifers per lot were used as follows: (1) Low fluorine soil, low fluorine water, good nutrition; (2) Low fluorine soil, low fluorine water, low nutrition; (3) Low fluorine soil, high fluorine water, good nutrition; (4) Low fluorine soil, high fluorine water, low nutrition; (5) High fluorine soil, low fluorine water, good nutrition; (6) High fluorine soil, low fluorine water, low nutrition; (7) High fluorine soil, high fluorine water, good nutrition; (8) High fluorine soil, high fluorine water, low nutrition; and (9) High fluorine soil, high fluorine water, low nutrition plus aluminum sulfate. The soil F concentration in low fluorine soil (LFS) pastures ranged from 380 to 600 ppm F and in high fluorine soil (HFS) pastures from approximately 2,000 to 4,100 ppm F. The following conclusions are reported: F content in soil, pasture and water caused no significant difference in weights and gains of cows. There was no significant effect from concentrations of F in soil or water, levels of nutrition, or the feeding of aluminum sulfate, upon the reproduction of cows or the average daily weight gains of calves. Increased age with continuous F ingestion resulted in highly significant increases in bone F storage. A study of all calf bone analyses showed that the higher level of F in soil caused highly significant increases of F concentration in these bones. Composite urine samples collected from cows on HFS pastures were found to have significantly higher concentrations of F than samples collected from the cows on LFS treatments. Highly significant increases in incisor teeth indexes were found in HFS cattle compared to

those on LFS treatments. The F levels in soil, vegetation and water or the levels of nutrition had no effect upon the general health of the animals.

C. S. Hobbs and G. M. Merriman

FLUOROSIS IN BEEF CATTLE. Tennessee Univ., Agr. Expt.

Sta. Bull. 351. (Oct. 1962.) 189 pp.

Cows were used in the study of physiologic effects of various levels of ingested fluorine. Fluorine as sodium fluoride or raw rock phosphate was added to concentrate feeds for some groups of cows while other groups consumed hay, or hay and pasture, contaminated with fluorine from an industrial source. Aluminum sulfate hydrate was added as an alleviator to rations containing sodium fluoride. Groups of cows were removed after approximately 100, 200, 400, 600, and 800 days on pastures contaminated with fluorine from an industrial source. Cattle were started on experiment at 14 to 22 months of age. The studies covered various periods up to 10 years, providing data indicating the following: (1) feed consumption; (2) weights and gains; (3) reproduction and calf records; (4) fluorine content of bones; (5) blood studies; (6) urinary fluorine; (7) teeth; and (8) gross changes in bone and other tissue. It is concluded that the occurrence and degree of fluorosis in cattle depends upon many factors including: (1) the level of fluorine ingested; (2) the age of the animal and the stage of tooth development; (3) the length of time exposed to the increased fluorine ingestion; (4) the initial fluorine stored in the animal's body; and (5) the solubility and availability of the fluorine material ingested. INJURY BY SULFUR DIOXIDE, HYDROGEN FLUORIDE, AND CHLORINE AS THEY WERE OBSERVED AND REFLECTED ON VEGETATION IN THE FD3LD. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa. (Presented at the Air Pollution Control Association, Annual Meeting, 60th, Cleveland, June 11-16, 1967, Paper 67-159.)

Plants were examined at three different locations in the eastern part of the United States to determine whether damage from air pollution had occurred. This paper discusses sulfur dioxide damage in the Metropolitan New York City Area, hydrogen fluoride damage near a glass fiber manufacturing plant in the Mid-west, and hydrochloric acid mist and chlorine damage from a manufacturing operation in an eastern state. The symptoms that developed in vegetation were often found to be similar. Chemical and microscopical analyses were helpful in diagnosing the toxicants. (Author abstract)

EFFECTS OF ACUTE HYDROGEN FLUORIDE AND NITROGEN DIOXIDE EXPOSURES ON CITRUS AND ORNAMENTAL PLANTS OF CENTRAL FLORIDA. Preprint.

(Presented at the 60th Annual Meeting, Air Pollution Control Association, Cleveland, Ohio, June 11-16, 1967, Paper No. 67-158.)

Six citrus varieties and six ornamental species of economic im-

portance to Central Florida were subjected to high concentra-

<xref image="2000WVJL.TIF|V3|2006:09:28:01:35:58.00|121684|0"> image: </xref>

tion-short duration exposures of gaseous hydrogen fluoride (HF) or nitrogen dioxide (NO₂). Post-fumigation observations showed that the effects of acute pollutant exposures differ markedly from those of chronic exposures. HF exposures of 0.5 to 10 ppm and durations of from 30 minutes to 8 hours induced tip, marginal, and intercostal chlorosis and necrosis and abscission of leaves of most plants tested. Injury was most severe on, but not limited to, young leaves. The effect of duration of exposure had a greater influence on abscission of young citrus leaves than did HF concentration. However, the effect of HF concentration on foliar F accumulation could not be separated from exposure time. NO₂ concentrations used ranged from 25 to 250 ppm for durations of from 10 minutes to 8 hours. NO₂ damage was characterized by rapid tissue collapse, necrosis, and defoliation. Injury was sporadic in appearance, affecting leaves of all ages. The relative contributions of concentration and duration to NO₂-induced injury were about equal. (Author abstract)

CYTOGENETIC EFFECTS OF HYDROGEN FLUORIDE TREATMENT IN TOMATO PLANTS. J. Air Pollution Control Assoc., 18(6):395-398, June 1968. 21 refs. (Presented at the 60th Annual Meeting, Air Pollution Control Association, Cleveland, Ohio, June 11-16, 1967. Paper 67-19.)

Seeds from tomato plants fumigated with hydrogen fluoride gas at a concentration of about three micrograms per cubic meter were planted in pots in the greenhouse. A number of plants in each culture were found to be developing abnormally. These abnormalities consisted of one, three or four cotyledons; deformed cotyledons; plumuleless seedlings; fasciated petioles, wiry seedlings, double stalk plants; and dwarf seedlings. Such abnormal phenotypes were the same as, or similar to known mutants. There was a trend toward a higher percentage of total phenotypic abnormalities with an increase in the treatment duration. Offspring of the fumigated plants showed the occurrence of fragments or bridges plus fragments. There was also a trend toward a higher percentage of chromosomal aberrations with an increase in the treatment duration except for the 4 day duration which was higher than most of the other treatments. It is believed that the occurrence of these aberrations was due to crossing over in heterozygous paracentric inversions. These results suggest that HF is a mutagenic agent probably blocking directly or indirectly, the replication of the DNA. (Author abstract)

Thompson, C. R., J. O. Ivie, and M. D. Thomas

CONTINUOUS RECORDING OF AIR POLLUTANTS AND THEIR EFFECTS ON BEARING CITRUS. Preprint., 1960

Decline in citrus production and fruit quality is reported by growers during the past 15 years in the Los Angeles Basin. Air pollution is considered to be a major factor contributing to this problem. An industry-agriculture-local government-university sponsored, cooperative study entitled the Agricultural Air Research Program was begun in 1960 to assess the economic effect of various air pollutants, principally oxidants and fluorides, on fruit yield, quality and tree growth. Measurements of photosynthesis and transpiration are used to supplement the longtime growth and yield observations. Automatic data recording is provided for: (1) apparent photosynthesis by carbon dioxide exchange; (2) plant transpiration; (3) nitrogen dioxide; (4) nitric oxide; (5) ozone; (6) total oxidants; (7) fluorides; (8) temperatures; (9) integrated sun light recording; (10) date, and (11) time of day. With punch card recording, direct automatic handling of the data on the 1620 IBM computer is possible. The initial experiment is being conducted at Upland, California on 24 lemon trees with six treatments as follows: (1) Clean Air; (2) ambient air; (3) fluoride-free air; (4) ozone-free air; (5) clean air with fluoride added; and (6)

fluoride and ozone free air. Four unenclosed trees serve as checks. Plans are underway for similar experiments in other locations with both lemons and oranges. (Authors' summary)

I. A. Leone, E. Brennan, R. H. Daines

PLANT LIFE AS AIR POLLUTION INDICATORS. Proc.

Northeast. Weed Control Conf. 18, 451-5 (1964).

Plants display a particular talent for indicating the presence of very low concentrations of pollutants in the atmosphere. Agricultural people are concerned with two broad groups of pollutants, the primary or single source emissions which are the result of a particular industrial or fuel-utilizing process, and the products of photochemical reactions which are the result of a whole complex of combustive activities in urban areas. The primary phytotoxic contaminants include hydrogen fluoride, chlorine, sulfur dioxide, ammonia, hydrogen sulfide, ethylene and perhaps illuminating gas. The remarkable thing about these phytotoxicants is that each one severely affects a particular group of plants which is more or less tolerant to the other pollutants. For that reason plant indicators are very useful in diagnosing the specific gas or gases responsible for an air pollution episode, if observed during their optimum growth period.

CYTOLOGICAL REACTIONS INDUCED BY SODIUM

FLUORIDE IN ALLIUM CEPA ROOT RIP CHROMOSOMES

. (Can J. Genet. Cytol. Ottawa) 8, 241-4 (1966).

The cytological effect of an aqueous sodium fluoride solution of 0.01 M was studied on onion root tip chromosomes. Root tip smears showed that this chemical agent was able to induce anaphase bridges and fragments. Tetraploid nuclei and multipolar anaphases were also observed. From the cytological results presented here, it is apparent that sodium fluoride in an aqueous solution has a specific action on onion root tip chromosomes as well as on the spindle. Not all of the cytological effects reported here were necessarily visible at the same time. The formation of anaphase bridges is considered to be the result of the development of dicentric chromosomes with the two centromeres of each dicentric chromosome oriented towards the opposite poles. The dicentric chromosomes presumably arise by the reunion of the two sister chromatids of a broken chromosome. Such fusion takes place at the time of chromosome duplication. This may indicate that sodium fluoride acts on chromosomes during interphase, since it has been shown that DNA replication occurs during this phase. Since the majority of the bridges were found after 14 and 48 hr. of treatment, it appears possible that anaphase bridges are being carried over from one mitotic cycle to the next through the initiation of a breakage-fusion-bridge-cycle.

IN VITRO EFFECTS OF FLUORIDE ON TRICARBOXYLIC

ACID CYCLE DEHYDROGENASES AND OXTOATTVE

PHOSPHORYLATION: PART I. J. Histochem. Cytochem. IS

(4), 195-201 (1967).

<xref image="2000WVJM.TIF|V3|2006:09:28:01:36:02.00|123304|0"> image: </xref>

It appears that an initial effect of fluoride on plants involves either inhibition or enhancement of respiration with the specific result depending upon plant species, fluoride concentration and extent of injury. This study is made in an effort to elucidate further the effects of fluoride on oxidative phosphorylation and succinic dehydrogenase in higher plants. The *in vitro* effect of fluoride on the succinic oxidase system was studied, utilizing mitochondria from cauliflower. Preincubation of mitochondria with fluoride did not increase inhibition of succinic oxidase. Various other tricarboxylic acid cycle substrates when tested showed no sensitivity to fluoride. A series of succinate concentrations in the presence and in the absence of fluoride showed increased activity of succinic dehydrogenase which indicated competitive inhibition. Various concentrations of phosphate in the absence of fluoride showed that phosphate had only slight effects on the succinic 2,6-dichlorophenolindophenol reductase component of the oxidase system. In the absence of phosphate, various concentrations of fluoride showed an initial increase in activity followed by a decrease in activity of the reductase. In the presence of phosphate, fluoride caused marked inhibition of the reductase. It is believed that this inhibition results from an enzyme-fluorophosphate complex which has a lower dissociation constant than that of the enzyme-substrate complex. An oxidative phosphorylation study indicated both respiration and phosphorylation were inhibited. (Author abstract modified)

HISTOCHEMICAL INVESTIGATIONS ON THE *IN VIVO* EFFECTS OF FLUORIDE ON TRICARBOXYLIC ACID CYCLE DEHYDROGENASES FROM PELARGONIUM ZONALE:

PART II. J. Histochem. Cytochem. 15 (4), 202-6 (1967).

In vivo effects of fluoride on tricarboxylic acid (TCA) cycle dehydrogenase enzymes of Pelargonium zonale, the variegated geranium, were studied using p-nitro blue tetrazoleum chloride. Plants were exposed to 17 ppb HF, and enzyme activities in treated plants were compared to those in controls. Leaves of control plants were incubated in 0.005 M sodium fluoride. Injuries observed in fumigation and solution experiments were similar. Leaf tissue subjected to HF or sodium fluoride evidenced less succinic p-nitro blue tetrazoleum reductase activity than did the control tissue. Other TCA cycle dehydrogenase enzymes were not observably affected by the fluoride concentrations used in these experiments. Excised leaves cultured in 0.005 M sodium fluoride exhibited less succinic p-nitro blue tetrazoleum reductase activity after 24 hr than did leaves cultured in 0.005 M sodium chloride. EFFECTS OF AIR POLLUTANTS ON APPARENT PHOTOSYNTHESIS AND WATER USE BY CITRUS TREES.

((Environ. Sci. Technol.,)) 1(8):644-650, Aug. 1967. 20 refs.

Because of the major damage to crops by air pollutants, studies were begun to measure under field conditions, the effect of various atmospheric phytotoxicants on agricultural crops in the Upper Santa Ana Drainage Basin. There was question as to whether photochemical smog and/or fluorides were responsible for major economic losses by the citric industry and if so, how much. Commercially producing lemon and navel orange trees were tested to determine the effects of ambient air pollutants which occur in the Los Angeles basin on water use (transpiration) and apparent photosynthesis. The entire trees were enclosed in plastic covered greenhouses and were supplied various fractions of the atmosphere to find whether ozone, peroxyacyl nitrates, or fluorides were causing deleterious effects. Nitric oxide was added to the air in one treatment

to reduce ozone selectively but in so doing, nitrogen dioxide in amounts equal to the ozone was formed. The results showed that the total photochemical smog complex reduced the rate of water use by lemon trees and also reduced the rate of apparent photosynthesis. Fluoride levels occurring in the atmosphere caused no detectable effects. Attempts to evaluate the separate effects of ozone and peroxyacyl nitrates were unsuccessful. Reduction of the ozone in the tree atmospheres by addition of nitric oxide failed to overcome the reduced water use and lowered apparent photosynthesis. (Author abstract modified)

Pack, Merrill R.

INFLUENCE OF HYDROGEN FLUORIDE FUMIGATION ON ACID-SOLUBLE PHOSPHORUS COMPOUNDS IN BEAN SEEDLINGS. Environ. Sci. Technol., 1(12): 1011-1013, Dec. 1967. 23 refs. (Presented at the Division of Water, Air, and Waste Chemistry, 153rd Meeting, ACS, Miami Beach, Fla., April 1967.)

Bean seedlings were grown for four days following emergence in an atmosphere containing hydrogen fluoride (HF) at 14 + micro of fluorine per cu. meter. Their acid-soluble phosphorus composition was compared with that of seedlings grown in a decontaminated atmosphere. The seedlings in the HF treatment accumulated 275 ppm of F but showed no symptoms of injury. The phosphorus compounds were extracted with 0.6N trichloroacetic acid and separated on an anion exchange resin column by elution with a variable gradient of formic acid and ammonium formate. There were no apparent differences between the atmospheric treatments with respect to the approximately 20 phosphorus compounds in the plant extracts. These results suggest that under some conditions plants can tolerate appreciable fluoride without significant inhibition of enzymes that catalyze reactions of phosphorus compounds (Author's abstract)

Katz, M.

EFFECTS OF CONTAMINANTS, OTHER THAN SULPHUR DIOXIDE, ON VEGETATION AND ANIMALS. In: Pollution and Our Environment: Conference Background Papers. Vol. 1, Montreal, Canadian Council of Resource Ministers, Paper A4-2-2, p. 1-18, 1967. 23 refs. (Presented at the National Conference, Canadian Council of Resource Ministers, Montreal, Oct. 31-Nov. 4, 1966.) Available from the Canadian Council of Resource Ministers, 620 Dorchester Boulevard West, Montreal, Canada.

It is apparent that air pollution can cause harmful effects on agricultural crops, and other species of vegetation. Apart from paper, the principal pollutants of serious concern are fluorides, ozone, photochemical smog products, ethylene and various aerosols occurring as suspended particulate matter. Gases such as chloride, hydrogen sulphide, oxides of nitrogen, and ammonia may constitute a hazard or cause damage to vegetation on occasion in localized areas. Suspended particulate matters consisting of small particles of smoke, sulphuric acid mist, soot and various metallic dusts, may be transported by wind for considerable distances from strong sources such as urban and industrial areas. These pollutants accumulate on leaf surfaces and clog the stomata to produce direct damage or retardation in growth. Unfortunately, there is a great lack of information on the extent of the damage to the Canadian economy

<xref image="2000WVJN.TIF|V3|2006:09:28:01:36:06.00|134649|0"> image: </xref>

from the diverse effects of these pollutants on agriculture and forestry. Little, if any, coordinated research is being conducted in Canada on the biological effects of air pollutants on plants. Some studies have been conducted occasionally to meet the needs of a specific problem, such as the effects of ozone on tobacco. With regard to the harmful effects of air pollution on animal health, the evidence of major air pollution disasters points to adverse symptoms in animals of a character similar to those suffered by man. Animals in these episodes have suffered acute respiratory distress, bronchitis, emphysema and heart failure. Fluorides, arsenic and lead are highly toxic pollutants that may cause diseases in animals by accumulation in the forage and other crops that constitute the principal diet of cattle and other farm animals. There are many other pollutants derived from the incomplete products of combustion of fuels and from specific industrial processes that possess lexicological properties. However, animal research in this field is virtually non-existent in Canada. There is a great need for a broad, well-balanced research program to determine the biological effects of specific air pollutants and of simple and complex mixtures.

Crampton, E. W.
HUSBANDRY VERSUS FLUORIDE INGESTION AS FACTORS IN UNSATISFACTORY DAIRY COW PERFORMANCE. J. Air Pollution Control Assoc., 18 (4):229-234, April 1968. 7 refs.
During 1965 and 1966 a critical study was made of the quality, condition, and performance of some 1000 dairy cows on 45 farms in four compass areas in the region centering on Arvida, Quebec, where an Aluminum Smelting operation emits effluent that results in a contamination of their forage of from about 10 to as high at times of 105 ppm fluoride. Cattle winter forage in this area is consistently poor in quality, partly because of the species that can be grown, but more importantly because of adverse spring climatic conditions which in many year prevent harvest of hay until the plants have fully matured and ripened. Its effective feeding value, measured by recorded voluntary consumption and in vivo digestibility, has been found to be about half that of high quality legume hay. Commercially prepared meal mixtures constitute the non-roughage portion of the winter rations fed, and these by analysis have been found individually to contain from 65 to 85 ppm fluoride contributed chiefly, and probably exclusively, by some form of rock phosphate included as a source of the necessary phosphorus supplement. The factors statistically examined in the study included: growthiness, size, fleshing, and milking cows; the incidence and degree of dental fluorosis, and skeleton accumulation of fluoride (by tail bone biopsy of 48 representative cows); the makeup and amounts of ration fed daily during the winter farm feeding; and the feeding and breeding management followed. The statistical procedures of variance and covariance, and of correlation and partial regression were computer analyzed. The results indicated that inadequacy of energy intake traceable largely to the nutritional nature of the hay fed was of significantly greater importance than any of the other factors recorded. Fluorine ingestion carried a statistical weight of only about 3 percent as a cause of the performance of the cattle. By difference it appeared that breeding and the generally unsatisfactory management of the cows, especially the feeding practice, was about twice as important as feed allowances as causes of the poor quality and performance of the cows. (The terms fluorine and fluoride and the symbol F are used interchangeably in this paper. Levels of fluorine are reported on the elemental basis.) (Author's abstract)

Pack, Merrill R. and Donald F. Adams
EFFECT OF HYDROGEN FLUORIDE ON FRUITING OF BEANS. Washington State Univ., Pullman, College of Engineer-

ing, National Center for Air Pollution Control Contract AP-00341-04, 11A-3801-0815, Proj. 0815, Rept. 68/1-28, 8p., March 1968. 7 refs.

The response of bean fruiting to hydrogen fluoride fumigation was investigated in a series of experiments. The plants were exposed to various concentrations of HF, either for 7 to 14 days at different times relative to flowering or continuously from seeding to harvest. Hydrogen fluoride treatments averaging up to 8.0 micrograms F/cu m for 9 days and 7.8 micrograms F/cu m for 14 days applied before, during, or after flowering, had no apparent effects on fruiting of any of the four varieties of beans. Fruiting was not affected in four bean varieties continuously fumigated at 2.2 micrograms F/cu m. Bean plants exposed continuously to HF at concentrations averaging 5.4, 6.6, and 13.9 micrograms F/cu m produced fewer fruit and/or fewer seeds per fruit than comparable control plants. Only Tendergreen beans were tested at 5.4 micrograms F/cu m. Tendergreen and Pencil Pod Wax varieties showed effects on fruiting at 6.6 micrograms F/cu m, but Red Kidney and Tendercrop varieties did not. Fruiting was affected in both bean varieties tested at 13.9 micrograms F/cu m (Red Kidney and Tendergreen). (Author summary modified)

STUDIES ON FLUORO-ORGANIC COMPOUNDS IN
PLANTS. I. METABOLISM OF (2)-14C-FLUOROACETATE.
Contri. Boyce Thompson Inst., 24 (2):2S-31, Jan.-March 1968.
17 refs.

The metabolism of (2)-14C-sodium fluoroacetate was studied in *Acacia georginae*, peanut, castor bean, and 'Pinto' bean. When this compound was supplied to sterile seedlings of these four plants, ¹⁴C₂ was evolved and ¹⁴C was incorporated into water-soluble fractions and lipids. Results indicate that the plants studied contain an enzyme system capable of cleaving the carbon fluorine bond. (Authors' summary)

EXPANDING POLLUTION IN ORCHARDS - DAMAGES ON
ORANGES OF THE KAMBARA AREA BY FLUORIDE
GASES. (Kadudai sum kajuen no kogai - fusso gasu ni yoru
Kanbara chiho no mikankogai). Text in Japanese. *Kajitsu Ninon*
(Japan. Fruits), 22(10): 1-4, Oct. 1967.
Approximately 100,000 tons of aluminum per year are produced at the Kambara plant of the Japan Light Metal Co., with 1262 tons/year of gaseous emissions produced from solvents such as fluorspar and aluminum fluoride. Although gases from the electrolysis furnaces are emitted through stacks, a considerable amount escapes into the factory and is discharged through the windows and ceiling. Necrosis, chlorosis, and early leaf fall occurred to bamboo, plums, cherries, maples, and persimmon, in the same year operation began. Orange leaves were affected most severely, with the harvest of the following year drastically reduced. Shrinkage of the leaves and deterioration of the trees occurred, until eventually the trees lost their capacity for fruition altogether. Orange flowers are particularly vulnerable to gases. Fluoride enters into leaves through the pores and concentrates at the tips of the veins. The cell membranes are damaged after a certain concentration is reached, chloroplasts are destroyed, and eventually metabolism and physiological functions completely cease. Control

AIR QUALITY STANDARDS FOR FLUORIDE VEGETATION

EFFECTS. Preprint, Utah Univ., Salt Lake City, Center for Environmental Biology, ((22))p., 1968. 34 refs. (Presented at the 61st Annual Meeting of the Air Pollution Control Association, Cleveland, Ohio, June 24-27, 1968, Paper 68-165.)

Facts that must be taken into consideration in developing fluoride standards for vegetation effects include: (1) Fluoride is an accumulative toxicant and injury is usually associated with long term exposure; (2) Gaseous and particulate fluorides differ in their phytotoxicity; (3) Plant species and varieties differ greatly in susceptibility to fluoride; (4) Extremely low concentrations can cause damage to sensitive species. Three possible approaches to standards are discussed: Atmospheric fluoride concentration, vegetation fluoride concentration, and the presence of leaf necrosis or chlorosis. Atmospheric fluoride concentration has the advantage that it fits the conventional concept of standards and that it is objective. Accurately measuring low fluoride concentration, separating gaseous from particulate fluorides in the air sample, and establishing a safe concentration present technical problems, however. Vegetation analysis may more closely represent fluorides available to affect the plant. The presence of significant amounts of fluoride-induced leaf necrosis (e.g. 3% of the leaf area) may be the most practical approach to standards for fluoride vegetation effects. Advantages are that the combined effects of the form of fluoride, species and varieties, and concentration-time relationships are all manifest in the factor that is measured. Relatively little time is required to examine the vegetation in a large area and only 2 or 3 surveys a year are required. (Author's abstract)

Suttie, J. W.

AIR QUALITY STANDARDS FOR THE PROTECTION OF

FARM ANIMALS FROM FLUORIDES. J. Air Pollution Control Assoc., 19(4):239-242, April 1969. 6 refs.

The ingestion of forage contaminated with inorganic fluorides from industrial sources constitutes an air pollution problem for domestic livestock. In cattle, the syndrome is characterized by dental and skeletal lesions, lameness, chemical evidence of increased fluoride ingestion, and effects on appetite and milk production in severe cases. The only practical basis for a standard appears to be one based on fluoride concentrations in forage. While a standard should protect cattle from loss of milk production and from severe dental fluorosis, it need not be set so low that the animals will be protected against any discernible deviations from normal which do not influence their general health, productive ability, or the soundness and wearing quality of their dentition. As there may be wide seasonal variations in forage fluoride concentrations, the basic standard should be expressed as a yearly average. However, as the developing teeth may be adversely influenced by short periods of high exposure, the standard should contain a provision which limits both the extent and duration of time that high concentrations may be tolerated even though they are balanced by lower values at other months. Based on these criteria, a tentative standard is proposed which limits forage fluoride to an average of 40 ppm, as well as the time that forage concentrations may exceed 60 or 80 ppm. FLUORINE AND FLUORINE TOLERANCES IN FODDER OF DOMESTIC ANIMALS. 2. PATHOPHYSIOLOGY OF

FLUORINE AND FODDER TESTS ON DOMESTIC ANIMALS. Berlin-Muench. Tieraerztl. Wochschr., 77(20):401-408, 1964. 297 refs. Translated from German by J. Chapin. National Institutes of Health, Bethesda, Md., Translating Unit, 23p., 1965.

The effect of fluorine on the animal organism is due mainly to resorption, fixation in hard tissues, and excretion interaction. Symptoms and experimental results are presented for acute, subacute, and chronic fluorine intoxication. Growth retardation must be included in the description of subacute fluorine intoxication. Morphological alterations in the bones and teeth are described for chronic fluorine intoxication. Animal experiments are critically assessed to determine how much fluorine can be tolerated without having an injurious effect on the animal. Important differences are noted between different types of animals with regard to dosage. In presenting the animal experiments, it is necessary to differentiate between indifferently and tolerable fluorine concentrations. The difference between these two terms is based on the fact that in those animals which receive tolerable fluorine concentrations during dental formation, slight changes can occur in the teeth. However, this molding leads neither to an increased abrasion of the teeth nor other damages. Metabolic disturbances, among which are included changes of the tooth structure, occur only at higher fluorine concentrations. It is also necessary to distinguish between poorly and readily soluble fluorine compounds. The tolerance of fluorine depends on the mineral supply of the animals, especially with calcium and phosphorus. A deficiency of one or both of these minerals results in a sensitivity toward fluorine.

Grieser, N. and K. Bronsch
FLUORINE AND FLUORINE TOLERANCES IN THE NUTRITION OF DOMESTIC ANIMALS. 1. BEHAVIOR OF FLUORINE IN METABOLISM. Berlin Muench. Tieraerztl. Wochschr., 77(19):373-379, 1964. 298 refs. Translated from German by A. A. Vildzius. National Institutes of Health, Bethesda, Md., Translating Unit, 19p., 1965. (References included in Aptic 10841.)

The most important facts concerning the toxicity of fluorine compounds are compiled and evaluated critically, with particular reference to the tolerated doses of F in the nutrition of domestic animals. Fluorine metabolism, its resorption, and distribution in the blood and tissues are considered. Excretion ratios are indicated. Effects of fluorine on calcium metabolism, enzymes, organ function, and symbionts are discussed. The toxic effect of fluorine can be explained essentially by enzyme inhibition.

EFFECTS OF AIR POLLUTANTS ON GROWTH, LEAF
DROP, FRUIT DROP AND YIELD OF CITRUS TREES.
Preprint, California Univ., Riverside, Statewide Air Pollution
Research Center, ((31))p., ((1968)). ((17)) refs.

Commercially producing lemon and navel orange trees were studied to determine the effects of the air pollutant complex, especially photochemical oxidants and fluorides, in the Los Angeles Basin on the following responses: growth as shown by increased tree girth and weight of prunings; leaf drop as measured by (a) total weight of dried leaves collected under the trees, and (b) the time which marked leaves remained on randomly selected branches; fruit drop; and yield of marketable fruit. The results showed that tree growth measured by increased girth and weight of pruning removed were not affected consistently by the experimental treatments. The rate of leaf drop was significantly less for lemon trees where carbon filtered air was supplied to the trees versus the unfiltered treatments. A similar trend was present in oranges but was not significant statistically. The percent of lemon leaves which remained on selected branches of trees receiving filtered air as compared to unfiltered treatments after 18 months was 72.4 vs. 34.4%. Fruit drop in lemons is of minor significance but in navel oranges represents a serious problem. Comparisons of check trees, unfiltered and carbon filtered air trees showed fruit drop to be 82.5, 59.7, and 39.6, respectively, all percents of which are statistically different at the 1% level. Yield of marketable fruit is also reduced significantly by photochemical oxidants. (Authors' abstract, modified)

SICKENING OF DOMESTIC ANIMALS THROUGH SMOKE
DAMAGE AND INDUSTRIAL WASTE WATER. ((Erkrankun-
gen der Haustiere durch Rauchschaeden und Abwaesser der In-
dustrieanlagen.)) Translated from German. Monatsh.
Veterinaermed., 11(2):662-6<S9, 1956. 77 refs.
The effects of industrial smokes containing sulfur compounds, arsenic compounds, lead, copper, fluorine, molybdenum, zinc, and selenium on domestic animals are reviewed. The most frequent intoxications result from lead, arsenic, SO₂, and fluorine. Fluorosis has gained considerable importance in the last 30 years and today represents the most important disease among the smoke injuries. Pneumoconiosis very seldom develops in animals as a result of flue ash. Clinical manifestations and pathological anatomy, the course of disease, the changing picture of the disease manifestations, and meteorological and topographic influences are discussed. Mechanical, chemical and physical effects of smoke are also considered.

ESTIMATING DAMAGES FROM TOXIC GASEOUS EFFLUENTS. ((Stima di danni da emanazioni gassose tossiche.)) Translated from Italian. Agric. della Venezia, Vol. 14, p. 364-383, 1960.

The estimation of damages caused by toxic effluents is illustrated in the case of seven agricultural claimants against a glass factory emitting fluorine compounds. The decay of topsoil, diminished or lack of production of the plantations, and damage to cattle through the ingestion of polluted fodder are basic criteria used in the evaluation. The nature of damage (including amounts of fluorine found) is discussed in detail. The estimation of indemnities (e.g. value of dead plants) for each of the seven claimants is outlined. Technical devices aimed at eliminating these emissions are briefly discussed

Bohne, H.

INDUSTRIAL SMOKE DAMAGE FROM FLUORIDE. ((Industrielle Rauchscha-den durch Fluor.)) Translated from German. Mitt. Deut. Landwirtschaft. Ges. (Frankfurt), 77(17):575-578, 1962.

The damage caused to plants and animals by air containing fluoride was investigated, and the extent of this damage and its economic importance evaluated. Damage to plants usually takes the form of discoloration of leaves. Chemical analyses were performed to determine the extent of cumulation of fluorine in cereals, truck crops and fodder plants, pastures, fruit trees, garden and decorative plants, and forest trees. The green portion of pear leaves gathered contained 8.5 percent fluorine, and the brownish edge of the leaves, 21.2 mg percent fluorine, illustrating that the discoloration was due to the effect of fluorine. Fluoride emissions exert quite evident damage on cattle. The animals eat contaminated fodder, grass, and hay, and also inhale quantities of fluorine. This explains why these animals suffer more in comparison to animals kept constantly in stables. The external symptom of such effects is a yellow to dark brown discoloration of the incisors, whose enamel sometimes breaks off. Increased deposition of fluorine in the bones sometimes results in stiff hobbling and painful walking. Chemical analysis proves that animals showing these symptoms of fluorine exposure have in their organism too much of this substance. These symptoms were also observed in hogs who were allowed to eat in pastures. Cattle show a reduction in the formation of milk and they conceive poorly as a result of fluoride emissions

SOME CASES OF CHRONIC FLUOROSIS IN SHEEP. ((Quelques cas de fluorose chronique chez des moutons.)) Translated from French. Annales de Medecine Veterinaire, 100(5):221-224, 1956. 63 refs.

Clinical observations of several sheep with chronic fluorosis in Belgium are discussed in detail. The observations are compared with those of several other authors. Numerous examinations of the blood, particularly studying the total calcium, inor-

<xref image="2000WVJQ.TIF|V3|2006:09:28:01:36:16.00|114380|0"> image: </xref>

ganic phosphorus, phosphatases and in some cases magnesium, polypeptides, urea, cholesterol, proteins, serum albumins and globulins, and glucose were made. Autopsy of these animals showed no specific characteristics, other than bone lesions and especially dental lesions. The limit safe dose of fluoride that a cow can absorb daily over a long period of time was investigated. No delayed growth or weight gain, or alteration in the general condition and hooves of lactating cows receiving 2 to 3 mg of fluorine in the form of natural phosphates, was observed.

DWARFISM IN FIRS AND BIRCHES CAUSED BY SMOKE

IMMISSIONS. ((Durch Rauchimmissionen bedingter Zwergwuchs bei Fichte und Birke.)) Translated from German. Centralblatt für das gesamte Forstwesen, 84(2-6): 156-173, 1967. 34 refs.

A morphological and anatomical study of dwarfed varieties of Norway spruce and birch was made. The varieties became established under the chronic influence of polluted air containing HF from an aluminum plant. A possible effect of minerals or water in the soil was excluded. The spruce specimen examined was 20, the Birch, 18 years old. The trees have a shrub-like, bushy appearance. This is due to the fact that the terminal shoot of the spruce fades out when it grows beyond a certain height, then occasionally the buds from the lateral twigs start to develop. The shape of the dwarfed birch is caused by the elongation of basal buds. The size of the needles and leaves is greatly reduced particularly on the weather side. The reduction is due to a decrease in number as well as size of the cells. The number of pith ray cells per unit area is increased as compared to normally developed spruce trees. With birch no different reaction was found. It is open for further investigation if this observation indicates a fundamentally different reaction of dwarfed soft- and hardwood.

FLUOROORGANIC ACIDS IN SOYBEAN LEAVES EX-

POSED TO FLUORIDE. Environ. Sci. Technol., 2(Sn8:367-370,

May 1968. 17 ref.

Soybean plants were fumigated with HF or grown in nutrient solution containing sodium fluoride or fluoroacetate, and the organic acid fractions of the leaf extracts were compared. Organic acid extracts from these treatments contained fluoroorganic compounds that were chromatographically similar to fluoroacetate and fluorocitrate. The fractions suspected of containing fluorocitrate were separated from HF- and NaF-treated leaf extracts and found to inhibit aconitase prepared from either pig heart or soybean leaves. The inhibition was similar to that exhibited by commercial fluorocitrate. Aconitase from soybean leaves was as sensitive to fluorocitrate as that isolated from pig heart. Fluorocitrate was identified in extracts of fluoride-treated plants by infrared spectroscopy. (Author's Abstract)

Heggstad, H. E.

DISEASES OF CROPS AND ORNAMENTAL PLANTS IN-

CITED BY AIR POLLUTANTS. Phytopathology, 58:1089-1097,

Aug. 1968. 80 ref.

Air pollution injury to crop and ornamental plants is increasing in the U.S.A. Estimates of annual losses to agriculture from air pollutants, which ranged from \$150 to \$500 million during the decade 1951-1960, are now \$500 million. Although most of the loss is due to growth suppression or chronic injury, it is the acute injury that suggests the nature of the air pollutant and reveals the distribution of the problem. Each pollutant tends to produce its own pattern of injury, leaving graphic

records of air pollution episodes. Photochemical oxidants, ethylene, sulfur dioxide, fluoride, and other pollutants produce marked reactions in various types of plants. The recent developments and current research trends in the assessment of these reactions are reviewed.

12045

Johnson, H.

THE HIGH COST OF FOUL AIR. The Progressive Farmer, 4 pp., April 1968.

The President's Science Advisory Committee reported in 1965 that air pollution damage to plants had been observed in 27 states, the District of Columbia, Canada, and Mexico. Total damage each year to crops in the United States is estimated at \$500 million. Weather fleck damage to tobacco, which is caused by ozone, has caused substantial crop loss in all producing states. Sulfur dioxide, fluorine, ethylene, and photochemical smog are known to be harmful to plants. A research program to solve unanswered questions, and a program to enforce the cleaning up of pollution sources is urgently needed.

12155

Leone, Ida A., Eileen Brennan, and R. H. Daines

EFFECTS OF AIR POLLUTION ON VEGETATION. Preprint, Air Pollution Control Association, New York City, 6p., 1962. (Presented at the Air Pollution Control Association, Mid-Atlantic States Section Meeting, Wilmington, Del., Oct. 26, 1962.) Phytotoxic pollutants are broadly categorized as primary or single source emissions and the products of photochemical reactions arising from urban expansion and vehicular traffic. Among the primary contaminants, classified according to their demonstrated order of toxicity to plants, are hydrogen fluoride, chlorine, sulfur dioxide, ammonia, and hydrogen sulfide; to these may be added ethylene and perhaps natural illuminating gas. The acute and chronic types of injury caused by SO₂, the earliest known offender, and by hydrogen fluoride are described. The latter is the most insidious of the phytotoxic pollutants, since it is injurious to certain sensitive species at fractions of a part per billion. The two most significant pollutants from photochemical reactions are ozone, which generally attacks the upper leaf surface of sensitive plants, and oxidized hydrocarbons. The chief offender of the oxidized hydrocarbons is peroxyacyl nitrate and its analogues. Plant injury from specific pollutants can be diagnosed by particularly susceptible species or indicators, by type of symptom, and by significant emission sources in the vicinity. Air quality and meteorological data from three New Jersey communities - Carlstadt, New Brunswick, and Bordentown - are briefly reviewed in relation to phytotoxic episodes. Possible control measures in combatting pollution damage to plants include anti-oxidant sprays and the breeding of resistant plant varieties.

Brandt, C. Stafford

EFFECTS OF AIR POLLUTION ON CROP PRODUCTION.

Preprint, lip., 1967. (Presented at the Ontario Pollution Control Conference, Toronto, Dec. 4-6, 1967.)

The contamination of vegetation by atmospheric sulfur dioxide and fluoride and by phytotoxicants associated with

<xref image="2000WVJR.TIF|V3|2006:09:28:01:36:18.00|116431|0"> image: </xref>

photochemical smogs is discussed. Identifiable plant injuries are summarized and a distinction is made between plant injury and damage. The former is considered to refer to the symptom or the response; the latter, only to the effect of the symptom or response on the desired use of a plant. In the case of sulfur dioxide, acute injury occurs whenever the atmospheric concentration at the leaf exceeds a certain threshold value. As long as the concentration stays less than this threshold, acute injury does not occur. Chronic injury may occur in time. This type of injury is almost impossible to identify with certainty in the field. The easiest description is that of premature senescence, a phenomena that is becoming more and more common in many areas. In the case of fluoride, atmospheric concentrations are of little importance, but the amount accumulated in the tissues is important. When the concentration exceeds certain values, acute symptoms develop. There is no recognizable chronic-type injury due to fluoride. A 10 to 12% reduction of plant productivity along the eastern seaboard is predicted as the result of air pollution in general and photochemical smog in particular.

STUDIES OF SPONTANEOUS FLUOROSIS IN RUMINANTS:

A NOTE ON PROPHYLAXIS. ((Ricerche sulla fluorosi spontanea die ruminanti: Nota preventiva.)) Text in Italian. *Annali d'igiene*, 45(6):399-404, 1935.

The opening of an aluminum refinery near a silkworm breeding region resulted in the destruction of silkworms on an increasing scale as the plant increased its operations. Investigations showed that the cause of death among the silkworms was the ingestion, along with the mulberry leaves, of fluorine discharged into the air by the plant. In the same region, but somewhat later, the following effects were noted in cattle: malnutrition, lower milk yield, and persistent lameness. Still later, goats in the region developed the same symptoms. From an examination of the relevant literature, the authors concluded that the above-described symptoms were instances of fluorosis or fluorine cachexia, of the type reported among animals living near superphosphate or aluminum plants. In a controlled experiment the authors found that three cows and two goats who received 0.38 to 1.8 g fluorine per day developed clinical fluoroses identical to the spontaneous form, whereas the controls did not.

FREQUENT OCCURRENCE OF OSTEOMALACIA AMONG

GRAZING CATTLE CAUSED BY HYDROFLUORIC ACID

CONTAINED IN THE FLUE GAS DISCHARGED BY A

CHEMICAL PLANT. ((Gehaftetes Auftreten von Osteomalacie

unter Weiderindern, verursacht durch Fluorwasserstoffsäure enthaltenden Fabrikrauch.)) Text in German. *Arch wissenschaftliche praktische Tierheilkunde* (Berlin), 60:21-39, 1929. 12 refs.

In the year 1928 a number of animals grazing in the vicinity of a chemical plant fell ill to a disease which was diagnosed as fluorosis. But the symptoms shown by the diseased animals were in many respects different from those commonly associated with such cases. The two front legs became lame, toes and ankles were swollen. The pulse rate was higher, an increased body temperature was measured and pain was felt. In some cases the hind legs became stiff. Furthermore an enormous loss of weight was observed and swellings appeared along the ribs. The milk production decreased. All these symptoms indicate osteomalacia. The grass on which these animals fed was examined but it was found lush and in no way lacking in Ca and phosphoric acid (osteomalacia is a deficiency of these two minerals). The toxicant was found to be the fluorine deposited on the grass and plants. Hydrofluoric acid attacks the calcium in the bones and dissolves it which means that the calcium is constantly reduced. The consequence is osteopro-

sis. The fluorine is discharged with the flue gas of the nearby chemical plant. The disease did not occur outside the range of the chemical plant. The condition of the animals visibly improved during winter time when they were fed with fodder coming from an unpolluted area. The animals were treated with nephritine which relieved them of their pain. The chemical physiological examinations which were conducted showed that the calcium of the bones is used to neutralize the hydrofluoric acid. The by-product of this neutralizing process, phosphoric acid, is discharged with the urine.

Narozny, J.

DENTAL FLUORISIS OF CATTLE. ((Dentalna ifluoroza hovad-zieho dobvtka.)) Text in Slovak. Veterinarni Medicina 7:421-424, 1965.

The syndrome of dental fluorosis was used for evaluation of the toxic effect of fluorine exhalates from a Slovak aluminum-producing factory, and of the territorial area thus contaminated. During 1964, 5,320 animals from 31 localities of the examined region were investigated. The findings were evaluated in accordance with Dean's 5-grade classification system which proved fully relevant of the experimental conditions selected. The emissions were found to be air-flown mainly in two directions and they affected the territory up to 16 km from the source of emission. The examined area was divided into five classification zones and the occurrence of dental fluorosis was evaluated and tabulated for each of them. The results indicate that unusual wear and abrasion of teeth, due to acute dental fluorosis, unfavorably affect the life span of cattle regardless of the fact that cattle can develop a certain adaptability to the fluorine compounds.

CALCIUM AND PHOSPHORUS IN RABBIT BLOOD SERUM

FOLLOWING SODIUM FLUORIDE POISONING. ((Le calcium et le phosphore du serum sanguin chez le lapin apres l'intoxication par le fluorure de sodium.)) Text in French. Compt Rend., Soc. Biol (Belgrade). 109:475-477, 1932. 3 refs.

The process involved in sodium fluoride poisoning is of interest in both the toxicology and the general pathology of bone and articulation sicknesses. We know little about the part played by fluorine in rachitis. Certain substances important in bone pathology have been determined in the blood, but the results obtained have not been interpreted. The initial weight of the rabbits used ranged between 1350 and 2200 gr. Calcium and phosphorus were determined in the blood serum before and after poisoning by injections of a 1% solution of sodium fluoride. Chronic poisoning was produced by daily injections increasing from 10 to 30 mgr of solution per animal kg over a period of 105 to 121 days. This caused calcium to diminish from 17.6 to 14.5 mgr per 100, and phosphorus to fall from 7.4 to 6.3 mgr per 100, against 18.1 to 17 and 9.6 to 6.3, respectively, in control animals. Acute poisoning was produced by a single injection of 60 mgr per animal kg. This caused the calcium to diminish from 16.6 to 14.7 mgr per 100, and phosphorus to fall from 7.3 to 5.5 mgr. No change was found in the control animals.

CHANGES IN THE THYROID GLAND UNDER FLUORIC

POISONING. ((Alterations de la glande thyroïde dans l'intoxication fluoree.)) Text in French. Compt. Rend. Soc. Biol. (Paris), 103:554-557, 1930.

Thyroid gland changes are studied in animals subjected to chronic poisoning by ingestion of small doses of alkaline fluorides or fluorsilicates. Because goiters are frequent in this area of the country, control animals were included in the experimental groups. Test results on 14 fluorinated animals (guinea-pigs) are tabulated. Death occurred in 19 to 94 days (average 53). All animals showed changes in the gland, the interstitial tissue. The changes here were rapid, but may be slower with smaller doses. All control animals were found to be healthy. Macroscopic changes in the pituitary body in cases of fluorosis. The different endocrine glands react differently to fluorine poisoning. The pituitary gland is difficult to study because this gland varies with age, sex, pregnancy, etc. of the subject. Use was therefore made of adult guinea-pigs 6 to 8 months old, which had died of fluorosis. Their pituitary body was compared to that of control animals of the same age and sex. Results are tabulated, showing a shrinking of the gland in the test animals, mostly in the nature of a flattening 2.25 mm (normal average) to an average of 1.7 mm (after poisoning).

FLUORIDE EMANATIONS FROM FACTORIES: EXPERIMENTAL STUDY OF THE ACTION OF FLUORINE PLANTS.

((Emanations fluorees des usines: etude experimentale de l'action du fluor sur les vegetaux.)) Text in French. Ann. Hygiene Publ (n.s.), 3:49-64, 1925. 17 refs.

Research work from 1883 onward and the authors' own experiments on the damages done to plants by fluorine emanations from aluminum and/or chemical fertilizer factories are reviewed. Fluorine compounds may act through the soil and water that feed the plants, or directly on the plant organs exposed to fluorine-polluted air. Of the various toxic gases, hydrofluoric acid is the most noxious since it forms thick fogs with the humidity in the air. The effects are cumulative and may not become visible before repeated exposure of the plants to the gases. The toxic action of NaF derives from its ability to precipitate lime and to attach itself to other substances, such as proteides. Also, fluorine salts have antiseptic action on unicellular elements, and this has had practical applications. At the doses utilized, alkaline salts of fluorine do not precipitate albumin, and can hamper microbial growth without harming soluble ferments. On the other hand, examination of plant lesions enables the detection of their fluorine, as opposed to other (sulfur, chlorine....) origin. Stoklasa claims that the amount of emanation and smoke has increased 100-fold in the last century, reducing the crops in some regions by 30 to 90%. The work on fodder from industrial areas was confirmed by experiments with fluorine compounds in air and in water.

EXPERIMENTAL RESEARCH ON THE TOXICITY OF

FODDER HARVESTED IN THE VICINITY OF AN ALU-

MINUM-PRODUCING FACTORY. ((Recherches experimentales

sur la toxicite des fourrages recoltes dans le voisinage d'une usine productrice d'aluminium.)) Text in French. Ann. Hygiene Publ., Ind. Sociale, 4:141-154, 1926. 7 refs.

Experiments were made from 1919 to 1924 on guinea-pigs whose diet contained, in part, fodder exposed to the emanations of an aluminum factory. The animals died after a time that depended on the amount of fluorine present in the fodder. Death was preceded by cachexy and symptoms similar to those exhibited by cattle in areas around the same factories.

Test results are tabulated. The fodder must contain more fluorine than normally present in such plants. These conditions were obtained around the subject factory, during intense production only. A second set of tests were made on fodders artificially altered by gases containing fluorine. The results were similar to those described above and showed that other gases than fluorine, which may additionally have altered the fodder, are not necessary for the production of the disease.

Ehrlich, C.

OBSERVATIONS AND INVESTIGATIONS OF CHRONIC FLUORINE POISONING IN CATTLE. ((Beobachtungen und Untersuchungen iiber chron. Fluorvergiftungen bei Rindern.)) Text in German. Deut Tieraerztl. Wochschr., 61:225-228, June 1954.

Fluorine poisoning of cattle grazing in the vicinity of an aluminum plant was observed which lead to extensive clinical, pathologic-anatomical, bacteriological, serological and parasitological examinations. The clinical symptoms shown by the diseased animals were loss of weight, retardation in the development of young cattle, lusterless skin, stiff and pain-stricken movement, swollen ankles, impaired fertility of female animals, brown and black colored teeth which became loose and exostoses at the jaw bones and ribs. Sometimes a difficulty in breathing developed with the pulse becoming weak and irregular. A closer investigation of the deformed ribs showed that at the sites of the exostoses, the bones could be cut through very easily. No parasitic or bacteriologic ailment was found in the animals. The chemical analysis yielded a high fluorine content in the teeth and bones which was on the average one to ten times as high as with healthy animals. The increase of the normal fluorine contents was lowest in the blood and highest in teeth, bones, claws and in the urine. To answer the question of how these toxic fluorine compounds entered the body, samples of the grass and soil in the vicinity of the aluminum plant (up to a diameter of 2 km) were examined. The fluorine contents of these samples was 31 to 56 times higher than of samples taken outside the range of the plant. Thus the animals consumed the fluorine with the fodder which was intoxicated either by fly dust and/or by nourishing on a soil rich in fluorine.

PARATHYROID AND FLUORIC HYPOCALCEMIA.

((Parathyroide et Hypocalcemie Fluorique.)) Text in French.

Compt Rend Soc. Biol. (Paris), 104:411412, 1930

The tests on dogs here described show that the parathyroids tend to maintain the calcemic level at its normal value, contributing to raise it when it otherwise may fall. Sodium fluoride served as hypocalcemic agent, injected intravenously (30 mg per kg animal weight). Calcium was measured in the blood serum, phosphates in the plasma, chlorides in the whole blood. In normal dogs, the calcium level ranged from 11 to 10.7 mg per 100 cc. After surgical removal of thyroid/parathyroid glands, the level dropped in 48 hours from 10.5 to 5.9 mg, with most of the animals falling into tetany. The injection in normal dogs produced hypocalcemia with a drop of 3.3 mg in 2 hours and then a gradual recovery to near-normal level after

<xref image="2000WVJT.TIF|V3|2006:09:28:01:36:26.00|121683|0"> image: </xref>

24 hours; inorganic phosphates increased from 3.2 to 5 mg; chlorides showed no regular changes. The same injection in dogs deprived of the glands caused a greater drop in calcium, yet smaller than the sum of the drops caused separately by the fluoride and the parathyroidectomy. But the lowered calcium level does not recover: the recovery seems to be due mostly to the operation of the parathyroidic function.

THE BIOLOGICAL EFFECTS OF AIR POLLUTION OF ANIMALS. (Effets biologiques de la pollution atmospherique sur les animaux). Text in French. Rev. Hyg. Med. Soc., 17(3):295-306, 1969. 2 refs.

Air pollution has many effects on animal organisms. Fluorine by-products, lead, and molybdenum are the major offending constituents in industrial air pollution. Cement dust and sulfur dioxide cause less of a problem. Pollution of agricultural origin is essentially linked to the more or less controlled use of pesticides. A temporary imbalance of natural fauna is most often indicated when domestic animals are victims of atmospheric pollution. The damage caused to livestock by this pollution will remain localized and its economic consequence will be relatively unimportant. The social consequences of this pollution are more severe, and it is as important to preserve the social climate as the health of the animals. The solution to these problems has long been in the hands of lawyers. Though indirect, the risk to the food cycle is serious. It will be necessary to institute strict tests for determining the amount of residual pollutants able to exist in food destined for men and to regulate the use of products absorbing these pollutants.

Lezovic, Jan

THE INFLUENCE OF FLUORINE COMPOUNDS ON THE BIOLOGICAL LIFE NEAR AN ALUMINUM FACTORY. Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 2(1):2S-27, Jan. 1969.

Quantitative and qualitative analyses of tissues, milk, and teeth, along with fluoride level determination of bones, show that animal and vegetable life near an aluminum factory is adversely affected by fluoride emissions. The factory is located in a mountain valley, within 300 meters of the nearest village. All trees examined showed a marked increase in the fluoride levels of their leaves or needles. The leaves of exposed fruit trees were harder, glossier, more fragile than normal, and covered with a whitish-gray crust. Similar changes occurred on leaves of garden vegetables, especially cabbage, turnips, and cucumbers. Fruit on trees was visibly deformed. The first signs of damage to animal life occurred two years after the factory went into operation, when about 95% of the goats and cattle were afflicted with fluorosis. Swine, horses, and poultry were less sensitive. The weight of the affected cattle gradually decreased to the point of cachexia. Calcium and phosphorous levels in the blood of the diseased animals averaged, respectively, 7.5 and 5.06 mg%. As an indicator of damage, fluoride deposits on snow were of the order of magnitude of 15 to 234.8 mg/sq m.

Allcroft, Ruth and K. N. Burns

ALLEVIATION OF INDUSTRIAL FLUOROSIS IN A HERD. Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 2(I):55-59, Jan. 1969. 2 refs.

To determine the alleviating effect of aluminum and calcium in fluorosis, a herd of 24 Ayrshire cows was exposed to airborne fluoride and divided into three groups. One group was given supplements of aluminum sulfate, another aluminum sulfate plus calcium carbonate and anhydrous sodium phosphate. The third group was used as control. Urinary fluorine excretion, skeletal fluoride accumulation, and the general health of the

animals were evaluated. Aluminum sulfate reduced bone fluoride storage by 22% in comparison with controls. The calcium phosphorous supplement did not enhance the effect of aluminum sulfate alone. However, it appeared that fluoride accumulation was merely delayed and storage to undesirable levels could not be prevented by the aluminum sulfate treatment. (Author summary modified)

Mohamed, Aly H.

CYTOGENETIC EFFECTS OF HYDROGEN FLUORIDE ON PLANTS. Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 2(2):76-84, April 1969. 8 refs.

Studies on the effects of hydrogen fluoride on meiotic chromosomes of tomatoes indicated a trend toward a higher frequency of chromosomal aberrations with an increase in the fumigation period. Hydrogen fluoride was shown to induce paracentric inversions with the possibility of deficiencies, duplications, or even translocations. The progeny of the treated plants, produced a number of abnormal phenotypes the same as, or similar to, known mutants. Further studies in maize microsporocytes for plants treated with HF confirm the cytological data reported for tomato plants. They offer clear evidence of inversions, translocations, and deficiencies. The results suggest that HF affects DNA synthesis by blocking, directly or indirectly, the replication of the DNA molecule. (Author summary modified)

Yopp, J. H., W. E. Schmid, and R. W. Hoist

DETERMINATION OF MAXIMUM PERMISSIBLE LEVELS OF SELECTED CHEMICALS THAT EXERT TOXIC EFFECTS ON PLANTS OF ECONOMIC IMPORTANCE IN ILLINOIS (FINAL REPORT).

Southern Illinois Univ., Carbondale, Illinois Inst. for Environmental Quality Proj. 10.022, Rept. 74-33, 281p., Aug. 1974. 525 refs. NTIS: PB 237654

A literature search on the toxic effects of various pollutants on plants of economic importance in Illinois is presented. The occurrence, uptake and accumulation, toxicity and toxic tolerances, visible effects, and economic consequences are outlined for aluminum, barium, beryllium, boron, bromine, cadmium, ethylene, chlorine, chromium, copper, fluorine, lead, manganese, mercury, molybdenum, nickel, nitrogen dioxide, peroxyacetyl nitrate, ammonia, nitrate, ozone, sodium, sulfur dioxide, sulfates, hydrogen sulfide, thallium, vanadium, and zinc. The degree of plant injury as a function of the source of the phytotoxic agent is also discussed. Recommendations for maximum permissible levels are given for both airborne and soil forms of the pollutants where possible.

STUDIES CONCERNING THE EFFECTS OF POLLUTANTS ON CROPS.

(Etudes concernant les effets des polluants sur les cultures). Text in French. Rev. Hyg. Med. Soc., 17(3):307-312, 1969.

Damage to crops and vineyards in certain areas of the Basses-Pyrenes was attributed to pollutants emitted by the industrial

<xref image="2000WVJU.TIF|V3|2006:09:28:01:36:30.00|113395|0"> image: </xref>

complex at Lacq, particularly to the sulfurous gas discharged by a desulfurization plant. Air measurements revealed the presence of SO₂ in the neighborhood of the factories and strong intermittent pollution at distant points. However, necrosis was observed on plants relatively resistant to SO₂-induced injuries and plant damage in the area of the factories is attributed to atmospheric fluoride components. In other areas, fluoride levels were not high enough to explain the necrosis. Laboratory studies indicate that fluoride and sulfur are normal components of plant tissues, so their presence is not a factor in determining pollution. Plants, especially apricot trees, are indicators of fluoride pollution. The acidity of rainwater cannot be assumed to have a direct relationship to plant damage. In controlled atmospheres, plants were enriched by subtoxic quantities of sulfur and fluorine. However, sulfur is metabolized by plants while fluoride is accumulated and can attain toxic levels.

Shupe, James L.

LEVELS OF TOXICITY TO ANIMALS PROVIDE SOUND BASIS FOR FLUORIDE STANDARDS. Environ. Sci. Technol., 3(8):721-726, Aug. 1969.

Fluorosis, a disease common to cattle, occurs when fluorine compounds are ingested for long periods of time. Hydrogen fluoride and silicon tetrafluoride are two phytotoxic gases encountered in air pollution which may accumulate on the vegetation eaten by livestock. There are no adverse effects on dairy cattle when the fluorine content of the daily ration is less than 30 ppm, while 40 to 60 ppm will result in moderate adverse effects. Acute fluorosis results from ingestion of 250 ppm fluoride and is characterized by stiffness, anorexia, weakness, high blood and urine fluoride, convulsions, and cardiac failure. Chronic fluorosis is typified by ingestion of 60 to 100 ppm fluorine/day, by severe dental malformations, and by bone lesions. Fluorine toxicity can be alleviated by administration of aluminum sulfate, aluminum chloride, or calcium carbonate, but the necessity for regulation of fluorine content in air water, food products, and soil is acute. A discussion by L V Cralley and John P. Jewell is included.

RESPIRATORY PATHWAY, FLOWER COLOR, AND LEAF AREA OF GLADIOLUS AS FACTORS IN THE RESISTANCE TO FLUORIDE INJURY. Botan. Gaz., 129(1):49-52, 1968. 13 refs.

Leaf disks from 36 varieties of gladiolus were supplied with either 1-C-14-labeled glucose or 6-C-14-labeled glucose. Ratios of C₆/C₁ were determined and correlated with the fluoride sensitivity ratings reported by Hendrix and Hall. Leaves of varieties which were sensitive to hydrogen fluoride generally had a higher C₆/C₁ ratio than leaves of varieties resistant to fluoride injury. The results provide circumstantial in vivo support of the hypothesis that the primary fluoride injury mechanism in intact leaves involves the inhibition of enolase. Resistant varieties may be somewhat more dependent on the pentose phosphate pathway and less dependent on the glycolytic pathway than sensitive varieties (Author abstract modified)

GROWTH RESPONSES OF PINTO BEAN AND ALFALFA TO SUBLETHAL FLUORIDE CONCENTRATIONS. Can. J. Botany, vol. 46:1207-1210, Oct. 1968. 12 refs.

A study was conducted to determine whether sublethal doses of fluoride impaired or stimulated the growth of Pinto bean and Ranger alfalfa plants. When bean plants were fumigated with fluoride, growth was accelerated and internode develop-

ment was conspicuously greater than in control plants. Fresh and dry plant weights were positively correlated with increasing fluoride content of the leaves. Statistically significant correlation coefficients of 0.91 and 0.98 were calculated between fluoride content and fresh and dry weights, respectively. When fluoride content exceeded approximately 200 ppm, weights decreased below those of the controls. Leaf chlorosis did not develop until foliar fluoride concentrations exceeded approximately 500 ppm. Fluoride sometimes stimulated growth of alfalfa, but results were inconsistent and no statistically significant relation existed between foliar fluoride content and plant weight. However, dry weight of fumigated plants whose foliar fluoride content exceeded 500 ppm was only 63% that of the control plants. No chlorotic or necrotic markings were observed on fumigated alfalfa plants. An understanding of the mechanisms for fluoride stimulation requires further investigation into morphological responses. REACTION OF SOME RELATIVELY RESISTANT PLANTS

TO SUDDEN INCREASE IN THE CONCENTRATION OF

FLUORINE EXHALATIONS. (Reakcia niektorých relativne rezistentných rastlín na narazové zvýšenie koncentrácie fluorových exhalacných splodín v okolí hliníkárne). Text in Slovakian. *Biologia*, 21(6):421-427, 1966. 19 refs.

Since 1961, annual studies have been conducted to determine the effect of fluorine emissions from an aluminum factory in the Hron valley, central Slovakia, on local vegetation. The checkered pattern of phytopathological symptoms observable on individual plants is the result of irregular diffusion and dispersion of pollutants, unequal intake of nutrients, and unequal physiological processes taking place in different parts of a plant. Different degrees of resistance to pollution encountered among plants of the same species are explained by plant location. In June 1964, large necrotic markings appeared on plant leaves, and the growth of plants relatively resistant to fluorine was inhibited. The spontaneous appearance of necrosis might have been provoked by a gradual accumulation of fluorine in the soil surrounding plant roots, finally reaching toxic levels, or by a sudden increase in fluorine concentrations emitted to both air and soil. The period of spontaneous necrosis was found to coincide with a period when, because of technical adjustments, factory emissions of fluorine were double the average of previous years. It is concluded that plants can serve as indicators of increased fluorine emissions resulting from modifications of electrolytic installations or breakdowns in operating procedures. Daines, Robert H., Eileen Brennan, and Ida Leone

AIR POLLUTANTS AND PLANT RESPONSE. *J. Forestry*,

65(6):381-384, June 1967. 15 refs.

The effects of a number of acid gases and photochemically-produced pollutants on plants are described. A great variation in susceptibility to damage by such gases as fluorides and SO₂

<xref image="2000WVJV.TIF|V3|2006:09:28:01:36:32.00|116023|0"> image: </xref>

exist both among plant species and within a single species. Injury from these gases occurs primarily to younger leaves, with little or no damage shown by old leaves. Symptoms usually consist of marginal and tip necrosis with accompanying discoloration of the affected areas. Limited studies with chlorine suggest that it is less phytotoxic than hydrofluoric acid, requiring about 0.1 ppm to injure the more sensitive plants. Among the photochemically-produced pollutants, ozone has been known for many years to be toxic to a wide variety of plant species; ozone toxicity symptoms appear as flecks, stipple, streaks, spots, and tip necrosis. Injury appears on mature leaves, with the oldest leaves of young plants and middle-aged leaves of old plants being most susceptible. Peroxyacetyl-nitrate (PAN) and its analogues are highly phytotoxic, producing symptoms called 'silver leaf' and 'leaf banding' in California, the northeastern U. S., and other urbanized areas. Like ozone, these compounds are believed to cause severe annual economic losses in crop damage. Investigations of damage caused by other photochemical pollutants, namely ozonated hydrocarbons, bisulfite reaction products, and nitrogen dioxide, are briefly summarized, and the major sources of all the pollutants discussed are noted.

MacLean, D. C., O. F. Roark, G. Folkerts, and R. E. Schneider

INFLUENCE OF MINERAL NUTRITION ON THE SENSITIVITY OF TOMATO PLANTS TO HYDROGEN FLUORIDE. Environ. Sci. Technol., 3(11): 1201-1204, Nov. 1969. 10 refs.

The influence of calcium, magnesium, and potassium on growth, fluoride accumulation, foliar injury, flowering, and fruiting of tomato plants exposed to gaseous hydrogen fluoride was tested. Tomato plants grown in sand culture and provided with a complete nutrient solution or solutions deficient in calcium, magnesium, or potassium were exposed to concentrations of hydrogen fluoride from 0 to 15.1 micrograms/cu m for periods of three, five, or 64 days. In magnesium-deficient plants, HF exposure resulted in a reduction in the dry weight of both tops and roots and an increase in the severity of magnesium deficiency symptoms on basal leaves. Foliar accumulation of fluoride was suppressed by magnesium deficiency. The effects of HF exposure on calcium-deficient plants were characterized by reduced top growth, increased foliar chlorosis, and an enhancement of necrosis on apical leaves. Fluoride accumulation was unaffected by calcium nutrition. The responses of potassium-deficient plants to HF were limited to increases in F accumulation and in necrosis on apical leaves. The differential responses of the elements to HF exposure were ascribed to differences in their mobility within plant tissues, the stability of fluoride salts formed, and/or their metabolic roles. Yu, Ming-no and Gene W. Miller

EFFECT OF FLUORIDE ON THE RESPIRATION OF LEAVES FROM HIGHER PLANTS. Plant Cell Physiol. (Tokyo), vol. 8:483-493, 1967. 28 refs.

The effect of fluoride on the respiration of leaves from *Chenopodium murale* and soybean (*Glycine max*, Merr., Hawkeye variety) was studied to establish whether respiration changes induced by fluoride could be correlated with ADP concentration by the use of 2,4-dinitrophenol (2,4-DNP) as an uncoupler. Fluoride treatment included both excised leaves cultured in nutrient solutions and leaves from plants fumigated with hydrofluoric acid atmosphere. Tissues treated with low fluoride concentrations which initially showed increased oxygen uptake eventually showed decreased oxygen consumption. Tissues treated with a high concentration of fluoride showed an increased oxygen uptake if analyzed soon after treatment initiation. Increase in respiration generally took

place before visible damage was manifested. Decrease in respiration was correlated with pronounced injury of tissues. Besides concentration of fluoride and the time lapse of treatment, the pH of the culture solution in which fluoride was supplemented, tissue age, and plant species were important factors affecting respiration. For example, the fluoride effect was greater at pH 4.5 than at other values tested and stimulation of respiration by fluoride was greater at all pH values when inorganic phosphate was added. The effect of 2,4-DNP on respiration was very similar to that of fluoride in that the effect differed with pH, concentrations, time of treatment, leaf age, and plant species. The respiration of fluoride-treated leaves was stimulated less by 2,4-DNP than that of control leaves. (Author abstract modified)

Treshow, Michael, Franklin K. Anderson, and Frances Harner

RESPONSES OF DOUGLAS-FIR TO ELEVATED ATMOSPHERIC FLUORIDES. Forest Sci., 13(2):114-120, 1967. 8 refs.

The response of Douglas fir trees to fluorides was studied near a phosphate reduction plant in Idaho, where about 200 acres of timber had been killed. Study trees, selected at increasing distances from the operation, were placed into groups according to the average fluoride content of the leaves. Radial growth, needle length, and dry weight of the trees in the various groups were compared before and during the operations. Radial growth of trees with a fluoride concentration under 50 ppm (the controls) was greatest when the phosphate plant was operating; at higher concentrations, radial growth was the least during operations, and significantly less than in the controls, even in the absence of leaf necrosis. Normal growth resumed following the closing of the phosphate plant. Needle growth followed an opposite pattern. Needle length was positively correlated with fluoride levels and negatively correlated with radial growth. Stimulation of needle elongation appeared to be the easiest response of needles to fluorides. Growth suppression was evident at higher concentrations. Needle burning and mortality developed when fluoride concentration of the leaves exceeded several hundred ppm. (Author abstract modified)

DISPERSION OF FLUORINATED GASES IN THE CENTRAL VALLEY. (La dispersion des gaz fluorés dans le Valais central). Text in French. Agr. Romande. Ser. A, 4(5):33-36, 1965.

The movement of air masses in the Rhone Valley, based on topography, have a considerable effect on the location and the amount of fluoride pollution from the aluminum plants in the area. A map of the Rhone Valley indicates that the area of greatest pollution seems to be on the south side of the valley near the town of Martigny. Fluoride levels were determined in plants at varying distances from the source of pollution. In general, plants in the Martigny area seemed to have the highest fluorine content; the highest fluorine samples were from trunks of poplar trees in the Martigny area. High levels were also recorded in pear trees, potatoes, and apricots in the same area.

FLUORIDE ACCUMULATION IN LEAVES DUE TO BORON-

CONTAINING FERTILIZERS. Fluoride Quarterly, J. Intern.

Soc. Fluoride Res., 2(4):222-228, Oct. 1969. 7 refs.

In Switzerland's Rhone Valley, apricot orchards and vineyards exposed to F(-) emissions from aluminum and phosphate fertilizer factories display typical fluoride-induced necroses of the foliage. Up to 600 ppm F(-) in dry matter is present in the plant tissue but, the damage is limited to a few strictly circumscribed, individually owned parcels of land. Field and pot-culture experiments showed that the high F(-) content in the plants resulted from boron-containing combined fertilizers obtained by direct reaction of sulphuric acid or nitric acid upon raw products. A particular chemical combination containing fluorine and boron is formed in the fertilizer during the manufacturing process. The action of this special combination is similar to that of potassium fluoroborate. Experiments on beans conducted in a greenhouse with several fertilizers, including the special combined boron-containing fertilizer, proved that F(-) could be partially eliminated by washing the leaves with water. The boron content of the same tissues remained unchanged by washing, suggesting that F(-) penetrates plants through the roots.

Halbwachs, Gottfried and Josef Kisser

DWARFISM IN FIRS AND BIRCHES CAUSED BY SMOKE

IMMISSIONS. Centralblatt fuer das gesamte Forstwesen, 84(2-

6):156-173, 1967. 34 refs. Translated from German. 29p.

A morphological and anatomical study of dwarfed varieties of Norway spruce and birch was made. Dwarfism was exclusively caused by the effect of fluorine containing emissions. This influence was exerted directly on the needles and leaves wherein the development was inhibited and the numbers were reduced as a consequence of chronic and acute damage. The metabolism was directly reduced as well as the assimilation performance of the cells that remained intact. The establishment of trees was only possible because of the protecting influence of the neighboring vegetation of lower plants. As soon as individual branches began to grow above this protecting layer, they reached the immediate zone of influence of emissions and died off. This process, repeated every year, prevents a height gain and leads to a dense, bushy growth. The shape of the dwarfed birch is caused by elongation of basal buds. The size of the needles and leaves was greatly reduced particularly on the weather side which was in direct contact with the fluorine emissions. The reduction was due to a decrease in number as well as the size of the cells. Both varieties had considerably more pitch rays which were considerably lower in height. The number of ray cells per unit area was increased as compared to normally developed spruce trees. With birch, this was not found; however, the ray cells were generally narrower and lower. Further study is needed to learn whether such changes in the number of ray cells per surface unit are specific only for coniferous trees or whether they represent a general characteristic of the wood structure of dwarfed tree forms due to different factors.

Garber, K.

THE IMPORTANCE OF AIRBORNE SALT AEROSOLS TO

PLANTS. (Ueber die Bedeutung der Salzaerosole in der Luft

fuer die Pflanzen). Text in German. Zentr. Aerosol-Forsch.

(Stuttgart), 12(1):24-33, June 1964. 29 refs.

Plant damage, observed after heavy storms on the coast of the North Sea, raised the question of possible injury by salt aerosols. The present knowledge of the effects of salts on plants is discussed. Numerous papers point out that sodium fluoride in 0.2% solution kills the leaves of trapa, elodea and

vallisneria within 24 hours, and a 0.025% solution has an adverse effect on germination. NaCl solutions (0.5 to 1%) cause hardly any injury, while KCl in 0.25 to 0.5% solution injures bean plants; KCL03 in 0.01 and 0.025% solution is toxic. Ammonia may harm plants in liquid as well as in gaseous states; NH₄OH is harmful even in 0.01% solution. As has previously been pointed out, Cl, Na, Mg, Ca, K, NH₃-N.B, etc. in weak concentrations serve as plant nutrients. The sensitivity of the various plants to salt solutions differs. Of the most common plants cultivated in Germany, summer barley is least sensitive; beans are highly sensitive; and leaves of plum trees are particularly sensitive. To test whether salt aerosols are as damaging as salt solutions, test plants were exposed for half an hour to the following salt aerosols in 5% solutions: Na₂CO₃, K₂SO₄, NaNO₃, NaCl, NaF and sea salt. Of these, NaF, NaCl, and sea salt had an injurious effect. The leaves were burned on the rim and began to roll up. NaCl discolored the needles of the picea excelsa. A table lists in detail all injuries observed on the various plants tested (begonia semperflorens, valerianella, gomphreno, lupinus luteus, picea excelsa).

A STUDY OF THE INTAKE OF TOXICANTS THROUGH

THE BARK OF TREES. (Ueber die Aufnahme von Schadstoffen durch die Rinde der Bäume). Text in German. Wiss. Z. Tech. Univ. Dresden, 11(3):549-552, 1962. 12 refs.

The retention of fluorine and its compounds in the bark of trees is discussed. Analysis of the barks of willows, poplars and alders stemming from the vicinity of a superphosphate plant showed considerable amounts of fluorine; hardly any traces were found in the wood. The quantitative analysis of fluorine by perchloric acid distillation showed that a relationship exists between the fluorine content in the bark and the distance of the emission source. Gassing experiments with hydrofluoric acid on three-year old barren trees and cut branches in the winter showed that the fluorine content rose to between 33 and 65 mg in 100 g dry substance, depending on the exposure time; 1.71 to 4.28 mg fluorine was found in the wood. In non-exposed trees, fluorine concentrations of 0.9 to 1.6 mg in the bark and 0.2 to 0.3 mg in the wood were found. A further series of gassing experiments with trees during the winter period showed that the fluorine content of the leaves was twice or three times as high as that of non-exposed trees. Maple leaves from trees whose bark was treated with a 1% sodium fluoride solution also showed an increased fluorine concentration. Trees in the vicinity of a tar and asphalt plant stored higher concentrations of tar containing substances in the bark and, to a less extent, in the wood. Barren trees in the winter were exposed to ammonia. NH₃ could be found in the bark; it was not found in the wood.

EXPERIMENTAL STUDIES OF PHYTOTOXIC HYDROGEN

FLUORIDE CONCENTRATIONS. (Experimentelle Unter-

suchnungen ueber pflanzenschaedigende Fluorwasserstoff-Konzentrationen). Text in German. Forschungsber. Landes Nordrhein-Westfalen, no. 2017:54p., 1969. 48 refs.

The resistance of important plant cultures to hydrogen fluoride and the HF concentrations which cause plant injuries at long-

<xref image="2000WVJX.TIF|V3|2006:09:28:01:36:40.00|126340|0"> image: </xref>

term exposure were determined. The test plants were exposed to certain HF concentrations in small plastic greenhouses. Studies of the resistance of certain agricultural and forest plants lead to the formation of various resistance groups which are important for diagnosis as well as for the selection of plants for cultivation in HF polluted areas. For diagnosing purposes, the resistance groups were established with respect to leaf resistance; the yield was used as a criteria for establishing resistance groups in the planning of plant cultures. Tuberous plants e.g., tulips, crocusses, narcissas, etc., are not suitable for cultivation in HF polluted areas. Peas, beans and lupines showed a higher yield reduction than oats, corn, and summer rap. HF pollution might lead to drastic changes, such as reduction of less resistant plants which in turn enhances the growth of resistant species. Concentrations of 1 to 2 microgram HF/cu m caused severe injuries in tuberous plants after several days of exposure. In grasses and various types of clovers, a fluorine accumulation of 9 mg/100 g dry substance was found at a 16 day exposure to an average concentration of as little as 0.85 microgram HF/cu m. Winter barley showed a yield reduction after 12 days of exposure to 3.3 microgram HF/cu m. Oats, lupines, and peas showed a growth retardation at concentrations above 4 microgram HF/cu m. Spruces, Weymouth pines, Japanese lark, and Nordmann hemlocks began to show needle injuries after several days of exposure to concentrations between 1.5 and 4 microgram HF/cu m. Older leaves generally showed higher fluorine accumulations than young ones.

Thomas, Moyer D.

AIR POLLUTION WITH RELATION TO AGRONOMIC CROPS: I. GENERAL STATUS OF RESEARCH ON THE EFFECTS OF AIR POLLUTION ON PLANTS. Agron. J., vol. 50:545-550, 1958. 39 refs.

Plant damage caused by sulfur dioxide, fluorine compounds, and smog is summarized. Sulfur dioxide causes two types of leaf injury: acute and chronic. The acute markings are marginal or interveinal collapse areas; their color is usually ivory. The chronic markings are areas of limited cell injury but not total collapse; the colors range from yellow to brownish-red to white and represent fumigation treatments or prolonged exposure to low concentrations. No reduction in yields have been demonstrated in plants exposed to sulfur dioxide unless there was leaf injury. The fluoride pollution problem as two aspects: direct injury to commercial and ornamental plants and the risk of fluorosis in cattle and sheep exposed to contaminated vegetation. Hydrogen fluoride and silicon tetrafluoride are extremely toxic to a few plant species. Hydrogen fluoride in ppb concentrations cause lesions resembling those due to sulfur dioxide. Photosynthesis experiments, the results of which are presented in tables and graphs, indicate that each crop has its own threshold limit which varies from 5 ppb for gladiolus to about 500 ppb for cotton. Smog damage to vegetation is of two kinds: that produced by London coal smoke or fog containing sulfur dioxide; and Los Angeles smog, which is a mixture of oxidants. California smog injury tends to appear as a band on a leaf. Owing to the presence of organic compounds, ozone damage is rarely found in the field. The question remains open whether leaf damage from London fog is due to sulfur dioxide or to other toxicants.

Hill, A. C., L. G. Transtrum, M. R. Pack, and W. S. Winters

AIR POLLUTION WITH RELATION TO AGRONOMIC CROPS: VI. AN INVESTIGATION OF THE 'HIDDEN INJURY' THEORY OF FLUORIDE DAMAGE TO PLANTS. Agron J., 50(9):562-565, 1958. 15 refs.

Moscow and Loren Blood tomato plants were injected with hydrogen fluoride for approximately four weeks, and the effect of fluoride exposure on the photosynthetic rate, respira-

tion rate, and chlorophyll contents of the plants were determined. The fluoride concentrations used were higher than are likely to be encountered around fluoride-emitting factories. Extremely high fluoride levels accumulated in the foliage under high fluoride treatment, but only small amounts in the fruit and peeling. The fluoride treatment, even at the highest levels, did not affect photosynthetic rates. Growth and vigor of thy plants were excellent under all treatments, while fruit size and set were good. Plant height was unaffected. The chlorophyll contents of the leaves and the respiration rate of the treated plants were not significantly higher than in control plants. The results strongly indicate that hidden injury to crops does not occur at the levels of gaseous fluoride present in the atmosphere around modern industries.

Takehara, Hideo

EFFECTS OF AIR POLLUTION ON PLANTS!. Preprint, no source given, 4p., 1968 (?).

Current and recommended future research studies by Japanese investigators on the effects of air pollution on plants are reviewed. Local universities and agricultural research stations are emphasizing studies of the possible damage caused by sulfur dioxide, hydrogen fluoride, chlorine, and chromium from industrial sources to farm crops, tea, fruit, forest and mulberry trees, and young silkworms. Systematic basic research is being carried out by national research institutes on such problems as the symptoms and mechanism of injury to crops exposed to HF, and on atmospheric diffusion phenomena; a program is also in the planning stages to study nationally the effects of pollutants on the flowering and fruiting of plants near factories and power stations and in urban green belts. A number of subjects are proposed for high priority in future research planning: these include chronic damage to plants from long-term, low-concentration exposure to pollution as opposed to the more readily known acute symptoms; effects of such pollutants as ozone, nitrogen compounds, and ethylene; improvement of the methodology of field observations and gas chamber tests; the variables in the plants themselves that affect their susceptibility to damage; control methods, including fertilizer improvements, planting and cultivation methods, and shading; selection of smoke-resistant species of various plants; and a listing of indicator plants in urban environments.

Hill, A. C. and M. R. Pack

OCCURRENCE OF FLUORIDE IN PLANTS AND ITS EFFECTS. Preprint, 72p., 1960 (?). 113 refs. (Published as a chapter in the book 'A Summary and Evaluation of the Problem of Air Pollution With Fluoride'. C. S. Brandt (?d.), U. S. Dept. of Agriculture.)

The available data on the relationship of atmospheric fluorides to plants is reviewed and evaluated. Fluoride occurs naturally in plants but is present in elevated levels in locations near certain industrial emitters. In contrast to the relatively low amounts of fluoride normally taken up from the soil, leaf concentrations of several hundred ppm have been reported for crops near fluoride emitters, entering the leaf primarily through the stomata. The rate of accumulation is apparently proportional to the atmospheric concentration of fluoride; the

<xref image="2000WVJY.TIF|V3|2006:09:28:01:36:42.00|122969|0"> image: </xref>

amount of fluoride in the plant is directly related to the exposure factor CT (concentration times time). The amount of fluoride deposited on or absorbed by the vegetation on a given area of land during a given time period tends to be constant; therefore, the greater the amount of vegetation present, the lower its probable fluoride concentration. Accumulation varies with species; tomato, potato, raspberry, carrot, larch, and pepper leaves show high levels while pine, fir, corn, laurel, rose, and gladiolus tend to be low. Rain is effective in reducing the fluoride content of vegetation; other sources of loss are under study. Samples collected in connection with injury studies are generally limited to the leaves, the usual site of damage. Periodic sampling of the forage being consumed by livestock is essential. Sampling methodology, the distribution of fluoride within the plant, and variables affecting plant susceptibility are discussed. Atmospheric fluoride concentrations in emitting locales usually average from a few hundredths to 2 or 3 micrograms/cu m. The forms emitted include hydrogen fluoride, cryolite, calcium fluoride, and silicon tetrafluoride. It appears that gaseous fluorides are much more phytotoxic than particulate emissions. In general, the gross symptoms of fluoride injury consist of necrotic leaf lesions; other signs of damage are reviewed in some detail for various types of plants. The effects of fluorides on growth and yield, tissue destruction, photosynthesis rates, inhibition of enzymes, respiration, and chlorophyll are discussed, and suggestions for future research are made.

Yamazoe, Fumio

SYMPTOMS AND MECHANISM OF INJURY TO CROPS EX-

POSED TO HYDROGEN FLUORIDE. (Fukkasuiso myoru

engai no jittai narabini kisaku nikansuru kenkyu). Text in

Japanese. Nogyo Gijutsu Kenkyusho Hokoku, Dojo. Hiryo (Bull.

Natl. Inst. Agr. Sci. Ser. B), no. 12:1-125, Feb. 1962. 111 refs.

The effect of hydrogen fluoride on the growth and yield of the

main crops of Japan and the typical symptoms and mechanism

of injury was studied, as well as a method for reducing injury.

A fumigation chamber was built in which several crops were

grown in Wagner's pots and exposed to hydrogen fluoride

which was colorimetrically determined with aluminum he-

matoxylin. A significant decrease in yield was obtained with 25

ppm HF for paddy rice or barley and 50 ppm HF for wheat

after fumigation for 1 hr. It was also found that the amounts

of nitrogen, silicon, and fluorine was related to injury. Injury

was more severe under high humidity and in daylight. Symp-

toms of fluorine toxicity in paddy rice were tip and marginal

scorching of the younger expanded leaf, greyish green color of

the terminal leaf, and wilting and yellowish brown color after

two days. Chlorophyll in the parenchyma was decolorized,

cytoplasm and cell membranes were decomposed, and the in-

jured part was chlorotic. The amount of transpired water was

reduced, carbon assimilation almost ceased, respiration was

accelerated, pH was lower, and nitrogen assimilation was re-

tarded. A recommended method of preventing plant injury was

to avoid excessive application of nitrogen fertilizers, add sub-

stantial amounts of silica to the nitrogen supply, and spray a

lime-suspension at the ear-forming, heading, or flowering

stage. The comparison of susceptibility to HF was made with

up-land and low-land rice, soybean, rape, garden radish, and

Chinese rape. Rape was indifferent, and up-land rice was more

sensitive than low-land rice. Soybean was very sensitive;

garden radish and Chinese rape showed symptoms of injury at

concentrations as low as 10 ppm HF. From the results of in-

frared absorption and solubility data, it was supposed that

fluorine exists chiefly as a slightly water-soluble fluosilicate in

the injured part of Gramineae and as a water-insoluble calcium

fluoride in Leguminosae or Cruciferae.

THE RELATIVE SUSCEPTIBILITY OF SOME POPULAR VARIETIES OF ROSES TO FLUORIDE AIR POLLUTION.

Proc. Am. Soc. Hort. Sci., vol. 91:771- 776, Dec. 1967. 9 refs. The relative sensitivity of various popular rose varieties to fluoride air pollution was studied. Fourteen varieties of hybrid roses were exposed to 2 ppb by weight F as HF for 6 months under controlled conditions in specially equipped greenhouse exposure chambers. All of the varieties used exhibited symptoms of F toxicity, but there was considerable variation in response among the varieties. Dry weights of tops were significantly reduced as a result of the F treatment in most varieties but this reduction in top weight was accompanied by an increase in total linear growth in 3 varieties. Foliar symptoms of F toxicity ranged from mild interveinal chlorosis to severe marginal necrosis. Of the varieties tested, 3 become chlorotic, 5 others exhibited slight to moderate marginal necrosis patterns and the remaining 6 developed both chlorosis and necrosis patterns as a result of exposure to HF gas. An apparent stimulation of shoot growth by exposure to HF resulted in more compact, dwarf-like plants with many weak branches. In some cases this resulted in more blooms per plant, but the flowers produced were of poor quality with short, weak, stems. Most of the F absorbed by the rose plant accumulated in the foliage. Stems and flowers contained one tenth to one twentieth as much F, respectively, as the leaves. (Author abstract modified)

INFLUENCE OF FACTORY SMOKE ON LICHEN DISTRIBUTION IN THE ROMANCHE VALLEY (ISERE). (Influence des fumees d'usines sur la distribution des lichens dans la vallee de la Romanche (Isere)). Text in French. Pollut. Atmos. (Paris), 10(38):95-99, April-June 1968. 15 refs.

Four manufacturing plants produce pollutants in the Romanche Valley, between Le Roure-d'Oisans and Vizille; one produces hydrogen fluoride and three produce particulate matter. The plant farthest down the valley produces calcium carbonate and gives off smoke, the solid matter of which consists of 50% calcium oxide and oxides of magnesium, silicon, iron, aluminum, and carbon. The second and fourth factories produce ferro-alloys and calcium carbonate and have similar pollutants. The third factory is an aluminum plant and produces fumes of hydrogen fluoride and other fluorides. Micrometeorological studies showed that the direction of the smoke was usually up-valley, with local and minor variations. The pH of the snow fall in the region of the factories averaged about 10, with values of 11.2 and 12.2 registered during February 1965 and December 1966. The pH of the rain averaged 10, and the pH of the bark of trees growing near the factories was also alkaline. Bark from similar trees near Grenoble had an acid pH. Rock surfaces in the area were covered with a gray-blue patina. Three zones of lichen growth were identified: poor growth of toxitolerant and coniophile lichens, up to approximately 500 meters from the factories; a transition zone; and a 'normal' zone, the boundaries of which varied within wide limits, but were approximately 1 km from the factory. Growth in the third zone corresponded to that in non-polluted areas. A list of lichen species identified is presented.

 INORGANIC FLUORIDE PROPELLANT OXIDIZERS.
 VOLUME II. EFFECTS UPON MICROORGANISMS, FISH,
 AND PLANTS. Oregon State Univ., Corvallis, Science Research
 Inst., Contract AF 33(61S)-1767, Proj. 6302, Task 630204,
 AMRL-TR-187 (vol II), 59p., Nov. 1968. 7 refs. CFSTI, DDC:
 AD 684176

The effects of the inorganic fluoride oxidizing agents (chlorine trifluoride, chlorine pentafluoride, bromine pentafluoride, oxygen difluoride, nitrogen trifluoride, and tetrafluorohydrazine) upon selected species of microorganisms, fish, and plants were studied. Interhalogens were directly injected into water in a closed vessel to provide a reaction mixture. The biological activity of accidentally released chemical agents cannot be studied without considering their reactions with soil, the atmosphere, and the aqueous phase of the environment. Whether gaseous intoxicants can contact biological species resident in aquatic media or soil depends on the probabilities of dispersion of any given gas and for its affinity for and/or reactivity with the physical substrate. Each of the compounds studied is a candidate oxidizer for missile propulsion. In acute exposure of less than 1 hour, the interhalogens, as gases, were destructive to plants at atmospheric concentrations of 10-30 ppm; in aqueous solution, they were lethal to fish and microorganisms at concentrations of 10-25 micrograms fluoride per milliliter. The latter effects resulted from formation of inorganic acids and various oxidizing species, either of which is lethal alone and which can be neutralized by basic compounds and reducing agents and by filtration through soil. Oxygen difluoride was toxic to plants at concentrations in air as low as 1.5 ppm over a 30-min exposure period but had no effect upon aquatic species. Nitrogen trifluoride and tetrafluorohydrazine are nearly innocuous to nonmammalian organisms. (Author abstract modified)

 Translated from Czech. Franklin Inst. Research Labs., Philadel-
 phia, Pa., Science Info. Services, 17p., April 1969.
 Investigations of smoke damage in the Annaberg, Marienberg,
 Freiberg, Tharandt, and Pirna National Forests of
 Czechoslovakia from 1964 to 1966 are described; spruce
 covered 85% of the area surveyed. Analysis of tree rings by
 borings showed a significant decrease in growth rates of
 spruce stands in the last 10 years. Spruce fascicles were
 shown to have the ability to store sulfur, but no relationship to
 the degree of tree damage was established. Analysis of the
 fluorine content in bark and of variations in acidity of the
 humus layer were also carried out, the degree of acidity does
 not appear to be correlated with the degree of injury. Trace
 elements found in the humus were in concentrations too small
 to be phytotoxic. A survey of existing and planned emission
 sources was made, including nearby areas of Germany, and a
 permanent network of 12 measurement stations for continuous
 atmospheric samplings of sulfur dioxide and dust was
 established along the border between Fichtelberg and Elbe; the
 stations will also make relevant meteorological observations.

EFFECTS OF VARIOUS FLUORIDE SOURCES ON CITRUS
GROWTH AND FRUIT PRODUCTION. Environ. Sci.
Technol., 3(4):378-381, April 1969. 10 refs.

The effects of fluoride accumulation by citrus trees were studied using several techniques of exposing the trees to soluble fluorine compounds. Weekly sprayings with dilute (0.00125 to 0.0025N) NaF or HF solutions resulted in gradual fluoride accumulation in citrus foliage and produced toxicity symptoms which were indistinguishable from those observed on similar trees exposed to low concentrations of HF gas. Results of intermittent exposure of young citrus trees to HF gas were very similar to those associated with comparable fluoride accumulation from weekly sprayings with NaF or HF solutions. Reduction in top growth of citrus exposed to soluble fluorides was closely correlated with reduced photosynthetic area resulting from smaller leaves and increased leaf fall. Continuous exposure to HF gas resulted in more severe growth retardation than intermittent exposure to higher concentrations or periodic sprayings with soluble fluorides even though approximately equivalent amounts of F were absorbed in all tree treatments. Mohamed, Aly H.
CYTOGENETIC EFFECTS OF HYDROGEN FLUORIDE ON
PLANTS. Fluoride Quart. Repts., 2(2):76-84, April 1969. 8 refs.

Studies on the effects of HF on meiotic chromosomes of tomatoes indicated a trend toward a higher frequency of chromosomal aberrations with an increase in the fumigation period. It was indicated that HF was capable of inducing paracentric inversions with the possibility of the induction of deficiencies, duplications, or even translocations. The progeny obtained from the treated plants produced a number of abnormal phenotypes, the same as, or similar to, known mutations. Further studies in maize microsporocytes for plants treated with HF confirmed the cytological results obtained in tomatoes with clear evidence of the occurrence of inversions, translocations and deficiencies. These results suggest that HF seems to affect primarily the DNA molecule by blocking its replication, probably through its action on the enzymatic systems. (Author's Summary)

Weinstein, Richard H. Mandl, and George N. Woodruff
EFFECTS OF ACUTE HYDROGEN FLUORIDE AND
NITROGEN DIOXIDE EXPOSURES ON CITRUS AND OR-
NAMENTAL PLANTS OF CENTRAL FLORIDA. Environ. Sci.
Technol., 2(6):444-449, June 1968. 11 refs.

<xref image="2000WVK0.TIF|V3|2006:09:28:01:36:50.00|118450|0"> image: </xref>

Six citrus varieties and six ornamental species of economic importance to central Florida were subjected to high concentration-short duration exposures of gaseous hydrogen fluoride or nitrogen dioxide. Postfumigation observations showed that the effects of acute pollutant exposures differed markedly from those of chronic exposures. Hydrogen fluoride exposures of 0.5 to 10 ppm for periods of from 0.5 to 8 hours induced tip, marginal, and intercostal chlorosis and necrosis, and abscission of leaves of most plants tested. Symptoms were most severe on, but not limited to, young leaves. The effect of duration of exposure had a greater influence on abscission of young citrus leaves than did HF concentration. However, the effect of HF concentration on foliar F accumulation could not be separated from exposure time. The NO₂ concentrations used ranged from 25 to 250 ppm for periods of from 10 minutes to 8 hours. Nitrogen dioxide damage was characterized by rapid tissue collapse, necrosis, and defoliation. Symptoms were sporadic in appearance, affecting leaves of all ages. The relative contributions of concentration and duration to NO₂ induced injury were about equal (Author abstract modified)

CHRONIC DISCOLORATION OF LEAF TIPS OF GLADIOLUS AND ITS RELATION TO THE HYDROGEN FLUORIDE CONTENT OF THE AIR AND THE FLUORINE CONTENT OF THE LEAVES. Neth. J. Plant Pathol., vol. 73:25-28, 1967. 5 rets.

The gladiolus variety Snow Princess, which is very susceptible to hydrogen fluoride, was used in field experiments to investigate the correlations between traces of HF occurring in the atmosphere, gradually developing leaf tip injury, and fluorine content of injured leaves. Seven experimental fields were laid out for investigation, one in an industrial area near the sea; one far from any industry but at the same distance from the sea; three on different soil types in Wageningen; and two in pollution free areas. At regular intervals, the plant injury was estimated by measuring the length of leaf tip injury. Fifteen cm lengths of injured leaf tips were cut and analyzed for their fluorine content. The average HF pollution in the atmosphere was estimated by using filter papers soaked in Ca(OH)₂. Fields where HF concentrations were low displayed very slight and very gradually developing leaf tip injury. In the four fields with measurable pollution, more serious injury occurred. The content of HF in the atmosphere also correlated with the fluorine content of the damaged leaf tips. It was concluded that leaf tip injury was caused by HF.

INFLUENCE OF AIR POLLUTION ON CROP PLANTS IN SOME INDUSTRIAL AREAS IN THE NETHERLANDS. (Invloed van luchtverontreiniging op land- en tuinbouwgewassen in cf nabijheid van enkele industriecentra in Nederland). Text in Ditch. Inst. of Phytopathological Research, Wageningen (Netherlands), Rept. 217, S8p., 1957 (?). 8 rets.

Prompted by serious damage to plant bulbs caused by air pollution in an area northwest of Amsterdam, the Institute of Phytopathological Research conducted a study in that area and two other relatively large areas: west of Rotterdam and east of Sluiskil (Zeeland, near the Belgian border). A field investigation was first made, using specially controlled flower beds of gladiolus and alfalfa, which are particularly sensitive to hydrogen fluoride and sulfur dioxide, respectively, these two industrial gases being considered the most dangerous to plant growth. Distribution of the intensity of damage on the experimental plots indicated the direction taken by the noxious gases, their manner of propagation, and the extent of damage caused. Damaged leaves were then analyzed chemically for

fluorine or sulfur content. Commercial crops were compared with those experimentally grown, and crops from areas known to be free of pollution were compared with those from the affected areas. Plants were also 'fumigated' at the Wageningen laboratory, under simulated practical conditions. Comparisons were made of varieties of the two kinds of plants that were known to be either sensitive or insensitive to the industrial gases. The freesia plant, which suffered extensive damage in Dutch greenhouses during autumn 1956, was also tested in the gas chambers. Two varieties of tulips were tested: Blue Parrot, which is sensitive to gases, and Preludium, which is not. Other plants tested were barley, broad beans, kidney beans, corn, lettuce, buckwheat, sugar beets, tomatoes, loosestrife, and knotgrass.

EFFECT OF VARIOUS LEVELS AND SOURCES OF FLUORINE IN THE FATTENING RATION OF COLUMBIA, RAMBOUILLET, AND TARGHEE LAMBS. J. Agr. Food Chem., 6(5):365-368, May 1958. 17 refs.

Ninety weanling wether lambs consisting of equal numbers of Columbia, Rambouillet, and Targhee breeds were used to study the effects of fluorine. Throughout the 14 week trial, the lambs were fed to maintain designated fluorine levels based on hay consumption. Two sources of fluorine were used: sodium fluoride added to normal hay; and hay containing a fluoride residue from the stacks of industrial plants. When the hay containing up to 160 ppm fluorine was mixed with varying amounts of grain, fluorine levels of 14, 18, 32, 58, and 112 ppm were achieved in the dry diet. Results showed that fluorine up to 112 ppm had no effect on feed consumption, weight gain, market grade, dressing percentage and pelt weights, carcass weight and grade, clinical and histological effects, wool weight, fiber and staple length, and fiber diameter. It was concluded that lambs can be fattened on hay containing at least 160 ppm fluorine when it is fed with 50% grain, provided the total dry matter consumed does not contain more than 112 ppm fluorine

Adams, Donald F.

RECOGNITION OF THE EFFECTS OF FLUORIDES ON VEGETATION. Air Pollution Control Assoc., 13(8):360-362, Aug. 1963. 25 refs. (Presented at the 29th Annual Pacific Northwest Pollution Control Association Meeting in cooperation with the Pacific Northwest International Section of APCA, Oct. 24-27, 1962. Salem, Ore.)

A review of the problem of recognizing the effects of fluorides on vegetation is largely confined to discussing the methodology for establishing the effects of fluorides and other air pollutants on plants, particularly on commercially grown plants, describing reported methods of protecting plants from airborne fluoride molecules, and of methods of removing fluorides from leaf tissue by washing. Basic to a discussion of air pollutants is the defining of 'effects' The effects of greatest concern are injuries which damage the plant for its intended use. Injury embraces all plant responses resulting from the action of the air pollutant, including alterations in assimilation rate on plant constituents, leaf necrosis, leaf or fruit abscission, or reduced or altered growth. Damage, on the other hand includes only

<xref image="2000WVK1.TIF|V3|2006:09:28:01:36:52.00|122603|0"> image: </xref>

those forms of injury which change significantly the value of the plant in relation to its intended use. In the specific situation of alleged vegetation injury from airborne chemicals, the following experimental steps, based on Koch's Postulates for scientific investigative procedure (originally developed for study of bacterial infection) must be undertaken: 1) chemical analysis of the air must show that the particular chemical agent is always associated with the particular diseased condition; 2) chemical analysis of the plant tissue must show that the particular chemical agent is always present in elevated concentrations; the same species and varieties of plant must be exposed under controlled conditions to the suspected agent in the same range of concentrations found in experimental step No. 1, in the sense that the exposed plants must develop the same symptoms as observed in the field; 4) chemical analysis of the air and the exposed tissue from step No. 3 must compare with the levels found in steps No. 1 and No. 2.

Berry, Charles R. and George H. Hepting
INJURY TO EASTERN WHITE PINE BY UNIDENTIFIED
ATMOSPHERIC CONSTITUENTS. *Forest Sci.*, 10(1):2-13,
1964. 16 refs.

A general decline of *Pinus strobus* L. in the Cumberland Plateau of Tennessee was determined, by an aerial survey, to be in the Kingston-Oak Ridge-Rockwood-Harriman industrial area. This disease, called post-emergence chronic tipburn, was also found in other industrial areas, including some which contained coal-burning power plants. Root and stem isolations yielded no primary pathogens. Pruning and fertilizing sometimes brought about improved vigor, but did not affect occurrence of needle tipburn, a primary symptom. Diseased trees transplanted out of the affected area recovered, while trees transplanted within the affected area continued to decline. Trees differed greatly in their susceptibility to the disease. Scions from susceptible trees displayed symptoms year after year, even when grafted to resistant trees in the affected area. Scions from resistant trees continued to be disease-free year after year, even when grafted to diseased trees. The grafting experiment furnished evidence that a virus was not involved and indicated that the cause of the trouble was an atmospheric agent. Members of susceptible clonal lines potted with the same soil mixture were injured when placed in the affected area, while others remained disease-free outside. This use of susceptible clones as biological indicators gave further evidence that the disease causal agent is atmospheric and that the level of resistance is genetically controlled. Analyses of diseased foliage showed that injury could occur without causing a conspicuous elevation of either sulfur or fluorine in needle tissues. Sulfur dioxide and fluorine are still regarded as possibly involved. (Author abstract)

Dean, Gerald L.
EFFECTS OF FLUORIDE ON THE VIRULENCE OF TOBACCO MOSAIC VIRUS IN VITRO. Utah Univ., Salt Lake City, Dept. of Botany, Thesis (MS), June 10, 1966, 34p. 41 refs.
The relationship between fluoride introduced into plant foliage and the activities of viruses was investigated. Each leaf was inoculated at the tip with one drop of tobacco mosaic virus. Inoculated leaves were cut in half along the middle vein with a scalpel. The half leaves were placed on the surface of 250 cc of 5% water agar that was poured into aluminum trays. Fluoride was introduced into the pinto bean leaves by mixing various concentrations of sodium fluoride into 250 cc of 5% water agar before pouring into the aluminum trays. Fluoride concentrations were made to 0.0001, 0.0005, 0.001, 0.0025, 0.005, 0.01, 0.025, 0.05 M. Controls contained no additional fluoride. After 24 hours, frequent observations were made for lesion development. The trays of half leaves were removed from the environmental chamber after 48 to 72 hours. High

concentrations of fluoride, 0.025 to 0.05 M, caused chlorosis of the leaves before the lesions appeared. The molarities of 0.0005, 0.001, 0.005, and 0.01 produced the optimal increase in the fluoride content of the supported leaves. The relationship between the molar concentrations of the supporting agar and the amount of fluoride in the test leaves were significant at the 1% level. As the fluoride levels in the leaves increased above 60-80 ppm, there was an increase in lesion numbers on tests compared with control leaves until fluoride levels reached 400-450 ppm. At this concentration, lesion numbers showed a decrease. Above 500 ppm fluoride, the lesion numbers decreased to a level significantly below those of the control. At levels above 600 ppm, there appeared to be a strong inhibition of lesion numbers.

EFFECT OF AIR POLLUTION ON PLANTS. In: Air Pollution

Handbook. P. L. Magil, F. R. Holden, and C. Ackley (eds.),

New York, McGraw Hill, 1956, Sect. 9, 44p. 129 refs.

The effects of sulfur dioxide, hydrogen fluoride, chlorine, hydrogen chloride, nitrogen oxides, ammonia, hydrogen sulfide, hydrogen cyanide, mercury, ethylene, and pesticides on plants are surveyed, with special attention to effects on alfalfa, barley, and wheat. Damage to crops in Los Angeles County has been estimated at \$500,000 yearly. The toxicity of sulfuric acid is attributed more to its reducing properties than to its acidity. (It is 30 times as toxic as sulfuric acid.) Analysis of plants for total sulfur and sulfate sulfur is a possible method of diagnosing sulfur dioxide injury. The relative sensitivities to sulfur dioxide of 90 cultivated plants and 29 native plants are given (alfalfa sensitivity equals 1.0). Time-concentration and yield-leaf-destruction equations are discussed. Hydrogen fluoride is poisonous to gladiolus and iris, to various types of grain, to pines and other coniferous trees, and some fruit trees. Susceptibility varies widely, even among species of the same plant. Some varieties of gladiolus are highly susceptible; others are highly resistant. Coal smoke as a source of atmospheric fluoride should not be neglected. Fluoride content of certain types of coal can be high as 295 ppm. In areas near Pittsburgh, readings of as high as 269 ppm of fluoride have been registered in tree leaves, and 53 ppm in grass. The effect of smog on plants is discussed, including a tabulation of the sensitivity of 47 plants cultivated in southern California and of 52 plants native to the area. The chemical composition of smog is also analyzed.

AIR QUALITY CRITERIA AND STANDARDS FOR

AGRICULTURE. J. Air Pollution Control Assoc., 15(10):476-

480, Oct. 1965. 36 refs.

Many food, fiber, forage, and forest crops and a number of animals are adversely affected by a variety of air pollutants.

The effects of ethylene, fluorides, ozone, peroxyacyl nitrates,

and sulfur oxides are discussed. Their effects upon animals

and plants can best be judged by criteria which describe the

reaction of biologic materials to pollutant concentration and

exposure time. Four criteria are recognized: interference with

enzyme systems; change in cellular chemical constituents and

physical structure; retardation of growth and reduction in

<xref image="2000WVK2.TIF|V3|2006:09:28:01:36:56.00|125838|0"> image: </xref>

production from altered metabolism; and acute immediate tissue degeneration. Information on tissue degenerative effects due to these pollutants is the most common. There are some reports on growth and productivity reduction, but little data are available on cellular alterations and interference with enzymes which are essential to the ultimate definition and prediction of the significance of the effects of pollutants on growth and productivity of agriculture. Dosage data are available which indicate the degenerative effects of some specific pollutants on certain tissues of hosts. Political-social judgments are made because of the knowledge of the effects of these specific pollutants. This knowledge permits the establishment of standards which define air quality necessary for the protection of agriculture. The setting of standards for a single pollutant effects upon crops and animals effectively serves as a precedent and indicates the necessity of establishing air quality values for pollutant mixtures emitted into and produced within the air resource at different geographic locations as the polluted air moves throughout the typically multi-government jurisdictions of the airsheds. (Author abstract modified)

Darley, Ellis F.

USE OF PLANTS FOR AIR POLLUTION MONITORING. J.

Air Pollution Control Assoc., vol. 10:198-199, June 1960. 22 refs. (Presented at the Air Pollution Control Association 52nd Annual Meeting, Los Angeles, Calif., June 22-26, 1959.)

Plants used to monitor air pollution, whether they occur naturally or are cultivated, must meet certain requirements: they must be susceptible and display symptoms characteristic of the pollutant in question; they should be growing in a suitable environment and have rather wide distribution; and plant injury from pollutants must be distinguishable from that caused by insects, frost, or heat. Where naturally suitable conditions do not prevail, susceptible species can be planted in approximate sites or grown under controlled conditions. The characteristic symptoms caused by oxidants, ozone, fluorides, sulfur dioxide, and ethylene are described. In a few cases, a plant may detect more than one toxicant simultaneously, although the symptoms cannot always be separated. Plants can monitor concentration levels of pollutants as well as kind of pollutant. Plant monitoring is particularly useful where costs are a significant factor or in areas where air pollution is not suspected and chemical monitoring is therefore not normally in effect. The occurrence and spread of oxidant plant damage in California is described as an example of the use of plants for pollution monitoring purposes.

Garber, K.

THE INFLUENCE OF FLUORINE CONTAINING EMISSIONS

ON PLANTS. (Die Beeinflussung der Pflanzenwelt durch fluorhaltige Immissionen). Text in German *Angevv. Botan.*, vol. 40:12-21, 1966. 18 refs. (Presented at the Botanikertagung, Bonn, Sept. 10, 1965.)

Typical symptoms of plant damage by fluorides are mottling of the leaves, bleaching of the leaf margin and tips, and necrosis and rolling of the leaves. The symptoms alone are sometimes not enough to make a correct diagnosis. It is necessary to determine the F-content of the plant. Several methods are available, such as distillation of the ashed substances with perchloric acid or sulfuric acid and subsequent determination of the F-content of the distillate by colorimetry or titrimetry. The natural F-content of plants must be known. It usually lies between 0.05 and 2.5 mg per 100 g dry substance. A table listing the natural F-concentrations of various types of plants is given. Tree barks can be used for the analyses if leaf samples are not available. A clear difference exists of F-concentration between the bark facing the F-source and the bark facing the

opposite direction. To diagnose injuries, plants can be exposed in the pots in the polluted area under equal conditions. In one instance, the injuries were traced to sulfur dioxide rather than F-containing emissions. This shows that a higher F-content in the plant than is natural does not always mean that the visible injuries are a consequence of the higher F-content. Soluble NaF or KF dust on plants may reduce the chlorophyll content of plants. The sensitivity of the plants to fluorides varies and is influenced by the site, nutrition, and the climate.

Bolay, A and E. Bovay

OBSERVATION OF DAMAGE CAUSED BY FLUORINE

COMPOUNDS IN VALAIS. (Observations sur les degats

provoques par les composés fluores en Valais). Text in French.

Agr. Romande, 4(6):43-46, 1965. 1 ref.

Observations made over a period of several years in the neighborhood of the Martigny and Chippis aluminum plants are reported. To determine whether plant damage has been caused by fluorine compounds, the conditions of three tests must be met: 1) accurate determination of the pathological symptoms in the plant; 2) chemical determination of fluorine; and 3) study of the typical symptoms of blight in related indicator plants. The intensity of damage due to fluorine blight is influenced by various factors: 1) atmospheric humidity and amount of precipitation; 2) sensitivity of a particular plant species; and 3) age of the plant. Damage to the leaves, flowers, buds, branches, and fruit of the apricot tree is discussed in detail. The tree is also subject to a type of chronic intoxication from fluorine that eventually leads to the death of the tree, but which is not always accompanied by visible symptoms. Also discussed are the effects on peaches, prunes, cherries, pears, apples, grapes, and strawberries. A list of 25 indicator plants is given.

POSSIBLE EXPLANATION OF FLUORIDE-INDUCED

RESPIRATION IN CHLORELLA PYRENOIDOSA. Science,

vol. 132:1553-1554, Nov. 25, 1960. 9 refs.

Increased oxygen uptake by Chlorella pyrenoidosa in the presence of sodium fluoride at various pH values was studied.

NaF concentrations up to 0.000105M resulted in increased respiration as high as 60% above normal; above this concentration, oxygen consumption sharply dropped to below normal.

A significant increase in phosphorylated nucleotides was found, suggesting that undissociated HF in the culture medium disrupts the basic energetic of the cell, thereby causing the increased oxygen uptake.

INVESTIGATION AND APPRAISAL OF FLU-GAS DAMAGE.

(Untersuchung und Begutachtung von Rauchscha-den. Part I.),

Translated from German. Hamburg Staatsinstitut fur Ange-

wandte Botanik Jahresbericht, 5(119-120), 1938. 3 refs.

Plants exposed to flue gas showed definite damage from fluorine (F) and acids of sulfur and nitrogen. A crystallization method utilizing the microscopic identification of silico-sodium fluoride proved best for qualitative fluorine analysis of the 102 samples examined through 1936. As in previous studies, the

<xref image="2000WVK3.TIF|V3|2006:09:28:01:36:58.00|121062|0"> image: </xref>

samples tested showed that F was taken in through the branch bark and leaves of cherries and pears. For the first time, however, the fruit itself was damaged and F detected there. Black, hard disks had formed around the flower and in the fruit adjacent to the flower. Samples examined long after damage took place showed no F present. Twenty-one samples were examined for acid damage. Large concentrations of nitrates were detected in the specimens by means of the diphenylamine-sulfuric acid reaction. Different plant species showed markedly different sensitivities to flue gases.

Garber, K., R. Guderian, and H. Stratmann
 INVESTIGATIONS OF THE FLUORINE INTAKE BY
 PLANTS FROM THE SOIL. (Untersuchungen ueber die Aufnahme von Fluor aus dem Boden durch Pflanzen.) Translated from German. Franklin Inst. Research Labs., Philadelphia, Pa., Science Info. Services, Contract No. CPA 22-69-30, Project No. C 2439, 20p., 1968. 9 refs.

This paper deals with the fluorine intake from the soil, and in particular, answers to the following questions are sought: 1. How great is the fluorine concentration of various types of plants grown in different soils? 2. What effect has a portioned fluorine addition to the soil on the F-concentration of the plant? 3 Are there fluctuations in the fluorine concentration of the plant during its vegetation period? 4. Are there any connections between the F-concentrations of various plant organisms? All investigations were performed in vitro and are based on the experiments on sulfur dioxide effects described by von Guderian (1960). The sites of the investigations are Hamburg, Biersdorf (Sieg) and Kettwig. With the majority of the experiments, the experiments, the computed fluorine concentrations were mixed with the soil prior to sowing. To determine the F-concentration in the experimental soils as well as in the sample plants the method by Oelschlager (1960) was used. The same types of plants show different F-concentrations which moreover do not correlate with the fluorine concentrations of the soils. The fluorine concentration of plants thus is not solely a function of the absolute fluorine concentration of the soil. been investigated for five years to determine (1) whether this resistance was due to genetic factors, better nourishment, more favorable water supply, etc., (2) what gas concentrations can be withstood by forest trees, and (3) if the selected spruces can withstand higher concentrations than other spruces of the same age and some deciduous trees which are known to be more resistant. The results indicate that (1) genetics is a very important factor and (2) forest damage from industrial pollutants can be reduced or eliminated if foresters would cultivate pollution resistant trees in industrial areas.

 INVESTIGATIONS INTO THE EFFECTS OF FLUORINE IM-
 MISSIONS ON CATTLE IN THE NEIGHBORHOOD OF A
 HYDROFLUORIC ACID PLANT. (Untersuchungen ueber
 Fluorimmissionwirkungen bei Rindern im Bereich einer Flus-
 saeure-Fabrik.) Translated from German. Franklin Inst.
 Research Labs., Philadelphia, Pa., Science Info. Services, Con-
 tract No. CPA 22-69-30, Project No. C 2439, 29p., 1968. 10 refs.

During the period of 3.5 years, twelve cows were kept under controlled conditions on a farm located in the emission area of a hydrofluoric acid plant. At the beginning of the test program the age of the cattle ranged from 3/4 to 9 years. The investigations covered the computation of the fluorine intake through the forage, the water and the air as well as the excretion by urine and incorporation in the bones. The state of health and the productivity of the cattle was constantly observed. The fluorine content of the farm-produced forage varied largely depending on the situation of the forage land with respect to the industrial plant. The monthly average of fluorine intake of the

cattle varied between 1.0 and 9.5 mg F per kg body weight. All cattle showed symptoms typical for chronic fluorine poisoning, i.e. changes in teeth and bones as well as disturbances in locomotion. No influence of the fluorine intake could be detected on the fertility or on the milk productivity if this was less than 20 liters per day. Calves of cows with chronic fluorosis were not injured but do have an increased fluorine content of their bones.

Garber, K.

THE FLUORINE CONCENTRATION OF PLANTS. (Ueber den Fluorgehalt von Pflanzen.) Translated from German. Franklin Inst. Research Labs., Philadelphia, Pa., Science Info. Services, Contract No. CPA 22-69-30, Project No. C 2439, 10p., 1968. 10 refs.

Data are presented which indicate (1) that the fluorine intake by plants is independent of the fluorine concentration of the soil, and (2) that the natural fluorine content of plants lies between 0.2 and 2.0 (maximum 3.0) mg per 100g dry substance. Any higher concentrations can be traced to F containing immissions.

EFFECTS OF FLUORINE ON CATTLE UNDER EXPERIMENTAL AND PRACTICAL CONDITIONS. (Fluor-Wirkungen beim Rind unter experimentellen und praktischen Bedingungen.) Translated from German. Franklin Inst. Research Labs., Philadelphia, Pa., Science Info. Services, Contract No. CPA 22-69-30, Project No. C 2439, 31p., 1968. 16 refs.

In the period from 1961 to 1967 fluorosis was experimentally induced in test cattle by feeding them primarily with locally grown, fluorine-containing forage to which sodium fluoride or cryolite had been added. The total fluorine intake by the NaF-fed cows was 1.94 mg F/kg body weight per day, and by cryolite-fed cows 2.48 mg F/kg body weight per day. The fluorine intake thus exceeded the threshold value of about 1.75 mg F/kg body weight per day given in the pertinent literature. Fluorine elimination with the feces was found to be about 0.5 g of F per animal per day with NaF-fed cows and 0.9 g of F per animal per day with cryolite-fed cows. Along with the urine, 0.45 mg of F per animal per day were discharged by NaF-fed cows and 0.3 mg of F per animal per day by cryolite-fed cows. The analysis of tail vertebrae biopsies yielded a fluorine retention of 245 to 890 mg F/100 g ash over the period from 1960 to 1966 for the NaF-fed cows, and of up to 655 mg F/100 g ash for the cryolite-fed cows. The clinical symptoms

<xref image="2000WVK4.TIF|V3|2006:09:28:01:37:02.00|118290|0"> image: </xref>

of fluorosis were slight to moderate yellowish, brownish spots as well as hypoplasia of the incisors, furthermore, weak and temporary functional disturbances of the motility were observed with some cows. The severity of these clinical symptoms were found to be dependent on the degree of fluorine emission. The general physical condition as well as the productivity of the test cows were in most cases satisfactory to excellent. Observations concerning spontaneous fluorosis in the Rheinfeldern (Baden) emission area during the past 15 years show that the number and the severity of the disease in six communities had reached a peak in 1958 from whereon a steady decrease of the number of cases is found. This downward trend was paralleled by a decrease of the average fluorine content in the locally grown forage below the tolerance limit.

18270

Woehlbier, W., W. Oelschlaeger, G. Gronbach, and H. Giessler

THE RESORPTION OF FLUORINE BY OXEN FROM SOIL AND FLY DUST OF AN ALUMINUM PLANT. (Die Resorption von Fluor durch Ochsen aus Erde und Flugstaub einer Aluminiumhuette.) Translated from German. Franklin Inst. Research Labs., Philadelphia, Pa., Science Info. Services, Contract No. CPA 22-69-30, Project No. C 2439, 15p., 1968. 8 refs. The resorption and retention of fluorine contained in three different substances such as NaF, fly dust from an aluminum plant and soil intermingled with fly dust which probably underwent a secondary fluorine reaction. All substances contained a fluorine compound with a relatively high water solubility. The fluorine retention was relatively high with soil, the fluorine excretion in the urine low. The supplementary feeding of the three fluorine-containing substances extending over 316 days brought various high levels of fluorine depositions which agreed with the quantities resorbed.

18271

Cohrs, P., H. Knosel, and Kl. Witte
INVESTIGATIONS ABOUT THE INITIAL STAGES OF THE MORPHOLOGICAL CHANGES OF ORGANS AND TISSUES IN DOMESTIC ANIMALS WITH FLUORINE POISONING. (Uuittersuchungen ueber die Anfangesstadien der morphologischen Organ- und Gewebsveraenderungen bei Fluorvergiftung der Haustiere.) Translated from German. Franklin Inst. Research Labs., Philadelphia, Pa., Science Info. Services, Contract No. CPA 22-69-30, Project No. C 2439, 10p., 1968. 11 refs.

Experiments are described in which sheep, pregnant sows, and weaned piglets were given fluorine orally in the form of an aqueous solution of sodium fluoride. Histological investigations were made and all organs, especially the endocrine glands, were investigated using usual methods and procedures. The fetuses of pigs and the suckling piglets showed no pathological changes in their developing teeth, in their bones and endocrine glands. Weaned piglets showed varied changes in teeth and bones according to the dose and duration of the application of NaF. Considerable weight reductions were observed in the thymus and adrenal glands of the test animals. No changes were observed in the pregnant sows. Sheep and lambs showed the same changes in teeth and bone tissue as were observed in the weaned piglets.

18272

Trautwein, K., R. Buchner, and Ch. Kopp
LABORATORY AND FIELD INVESTIGATIONS OF FLUORINE EFFECTS OF BEES. (Laboratoriums-und Felduntersuchungen ueber Fluor-Wirkungen bei Bienen.) Translated from German. Franklin Inst. Research Labs., Philadelphia, Pa., Science Info. Services, Contract No. CPA 22-69-30, Project No. C 2439, 10p., 1968. 22 refs.

According to experiments, no damages occurred to bees

through dust and powdery substances containing fluorine. The following toxicity of dissolved fluorine compounds was found: a) Sodium fluoride; lethal dose equals 20 micrograms F per bee per 24 hours; 50% lethal dose equals 11 micrograms F per bee per 24 hours, b) Hydrofluoric acid lethal dose equals 10 micrograms F per bee per 24 hours; 50% lethal dose equals 5 micrograms F per bee per 24 hours. There are different sensitivities between the strains of bees and there is a repellent effect of hydrofluoric acid depending on its concentration. In 57 samples of 100 normal bees each, average values between 0.63 to 4.81 micrograms F per bee were found. The bees came from various regions with and without fluorine emissions. In the Rheinfeldern emission area, only normal values of 0.6 to 2.8 micrograms F per bee were found in bees which were said to have died from fluorine emissions. Test colonies at a distance of 300 m from the plant showed no disorders after three years. In the Seelze emission region limiting values from 0.9 to 10.6 micrograms F per bee were found in bees which were said to be injured by fluorine emissions. Of two test colonies placed at a distance of 300 m from the plant, one died, the other developed badly during the three years of observation. In the examination of bees which are suspect of fluorine intoxication, other important diseases and aggravating factors must be recognized by differential diagnosis.

Leithe, W.

RECENT RESULTS AND PROBLEMS CONCERNING THE ANALYSIS AND DAMAGES OF AIR POLLUTION. (Neue Ergebnisse und Probleme zur Analytik und Schadwirkung von Luftverunreinigungen.) Text in German. Allgem. Prakt. Chem. (Vienna), 20(2):36-37, Feb. 1969. 11 refs.

Nitrogen oxide has recently become increasingly important to air pollution not only because it is contained in automobile exhaust gases (up to 0.4% by volume) but because also it occurs in cigarette smoke (up to 0.1% by volume). Its toxicity, however, is only one-fifth of that of NO₂. Its presence is determined by means of azo dyes after conversion into NO₂. The injury threshold of NO₂ for plants has recently been set at 0.4 ppm by H. van Haul and H. Stratmann, formerly, Czech and Nothdurft had placed the threshold at 30 ppm; their exposure time, however, was much shorter. Addition of NO to NO₂ does not increase the toxicity. Present work has shown that even under unfavorable meteorological conditions no plant injuries were observed at an exposure of 0.4 ppm of NO₂. A new analytical method for determining small concentrations of ammonia was developed. No description of the new method is given. It is remarkable that impingers retain less fluorine than fritted scrubbers. The SO₂ injury threshold is still highly controversial. Some authorities believe that the SO₂ emissions may be a useful function in plant nourishment. Sulfur dioxide exists for only about four days in the atmosphere. It is then washed out and penetrates the soil as sulfuric acid where it supplies the plants with the required sulfur. However, some experts view it only as a toxicant. Possible toxicity is a function of concentration.

METHODS FOR SELECTION AND CULTIVATION OF EMISSION - RESISTANT WOODS. (Methoden der Auslese und Zuechtung Immissionsresistenter Gehoelze). Text in German. Preprint, International Union of Forest Research Organizations, Vienna (Austria), p. 2-21, 1967. 27 refs. (Presented at the International Union of Forest Research Organizations, Congress, Munich, West Germany, 1967.)

The need to select and raise woods resistant to air pollution in order to provide forests around urban areas is discussed. Sulfur dioxide, hydrogen fluoride, and ozone are probably the most noxious pollutants to coniferous species. Whether resistance to one of these phytotoxicants is independent or whether it enhances resistance to a whole range of pollutants should be investigated, as well as the mechanism of inheritance of resistance. Climate and soil conditions must be considered in planning selection experiments. Procedures applied to date to coniferous cultures throughout the industrial areas of Germany are reviewed.

Johnson, Folke, D. F. Allmendinger, V. I. Miller, and C. J. Gould

LEAF SCORCH OF GLADIOLUS CAUSED BY ATMOSPHERIC FLUORINE EFFLUENTS. *Phytopathology*, 40(3):239-246, March 1950. 3 refs.

A hitherto undescribed disease, leaf scorch of gladiolus, was observed in areas polluted with fluorine compounds emitted from alumina reduction factories. The plant symptoms were reproduced by fumigation with hydrogen fluoride and were examined. Of the 72 varieties studied for their reactions to fluorine emissions and the amount of foliage injury or injury index, 7 were resistant (index less than 10), 13 were very susceptible (index 30-60), and the balance was between the two extremes. In general, the resistant varieties contained more fluorine in the foliage than the susceptible ones. The fluorine content of scorched plants from polluted areas was higher than that from unscorched plants in remote areas. (Author summary modified)

AUTOMATED VARIABLE LEVEL DISPENSING EQUIPMENT FOR HYDROGEN FLUORIDE. 9p., 1962 (?). 1 ref.

In a large field study of the effects of air pollutants on citrus, it was desired that hydrogen fluoride be added to the incoming atmosphere of greenhouses installed over individual trees. By substituting a series of valves with increasing sized orifices in place of the fixed bleeder valve, the fluoride dispensing system was modified to supply varying levels of the pollutant to the greenhouses so that the trees inside would be subjected to the same fluctuating levels of fluoride on an hourly basis as those in the ambient air outside. The automatic fluoride dispensing equipment is described.

Compton, O. C., L. F. Remmert, J. A. Rudinsky, L. L. McDowell, F. E. Ellertson, W. M. Mellenthin, and P. O. Ritcher

NEEDLE SCORCH AND CONDITION OF PONDEROSA PINE TREES IN THE DALLES AREA. Preprint, Oregon Agricultural Experiment Station, Corvallis, Miscellaneous Paper 120, 6p., 1961. 8 refs.

A survey was designed to determine the nature of the injury to pine trees growing in and around the Dalles area in Oregon. Considerable injury from 'blight', or needle scorch, was found. Scorched needles contained considerably more fluorine than unscorched needles and were typical of 'ponderosa pine blight.' In the Dalles area, the percentage of scorch in 1960 needles varied from 0.9% at Station 12, which was 4 miles

south of an aluminum factory, to 67.7% at Station 4, which was 1.2 miles WNW of the factory. The fluorine contents were 23% and 98%, respectively. The greatest amount of scorch was associated with higher fluorine content. No scorch was found in samples outside the Dalles area, and these samples were low in fluorine content. There was no pathological, entomological, or soil conditions that would account for the needle scorch found in the area. (Author conclusions modified)

FLUORINE INJURIES TO VINE. (Fluor-bedingte Immisionsschaeden an Reben). Text in German. Die Wein-Wiss., 21(4):141-149, April 1966. 8 refs.

the vicinity of a lime kiln, injuries were observed on the leaves of the plants in the nearby vineyard in the extremely wet and cool summer of 1965. The leaves were necrotic, and the grapes had an extremely low sugar content. Measurement of the fluorine content in the medium to heavily injured leaves revealed concentrations which were 10 times higher than that of control plants. Fluorine concentration was only 8 times as high in the dead leaves as that in the control leaves, that the wash-out effect obviously becomes more apparent in entirely dead material. Since several rainy days had passed between the appearance of the symptoms and sampling, it is assumed that originally the fluorine concentrations in all samples must have been even higher.

19211

Yamazoe, Fumio

EFFECTS OF HYDROGEN FLUORIDE ON PLANTS. (Fukukasuiso no shokubutsu ni oyobosu eikyo nitsuite). Text in Japanese. Kogai to Taisaku (J. Pollution Control), '6(7):515-520, July 15, 1970. 8 refs.

Symptoms of fluorosis in plants are chlorotic markings around the tip or edges of young leaves. Examples of damage to plants and livestock by fluorides are listed, including the retarded growth of silkworms fed on mulberry leaves polluted by more than 30 ppm fluorides. Plants can be classified into six groups according to their resistance to hydrogen fluoride. Threshold values of the fluoride concentration range from 5-10 ppb for the plants. Gladiolus is normally employed as a plant indicator for hydrogen fluoride and silkworms as indicator insects. The relationship between plant damage by fluorides and exposure time, density, soil, fertilizer, meteorology and location are examined. The mechanism of the damage is also analyzed. In a calciculous plant, Si-F bond, which is rather difficult to dissolve in water, is formed. In a calciculous plant, on the other hand, a Ca-F bond, which is difficult to dissolve, is formed. In evaluating plant damage, 100 g of leaves are collected from several locations in an area. After rinsing by water, the sample is dried for 30 min at 90-100 C, and subsequently at 60-70 C for several hours. The sample is powdered, screened by 1 mm screen, and subjected to chemical analysis. Several preventive measures are listed, including the spraying of water or lime on plant leaves. It is concluded that the establishment of an environmental standard is difficult because of the extremely high sensitivity of the plants to the gas.

COMPARISON OF FLUORINE LEVELS IN CROPS BEFORE

AND AFTER ALUMINUM FACTORY OPERATIONS IN THE

DALLES AREA. Oregon Agricultural Experiment Station, Cor-

vallis. Miscellaneous Paper 95, 27p., 1960. 7 refs.
The fluorine content of seven crops in the Dalles fruit area in Oregon were studied, beginning in August, 1953. Determinations of leaf fluorine were made four times previous to and three times since July 26, 1958, when a local aluminum reduction factory began operations. Leaf samples taken before July 1958 averaged less than 12 ppm fluorine. Similar samples taken after the start of operations at the factory ranged from 16 to 197 ppm, averaging 68 ppm fluorine. The June 1959 samples ranged from 6 to 106 ppm, averaging 26 ppm fluorine; those collected in August ranged from 18 to 207 ppm, averaging 73 ppm fluorine. The fluorine samples taken in October 1958 decreased from an average 140 ppm, 1 mile from the factory to 54 ppm, 4-5 miles away. Fluorine burn on leaves was severe in 1959 on certain apricot and prune trees growing within 2 miles of the factory. Peaches collected in 1959 showed a premature ripening and softening along the suture, the swelling often extending to the apex. This condition has not been observed previously in this area. (Author summary modified)

THE EXTENT OF PLANT DAMAGE CAUSED BY GASEOUS

FLUORINE AS A FUNCTION OF ENVIRONMENTAL FAC-

TORS AS WELL AS BY PULVERULENT FLUORINE AND

FERTILIZER. Staub (English translation from German of:

Staub, Reinhaltung Luft), 29(9):38-40, 1969. 9 refs.

Gaseous fluorine is the form of hydrogen fluoride and silicon tetrafluoride is the primary cause of plant damage caused by fluorine emissions. The toxic effect is governed by a number of factors including the fluorine content of air, the duration of absorption, the nature and age of the vegetation, rainfall and nutrient absorption, and fertilizers. Water conditions and nutrient supply constitute an essential factor for the necrosis caused by fluorine; at optimum nutrient supply, the resistance of forest trees to fluorine is higher. Increased light intensity and the associated high assimilation enhances the damaging effects. Soil with a high proportion of fluorine was used to grow various trees, and fly ash from an enamel shop was appb'ed to the leaves. Solid fluorine particles were found to be less damaging than gaseous fluorine. Outside fluorine emission zones, plants can absorb large amounts of fluorine and be damaged by PK and NPK fertilizers containing boron in the BF₄(-) complex.

Webster, C C.

THE EFFECTS OF AIR POLLUTION ON PLANTS AND

SOIL. London, Agricultural Research Council, 1967, 53p. 198

refs.

Recent trends in the emissions and concentrations of smoke, deposited matter, and sulfur dioxide in Britain and the effects of these pollutants on plants and soil are presented. Factors affecting the action of sulfur dioxide on plants are susceptibility of different species and varieties, stage of growth, time of day, environmental conditions, concentration of gas and time of exposure, intermittent exposure, and fluctuating concentration of gas. The effects on plants and soil of fluorides and photochemical or oxidant smog are considered. The contamination of plants near highways with lead from the exhaust fumes of motor vehicles is included. Plants as indicators of pollution are also discussed.

Weinstein, Leonard H. and Delbert C. McCune

IMPLICATIONS OF AIR POLLUTION FOR PLANT LIFE.

Proc. Am. Phil. Soc. 114(1):18-21, Feb. 1970. 17 refs. (Presented at the Symposium on Atmospheric Pollution: Its Long-Term Implications, April 25, 1969.

The effects of an air pollutant on a plant may vary with respect to their manifestation and the circumstances of their occurrence. The best known are the visible lesions that appear on the foliage taking the form of chlorotic or necrotic areas distributed on the leaf in patterns characteristic of the plant and the pollutant. In affected broad-leaved plants, fluoride symptoms appear as marginal areas of chlorosis or necrosis. Sulfur dioxide effects are irregular necrotic areas between the veins. The symptoms of ozone injury may be flecks or patches of dead tissue on the upper surface. Peroxyacetyl nitrate attacks the underside of the leaf, giving it a glazed appearance. In the narrow-leaved plants, the foliar symptoms of pollutant injury are banding of the tips of the leaves. There are other changes that are not immediately apparent in occurrence or significance, such as effects on growth, yield, crop quality, physiology, and metabolism. Two basic approaches may be taken for control of pollutants that damage plants. The access of the pollutant to the plant may be restricted, or the pollution source may be removed from the receptor. It is also suggested that plants be developed that will be more resistant, or that practices be developed that will modify the response of plants to air pollutants. A brief history of the damaging effects of pollution on plants is presented.

Pack, M. R.

EFFECTS OF HYDROGEN FLUORIDE ON PRODUCTION AND FOOD RESERVE CONTENT OF BEAN SEED. Preprint, Washington State Univ., Pullman, Air Pollution Research Section, 7p., 1969. 16 refs.

Mature seeds of Tendergreen bean plants, grown under continuous exposure to hydrogen fluoride at 10.5 micrograms F/cu m, had a shrivelled appearance and lower starch content than seeds of control plants. Two more experiments were conducted in which bean plants were exposed continuously to HF at 2.1 and 9.1 micrograms F/cu m. These seeds also matured more slowly in the HF treatment and tended to be shrivelled and distorted. They had a faded blue-black color rather than the glossy black of the control plants. These differences were most pronounced in the higher HF treatment. The seed of the HF treated plants also had a lower starch content, suggesting that the fluoride interfered with starch synthesis. The HF treatments had no apparent effects on the reducing sugars, total sugars, water soluble polysaccharides, protein, or ether extract of the bean seed. Seedlings grown from the HF affected seed showed delayed emergence and less vigorous growth than control seedlings. The cordate primary leaves were abnormally small and distorted. CHANGES OF CONCENTRATION OF FREE AMINO ACIDS IN PLANTS UNDER THE INFLUENCE OF HYDROGEN FLUORIDE AND SULFUR DIOXIDE. (Konzentrationsänderungen bei freien Aminosäuren in Pflanzen unter dem Einfluss von Fluorwasserstoff und Schwefeldioxid). Text in German. Staub, Reinhaltung Luft, 30(6):256-259, June 1970. 26 refs.

After treating different types of plants for 14 days with air containing 6 micrograms of hydrogen fluoride/cu m or with air

<xref image="2000WVK7.TIF|V3|2006:09:28:01:37:12.00|121098|0"> image: </xref>

containing 0.7 mg of sulfur dioxide/cu m, their contents of free amino acids were determined by two-dimensional chromatography and were compared with those of the control plants. The individual amino acids were identified with the aid of calibration curves prepared using commercially available amino acids. Analyses of damaged plants showed, in general, increases of concentration of the individual acids. The same result was obtained after treating grass with HF in which no external symptoms of damage were evident. Plants treated with SO₂ and appearing undamaged, exhibited varying changes in concentrations of the individual amino acids, but there was also a trend towards higher total amino acid concentrations in this case. This suggests the possibility of utilizing the metabolic reactions investigated above as indicators of emission effects. To obtain a higher detection sensitivity of metabolic reactions, which are desirable as early indicators of emission effects, further studies are planned in which no extracts from the entire plant body but only those from certain cell complexes will be analyzed. This kind of sampling separates the various metabolic circuits from each other, which may react differently to the same emissions and, hence, lead one to expect more unequivocal results.

19713

AIR POLLUTION: PLANT KILLER, Environ. Sci. Technol., 4(8): 635-636, Aug. 1970.

Agricultural losses caused by increasing air pollution are estimated to reach \$500 million annually in the U. S., most of the losses being due to growth suppression or plant injury. However, acute injury suggests the nature of the air pollutant and reveals the distribution of the problem. Visible effects of sulfur-dioxide injury are the bleaching of leaf areas to a light tan or ivory color or the complete bleaching of leaf. Injury from fluoride causes tissues to die at the margin and tip of the leaf. The dead tissues may be gray or light green at first, later becoming reddish-brown or tan. Typical patterns of ozone injury are bleached or light flecks or stipples on the upper surface of leaves. Injury from peroxyacetyl nitrate is characterized as glazing and browning of the lower leaf surfaces and attack of the younger leaves. A number of research programs are attempting to find a cure for pollution damage to vegetation. These programs include work on the development of crop species that are genetically resistant to atmospheric pollutants and on chemical compounds that would permit plant growth in polluted atmospheres.

Mohamed, Aly H.

CYTOGENETIC EFFECTS OF HYDROGEN FLUORIDE ON PLANTS. Fluoride Quart. Repts., 2(2):76-84, April 1969. 8 refs.

Fluorocompounds, either organic or inorganic, are considered to be potential pollutants. These compounds are by-products of various industrial processes, such as the production of phosphate-fertilizers, ceramics, and certain metals such as aluminum. Gaseous hydrogen fluoride is one of the most phytotoxic of the halogen compounds occurring as air pollutants. Fluoride gas in the atmosphere may cause severe damage to plants, even when the concentration is below the level required to produce visible morphological symptoms. Experiments were conducted on tomato plants and maize to determine their reaction to fumigation with hydrogen fluoride gas. Chromosomal aberrations resulted in the tomato plants. Similar cytological results occurred in the maize. HF seems to affect primarily the DNA molecule by blocking its replication, probably through its action on the enzymatic system. Garber, K.

EFFECTS OF FLUORINE. PERTAINING TO THE
FLUORINE CONTENT OF PLANTS (1). (Fluor-Wirkungen).
Federal Inst. of Applied Botany, Hamburg (West Germany),
RR-14, p. 42-48, 1967. 10 refs. Translated from German. Belov
and Associates, Denver, Colo., 8p., May 26, 1970. (Also:
Qualitas Plant. Mater. Vegetables, 15(1):29-36, 1967.)

Several years of research on the fluorine content of plants in
non-industrial regions have shown that the natural fluorine
content may vary between 0.2 and 2.0 mg/100 g dry matter.
The uptake of fluorine from the soil will continue independent
of the fluorine content of the soil. From these investigations, it
was concluded that fluorine contents higher than the natural
values indicate the influence of fluorine emissions. The
fluorine contents of various plants are presented in tabular
form.

Halbwachs, G.

INVESTIGATIONS ON DIRECTED ACTIVE FLOW AND
MATERIAL TRANSPORT IN THE LEAF. Flora (Jena), vol.
153:358-372, 1963. Translated from German. Belov and As-
sociates, Denver, Colo., 34p., Feb. 20, 1970.

Damage by acidic gases, such as sulfur dioxide, hydrochloric
acid, and hydrogen fluoride, is expressed in leaves as irregular
necrotic spots distributed across the entire leaf surface, or as
localized necrosis at the leaf edges and tips. The acidic gases
enter the interior of the leaf through the pore openings. Thus,
their opening condition is of importance for the extent and
speed of damage. Spot-shaped necroses appear in the direct
area of the entry locations as a result of tissue damage from
high concentrations. Edge and border damage occurs only at
low concentrations, which are different for the individual
acidic gases, depending on their toxicity. This localization of
damage requires transporting the gases toward the leaf edges
and tip, and an effective suction at these leaf parts. The ex-
istence of such a suction effect, which is significant with
respect to the problem of water and substance distribution in
the leaf, was made probably by experiment i with cut
branches, allowing them to absorb dilute HO and sodium
hydroxide solutions and chromium fluorides. The results
showed that the preconditions for water and substance flow in
the leaf are created by leaf pressure and evaporation, but that
the finer distribution in the leaf is regulated by the leaf itself.

FLUORIDES IN ANIMALS IN THE DALLESPORT AREA.

Wash - State Univ. Agr. Exp. St., St. Circ., no. 353, 8p. 1959. 2
refs.

The natural levels of fluoride intake, storage, and excretion
were determined in farm animals in the area of a new alu-
minim reduction factory, prior to start-up of the plant. In addi-
tion, the local prevalence of other diseases that might be con-
fused with fluorosis were to be established. Animals and feeds
in the Dallesport, Washington area of Klickitat Country and
The Dalles, Oregon area had a normal fluoride level. Water
from 13 ranches had from 0.05 to 1.26 ppm fluoride with a
mean of 0.25. Hay from twelve ranches had from 0 to 8.3 ppm
fluoride with a mean of 4.4. Analyses of urine, horn, hoof,
<xref image="2000WVK8.TIF|V3|2006:09:28:01:37:16.00|118348|0"> image: </xref>

teeth, and bone from cattle (mostly beef) disclosed normal levels of excretion and storage. Physical examination of cattle on 11 ranches disclosed normal teeth in most individuals and only one case of lameness. It was concluded that no unusual or abnormally high sources of fluoride are available to the animals in the area. (Author summary modified)

Van Brackle, Richard D.

THE FARMER'S STAKE IN AIR POLLUTION. Crop Soils
Mag., 20(1):17-19, Oct. 1967.

The assessment of agricultural problems caused by air pollution is difficult, since air pollution injury is not easily distinguishable from insect or disease injury; pollution makes crops more susceptible to insects and disease; and some pollutants cause damage at very low concentrations and may not be suspected. The \$15 million of visible damage done to crops in California does not include such factors as reduced vigor, longer growing season, extra water and fertilizer, and lowered quality. Photochemical air pollution is considered the most dangerous type for agriculture. More than 300 types of plants are affected by air pollution, the average California automobile is 5 1/2 years old, has had two owners, is driven approximately 9,000 miles per year and makes about one 25-mile trip per day; this results in a daily emission of 6 1/2 pounds of contaminants, which in turn results in a total figure for 1963 of 56 million pounds. Among the major pollutants that damage plant life are ozone, peroxyacetyl nitrate various types of fluorides, sulfur dioxide, and ethylene. Air pollution has had an adverse effect on agriculture for over a century.

Zimmerman, P. W.

CHEMICALS INVOLVED IN AIR POLLUTION AND THEIR
EFFECTS UPON VEGETATION. Proc. Governor's Conf. Ex-
hibit Atmospheric Pollution, New Jersey, 1952, p. 23-31. 33 refs.
(Feb. 19-20.)

Results of studies on the effects of various gases on plants are summarized for sulfur dioxide, hydrogen fluoride, chlorine, hydrogen sulfide, ammonia, mercury vapor, ethylene and carbon monoxide, and the vapors of 2,4-D and other hormone-type chemicals. Measurements of the atmosphere at Yonkers, New York, show an average of 0.01 ppm of SO₂ for 62% of the year. A maximum concentration of 0.75 ppm occurred in January. Leaves of alfalfa and buckwheat exposed to a concentration of 0.40 ppm for 7 hours became spotted. Working with concentrations of 0.1-0.2 ppm of SO₂, the following observations were made: there is more SO₂ resistance at or below 40 F, and SO₂ sensitivity does not change with minor variations in soil moisture. The sulfate content of the nutrient supply did not affect sensitivity, although the growth rate of sulfur-deficient plants increased under fumigation with 0.1-0.2 ppm SO₂. Plants recover between treatments if these are sufficiently spaced. Sensitivity was not affected by wetting the leaf surface. Young plants are more resistant than old plants; older leaves are more resistant than younger ones. HF gas tends to injure the margin of the leaf more frequently than SO₂. Application of sodium fluoride to soil caused similar injuries to those induced by HF fumigation H₂S gas is less toxic than the other gases tested, and injured the younger rather than the older leaves. Substituted phenoxy acids are extremely selective, stimulating growth in some plants and injuring or deforming others.

Adams, D. F. and C. W. Sulzbach

NITROGEN DEFICIENCY AND FLUORIDE SUSCEPTIBILITY OF BEAN SEEDLINGS. Science, vol. 133:1425-1426, May 5, 1961. 6 refs.

The influence of nutrition on the susceptibility of beans to visible foliar injury from atmospheric fluorides was studied.

Groups of bean seedlings were grown concurrently in cleaned and fluoride-containing (4 to 7 micrograms/cu m) air in plant-growth chambers for 10 and 20 days with six water-culture treatments. Hoaglund's formulation and Hoaglund's minus potassium, calcium, nitrogen, phosphorus, and iron. An inadvertent 15-hour exposure on day 15 (at 42 micrograms/cu m) produced foliar fluorosis symptoms only on the nitrogen-deficient plants fumigated 20 days, although higher fluoride concentrations were present in the foliage of similar plants grown in the other nutrient-deficient solutions. Thus it appears that production of necrosis, within a single variety, is not solely related to the fluoride concentration in the tissue and that fluoride susceptibility must therefore be biochemically associated with other metabolic processes in mechanisms which remain to be elucidated. A METHOD FOR DETERMINING THE BIOLOGICAL EFFECTS OF AIR POLLUTION BY TRANSPLANTED LICHENS. Staub (English translation from German of: Staub, Reinhaltung Luft), 29(1):17-21, Jan. 1969. 21 refs.

A method for transplanting the leaf lichen *Parmelia physodes* for use as an indicator of various air pollutants is described. This type of lichen is relatively indifferent to its base, its natural ecological conditions can be disregarded for at least six months, and the medium into which the lichen and its substrate are transplanted has little significance over an even longer period. The method entails removing the lichen from the tree (preferably oak), transplanting it into exposure boards of wood or other material, exposing the lichen in the area being investigated at a height of 1.5 m, recording withering effects (manifested by color changes) photographically, and grading the intensity of damage. The method is expected to simplify and reduce costs of certain air quality measurements, especially for sulfur dioxide and fluorine emissions, and also indicate changes in air quality due to such conditions as wind direction.

CONTAMINATION OF CITRUS FOLIAGE BY FLUORINE FROM AIR POLLUTION IN MAJOR CALIFORNIA CITRUS AREAS. Proc. Am. Soc. Hort. Sci., vol. 65:121-127, 1954. 22 refs.

As a preliminary phase of an investigation of the effect of fluorine on citrus growth, the extent of fluorine contamination in citrus foliage was determined. Leaves from approximately 130 citrus groves, collected in both heavily polluted areas and areas far removed from pollution, were analyzed for fluorine. Citrus leaves from the Coachella Valley of Riverside County, and from San Diego, Ventura, and Tulare counties disclosed concentrations of 1 ppm F or less. Leaves collected in industrialized areas disclosed values up to 211 ppm F. The greatest fluorine accumulation was evident in leaves from the San Bernardino Valley, San Bernardino County, especially from the vicinity of Fontana, where a steel plant is located. Signifi-

<xref image="2000WVK9.TIF|V3|2006:09:28:01:37:18.00|115925|0"> image: </xref>

cantly elevated accumulations were also found in leaves from the Los Angeles area, presumably as a result of emissions from aluminum, ceramic, phosphate, and chemical plants. Elevated fluorine values were not associated with any visible damage to the trees. Sampling of leaves of 12 groves over a 9-month period disclosed a maximum accumulation of fluorine during the summer and fall months. Foliar concentrations of fluorine increased very little, once the winter rains began. (Author summary modified)

Shupe, James L

FLUORINE TOXICOSIS AND INDUSTRY. Am. Ind. Hyg, Assoc. J., 31(2):240-247, March-April 1970. 10 refs.

Fluorosis in livestock can be accurately diagnosed and controlled when the complexity of the disease is realized, and the symptomatology, pathogenesis, and lesions are properly correlated, interpreted, and evaluated. Tooth classification and the amount of fluorine in bone can be used to diagnose and evaluate the degree of fluorosis with a high degree of accuracy. Some products can counteract and lessen the potential damage that ingested fluorides can cause. Aluminum sulfate, aluminum chloride, calcium aluminate, calcium carbonate, and defluorinated phosphate can reduce the toxicity of fluorine in animals. Multiple correlation formulas useful in diagnosing fluorosis, and livestock fluorine tolerances are included in tabular form. A comprehensive guide is also presented which facilitates diagnosing and evaluating fluorosis. (Author conclusion modified)

ON THE ATMOSPHERIC FLUORIDE POLLUTION. PART I.

(Fukkabutsu ni yoru taiki osen chosa (1)). Text in Japanese.

Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 4(1): 147, 1969. (Proceedings of the 10th Annual Meeting of the Japan Society of Air Pollution, 1969.) PART II. Ibid., 4(1):148, 1969.

Fluorine compounds emitted from chemical fertilizer, ceramics, and chemical industries were suspected to be the cause of death of 70 oxen for agricultural use between 1953 and 1964 in the outskirts of Osaka. Fluoride analysis was conducted on the urine of Japanese oxen in the area in order to determine the extent to which fluorides in air enter grass and feed. Fluoride content was found to be as high as 20 ppm. Further investigation was performed in order to determine the relationship between the fluorine compound content in the bones of the dead oxen and dust fall, plants, animal feed, and soil characteristics. A substantial amount of fluorides was discovered in the bones, and it became apparent that the compounds originated from the factories. It was not obvious whether they were the direct cause of death, because some inorganic fluorine compounds do not lead to death even at high concentrations. Since the oxen were also used for ploughing the fields, conclusions could not be drawn as to the real effects of the fluorides on the animals.

Hasegawa, T. and Y. Yamazaki

ON THE ATMOSPHERIC FLUORIDE POLLUTION. PART II.

(Fukkabutsu ni yoru taiki osen chosa (2)). Text in Japanese.

Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 4(1): 148, 1969. (Proceedings of the 10th Annual Meeting of the Japan Society of Air Pollution, 1969.) PART I. Ibid., 4(1):147, 1969.

In East Osaka, agricultural crops either died or showed poor growth in the neighborhood of a factory producing white cosmetic bottles. Since fluorite was used as a material and there was no damage before the establishment of the factory, it was suspected that fluorine compounds were causing the damage. Quantitative analysis was performed on the agricultural crops and the exhaust gas as well as the dust particles in order to determine the fluorine content. Gas samplers were

used to collect the dusts from the surrounding atmosphere. Fluorine content of dust near the factory was on the average about 93 mg per cubic meter per day, and in some parts, as high as 1.54 mg per cubic meter per day. Relatively larger quantities of fluorine were measured at the southwestern and southeastern area of the factory, corresponding to the general wind pattern. Rice and soy beans from the neighborhood of the factory showed concentrations of fluorine and, especially in the leaves of the damage crops, the concentrations were several hundred times higher than those of the undamaged leaves.

Rippel, A

LONG TERM EFFECT OF FLUORIDE EMISSIONS UPON VEGETATION. Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 3(I):18-21, Jan. 1970. 7 refs.

The results are presented of an eight-year study of the fluoride content of fruit, vegetables, and grain grown in four communities near a Czechoslovak aluminum factory. In the community nearest the factory, the fluoride levels in fruit and grain were five and six times higher, respectively, than those of controls. However, the fluoride levels in grain were only 2.6 times as high as in the controls. Root vegetables, especially potatoes, exhibited only minor changes in fluoride content, suggesting that fluoride uptake by plants is independent of fluoride levels in soil. In tuberous vegetables, fluoride accumulated in the portions of the plants growing above ground rather than in the tubers. This fact points to fluoride uptake from the air. The fluoride levels observed after the long-term exposure of plants were above normal. Fruit trees deteriorated progressively, particularly the sensitive plum trees and grape vines. The long-term emissions also distinctly decreased the biological and organoleptic values of the agricultural product and the productivity of agricultural plants

INTERLABORATORY STUDY OF ANALYTICAL

TECHNIQUES FOR FLUORINE IN VEGETATION. J. Assoc.

Offic. Anal. Chemists, vol. 52:894-899, Sept. 1969. 21 refs.

(Presented at the 60th Annual Meeting of the Air Pollution Control Association, Cleveland, Ohio, June 14, 1967.)

An interlaboratory study of fluorine analyses on plant tissues was performed to determine the current levels of within- and between- laboratory precision. Homogeneous, ground, fluoride-containing leaf tissues of alfalfa, citrus, gladiolus, pine, and orchard grass were analyzed by the routine methods currently in use in 31 different laboratories. The data reported by the laboratories are summarized. The mean values obtained for each tissue are as follows, alfalfa, 53.2 ppm; citrus, 117.5 ppm; gladiolus, 54.0 ppm, pine, 74.4 ppm; and orchard grass, 55.3 ppm. The variation between laboratories was estimated by calculating standard deviations, which ranged from 11.0 ppm for alfalfa to 14.0 ppm for citrus tissues. Relative standard deviations ranged from 12.7% for citrus to 24.5% for gladiolus. Deviations between the fluorine content of paired samples provide estimates of within- laboratory reproducibility. Some laboratories obtained highly reproducible results, but 14 reported at least one pair of duplicate values which differed

<xref image="2000WVKA.TIF|V3|2006:09:28:01:37:22.00|117569|0"> image: </xref>

from each other by 10 ppm or more. The results show that, despite the use of generally similar methods, there are marked differences in procedures, techniques, and reagents from laboratory to laboratory. A marked improvement in agreement is urgently needed to improve the usefulness of current fluorine measurements.

20917

Oarber, K.

FLUORIDE IN RAINWATER AND VEGETATION. Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 3(1):22-26, Jan. J970. 5 refs.

Fluoride levels of rainwater in industrial areas of Germany ranged from 0.28 mg/l to 14.1 mg/l, depending on the kind of industry, the distance from industrial complexes, and the extent to which coal was used. Fluoride assays of various plant species showed the same trend as those in rainwater, the fluoride content of the plants increased with increased fluoride levels of air. In a hothouse experiment, plants grown in soil from the contaminated areas exhibited fluoride levels only four times higher than those in control plants. In contrast, plants exposed to airborne fluoride near a factory showed 22- to 200-fold increases in fluoride values. Even when fluoride levels in rainwater were only 10 times higher than normal, plants cultivated near rainwater testing stations were markedly damaged by fluoride emissions, suggesting that high concentrations of fluoride compounds entered the plants during brief, short-term exposures.

McCune, D. C, L H. Wemstein, and Jill F. Mancmi

EFFECTS OF HYDROGEN FLUORIDE ON THE ACID-SOLUBLE NUCLEOTIDE METABOLISM OF PLANTS. Contrib. Boyce Thompson Inst., 24(19):213-225, Jan.-March 1970. 26 refs. (Presented at the Air Pollution Control Association 60th Annual Meeting, Cleveland, Ohio, June 11-16, 1967.)

Experiments were undertaken to explore the problem of fluoride effects on phosphorus metabolism in reference to acid-soluble nucleotides in 'Tendergreen' and 'Pinto' beans, 'Bonny Best' tomatoes, and 'Marcross' corn. Procedures and methods are described for six distinct experiments. Hydrogen fluoride (HF) in the atmosphere at concentrations of 4.8 to 10.7 mg Fluorine/cu m for periods of 4 to 12 days had no consistent effect on the levels or composition of acid-soluble nucleotide pools in leaves of the plants. The distribution of phosphorus (P) among the various nucleotide fractions was not affected by HF fumigation, but the incorporation of P by the whole-acid soluble nucleotide pool was reduced in corn leaves. In general, there was less apparent effect on the metabolism of acid-soluble nucleotides by HF exposure than has been reported for other metabolic systems of the plants. (Author abstract modified)

Sobocky, E.

PRELIMINARY RESULTS OF ECONOMIC AND SYLVICULTURAL MEASURES AGAINST THE EFFECTS OF FLUORINE IN THE REGION OF ZIAR N.HRONOM.

(Predbezne vysledky lesnickohospodarskych opatreni proti pusobeni fluoru v oblasti Ziaru n.Hronom). Scientific and Technical Society, Prague (Czechoslovakia), Agriculture and Forestry Section, Proc. Conf. Effect Ind. Emissions Forestry, Janske Lazne, Czechoslovakia, 1966, 10 refs. (Oct. 11-14.) Translated from Czech. Franklin Inst. Research Labs., Philadelphia, Pa., Science Info. Services, p. XIII-1 to XIII-13. April 24, 1969.

Results of research and sylvicultural and economic measures taken to reduce the harmful effects of emissions in the area of Ziar N.Hronom were summarized. The source of the emissions was a metallurgical plant producing aluminum. The sylvicul-

tural measures were first directed toward the most severely attacked zone I of the area, and on non-sylvan areas, which were not used to grow trees, located within the reach of the maximum smoke attack between the forest boundary and the plant. In zone I, practically all degrees of injury were found, starting with depigmentation and necrosis formation in assimilation organs, up to the loss of foliage and decay of conifers. From among four-year plants on unforested land, which were subjected to various cultivation operations including mineral fertilization, best results were obtained for black alder, birch, red oak, pedunculate oak, and Austrian pine. Fertilization with lime and ground Thomas slag proved efficient only in the case of black alder. A much better result was provided by hoeing and mowing. Successful foresting depends not only on exposure to the emitting source, but also on a lower HF concentration. Terrian relief creates a natural barrier to penetrating emissions. The beech stand, situated 2110 m eastward of the emitting source, reduced the detrimental effect of HF in its above surface layer by approximately 30% in comparison to a free area in front of the stand boundary. A ten-year pine culture, 1950 m south-southeast from the source, reduced the harmful effect of HF by approximately 50% by comparison to total clearing, and thus fulfilled the protective function by being in front of the sheltered trees.

Thompson, C. R.

EFFECTS OF AIR POLLUTANTS ON LEMONS AND NAVEL ORANGES. Calif. Agr., 22(9):2-3, 1968.

Lemon trees were divided into 6 groups of four, and each group received an experimental treatment of an atmospheric phytotoxicant previous to water use determination. Activated carbon filters removed ozone and peroxyacyl nitrates, both components of photochemical smog; limestone removed acid fluoride gases, such as hydrogen fluoride; and nitric oxide reacted to remove ozone. Levels of total oxidants, fluoride, and temperatures in the air were recorded continuously. Trees receiving filtered air required more extra irrigation than those with ambient air, and trees receiving filtered air and filtered air plus fluoride had a higher rate of apparent photosynthesis than those receiving ambient air. Preliminary evaluation indicates that trees which get ambient air have an increased leaf drop (up to 30%) and yield less fruit than trees which receive carbon-filtered air.

Shikenjo, Norinsho Sanshi

AIR POLLUTION AND SERICULTURE. (Taikiosen to yosan-sogo shoroku). Text in Japanese. Sanshi Shikensho Shiryo (J. Sericultural Experiment Station), no. 20:102p., April 1966. 518 refs.

Various types of sericulture damage by atmospheric pollutants are considered in terms of responsible sources, in addition to the effects of the pollutants on mulberry leaves and silk worms. Damages are classified as follows: (1) sericulture damage due to gaseous, solid, and liquid wastes, the major contaminants of which are sulfur dioxide, hydrogen fluoride gas, chlorine gas, smoke dusts, and aerosols; (2) damage due to stack smokes generated by charcoal burning, heavy-oil burning, the skyrocket type of fireworks, and rubber-tire burning; (3) damage due to motor vehicle exhaust gas, dust clouds, mud, and mire; (4) damage due to aerially sprayed agricultural chemicals; (5) damage due to irradiated substances; (6) damage

<xref image="2000WVKB.TIF|V3|2006:09:28:01:37:24.00|120292|0"> image: </xref>

due to volcanic ashes; (7) damage due to salt-containing sea wind; (8) and damage due to hazardous substances, such as nicotine, contained in tobacco plants cultivated on adjacent farms or to other hazardous plants and crops such as pyrethrum, *Picrasima quassioides* Benn, bindweed, and peppermint. A bibliography is provided in which references are classified according to specific sources and their respective effects on both mulberry trees and silkworms.

Kuribayashi, Shigeharu

INJURY OF MULBERRY TREES BY AIR POLLUTION.

(Taikiosen ni yoru yoso no higai). Text in Japanese. *Sanshi Kagaku to Gijul.su (Sericultural Sci. Technol.)*, 8(8):64-67, Dec. 1969.

Atmospheric pollutants and their effects on mulberry leaves are discussed. At present the diagnosis of the effect of air pollution is largely dependent on chemical analysis and observations of the growth of mulberry trees and of silkworms, together with simultaneous analysis of atmospheric and soil samples. In observing symptoms of injury, it is important to remember that some symptoms may be transient or analogous to those caused by insects or fertilizers. For this reason, a comparative study of injured and healthy leaves should be undertaken to determine the level of injury and the responsible sources. The types of injuries caused by different pollutants are outlined. Dechlorized and spotted leaves are representative of the effect of 0.1-0.2 ppm, or higher concentrations of silkworms fed these leaves initially show loss of appetite, then inhibited growth, and finally death. The visible symptoms produced by 150-200 ppm hydrogen fluoride gas are brown spots at leaf tips and edges. Levels half as low are sufficient to kill silk. Silkworms leaves injured by chlorine gas also show decreased appetite and sometimes vomit silk thread. Gaseous contaminants containing stack smoke and carbon particles are generally sticky, insoluble in water, and extremely detrimental to the growth of mulberry trees. The effect of dusts and suspended particles from adjacent plants varies according to size and components.

Noble, Wilfred

SMOG. *Lasca Leaves*, 15(1): 1-24, 1965. 20 refs.

The various effects that smog has on plants in the Los Angeles area, and the effects of particular pollutants are discussed. One of the chief characteristics of pollution in this area is its high ozone concentration and the resulting strong oxidizing ability. Some of the components of this pollution has been determined. Peroxyacetyl nitrate (PAN) has been shown to cause silvering, banding, growth reduction, and cellular collapse. Ozone primarily attacks the older leaves and particularly affects woody plants. In contrast to PAN, which attacks the lower leaf surface, ozone affects the palisade layer of the upper surface, causing small clusters of cells to darken and eventually turn brown-black. Only orchids and carnations have shown serious injury due to ethylene. The gas causes dry sepal on orchids. In carnations, the opened blossom reverts back to a bud, and effect called 'sleepiness'. Fluorides are cumulative when absorbed by plants and translocated within the plant, concentrating in the tips and edges of leaves. There they cause a cocoa brown discoloration with well defined borders. Acute injury from sulfur dioxide appears as a tan to white area between the veins, with most severe symptoms appearing on the younger leaves. Presently, not much is known about the effects of nitrogen oxides on plants. After considerable study, it was determined that the only satisfactory means for growing undamaged plants was to filter air through activated carbon. A study of air pollution using plant indicators is also discussed.

Schoenbeck, H., M. Buck, H. van Haul, and G. S:holl

BIOLOGIC AIR POLLUTION MEASUREMENT METHODS.

(Biologische Messverfahren fuer Luftverunreinigungen). Text in German. VDI (Ver. Deut. Ingr.) Ber., no. 149:225-234, 1970. 49 refs.

Plants can be used as indicators for air pollution. Test plants grown under comparable conditions in various distances from the emission source; help to detect not only the type of pollutant causing injuries but also the effect of dust sediments in the soil. This method used in the vicinity of a zinc smelting plant revealed that sulfur, zinc, and lead containing emissions caused the observed plant injuries. *Lolium multiflorum* and *L. perenne* growth in synthetic pots and set up at various distances from a fluonne emitting plant provided indication of the quantities emitted at each point. Transportable plexiglass chambers can be used as covers for the plants at greatly different climatic conditions among the various exposure sites. Filtered and unfiltered air is drawn into the chambers. Apart from higher plants, lower epiphytic organisms such as lichens or moss can be used as indicators for air pollution. The widely spread *parmelia physodes* can be transplanted onto carrier plates and exposed. A clear relationship between the growth rate of these lichens and the SO₂ and HF concentration of the ambient air could be found.

EFFECT OF FLUORIDE ON NUCLEOTIDES AND RIBONUCLEIC ACID IN GERMINATING COK:N SEEDLING

ROOTS. *Plants Physiol.*, 43(5):669-674, May 1968. 24 refs.

An investigation was made to determine the offset of fluoride on plant growth, acid soluble nucleotides, and RNA in germinating corn seedling roots. Fluoride suppressed root growth to a range of two-thirds to one-third the control value depending on fluoride concentration. The rate of growth inhibition was positively related to fluoride content. Column chromatographic analyses demonstrated that fluoride modified ratios of acid soluble nucleotide species. The relative amount of nucleotides is altered mainly due to triphosphate nucleotides of which ATP is most accumulated. Paper chromatographic analyses showed that fluoride induces changes of RNA structure. It is characterized by lowered relative content of cytosine, and by an increased ratio of cytosine to guanine. Adenine is depressed only in the root tissue treated by the highest fluoride concentration (Author abstract modified)

McNulty, I. B. and D. W. Newman

MECHANISM(S) OF FLUORIDE INDUCED CHLOROSIS.

Plant Physiol. 36(4):385-388, July 1961. 17 refs.

An investigation was conducted to elucidate the mechanism of action of fluoride-induced chlorosis. Leaf tissue was cultured in a calcium-free mineral nutrient solution, with and without fluoride, under constant light and temperature. Analyses were made on the chlorophylls, photochlorophylls, carotenes, and ether soluble magnesium compounds. Sodium fluoride prevented the accumulation of chlorophyll a, chlorophyll b, and photochlorophyll in bean leaves. However, the photochlorophyll to chlorophyll a transformation was not affected. The chlorophylls, the carotenes, and total ether soluble magnesium containing compounds were all affected properly-

<xref image="2000WVKC.TIF|V3|2006:09:28:01:37:28.00|121285|0"> image: </xref>

tionately. The similarity in total ether-soluble-magnesium containing compounds indicates there was no inhibitor! of pigment synthesis following the attachment of the magnesium atom to the ring structure. These results suggest that the inhibition of pigment synthesis must occur very early in the synthesis of pigment components, or with some phase of basic metabolism necessary for their synthesis. The apparent dissolution of chloroplast structure that occurs concurrently with the appearance of chlorosis could explain the similarity in decrease of all pigments. Thus, fluorides may affect the early stages of pigment synthesis, or induce the degradation of chloroplast structure. (Author summary modified)

Threshow, Michael, Gerald Dean, and Frances M. Harner
STIMULATION ON TOBACCO MOSAIC VIRUS-INDUCED
LESIONS ON BEAN BY FLUORIDE. *Phytopathology*, vol.
(S7):7S6-758, July 1967. 4 refs.

The possible effect of fluoride on the number of local lesions developing on Pinto bean leaves following inoculation with tobacco mosaic virus was studied. Plants were grown in fumigation chambers where atmospheric fluoride concentrations ranged from 0.2 to 2.5 micrograms/ cu m; foliar fluoride concentrations ranged from 20 to 637 ppm. The number of lesions increased with foliar fluoride concentrations up to 500 ppm, above which the number decreased. Lesion numbers on plants in the unfumigated chambers served as a control, and these values represented 100%. The lesion numbers on leaves with fluoride concentration of 100-200, 200-300, 300-500 ppm were 121%, 157%, and 179%, respectively. When lesion numbers were grouped according to leaf age, lesions were most prevalent on the first trifoliolate leaves. The number of lesions decreased on older leaves and plants. When leaves were fully developed and plants had reached the four- to five-leaf stage, no lesions could be induced. (Author abstract modified)

Treshow, Michael and Merrill R. Pack
FLUORIDE. In: *Recognition of Air Pollution Injury to Vegetation: A Pictorial Atlas*. Jay S. Jacobson and A. Clyde Hill (eds.), Pittsburgh, Pa., Air Pollution Control Assoc., 1970, p. D1-D17.
29 refs.

The damaging effects of fluoride on plant foliage, flowers, and fruits are discussed. Fluoride injury results from the gradual accumulation of fluoride in the plant tissue over a period of time. Therefore, the duration and the atmospheric concentrations are important in determining the severity of injury. Different plant species, varieties or clones of a single variety, and plants from different seed lots differ in their susceptibility to fluoride. A list of some common plant species, which are sensitive to fluoride, is presented in tabular form. The characteristic symptom of fluoride injury on many broad-leaved plants is necrosis, which occurs primarily at the leaf tips and margins where the fluoride has accumulated. This symptom is seen in apricot, gladiolus, European grape, and conifers. Fluoride sometimes causes a distinctive injury symptom in lilacs. A reddish-purple discoloration develops along the leaf margins and extends into a mottled reddish pattern between the veins. More severe injury results in chlorosis and necrosis. Fluoride also causes chlorosis in citrus, poplar, sweet cherry, and corn. Fluoride injury results in marginal necrosis of the petals and sepals of flowers, and in soft suture in some fruits.

Compton, O. C, L. F. Remmert, and W. M. Mellenthin
FLUORINE LEVELS IN CROPS OF THE DALLES AREA IN
1962 AND 1963. Oregon Agricultural Experiment Station, Corvallis, Special Rept. 187, 37p., 1965. 8 refs.
The fluorine content of forage or foliage of alfalfa, apricot, sweet and sour cherry, grape, peach, and prune crops grown in The Dalles area in Oregon in 1962, and of alfalfa, cherry,

and peach crops in 1963 are reported. These data are compared to similar data obtained periodically since 1953. Leaf samples collected in July 1962 ranged from 4 to 362 ppm fluorine, averaging 31 ppm. Samples collected in October ranged from 17 to 474 ppm, averaging 92 ppm. Similar samples from the Corvallis area had less than 15 ppm fluorine. Alfalfa forages from The Dalles area averaged 31 ppm in July and 81 ppm in October with maximums of 84 and 166 ppm, respectively. A marginal necrosis characteristic of fluoride injury was found on apricot leaves, with the weaker trees showing the most severe injury. In June 1963, sweet cherry leaf samples ranged from 4 to 34 ppm, averaging 13 ppm fluorine, while those collected in September ranged from 9 to 72 ppm, averaging 22 ppm. Similar samples taken in July and October 1962 averaged 32 and 95 ppm, respectively. Fluorine in the air was determined on a few samples in 1963. The amounts varied from none to 12.9 micrograms fluorine/cu m of air varying with the location and season. The data are insufficient to relate air and foliage fluoride. (Author summary modified)

22085

Compton, O. C., L. F. Remmert, and W. M. Mellenthin
FLUORINE LEVELS IN CROPS OF THE DALLES AREA IN
1964. Oregon Agricultural Experiment Station, Corvallis, Special Rept. 204, 21p., 1965. 5 refs.
In 1964, the fluorine content of sweet cherry leaf samples collected in July ranged from 4 to 31 ppm, averaging 11 ppm. Samples collected in September contained from 6 to 52 ppm fluorine, averaging 19 ppm. The data for peach trees were similar. Even though these fluorine levels were much lower than in 1960-62, the effect of distance and direction from the aluminum reduction factory is evident. There was no discernible trend in fluorine levels because of location within The Dalles area before the operation of the factory. Fluorine samples from the air varied from none to 2.5 micrograms/cu m of air. The relationship between the fluorine in the air and in foliage of Royal Ann cherry trees indicated that the higher the air fluorine, the greater was the leaf fluorine content. (Author summary modified)

Compton, O. C., L. F. Remmert, and W. M. Mellenthin
FLUORINE LEVELS IN 1961 CROPS OF THE DALLES
AREA. Oregon Agricultural Experiment Station, Corvallis, Special Rept. 153, 25p., 1963. 6 refs.
The fluorine content of the foliage or forage of alfalfa, apricot, cherry, sour cherry, grape, peach, and prune crops grown in The Dalles area in Oregon during 1961 are reported. These data are compared, in tabular form, to similar data obtained previously. Leaf samples collected from the crops in July 1961 ranged from 12 ppm to 217 ppm fluorine, averaging 65 ppm. Samples taken in September ranged from 16 to 204 ppm, averaging 68 ppm fluorine. Leaf Scorch on apricot trees and soft suture on peaches were observed. These conditions were noted in 1959 and 1960, but not before the operation of an aluminum factory located in this area. The effects of calcium chloride and fluoride spray treatments were also investigated. (Author summary modified)

HISTOLOGICAL RESPONSES OF SOME PLANT LEAVES

TO HYDROGEN FLUORIDE AND SULFUR DIOXIDE. *Am. J.*

Botany, vol. 43:755-760, Dec. 1956. 20 refs.

The effects of hydrogen fluoride and sulfur dioxide on plant leaves were investigated. Morpark apricot, Italian prune, and Winesap apple trees were fumigated eight hours daily, five days per week, at 5 ppb HF. Pinto bean and tomato seedlings were fumigated with 0.5 ppm SO₂ and 5 ppb HF. Fumigations with a mixture of HF and SO₂ were conducted with the same concentrations in combination. Samples of injured and control leaves were processed microtechnically and examined microscopically. Histological responses to HF and SO₂ were indistinguishable. Microscopic injury was first apparent in the spongy mesophyll cells and the lower epidermal cells. The mesophyll cells were readily injured and the most common degree of injury was total collapse; the lower epidermal cells were observed to distort and collapse when the mesophyll cells did. Disintegration of the chloroplasts occurs in those cells injured by HF and SO₂ before complete collapse of all the leaf tissues occurs. Various postulates are discussed concerning the means and pathways by which a phytotoxic air pollutant may enter the leaf and produce injury.

ASSORTMENTS OF GAS-RESISTANT LAWN GRASSES. In:

American Institute of Crop Ecology Survey of USSR Air Pollution Literature. Effects and Symptoms of Air Pollutants on Vegetation; Resistance and Susceptibility of Different Plant Species in Various Habitats, In Relation to Plant Utilization for Shelter Belts and as Biological Indicators. M. Y. Nuttonson (ed.), vol. 2, Silver Spring, Md., American Institute of Crop Ecology, 1969, p. 50-55. (Also: *Tr. Inst. Ekologii Rasteniy Zhivotnykh (Sverdlovsk)*, vol. 54:91-95, 1967.)

Investigations concerning the gas resistance of lawn grasses were conducted at a Ural aluminum plant where fluorine pollution is present. Photosynthesis and the water regimen were studied in meadow fescue, red fescue, Kentucky bluegrass, red top, and timothy grass. Damage was observed in early spring when the leaves were appearing. There was burn on the tips of the leaves; then spotting and blotching appeared. The damage increased and reached a peak toward the end of the growing season. The smallest percentage of damage was observed on meadow fescue, red fescue, and Kentucky bluegrass, while the greatest damage was found on red top and timothy grass. Fluorine compounds decreased photosynthesis, water-holding capacity, and the quantity of free water. Slightly damaged species have a lower photosynthetic intensity, greater water-holding capacity, and more free water than the severely damaged grasses. Meadow fescue, red fescue, and Kentucky bluegrass are recommended for industrial sectors with severe fluorine pollution. Red top, 'regnena', Awnless bromegrass, and timothy grass are suggested for sectors with little pollution.

TYLOSIS FORMATION IN RESPONSE TO FLUORIDE FUMIGATION OF LEAVES. *Phytopathology*, vol. 59:518-519,

April 1969. 6 refs.

Occurrence of tyloses in the petiole of geranium plants fumigated with fluoride gives evidence that injury may influence function of tissues some distance from the actual site of visible damage, for in the early stages of hydrogen fluoride fumigation, light-brown colored areas appeared at three white margins of leaves; these became necrotic zones as the fumigation was prolonged. Intermediate-age leaves were injured more severely than either younger or older leaves. All tissues were affected in severely injured edges, although some upper epidermal cells

still appeared nearly normal. In the zone adjacent to the severely injured area, the upper half of the leaf was normal, while the spongy mesophyll cells became plasmolyzed and collapsed. Distortion of chloroplasts and starch grains was noted in parenchyma cells near the injured area. Severely injured and necrotic regions stained very heavily with safranin. The first occurrence of injury in the spongy mesophyll is consistent with the suggestion that fluoride enters mainly through the stomata. Fluoride effects are more evident in the vascular region than other areas, and it is possible that the fluoride damage produces early senescence that in turn causes the tyloses to form. In the phloem, cylinder-like depositions were noted on sieve plates which were identified as callose by strong fluorescence when stained with aniline blue and illuminated with ultraviolet light.

Garber, K., R. Guderian, and H. Stratmann
INVESTIGATIONS OF THE UPTAKE OF FLUORINE BY
PLANTS FROM THE SOIL. (Untersuchungen über die Aufnahme von Fluor aus dem Boden durch Pflanzen). *Qualitas Plant. Mater. Vegetables*, vol. 14:223-236, 1967. [? refs. Translated from German. Belov and Associates, Denver, Colo., 24p., May 30, 1970.

Experiments were conducted with different soil types to determine the fluorine uptake by plants from the soil. Identical plant species showed different fluorine contents on different soils, and there was no correlation between the F-values in the soils. Additions of sodium and calcium fluoride of 5 mg F per 100 g soil (F mg%) to the soil had no effect on the F-level of the plants. Some one year old plants indicated necrosis and discoloration, especially at the leaf tips, and a decrease in yield which was stronger for soil with CaF₂-additions. The uptake of fluorine, necrosis, discoloration, and decreased yield were more pronounced on sandy soil than on rrsarshy or clay soils. Equal amounts of fluoride when added in one portion had a more damaging effect on the growth of *Trc.descantia* and tomato than when added in three partial portions. The addition of NaF to oats in one portion before seeding had no effect on the F-content, but experiments with gradual additions showed a strong increase of the F-value. Soils taken from regions with flourine emissions were used to grow beans. The increased F-level in the beans is considered as proof that fluorine emissions act directly on the plant parts above the soil, and indirectly through the soil. (Author summary modified)

Coleman, Charles H.
HOW PLANTS TEST AIR. *Org. Gardening Farming*, 1961:71-78, March 1961.

Although laboratory tests tell when phytotoxicants are present in the atmosphere, only plants will tell when they combine to form fog-burn contaminant injurious to crops. Moreover, in many instances, plants provide the first warning of early air pollution. The reliance scientists place on plant indicators is exemplified by a San Francisco program in which plant data is fed into electronic machines to determine the extent and origin of pollution damage. Plants susceptible to ail pollution are listed and the effects of oxidants, ozone, fluorides, sulfur dioxide, ethylene, smog, and herbicides on plants are summarized. It is noted that air pollution damage to crops is \$7 1/2

<xref image="2000WVKE.TIF|V3|2006:09:28:01:37:34.00|124030|0"> image: </xref>

billion per year and that plants will become increasingly important for monitoring pollutants.

Miller, Vernon L.

THE EFFECT OF ATMOSPHERIC FLUORIDE ON WASHINGTON AGRICULTURE. In: Air Pollution. Louis C. McCabe (ed.), New York, McGraw-Hill Book Co., Inc., 1952, Chapt. 11, p. 116-122. 7 refs.

A variety of studies on fluorides and vegetation are briefly reported. A new disease of the gladiolus Italian prune, characterized by brown, marginal leaf scorch and premature defoliation, is caused by industrial fluoride emissions. Fluorine scorch of gladiolus may be controlled by lime sprays under field conditions, and early results suggest that some varieties of gladiolus may serve as indicator plants in areas where fluorine effluents are a factor. Fluorosis of cattle in Washington was diagnosed, caused by ingestion of forage containing fluoride from air pollution. Extensive research is in progress on a number of possible causes of the ponderosa pine blight, including air pollution, climatic factors, insect damage, and fungus diseases; conclusive results are not yet available.

Bulgakov, M. V.

AN EXPERIMENT IN CREATING PROTECTIVE PLANTINGS IN THE CITY OF KRASNOURAL'SK. In: American Institute of Crop Ecology Survey of USSR Air Pollution Literature. Effects and Symptoms of Air Pollutes on Vegetation; Resistance and Susceptibility of Different Plant Species in Various Habitats, In Relation to Plant Utilization for Shelter Belts and as Biological Indicators. M. Y. Nuttonson (ed.), vol. 2, Silver Spring, Md., American Institute of Crop Ecology, 1969, p. 79-84. (Also: Akad. Nauk SSSR Ural. Filial. Ural. Gos. Univ. Im. A. M. Gor'kogo. Okhrana prirody na Urale (Sverdlovsk), vol. 4:189-195, 1964.)

Krasnoural'sk is a large center of copper smelting and chemical industry in the Central Urals. Large amounts of sulfur dioxide and fluorine, which are harmful to vegetation and man, are discharged to the atmosphere. The local natural forest was destroyed by SO₂, and as a result the city became unattractive and dusty. An arboreal nursery was established to aid in the selection of trees and shrubs adapted to local environmental conditions. An assortment of gas-resistant species for city plantings was developed, including poplar, birch, cedar, larch, maple, elm, Siberian pea shrub, elder, dogwood, sweetbrier, and others. Siberian pea shrubs from the local nursery and from another nursery were planted in a city park. The leaves on the plants from the local nursery remained normal in appearance, while those from the other nursery were severely damaged by SO₂. This confirms the fact that the trees and shrubs for gas-polluted areas should be exclusively local, raised in the same noxious medium where they are to continue their growth. If frost-resistance is also desired, the plants should be raised under rigorous, spartan conditions. The establishment of parks and plazas, and the great number of trees and shrubs along the streets have made the air of the city cleaner and resulted in a milder microclimate.

INDUSTRIAL WASTES OF THE CITIES OF BAKU AND SUMGAI AND THEIR EFFECT ON GREEN PLANTINGS.

In: American Institute of Crop Ecology Survey of USSR Air Pollution Literature. Effects and Symptoms of Air Pollutes on Vegetation; Resistance and Susceptibility of Different Plant Species in Various Habitats, In Relation to Plant Utilization for Shelter Belts and as Biological Indicators. M. Y. Nuttonson (ed.), vol. 2, Silver Spring, Md., American Institute of Crop Ecology, 1969, p. 6-7. (Also: Akad. Nauk SSSR Ural. Filial.

Komis. po Okhrane Prirody. RastiteP nost' i promyshlennye zagryazneniya. Okhrana prirody na Urale. V (Sverdlovsk), 1966, p. 37-38.) The industrial centers of the Apsheron Peninsula discharge a great amount of wastes, particularly carbon monoxide, sulfur dioxide, fluorine compounds, hydrocarbon vapors, chlorine, and hydrogen sulfide. In most cases, these compounds adversely affect green plants which function, at times, as protection against gas and smoke. When the air is polluted by irritant gases dark brown burns appear on the leaves. Partly withered and some yellowed leaves are also found. The toxic action of these pollutants also affects the root system. Trees which exhibit gas resistance include elm, maple, pistachio, oleaster, almond, honeysuckle, and others. The establishment and development of green trees are important as a means of combatting air pollution and for the sanitary well-being of the industrial areas. Several recommendations for establishing green plantings in industrial areas are included.

Rohmeder, E., W. Merz, and A. V. Schoenborn
THE BREEDING OF SPRUCE AND PINE SPECIES WHICH
ARE RELATIVELY RESISTANT AGAINST INDUSTRIAL
WASTE GASES. (Zuchtung von gegen Industrieabgase relativ
resistenten Fichten- und Kiefernarten). Forstwiss. Zentr., vol.
81, 1962. 14 refs. Translated from German. Belov and As-
sociates, Denver, Colo., 19p., July 7, 1970.
Methods for determining the relative sensitivity of various
types of coniferous trees to industrial waste gases are
discussed, and attempts to breed more resistant strains of
trees are described. Phenotypically resistant spruce trees are
selected from damaged areas and used to supply grafts for
testing purposes. The fact that the resistance is based on
heredity is determined by exposing the grafts, along with pure
sensitive samples, to varying concentrations of sulfur dioxide
gas and hydrogen fluorine gas. No visible damage occurred on
the grafts, while the others indicated symptomis. The chemical
analysis of needles from resistant trees shows that they have
lower sulfur values than more sensitive trees do. The resistant
cuttings can be propagated and distributed in areas where
more sensitive trees cannot survive.

Griffin, S. W. and B. B. Bayles
SOME EFFECTS OF FLUORINE FUMES ON VEGETATION.
In: Air Pollution, U. S. Technical Conference on Air Pollution.
Louis C. McCabe (ed.), New York, McGraw-Hill, 1952, Chapt.
10, p. 106-115. 1 ref.
Peach, apple, wild black cherry, Norway spruce, buckwheat,
tomato, and corn plants were fumigated with relatively low
and moderate concentrations of hydrofluoric acid gas in order
to determine concentrations that might cause injury to various
species, the appearance and character of injury, and the ab-
sorption of fluorine by plants. A wide variety of soil,
meteorologic, and plant variables are noted that must be con-
sidered in interpreting the data from these tests. The leaves of
peach, wild black cherry, buckwheat, tomato, and corn are
very susceptible to acute damage when exposed to small
amounts of hydrofluoric acid in the air. Apple foliage was less
susceptible. Acute leaf injury resulted from fumigation at night
as well as in daylight, although the injury was less. Pin-point
chocolate-colored lesions produced at the tip ends of peaches
<xref image="2000WVKF.TIF|V3|2006:09:28:01:37:38.00|120964|0"> image: </xref>

served as the entry point for fungi which caused rotting. Fluorine content of leaves was markedly increased, but even relatively heavy exposures caused little increase in the fluorine content of the fruit. Exposure of peach trees for a few hours to hydrofluoric acid gas concentrations as low as 0.05 to 0.1 ppm may cause acute damage to a small percent of the leaves, but that higher concentrations or longer exposures are required to cause twig or shoot damage. The usefulness of buckwheat and various coniferous species as indicators of fluorine and other toxic gas pollution is discussed, as well as the fluorine content of soils. Lime applied to soils to which fluorine had been added greatly reduced the uptake of fluorine from the soil and prevented plant injury. (Author summary modified)

Antipov, V. G.

THE EFFECT OF INDUSTRIAL SMOKES AND GASES UPON CONIFEROUS FORESTS GROWING UNDER CONDITIONS OF INCREASED HUMIDITY IN THE MOSCOW RE-

GION ('PODMOSKOV'E'). In: American Institute of Crop Ecology Survey of USSR Air Pollution Literature. Vol. III. The Susceptibility or Resistance to Gas and Smoke of Various Arboreal Species Grown Under Diverse Environmental Conditions in a Number of Industrial Regions of the Soviet Union. M. Y. Nuttonson (ed.), Silver Spring, Md., American Institute of Crop Ecology, 1970, p. 39-44. 12 refs. Translated from Russian. (Also: Byull. Gl. Bot. Sada, no. 46:41-46, 1962.)

An investigation of the relationship between industrial pollution and damage to coniferous trees is presented. A definite correlation between the destruction of pines and their distance from industrial enterprises is noted. The accumulation of sulfates, by the assimilating mechanism, is one of the verified symptoms of damage to plants from sulfur dioxide. The effect of humidity upon the concentration of atmospheric pollutants is discussed. The presence of fog increases the concentration of pollutants. Increased humidity is not only conducive to acidic fogs, but also prevents the closing of the stoma, a condition which allows easier penetration of pollutants. The toxicity of sulfur gases is increased if carbon monoxide, nitric oxides, aldehydes, and ozonides are present. Ammonia, hydrogen sulfide, and hydrogen fluoride are other serious contaminants.

23386

Cormis, L. de

ABSORPTION AND ACCUMULATION OF ATMOSPHERIC FLUORINE BY THE LEAVES OF CERTAIN HERBACEOUS

PLANTS. (Absorption et accumulation du fluor atmosphérique par les feuilles de certains végétaux herbacés) Ann. Physiol. Veg., 10(4):251-262, 1968. 16 refs. Translated from French. Belov and Associates, Denver, Colo., 24p., June 18, 1970.

The effects of atmospheric fluorine compounds, such as are emitted from aluminum industries, on various leafy plants are investigated. Tomato, bean, and tobacco plants were grown under controlled conditions and subjected to varying hydrogen fluoride concentrations and different atmospheric conditions. The rate of absorption of atmospheric fluorine is clearly proportional to the concentration, time of exposure, and relative humidity. The fluorine is accumulated near the edges of the leaves and results in necroses in that area. The level of toxicity varies from plant to plant. It can be attained from a heavy concentration of short duration, or more probably from a semi-permanent pollution of low concentration. The difference between fluorine and sulfur dioxide absorption is explained.

23516

NEW TECHNIQUE AIDS STUDY OF SMOG EFFECTS ON

CITRUS PLANTS. Chem. Eng. News, 39(8):42-43, Feb. 20, 1961.

A technique for removing oxidants from smog without affecting the concentration of fluorides was developed for use in a

long-term study of smog damage to citrus trees. The technique is based on the gas-phase reaction between oxidants and nitric oxide, which removes virtually all the ozone though not all the peroxyacyl nitrates. The oxidants are first mixed with filtered room air and fluoride, then with the reductant in a large polyethylene reaction chamber. If desired, hydrogen sulfide can be added to air leaving the chamber to promote further oxidant removal. Effluent from the chamber is divided between a fluoride recorder and an oxidant recorder. The possibility that hydrogen sulfide might protect plant leaves from oxidants is noted.

23576

Bolay, A. and E. Bovay

OBSERVATIONS ON THE SENSITIVITY TO FLUORINATED GASES OF SOME PLANT SPECIES OF VALAIS. (Observations sur la sensibilite aux gaz fluores de quelques especes vegetales du Valais). Phytopathol. Z., vol. 53:290-298, 1965. 11 refs. Translated from French. Belov and Associates, Denver, Colo., 17p., June 18, 1970.

Observations made over a period of 15 years on the relative sensitivity of various plants to fluorine compounds are reported. The three methods used in evaluating damage to plants are: observation of typical necroses appearing on the foliage, chemical analyses of the fluorine content of the plants, and utilization of certain indicator species to detect fluorine. Examinations of tree leaves permit the establishment of sensitivity limits. No injury occurs below 25 ppm, variable reactions occur from 25-105 ppm, depending on the climate and health of the plants, and burns are almost always present from 105 ppm on. Plant species are separated into 4 classes based on their sensitivity. The most sensitive plants can be used as indicators of the presence of fluorine, both in terms of the degree of contamination and the limits of the contaminated zone.

THE INFLUENCE OF ALUMINUM-WORKS EJMALATIONS ON THE CONTENT OF FLUORIDES IN SOIL AND GRASS.

Pornohospodarstvo, 10(4):257-262, 1964. Translated from Slovak. Belov and Associates, Denver, Colo. 7p., June 26, 1970. Between 1958 and 1962, fluoride analyses were carried out on 338 soil samples and 72 grass samples from the vicinity of an aluminum plant. Soil from the south side of the plant showed fluoride values as high as 91.0 mg. Values for the remaining area ranged from 4.8 to 53.1 mg, averaging 20 to 29 mg. In contrast, the average fluoride value for soil from an uncontaminated area was 13.6 mg. Grass samples showed fluorides to a value of 118.7 mg in 100 g of dry substance, while the fluorine content of light dust reached a value of 5.0 mg/100 g of fresh grass. The content of fluorine compounds in soil and grass decreased with increasing distance from the plant. The determined values in the proximity of the plant represent a multiple transgression of the natural content of fluoride in soil and grass.

FLUORINE DAMAGE IN THE LOWER FRICK VALLEY.

(Die Fluorschaden im unteren Frichtal). Schweiz. Arch. Tierheilk., 101(1): 1-4, 1959. (Presented at the Swiss Veterinary Society, General Convention, Brunnen, 1959.) Translated from German. Belov and Associates, Denver, Colo., 5p., July 10, 1970.

Even though the only aluminum produced in Germany today is manufactured by an electrolytic method, fluorine emissions are still 500 kg per day. In the area of one plant, the quantity of fluorine sedimented per acre in 1956 amounted to approximately 7 kg at 300 m from the plant, decreased rapidly to 0.9 kg at 700 m, and then decreased slowly with increasing distance. Severe clinica phenomena have been observed on vegetation at quite distant locations and can be attributed only to airborne fluorine. Moreover, feed plants (hay and grass) have been damaged, even when their fluorine levels were below those considered toxic by most authors.

EFFECTS OF SOME EXHALATIONS ON AGRICULTURAL

ANIMALS. (Ucinky nekteryeh exhalaci na hospodarska zvirata).

Ochrana ovzduši, 1969:122-125, Aug. 1969. 15 refs. Translated from Czech. Belov and Associates, Denver, Colo., 14p., June 16, 1970.

The effects of various pollutants on farm animals are discussed. The emissions from such sources as power plants, metal processing, cement works, chemical industries, fertilizing, and nuclear installations are described. The effects of the various pollutants can vary, depending upon such factors as concentration, climate, age of animals, health of animals, and individual sensitivity. Inhalation of ashes, cinders, or other light particulates causes irritation and inhibits important digestive processes. Sulfur dioxide irritates mucous membranes and disrupts metabolic processes. The symptoms of acute and chronic arsenic poisoning are discussed. A considerable degree of toxicity for cattle is noticed from power plant ashes. Bees show a marked effect from exposure to arsenic compounds. Typical symptoms of fluorosis in cattle are dental changes. Synergistic effects of pollutants are mentioned. The general air quality of Czechoslovakia is discussed, and current legislation, including air quality standards, is described. An estimation of economic damages due to air pollution is given

FLUORINE ABSORPTION THROUGH THE BARK OF

SHOOTS AND ITS EFFECTS. Angew. Botan., vol. 19:172-181, 1937. Translated from German. 10p.

The effects of fluorine absorption on the shoots of plants and trees are investigated. The primary goal of the research is to determine whether the fluorine compounds which penetrate the bark of the shoots in an earlier season can affect the spring growth of the plant and/or effectively disturb the identification of fluorine fume damage on spring growth. Shoots accumulate fluorine-containing waste gases more or less in their barks, as much a result of exposure in winter as in summer. They are also capable of, but seldom do, store up accumulations in the xylum in water soluble and insoluble forms. The blossoming of branches and the further development of new growth are not noticeably injured by the fluorine compounds which are stored in the bark. All new outgrowths of riuorine-containing branches remain free of fluorine in a fume-free atmosphere. Proven fluorine content in spring growth is regularly a proof of a new fluorine fume effect during or after the blossoming.

Garber, Kurt

ON THE ABSORPTION OF HARMFUL SUBSTANCES

THROUGH TREE BARK. Wiss. Z Tech. Univ. Dresden, vol. 3,

Nov. 14, 1961. 12 refs. Translated from German. 1Op.

The absorption of fluorine, fluoride compounds, tar, asphalt vapors and ammonia through the bark of trees and bushes is reported. Absorption of these substances through bark during the dormant winter season was demonstrated in simulated laboratory experiments. Examination of field specimens obtained in the vicinity of a superphosphate plant indicated that the fluoride content of the bark was inversely in agreement with the distance from the source. A similar observation was made of the woody material but to a considerably lesser degree. Exposure of trees and pruned branches to HF vapor resulted in a bark concentration dependent on the exposure time and a wood concentration reflecting the exposure intensity. Applying a 2% solution of sodium fluoride to the branches caused a 50 % increase in the observed fluoride content of the wood portion. Almost all the fluoride vapor exposed trees were damaged as exhibited by delayed spring growth. The leaves of exposed trees contained 2-3 times the fluoride as the control specimens. Examination of dormant branches from the vicinity of tar and asphalt processing facilities clearly indicated the presence of these substances stored in the bark, and, depending on the kind of plant, that more or less of these substances were transferred to the wood. Rough bark appeared to enhance the pick-up of the substances. The transfer of these materials to spring growth was in most cases very slight. Similarly, dormant branches were exposed to ammonia and, while NH₃ could be detected in the bark in all cases, it could not be detected in the wood in all cases. The effect of low concentrations for long periods of time was greater than that of high concentrations for short periods of time. High-concentration, short-term exposure of NH₃ acted as a fertilizer, causing earlier sprouting and better leaf color. Low-concentration, long-term exposures had a detrimental effect. By late May, the ammonia content of the test specimens was the same as that of the control specimens.

Adams, Donald F.

THE EFFECTS OF AIR POLLUTION ON PLANT LIFE.

A.M.A. Arch. Ind. Health, vol. 14:229-245, July-Dec. 1956. 86

refs. (Presented at the American Industrial Hygiene Association, Annual Meeting, 17th, Philadelphia, Pa., April 23-27, 1956.)

Knowledge of the range of foliar expressions of plants exposed to atmospheric pollutants is extremely useful to those engaged in the study of the scope and severity of an air-pollution problem. The wide variations in susceptibility and characteristic response of common species to typical contaminants provide a convenient method for identifying, determining the distribution of, estimating the level of, and providing a collection medium for subsequent chemical analysis for a pollutant.

A detailed review of the progress of research on the effects of sulfur dioxide, hydrogen fluoride, and 'Los Angeles-type' smog since 1950 is presented (with work published prior to 1950 cited to provide continuity whenever necessary). Fluoride appears to be a cumulative phytotoxicant which may move through the plant vascular system to the leaf tip or margin and produce foliar necrosis upon accumulation of a 'threshold con-

<xref image="2000WVKH.TIF|V3|2006:09:28:01:37:44.00|121690|0"> image: </xref>

centration.' Evidence also points toward possible enzymatic inhibition. Sulfur dioxide and smog exposures result in foliar injury only if the rate of tissue absorption exceeds the rate at which the plant can effectively neutralize the toxic agent. Smog, however, can produce growth inhibition without producing visible injury, whereas sulfur dioxide does not produce this so-called invisible injury. Reference is made to a catalogue of common weeds according to their characteristic foliar response and susceptibility to a number of pollutants. (Author summary)

Bossavy, M. J.

NECROSIS CAUSED BY FLUORINE. (Les necroses due au fluor). Pollut. Atmos. (Paris), 8(30):176-184, June 1966. Translated from Frtnc. Belov and Associates, Denver, Colo., 9p., Sept. 4, 1970. (Also: Revue Forestiere, no. 12, Dec. J965.)

The shape, color and evolution of necrosis due to fluorine are described for a certain number of leaf-bearing coniferous vegetatio according to the stage of development of the leaf. The experiments of Professor Holland, 1908-1909, and his album containing pen sketches and a collection of samples are presented. The only common characteristic to note is that such flaws begin to be seen at the tips of the needles; in the leaves, they will be noticed either at the very tip of the leaves, in long narrow leaves, or els almost simultaneously at the tip and on the edge of the leaf if sue is a wide and whole leaf. If the leaf has serrated edges, the necrosis is evident at the points of tips of the lobes. Often the tainted parts assume a 'V shape, the point directed towards the leaf stalk, but it quickly moves along the leaf blade and assumes a very different shape. In the cherry and other plants, the tainted parts will be easily detachable, leaving an undulating line where they have been severed. Little patches of yellowish color will often be dispersed along the blade and inside the leaf itself. The color of the damaged parts varies from black to a brown or ruse color. Sometimes all needles of the same age on a given branch wil show necrosis of the same color obviously in the same stage of development. Characteristics are cited for the cherry tree, chestnut, alfalfa, walnut, peach, pear, sainfoin, vine, lime tree, larch, hawthorn, saffron, barberry, gentian, millepertuis, myrtle, lily of the valley, Solomon's seal, silene, the common pine, pectin fir, and spruce. Meteorological factors are also mentioned.

Kotte, W.

SMOKE DAMAGE TO STONE FRUIT. (Rauchscha den an Steinobst-Fruchten). Nachrbl. Deut. Pflanzenschutzdienst (Berlin), no. 9:91-92, 1929. Translated from German. Belov and Associates, Denver, Colo., 4p., Sept. 8, 1970.

Of the fruit trees in the neighborhood of a brickyard, the apples and cherries were undamaged, while in contrast the damson plums, yellow plums, and yellow Victoria plums showed damage on foliage and fruit. Damage symptoms of the damson plums were necrotic spots of tissue that appeared either as sunken patches about fingernail size or, in cases of greater extend, as an apical zone of retarded growth. The diseased tissue was coffee brown in color, and beads of sap frequently could be found around the border of the necrotic zone. Microscopic examinations revealed that the epiderma cells were filled with brown granular masses instead of dark blue anthozyan. The pericarpal tissue, which in a healthy condition exhibits vesicular, almost empty appearing cells with transparent walls, was small-celled, with brown colored cell walls covered with brown granular concretions. Limitation of the damage to the end of the fruit is explained by the fact that here the rain drops hold on longest and the gases dissolved in the water have their strongest influence. The cause of the smoke damage is attributed to hydrofluoric acid.

Bovay, E.

EFFECTS OF SULFUR DIOXIDE AND FLUORINE COM-
POUNDS ON VEGETATION. (Effets de l'anhydride sulfureux
et des composés fluorés sur la végétation). Station Federate de
Recherches de Chimie Agricole, Liebefeld-Bern, Switzerland,
Air Pollution Proceedings of the First European Congress, on
the Influence of Air Pollution on Plants and Animals, Wagenin-
gen, Netherlands, 1968, p. 111-135. 81 refs. Translated from
French, Belov and Associates, Denver, Colo., 34p., Aug. 28,
1970.

The sources of sulfur dioxide and fluorine pollutants are
described and the damage caused to plants by these com-
pounds are related. Sulfur dioxide penetrates to the interior of
plants through the stoma; therefore every condition favoring
the opening of the stoma also increases the assimilation of
SO₂. The caustic action of SO₂ is due to its reducing action,
which can affect plant metabolism. Sensitivity to SO₂ depends
on such factors as age, nutritive state, and individual
tolerances. Relationships between pollutant concentration and
time of exposure are a determining factor in threshold limita-
tions. A distinction between plant injury and damage is made.
Various attempts to observe and control atmospheric pollution
are described. Fluorine compounds are among the most toxic
of pollutants. Fluorine accumulation in soils and plants is
discussed. The effects of fluorine on various types of plants
are noted. Synergistic action can occur when certain elements
introduced by fertilizers react with fluorine compounds found
in the atmosphere. Most plants seem to have a fluorine
threshold beyond which photosynthetic processes can be in-
visibly damaged. Certain plants, due to their highly sensitive
nature, can act as indicators of atmospheric pollution. Recent
experiments involving the effects of fluorine on fruit trees are
described.

Wentzel, K. F.

SENSITIVITY AND DIFFERENCES IN THE RESISTANCE
OF PLANTS TO AIR POLLUTION. (Empfindlichkeit und Re-
sistenzunterschiede der Pflanzen gegenüber Luftverun-
reinigung). In: Air Pollution on Plants and Animals. Wagenin-
gen, Netherlands, Center for Agricultural Publishing and Docu-
mentation, 1969, 357-370. 27 refs. Translated from German.
Belov and Associates, Denver, Colo., 17p., Sept. 28, 1970.
Until 1940, 2 ppm of sulfur dioxide in the air was supposed to
be the maximum acceptable concentration for long duration
pollution. Recent experiments in the field in various areas
have shown that the limit has to be reduced to 0.02 ppm and
for HF it must be considerably lower. It is better to charac-
terize air pollution by the frequency and duration of the times
a certain critical concentration is exceeded, rather than by
average concentration. The resistance of plants varies with the
type of emission, conditions of growth, phase of development,
and exposure. A distinction must be made between experimen-
tal resistance gauged by leaf sensitivity and resistance in the
field measured by yield and endurance. A generally valid
sequence of potential damage areas for plants cannot be made,
but a scheme for their classification into three groups is given.
In order of generally increasing sensitivity, plants can be
grouped in the following manner: agricultural crops, deciduous
forests, gardens and fruit plants, fodder crops and coniferous
<xref image="2000WVKI.TIF|V3|2006:09:28:01:37:48.00|124086|0"> image: </xref>

forests. This investigation into the sensitivity of plants to air pollution and the differences in their resistance to various types of pollutants has revealed that this can be counted among the most complicated problems of biology. Nevertheless, the illusion is widespread that this matter may be judged casually and simply. Only by recognizing the severity of the problem can progress be made. (Author summary modified)

Yamazoe, Fumio and Teruo Nakamura
ON NUTRITIVE CHANGES OF WATER FIELD RICE
PLANT CAUSED BY HYDROGEN FLUORIDE. FUNDAMEN-
TAL RESEARCH CONCERNING SMOKE POLLUTION ON
PLANTS. (REPORT 3). Nippon Dojo-Hiryogaku Zasshi (J. Sci.
Soil Manure Japan), vol. 31:29-32, 1960. 12 refs. Translated
from Japanese. Belov and Associates, Denver, Colo., lip., Sept.
30, 1970.

In order to investigate nutritive effects of smoke pollution caused by hydrogen fluoride gas on plants, hydroponic cultures of water field rice plants were made and contacted with hydrogen fluoride at 500 ppm concentration for 1 hour. The samples were then picked out at the times of minimum and maximum assimilation of carbon after two days, and the yields of every section of the plant as well as various components were measured. Their changes were checked by comparison with those in the control lots. Chlorophyll contents in the rice plants above the ground in the contact lots decreased immensely, accompanied with a decline of increase of carbohydrate at the time when the afternoon assimilation function reaches its highest. This shows clearly that the carbon assimilation deteriorates. Among carbohydrates, the decrease of production of non-reducing sugar was especially noteworthy. Nitrogen in the contact lots, as compared with that in the control lots, showed a decline in pure protein ratio, and demonstrated a tendency toward a large ratio of amide-ammonia-nitrogen which was not completely assimilated to the plants. Among inorganic components, the absorption of potash declined considerably after gas contact, and magnesia tended to stay in the roots. Lime, however, showed scarcely any damage. Silicic acid tended to show an increasing absorption. The sections in the plants where fluorine is contained are the leaf blade, sheath, and root, in that order. Most fluorine exists in the leaf blades. The fluorine doesn't seem to move around in the system after gas absorption; neither does it purge from the roots. For the prevention of such injurious components and to promote recovery from abnormal metabolism, lime, magnesia, silicic acid, and so forth, should be valuable. (Author summary modified)

Radeloff, H.
INVESTIGATION AND APPRAISAL OF FLU-GAS DAMAGE.
(Untersuchung und Begutachtung von Rauchscha-den). Hamburg
Staatsinst. Angew. Botanik Jahresber., vol. 6:126-127, 1939. 1
ret. Translated from German. Belov and Associates, Denver,
Colo., 4p., June 12, 1970.

Waste gases containing fluorine and sulfurous acid are reported to damage plants and bees. Branches of fruit trees afflicted by fluorine had leaves which showed numerous spots, intercostal discolored stripes, or also withered tips and periphysis. All which remained, in some cases, were the blackish brown withered remains of the leaves. At a location in central Germany, the bees of a migrating stand died without any immediately apparent reason. However, they had then-hives in the vicinity of a plant working with fluorine, and the mass dying started quite suddenly with the same day on which the wind had changed in their direction. An investigation for sulfurous acid in 36 plant samples resulted in various causes, from manufacturing plant flue gases to gas remnants coming from a habitation treated with sulfur.

Baldacci, Elio and Vincenzo Ceccarelli
AIR POLLUTION AND PLANT LIFE. World Health Organization, Copenhagen (Denmark), Regional Office for Europe, Proc. Conf. Public Health Aspects Air Pollution Europe, Milan, Italy, 1957, p. 76-95. (Nov. 6-14.)

The use of plants as indicators of air pollution is discussed in detail. Five requirements are reviewed as necessary for a scientifically rigorous study of symptomatology: (1) on-site inspection of injury; (2) exclusion of other causes; (3) comparative examination of injured and uninjured species in the area; (4) comparative examination of species and varieties injured in the area; and (5) topographic and climatologic investigations. In summarizing many years of experience in studying plant injuries from atmospheric pollutants, two tables are presented giving the relative susceptibility of a large variety of plants to sulfur di- and trioxide, chlorine, fluorine, and ammonia, with particular relevance to conditions prevalent in various parts of Italy. It is noted that plant injury cannot be judged solely on the basis of chemical analysis; neither is plant inspection always sufficient, since there are no leaf injuries, however typical, that cannot also be produced by causes having nothing to do with air pollution. It is concluded that the use of plants as indicators of air pollution is possible and advisable if precise and exact rules for their use are followed, and that estimation of damage is made by a fully-qualified and experienced phytopathologist in order to avoid the many gross errors which can otherwise be easily made.

Houten, J. G. Ten and F. Spierings
AIR POLLUTION AND ITS INFLUENCE ON VEGETATION.
World Health Organization, Copenhagen (Denmark), Regional Office for Europe, Proc. Conf. Public Health Aspects Air Pollution Europe, Milan, Italy, 1957, p. 70-75. (Nov. 6-14.)

Investigations on the effects of hydrogen fluoride and sulfur dioxide on plants are reported. Fumigation chamber experiments established that the gladiolus variety 'Sneeuwprinses' is extremely susceptible to HF, whereas alfalfa appears to be a useful SO₂ indicator. Gladiolus leaf analysis indicated a connection between the intensity of damage and fluorine content, and between these factors in relation to distance from the emitting source. Because of the high sulfur content of alfalfa leaves outside industrial areas, leaf analysis is a useful method for detecting SO₂ damage primarily in cases of severe plant injury. Air quality measurements were made in different areas to establish any correlations with chemical leaf analysis. As a result of 110 measurements with SO meters in an area containing SO₂ pollution, a daily average of 3-4 mg SO₂ was calculated as about the danger limit for plant damage. A monthly total amount of 30-60 ppm fluorine taken up by lime soaked filter paper was the limit at which damage was found on the susceptible gladiolus variety planted next to the measuring point. At 60-120 ppm, slight damage was found on less susceptible crops. Severe smoke damage to fruit trees due to HF was established, the adjacent HF apparatus absorbing as much as a monthly total amount of 304 ppm.

Rohmeder, E. and A. von Schonborn

THE INFLUENCE OF ENVIRONMENT AND HEREDITY ON THE RESISTANCE OF FOREST TREES TO THE ATMOSPHERIC IMPURITIES ORIGINATING FROM INDUSTRIAL WASTE GASES. A CONTRIBUTION FOR THE BREEDING OF A RELATIVELY FLUE GAS RESISTANT SPECIES OF SPRUCE TREES. Forstwiss. Zentr., vol. 84:1-3, 1965. 9 refs. Translated from German. 20p.

Experiments to determine to what extent the resistance to flue gas can be determined by environmental factors and heredity are described. In addition, the limits of gas concentrations within which young trees can survive and thrive are determined. The environmental factors studied include nutrition, water supply, relative humidity, and others. Varying concentrations of sulfur dioxide and hydrogen fluoride are administered under controlled conditions to determine resistance. Damage increases with increasing humidity and light intensity. An optimum supply of nutrients increases resistance. For SO₂, the first damage symptoms occurred after a ten day exposure to 0.5 mg/cu m; at 2.0 mg/cu m all assimilation organs are destroyed. For HF, the first damage symptoms occurred at 0.025 mg/cu m; total damage occurred at 0.25 mg/cu m. The resistance of oak and poplar is much greater than spruce, larch, or fir. Also, the grafts of the resistant strains are more resistant, indicating heredity as a cause of resistance.

MacIntire, W. H. et. al.

EFFECTS OF FLUORINE IN TENNESSEE SOILS AND CROPS. Ind. Eng. Chem., 41(22):2466-2475, Nov. 1949. 78 refs. Findings are reported from 20 years of experimentation upon the fate of soil incorporations of various fluorine materials such as insecticides, fertilizers, sodium, potassium, and magnesium fluorides, slags, rock phosphate, and cryolite through determinations of induced chemical and bio-chemical phenomena, retention of fluorine against lysimeter teachings of rain waters, and fluorine content of roots and top growth in greenhouse cultures. The early lysimeter experiments and greenhouse studies as to uptake of fluorides were extended to ascertain fluorine occurrences in the atmosphere, in rain waters, in soils, and in vegetation on farms in locales where injurious effects upon plant and animal life were purported to have been caused by atmospheric effluents from the increased manufacture of aluminum in Blount County in east Tennessee and from expanded operations in the processing of rock phosphate in Maury County in middle Tennessee. Soils possessed remarkable retention of the fluorine carried by insecticides, fertilizers, and various fluorine compounds, while yielding abnormal concentrations of fluorides to the rain water teachings from incorporations of electric furnace slag. Vegetation effected virtually no enhancement in the uptake of fluorine from soils that possessed adequacy of calcium, either naturally contained or added. Comparative analyses of crops grown on soils, in place and after transportation to unaffected points, served to support the conclusion that abnormal incidence of fluorine in field vegetation is attributable to atmospheric contaminants. (Author abstract modified)

THE FLUORINE CONTENTS OF VEGETABLE, ANIMAL,
AND OTHER MATERIALS FROM AREAS WITH OR
WITHOUT EMISSIONS OF FLUORINE. COMMUNICATION

I. THE FLUORINE CONTENTS IN VEGETABLE, ANIMAL,
AND INORGANIC MATERIALS FROM AREAS WITHOUT
EMISSIONS OF FLUORINE. (Ueber Fluor-Gehalte pflan-
zlicher, tierischer und anderer Stoffe aus Gebieten ohne und mit
Fluoremissionen. I. Mitteilung. Fluor-Gehalte pflanzlicher,
tierischer und anorganischer Stoffe aus Gebieten ohne
Fluoremissionen). Text in German. Landwirtsch. Forsch., vol.

20: 199-209, 1967. 11 refs.

For investigations regarding the effects of fluorine on plants and animals, it is important to know what the normal level of fluorine is in plants, animals, and certain inorganic substances. In other words, what would (be) the fluorine content be if the substance was in an area without the effects of industrial fluorine contamination. The fluorine content of samples of leaves from fruit trees, forest trees, shrubs, bushes, and vegetables and of needles from coniferous trees and farm-grown feeds is determined. The fluorine content in a number of commercial samples of leguminous seeds, oil seeds and oil seed residues, side products of the fermentation industry and of starch and sugar mills, and mineral feed supplements is also determined. The investigations prove that considerable amounts of fluorine are concentrated in some commercial feeds by industrial processing. (Author abstract modified)

Brandt, C. Stafford

SPECIAL JUBILEE SYMPOSIUM: AIR POLLUTION WITH

RELATION TO AGRONOMY CROPS. Agron. J., vol. 56:544,

1958. (Presented at the American Society of Agronomy, 50th Anniversary Meeting, Atlanta, Ga., Nov. 20, 1957.)

That agriculture may be adversely affected by local air pollution is generally recognized and accepted. M. D. Thomas has presented a paper at the special jubilee symposium on what has been done, while the other six papers indicate the spectrum of work being done. Two papers present different approaches to the potentialities and problems of using vegetation as an index of air pollution and indicator of pollutant dispersion. The problem of 'hidden injury' is supported in the case of smog on citrus and denied in the case of fluorides on tomatoes. Fluoride uptake from soils and its relation to air pollution with fluorides is discussed. In another paper, a new disease of grapes is described and attributed to air pollution.

SPANISH MOSS AND FILTER PAPER EXPOSURES FOR

DETECTION OF AIR-BORNE FLUORIDES!. J. Agr. Food

Chem., 4(7):613-620, July 1956. 12 refs.

The washdown of fluorides and their fixation by Spanish moss can indicate atmospheric emissions which are responsible for the abnormal incidence of fluorine in nearby field crops. Intensities of fluorine emissions to the atmosphere in certain eastern and central Tennessee locales were determined by month-long covered field-exposures of Spanish moss in cotton (cord), nylon, and dacron bags and of 12.5-cm lined "liter papers. Fixations in covered cord and nylon bags were similar to and greater than fixations in the less porous dacron bags, and were greater in the outer zones than in the cores of the moss. Drying the moss decreased its capacity to fix air-borne fluorides. Fixations by the moss in the protected cord and nylon bags and by protected lime filter papers were consistently concordant in spotting high and low occurrences of fluorine in the atmosphere. Commonwealth Bureau of Soils, Harpenden, England
BIBLIOGRAPHY ON ATMOSPHERIC POLLUTION OF
PLANTS AND SOIL (1964- 1949). Rept. 981, 16p., 1965 (?). 86
refs.

An annotated bibliography of articles dealing with the effects of atmospheric pollution on plants and soils is presented. The contaminants covered include sulfur dioxide, fluorine, fly ash, smog, fertilizers, and others. Various types of vegetable plants are discussed, as well as trees and crops. The effects of air pollution are considered in terms of plant damage, plant growth, metabolic processes, and threshold levels. The articles included were published between 1949 and 1964.

Bolay, A., E. Bovay, C. Nuery, and R. Zuber
RELATIONSHIP BETWEEN FERTILIZATION AND THE
BURNING EFFECT OF FACTOR EMISSIONS CONTAINING
FLUORIDES. (Interaction entre la fumure et la causticite des
immissions fluorees). Air Pollution Proc. First European Congr.,
Influence of Air Pollution on Plants and Animals, Wageningen,
The Netherlands, 1968, p. 143-160. 13 refs. Translate from
French. Belov and Associates, Denver, Colo., 26p., Sept. 11,
1970.

Studies made of the vineyards and apricot orchards in the central part of the Valais district of Switzerland, an area exposed to atmospheric pollution from aluminum foundries and fertilizer plants show that the causticity of emitted fluorides and the fluorine content of the leaves depend closely on the kind of mineral fertilizer used on the plants. Just how this interaction works is still not known but three possible hypotheses are possible to explain the interrelationship: presence of chlorides, presence of boron and, finally, an unidentified substance, particular to certain phospho-potassium fertilizers. The effect of the fluoride pollutio is made significantly worse by the almost linear diffusion created by the winds of this alpine valley.

RELATIONSHIP AMONG EXPOSURE PERIODS, FOLIAR
BURN, AND FLUORINE CONTENT OF PLANTS EXPOSED
TO HYDROGEN FLUORIDE. Agr. Food Chem., S(2):108-116,
Feb. 1957. 32 refs. (Presented at the American Chemical Society,
126th Meeting, Air Pollution Symposium, New York, Sept.
1954.)

Observations of a pathological condition attributed to fluorides in a wide range of plant species resulted in initiation of controlled fumigation experiments to determine the effects of environmental variables upon the rate of foliar response to hydrogen fluoride. Forty plant variaties were exposed to atmospheric concentrations of 1.5, 5, and 10 ppb of HF in daylight and darkness. A consideration of the exposure factors, the product of the hours exposed and the fumigation concentration in ppb of HF, indicates that plants exposed in darkness were on the average 91.3% as responsive to fluoride in the production of visible foliar injury in the darkness as in the daylight. Plants exhibited greater response to fluoride when fumigated daily for 8 hours at 1.5 ppb HF than when fumigated either 8 hours every third day at 5 ppb HF or 4 hours every third day at 10 ppb HF. Correlation coefficients of exposure factor versus foliar fluoride content were generally found to increase in significance as the plant classifications were narrowed from family to genus to species. ropean Congr. Influence Air Pollution Plants Animals,

Wageningen, Netherlands, 1968, p. 53-73. 17 refs. Translated from German. Belov and Associates, Denver, Colo., 28p., Sept. 15, 1970.

The use of indicator plants for detecting air pollutants and their range of distribution is gaining ground as a supplement to physical and chemical analyses of air. Plant reactions considered to constitute proof of pollution include the amount of pollutant accumulated and visible symptoms such as necrosis or the presence of certain kinds of lichen, it also seems likely that products produced by metabolic responses of a plant to absorbed pollutants are useful indicators. Combining these indicators with the specific sensitivity of individual plants or species could lead to manifold possibilities. Trials in progress involve the use of indicator chambers, which have an advantage over field indicators in that no damaging substances are absorbed through soil. Using combinations of indicator plants should permit identification of pollutants responsible for damage, even when several pollutants are simultaneously present, as in most industrial areas. A list is included of indicator plants suitable for sulfur dioxide, hydrogen fluoride, gaseous and stable inorganic fluoride compounds, and ozone.

AIR POLLUTION WITH RELATION TO AGRONOMIC
CROPS: VH. FLUORIDES UPTAKE FROM SOILS. Agron. J.,
vol. 50:565-568, 1958. 10 refs.

Five soils, varying in such characteristics as pH, lime, clay, organic matter, and soluble salts, were treated with sodium fluoride at the rate of 0, 200, 400, 800, and 1600 ppm of fluorine. Turnips and alfalfa were grown, harvested, and analyzed for fluorine. Similar experiments were conducted using treatments with sodium fluorosilicate instead of sodium fluoride. Plant yields were generally reduced when the fluoride content of the tissues exceeded 60 ppm on a dry weight basis. Reduction of fluoride uptake was associated with increased content of lime, clay, and organic matter in the soils studied. In general, the fluoride was absorbed less readily from sodium fluorosilicate than from sodium fluoride, and reductions in yield were also less with the fluorosilicate. Fluorine uptake from soils which were exposed to several years of airborne fluorine contamination was not appreciably higher than fluorine uptake from several soils taken from an area of little or no contamination. RELATIONSHIP OF ATMOSPHERIC FLUORIDE LEVELS
AND INJURY INDEXES ON GLADIOLUS AND PONDEROSA
PINE. Agr. Food Chem., 4(1):64-66, Jan. 1956. 8 refs.

Injury indexes for two species, Ponderosa pine and gladiolus, exposed to the atmosphere at three locations within an area of fluoride pollution have been related to the average atmospheric fluoride levels for the period July 17 to Aug 2, 1951. The relationship between the atmospheric fluoride levels and the observed injury is shown to be approximately linear in nature at the atmospheric fluoride levels existing at the test sites.

<xref image="2000WVKL.TIF|V3|2006:09:28:01:37:58.00|121328|0"> image: </xref>

Correlation coefficients showing the relationship between injury indexes and average atmospheric fluoride levels indicate an excellent degree of association between the two variables. The gladiolus showed a greater foliar response to atmospheric fluorides at the lower exposure levels than did the Ponderosa pine. However, the Ponderosa pine exhibited a greater degree of foliar burn, as expressed by the injury indexes, at the higher exposure levels than did the gladiolus. (Author summary)

SOME DATA ON THE WATER BALANCE IN PLANTS IN THE PRESENCE OF FLUOR IN THE SUBSTRATE. (Beitrag sur Kenntnis der Wasserhaushalt der Pflanzen bei Anwesenheit des Kluors im Substrat). Air Pollution Proc. First European Congr. Influence Air Pollution Plants Animals, Wageningen, Netherlands, 1968, p. 91-97. Translated from German. Belov and Associates, Denver, Colo., 7p., Oct. 28, 1970. Studies were conducted of the water balance of the Senator variety of *Pisum sativum* in the presence of fluor (in the form of sodium fluoride) in the substrate. The effect of fluor was seen in a withering of those portions of the plant above the soil. The unfavorable hydration condition observed is the result of changes in the amount of water assimilated and the amount given off. The presence of fluor first stimulated and then reduced the amount of water given off. No preliminary increase was noted before the amount of water taken in was reduced, and plants assimilated no water after 68 hrs in the presence of 0.29 and 0.25 g/l F. A balance between the amount of water taken in and given off was reached only after approximately 27 hrs at a level of approximately 40% of the original transpiration and approximately 90% of the original water content of the plant.

Cormis, L. De

COMPARISON OF THE EFFECTS OF SULPHUR DIOXIDE AND OF THE DERIVATIVES OF FLUORINE ON A FEW PLANTS. (Action Compare de l'anhydride sulfureux et des derives fluores sur quelques vegetaux). Proc. Intern. Clean Air Cong., London, 1966 (Part I), 6(S):171-173. Translated from French. Belov and Associates, Denver, Colo., 9p., Sept. 9, 1970. The frequent absence of a correlation between plant damage and air pollution in the vicinity of a plant emitting 400 tons per day sulfur dioxide and 150 kg per day fluorine led to studied of the nature of the absorption of both pollutants in plants. Both fluorine and sulfur dioxide are absorbed by leaves of tomato plants in proportion to the amount applied. However, absorbed sulfur migrates within the plants and is distributed as the sulfur normally found in plants. Fluorine is accumulated by the leaves, resulting in eventual necrosis beyond a certain limit; these limits have to be separately defined for each species of vegetation. Because sulfur is metabolized in part by the plant, it cannot have a cumulative toxic effect when applied in subtoxic quantities.

Bossavy, J.

INFORMATION ON DAMAGE CAUSED BY AIR POLLUTION TO THE PLANTS AND ANIMALS IN EUROPEAN COUNTRIES. (Informations sur les dommages causes par la pollution de l'air aux plantes et aux animaux dans les pays europeens). Air Pollution Proc. 1st European Congr. on the Influence of Air Pollution on Plants and Animals, Wageningen, The Netherlands, 1968, p. 15-26. Translated from French. Belov and Associates, Denver, Colo., Sept. 3, 1970. All specialists agree that sulfur dioxide and fluorine compounds are particularly important plant toxins; *Picea abies*, *Abies alba*, and *Pinus sylvestris*, by far the most important trees cultivated in Central Europe, are highly susceptible to

these two pollutants. The damage caused by them reaches alarming proportions, endangering the existence of forests in many areas. The total area of damaged forests probably approaches 400,000 hectares. Damages to land under cultivation are less spectacular because growing conditions can be artificially improved. Pollution effects are often limited to the yield or partial loss of quality for one growing season. The influence of fluorine on animal teeth and bones is well known: the effects can be partly averted by adding correct amounts of phosphate and calcium to animal rations or by supplying feed containing sufficient minerals. In general, research on the effect of pollutants on vegetation is directed toward the absorption of pollutants, their transport in leaf parenchymas, and their effects on physiological processes. Creation of new species or varieties of domestic plants capable of supporting high pollution levels seems possible. (Author abstract modified)

Shupe, James L.

LEVELS OF TOXICITY TO ANIMALS PROVIDE SOUND BASIS FOR FLUORIDE STANDARDS. Environ. Sci. Technol., 3(8):721-726, Aug. 1969. 4 refs.

Results of controlled fluorosis experiments and clinical experience with more than 77,000 animals in enzootic fluorosis areas confirmed that factors which govern the reactive processes of animals ingesting fluorides include the level or amount of fluoride ingested, duration of ingestion, the type and solubility of fluoride ingested, age of animal at time of ingestion, level of nutrition, stress factors, and individual biological response. Normally, birds are more resistant than mammals to the toxic effects of fluoride ingestion, and rodents tend to be more resistant than larger animals on a body weight basis. Signs and symptoms of acute and chronic fluorine toxicosis are described. Both enamel and dentine are affected by elevated levels of fluoride ingestion during the formative stages of the tooth. The degree of dental fluorosis can be correlated with the amount of fluoride in the bones, degree of osteofluorosis, duration of exposure, age of animal during fluoride ingestion, amount of fluoride ingested during tooth formation, and other reactive processes of the body. Effects of fluoride on bones are discussed; the most consistent measurement of fluorosis is the amount of fluoride retained in the normal mineralizing matrices of the body. It appears that three mechanisms are involved in abnormal bone formation: impairment of the mechanical properties of normally formed bones by excessive fluoridation; precocious remodeling and excessive proliferation; and direct inhibition of normal osteoblastic activity by excessive blood and tissue fluid levels of fluoride. For dairy cattle that received 93 or 49 ppm of fluoride for 7-1/2 years, observations are included for the hair and skin, hoofs, soft tissues, blood, placental transfer, reproduction, and milk production. Aluminum sulfate, aluminum chloride, calcium aluminate, calcium carbonate, and defluorinated phosphate have reduced the toxicity of fluoride in animals.

NATURAL DECREASE OF PINE NEEDLE FLUORINE FROM ATMOSPHERIC IMMISSIONS. (Naluerliche Abnahme des aus Immissionen aufgenommenen Fluors in Fichtennadeln).

<xref image="2000WVKM.TIF|V3|2006:09:28:01:38:02.00|121779|0"> image: </xref>

Text in German. Staub-Reinhaltung Luft, 30(9):384-385, Sept. 1970. 15 refs.

Analyses of fluorine content of atmospheric origin in pine needles performed immediately following exposure and after a 5 months recovery period during which the pine stands were not exposed to fluorine emission disclosed a natural decrease of the fluorine content to only 10 to 17% of the original accumulation. The causes may be leaching out through precipitation, evaporation of volatile fluorine compounds from the needles, transport into other parts of the tree and loss of fluorine to the soil through roots. Experiments with tomatoes and beans speak for the first assumption as the principal cause of the fluorine decrease. The filtering capacity of pine stands for fluorine is greater than was assumed because the results of fluorine analysis represent only part of the absorbed F. It follows that plant fluorine analyses must not be evaluated statically but that they must be interpreted in the context of the dynamics of fluorine intake and outgo.

FLUORIDE IN FORAGE: FACTORS DETERMINING ITS ACCUMULATION FROM THE ATMOSPHERE AND CON-

CENTRATION IN THE PLANT. Preprint, International Union

of Air Pollution Prevention Associations, 17p., 1970. IS refs.

(Presented at the International Clean Air Congress, 2nd, Washington, D. C., Dec. 6-11, 1970, Paper MB-40B.)

The results of a series of experiments on field plots were analyzed to determine the relationship of the concentration of hydrogen fluoride and duration of the exposure period to the accumulation of fluoride in alfalfa (*Medicago saliva* L.) and orchard grass (*Dactylis glomerata* L.). Replicate groups of plots containing alfalfa and orchard grass were exposed to HF at mean concentrations of 0.5 to 7 microgram F per cu m for 3-, 6-, or 9-day periods. Additional groups of plots containing alfalfa alone were exposed to the same range of HF concentrations for 7 days to give a total of 270 separate fumigations over a period of 4 years. The mean concentration of fluoride in forage that was not exposed to HF was 5.3 ppm (microgram F per gram dry weight) in alfalfa and 4.4 ppm in orchard grass with standard deviations of 2.0 and 1.9 ppm F, respectively. Overall regression of fluoride concentration in ppm (F) on mean concentration of HF in microgram F per cu m (C) for duration of exposure in days (T) gave the equation $F = 1.13CT - 1.17$ for orchard grass and $F = 1.89CT + 0.74$ for alfalfa with plants exposed to HF for 3, 6, and 9 days. Some variation in the concentration of fluoride in forage could also be accounted for by a loss due to weathering or dilution by growth after fumigation. Although the regressions were highly significant standard deviations from regression of 13.8 and 16.8 ppm for orchard grass and alfalfa, respectively, gave relatively broad confidence limits for the predicted fluoride concentration of a single sample of forage at a given concentration of HF and duration of exposure. Thus, the monitoring of forage rather than the monitoring of air affords better protection against fluoride-induced damage to livestock. (Author abstract)

FLUORIDE PHYTOTOXICITY: ITS ALTERATION BY TEM-

PERATURE. Preprint, International Union of Air Pollution Prevention Associations, 14p., 1970. 23 refs. (Presented at the International Clean Air Congress, 2nd, Washington, D. C., Dec. 6-11, 1970, Paper MB-40C.)

Experiments concerning the effects of gaseous fluorides on vegetation are presented. Gladiolus and sunflower plants were placed in controlled environment fumigation chambers at 16, 21, or 26 C and at relative humidities selected to give the same vapor pressure difference between the intercellular spaces of

the mesophyll (100% RH assumed) and the surrounding atmosphere at each temperature. All plants were exposed to hydrogen fluoride (ca. 4.7 microgram F/cu m) continuously for 104 hr followed by a one-week period under the same environmental conditions to allow for symptom development. Symptoms were not apparent in sunflower foliage at any temperature regime. Foliar accumulation of fluorine, as both amount (microgram F/cu m plant) and concentration (ppm F), was about the same at 16 and 21 and increased significantly at 26 C. The severity of necrosis on gladiolus leaf blades was affected by both temperature and the age of the leaf. The older leaves were most resistant and the younger leaves were usually most susceptible. Necrosis was significantly greater at 21 or 26 than at 16 C. Whereas injury generally increased as temperature increased, F accumulation by gladiolus decreased, suggesting that the threshold level for injury is effectively reduced at higher temperatures. INDUSTRIAL EMISSION--A POTENTIAL DANGER TO KEEPING AND QUALITY OF FARMING ANIMALS. (Industrielle Emissionen, eine potentielle Gefahr fuer die Haltung und Leistungssteigerung iandwirtschaftliche Nutztiere). Text in German. Monatsh. Veterinaermed., 22(16): 526-528, 1968. 2 refs. In industrialized nations where agriculture is highly developed, more emphasis should be placed on the pathogenesis of chronic diseases in livestock. Particular attention should be paid to particles emitted by foundries, metal-processing plants, and the building materials industry. Examples of particles from these sources are lead, copper, zinc, manganese, arsenic, fluoride, and sulfurous compounds. Severe effects can also be attributed to compounds such as phenols and cyanides present in sewage from chemical industries. Legal provisions governing these emissions are essential in securing the health of animals and humans. (Autho abstract modified)

Imzon, Samuel N.

FLUORIDE EFFECTS ON VEGETATION IN ONTARIO. Preprint, International Union of Air Pollution Prevention Associations, 56p., 1970. 14 refs. (Presented at the International Clean Air Congress, 2nd, Washington, D. C., Dec. 6-11, 1970, Paper MB-40A.) Vegetation studies were carried out during the growing season of 1969 in the vicinity of fluoride-emitting industries in four areas of Ontario, manufacturing aluminum, fiberglass, diammonium phosphate fertilizers, and superphosphate fertilizers, and located in or adjacent to urban, rural, or agricultural communities. Snow Princess variety gladiolus indicator plots were examined monthly for growth and per cent leaf tip-burn. At the end of the growing season the leaves were chemically analyzed for fluoride and chloride, and for boron at the fiberglass plant. The severity of fluoride-injury found on vegetation at the sample stations in each area was related to the average concentrations of fluoride for the growing season found in the air and in the sampled foliage. High concentrations of fluoride were found in the atmosphere and in vegetation at the stations closest to three major sources of fluorides. Typical symptoms of fluoride-injury were observed on certain plant species. Atmospheric fluorides rarely injure flowers or
<xref image="2000WVKN.TIF|V3|2006:09:28:01:38:06.00|126544|0"> image: </xref>

fruit on plants. However, near the fiberglass plant, severe fluoride-injury was observed on the wings and seed casings of the key fruit of silver maple trees. The Snow Princess gladiolus plant exhibited severe leaf tipburn and relatively high concentrations of fluoride within their leaves at the plots located closest to the three major sources of atmospheric fluorides. At these plots the conns were reduced in weight and size. Where both fluoride and boron were affecting gladiolus plants the symptoms of leaf injury were similar to those caused by fluorides alone, with the addition of necrotic lesions occurring below and confluent with the fluoride-induced tipburn. The uptake of chloride from the soil by the gladiolus plants were found to be drastically inhibited on the plots located closest to the major sources of fluoride where the gladiolus leaves had absorbed excessive amounts of fluoride from the air. Abatement measures undertaken by the superphosphate fertilizer plant prior to and during 1969 resulted in an average of 66 microgram f/sq cm being recorded at 16 air sampling stations during the growing season of 1969. This represented a drastic reduction from an average of 516 microgram f/sq cm which was recorded at the same 16 stations in 1965. Vegetation injury was slight and restricted to within one mile northeast and east of this fertilizer plant in 1969. Chloride uptake by the gladiolus plants was not inhibited in any of the indicator plots in this area. (Author abstract modified)

Hart, Gary E.

CYTOGENIC EFFECTS OF FLUORIDE: TECHNICAL
PROGRESS REPORT. Texas Agricultural and Mechanical
Univ., College Station, Research Grant AP 00447, 6p., 1969 (?).
13 refs.

Chromosomal, meiotic, and mitotic abberations observed in plant roots, leaves, and seedlings exposed to sodium fluoride and hydrogen fluoride are reported. Treatment with HF suggested that the compound is a mutagenic agent that probably blocks replication of DNA. The different types of mitotic abberations caused by sodium fluoride treatment were cured by recovery treatment with 0.002 sodium pyrophosphate. This suggests that fluoride may form an inactive fluoro-pyrophosphate complex, the activities of which could be expected to inhibit mitotic rates as a result of DNA depolymerization. The addition of glycine to NaF caused a very marked reduction in the frequency of NaF-induced abberations. Plant growth was also inhibited by dimethyl-sulfoxide, ethyl-methane-sulfonate, and colchicine.

THE INFLUENCE OF FLUORINE EXHALATION ON THE
FLORA IN THE SURROUNDINGS OF AN ALUMINUM
PLANT. (Der Einfluss von Fluorexhalaten auf die Pflanzwelt
in der Umgebung eines Aluminiumwerkes. Air Pollution Proc.,
First European Congr. Influence Air Pollution Plants Animals,
Wageningen, 1968, p. 173- 178. Translated from German. Belov
and Associates, Denver, Colo., 5p., Nov. 3, 1970.
Examinations of the forest vegetation and agricultural life in
the surroundings of an aluminum plant over a period of six
years revealed intoxication and injuries to the vegetation by
fluorine compounds. The degree of injury differed in correla-
tion with the distance from the plant and the prevailing wind
direction. Further studies revealed that plums were a more
sensitive indicator to fluorine pollution than apples, pears,
cherries, and grapes. Among vegetables the most striking dif-
ferences were noted with leaf vegetables such as lettuce and
cabbage. Wheat showed higher fluorine contents than rye.

THE EFFECT OF FLUORINE EXHALATION ON ANIMALS
IN THE SURROUNDINGS OF AN ALUMINUM PLANT. (Der

Einfluss von Fluorexhalaten auf die Tiere in der Umgebung einer Aliuniniumfabrik). Air Pollution Proc., First European Congr. Influence Air Pollution Plants Animals, Wageningen, 1968, p. 275-279. Translated from German. Belov and Associates, Denver, Colo., Sp., Nov. 3, 1970.

In the vicinity of an aluminum plant, the presence of fluor was examined in the air as well as in the organs of house sparrows and pigeons. The fluor in milk and eggs produced in the immediate vicinity was simultaneously determined. To a various extent and in the majority of samples, a significant increase of fluor contents was observed. The first evidence of damaging results was fluorosis in the cattle. (Author summary modified)

THE EFFECT OF FLUORINE ON DAIRY CATTLE. V.

FLUORINE IN THE URINE AS AN ESTIMATOR OF

FLUORINE INTAKE. Am. J. Vet. Res., 24(99) :300-306, March

1963. 10 refs.

An investigation to determine if the amount of fluorine in the urine could be used as an indicator of the amount of fluorine ingested in the dry matter is described. Thirty-two Holstein-Friesian cows were fed four levels of fluorine, two levels of calcium-phosphorus mineral, and two levels of concentrate mix from about 3 months to 7.5 years of age. Two digestion and balance trials were conducted before calving and three after the animals started to lactate. In addition, after the cows were on trial for 7 years and 52 days, urine was collected approximately every 1.5 hours and composited for each 3-hour interval over a 24-hour period. Urine samples should be taken in the morning for best results; when possible, samples of urine should be obtained from several cows and the results pooled to give a reliable index of the fluorine consumed. The determination of the fluorine-creatinine ratio has merit as a means of adjusting for differences in urine volumes. A correlation exists among concentration of fluorine in the urine, amount of fluorine in dry matter consumed, Eind length of time that fluorine is ingested. By determining parts per million of fluorine in the urine and combining this with a knowledge of the length of time the animals had ingested fluorine, the ppm of fluorine in the ingested dry matter could be estimated. Taken alone, however, this measurement was an adequate criterion for a definite diagnosis of fluorosis in cattle. (Author summary modified)

DAMAGE CAUSED DUE TO FOUNDRY SMOKE. Allg. Forst

Jagdzt., no. 67:220, June 12, 1891. Translated from German.

Belov and Associates, Denver, Colo., 12p., Oct. 30, 1970.

A strong red discoloration of pine trees and damage to other trees were observed in the vicinity of a factory located by the Rhine River which processes phosphorites. The Belgian phosphorites used by the factory in question contained 5.25% calcium fluoride; in the reaction with concentrated sulfuric acid, there was consequently a capacity to generate 2.7% hydrofluoric acid. Hydrofluoric acid vapors are exceedingly soluble in water and upon contact with moist objects they were completely trapped. Leaf damage occurred when sulfuric acid was experimentally poured over two grams of calcium fluoride and the vapors generated were fumigated over a plant.

<xref image="2000WVKO.TIF|V3|2006:09:28:01:38:10.00|125339|0"> image: </xref>

Further observations indicated that a very rapid condensation of the acid vapors occurs in the presence of a moist atmosphere. The presence of fluorine was determined in almost all lead samples from the area in the vicinity of the factory.

Davis, Donald D.

AIR POLLUTION AND SOUTHERN FORESTS. Forest
Fanner, 29(10):6-7, 18, Oct. 1970.

The most common pollutants capable of causing injury to forest trees include sulfur dioxide, fluoride compounds, and oxidants such as ozone. A major source of SO₂ is the burning of coal, petroleum, or gas; petroleum refining, smelting and refining of ores, and the utilization or manufacturing of sulfur containing compounds may also produce SO₂. Common sources of fluorides include petroleum refineries, aluminum reduction smelters, and steel manufacturing plants. In the South, a major source is phosphate fertilizer plants. Concentrations of ozone high enough to cause plant injury may result from thunderstorm turbulence which brings oxidants down from the upper stratosphere. Compounds emitted from automobiles and industries react chemically in the air under the influence of sunlight, yielding large quantities of oxidants. Topographic features, such as the large mountain ridges typical of areas of Kentucky, North Carolina, Tennessee, and Virginia, help in trapping these pollutants. Acute injury to conifer needles is usually seen as death and browning of the needle tips or the entire needle, while chronic injury is often seen as a yellowing, dwarfing, and premature shedding of the needles. Chronic O₃ injury often causes a mottled appearance to the needle. Some differences among SO₂, hydrogen fluoride, and O₃ injury to broadleaved plants are cited. Such factors as leaf age, environmental conditions, length of exposure time, herbicides, insects, and fertilizers also may influence symptom development. It is likely, too, that air pollution is responsible for secondary effects, such as predisposing trees to attack by those insects or fungi which are more aggressive on weakened trees.

Palm, Einar W.

WHAT AIR POLLUTION DOES TO YOUR PLANTS. Crop
Soils Mag., 24(3): 14-17, Jan. 1971.

Air pollution causes an estimated \$500 million in plant losses each year. The invisible chemicals, such as sulfur dioxide, hydrogen fluoride, ozone, nitrogen dioxide, ethylene, and peroxyacetyl nitrates in smog are much more injurious to plants than the black emission from smokestacks, diesel trucks and buses. Plants injured by air pollution will be more susceptible to parasitic diseases, while diagnosis is often complicated because two or more chemicals may work together to increase the injury. Some pollutants, such as ozone, will react differently on different species or even varieties of the same plant species. Sulfur dioxide, produced in the smoke stacks of industrial plants, can be a double threat. The chemical itself is damaging to plants, and it may also combine with moisture to form droplets of sulfuric acid which can injure plant tissues. Certain indicator plants can be used to help determine what pollutants are the cause of plant injury. Finding a plant variety or substitute crop that is less susceptible to foul air is one step that can be taken, or high-value crops might be sprayed with pollution-reducing materials such as ozoban and ascorbic acid. Plant breeding in the future will be directed toward the identification, selection, and production of plants which can actually filter pollutants out of the air. However, government, industry, and our universities must work together to reduce the toxic materials in our air. Sources, plant response, and symptoms are presented tabularly for sulfur dioxide, hydrogen fluoride, hydrogen chloride, nitrogen dioxide, ozone, peroxyacetyl nitrate, ethylene, and particulate matter.

THE CHEMISTRY, HISTOLOGY, AND ROENTGENOLOGY
OF THE TEETH AND BONES OF LARGE ANIMALS. A.M.A.
Arch. Ind. Health, 21(4):346-347, April 1960.

When more than 50,000 cattle and sheep were classified according to effects of fluoride, it became evident that molar teeth were of importance in evaluating fluorosis, but the examination of the area was difficult. It was important not to confuse a black discoloration with the stain due to fluoride, which cannot be scraped from the surface of the teeth. Some areas of compact bone showed increased numbers and closer concentration of haversian canals, suggestive of new bone formation and bone reconstruction. Definite microscopic abnormalities were observed only in those bones that contained as much as, or more than, 4000 parts of fluoride per million. Abnormalities were characterized roentgenologically by an increased density or apparent abnormal porosity of bone, periosteal feathering and thickening, increased trabeculation, thickening of the compact bone and narrowing of the marrow cavity.

Hanson, George P.

MAN AND AIR -- THREATS TO PRAIRIE SURVIVAL. Lasca
Leaves, 20(4):78-81, 92, Dec. 1970. 6 refs. (Presented at the
Prairie Conference, 2nd Midwest, Madison, Sept. 20, 1970.)

Most pollutants enter the leaf through tiny pores in the leaf surfaces and cause internal leaf damage. These tiny pores or stomates are the passages through which gas exchanges take place during photosynthesis and respiration. At a given pollutant level, other things being equal, a plant growing under conditions of high humidity will take in more pollutant and become more severely damaged than a plant growing under arid conditions. Once the pollutants have entered the leaf, each has its own characteristic type of interaction with the plant tissues. Small animals living along a busy highway could accumulate lead by consuming lead-containing herbage or breathing lead laden air. Fluoride air pollutants damaging to plants are hydrogen fluoride and silicon tetrafluoride. The characteristic symptom of fluoride damage is necrosis on leaf tips and margins where the fluoride has been concentrated. Ethylene causes a general reduction in growth, decreases apical dominance, and stimulates lateral development. Ozone enters through the stomates and attacks the palisade tissue, while sulfur dioxide enters the leaf through the stomates and reacts with water on the moist cell surfaces to form sulfite which is in turn slowly oxidized to sulfate. Peroxyacetyl nitrate enters the leaf through the stomates where it attacks the cells of the spongy mesophyll, and nitrogen dioxide causes growth reduction and defoliation at concentrations often present in polluted areas. Air pollution is having a detrimental economic effect on agriculture in the nation, while also altering the ecological relationships of plants and animals. Fortunately, most species have a great wealth of genetic variation in sensitivity to air pollution. The mechanism of plant tolerance to air pollutants is mentioned.

Osterli, Victor P.

EFFECTS OF AIR POLLUTION ON AGRICULTURE AND

FORESTRY: ANIMALS. In: Project Clean Air. California

Univ., Berkeley, Task Force No. 5, Section 3, 3p., Sept. 1, 1970.

6 refs.

Serious economic losses have occurred when animals have been subjected to certain metallic compounds. Symptoms of fluorosis, which occurs when the diet contains more than 30 to 40 ppm of fluorides per day, include excessive wearing of the teeth, staining pitting of the enamel, and exposure of the dentine. In severe cases, joints may become enlarged and bone density increases significantly. Pasture grasses collected at the intersection of two U. S. highways near Denver contained 3000 ppm lead, while grasses collected next to a less travelled roadway contained 700 ppm lead. Suggested research needs with respect to lead pollution and its effects on animals would include the relative availability of lead to humans and animals from the different sources (air, water, and soil) and the transfer mechanism involved; the relative importance of surface contamination and absorption of lead; and whether the lead content of plants comes only from the air or also is taken up from the soil.

26158

Osterli, Victor P.

EFFECTS OF AIR POLLUTANTS ON AGRICULTURE AND

FORESTRY: PLANTS. In: Project Clean Air. California Univ.,

Berkeley, Task Force No. 5, Section 2, 23p., Sept. 1, 1970. 174

refs.

The effects of air pollutants on plants are usually noted on the leaves because they are the site of gas exchange and photosynthesis. Pollutants often produce characteristic markings on a given plant species, providing a means of pollutant identification. Severity of injury varies with pollutant, concentration, duration of exposure, and plant species. Specific effects are cited for sulfur dioxide, fluorides, photochemical oxidants, oxides of nitrogen, ethylene, pollutant combinations, and particulates. A recent estimate of air pollution damage to California crops is reported at \$44.5 million annually. Increased attention must be given to the following research needs: improved accuracy in the assessment of economic losses to agriculture and forestry resulting from air pollution; the growth depression effect on plants due to long-term low-level exposure to ethylene, sulfur dioxide, fluoride, and oxides of nitrogen; the synergistic effect of combined sublethal concentrations of air pollutants on plants; the effects of air pollutants on biochemistry, metabolism, and anatomy of plants; the relative sensitivity of the various needle-leaf species; the quality of the forest air environment; the impact of long-term oxidant exposure on growth; and more accurate methods for determining the extent and severity of smog damage.

OUS KINDS OF TREES WITH RESPECT TO EMISSION OF

SO₂, HF, AND MAGNESITE DUST. (Beobachtungen ueber die

Empfindklichkeit vershiedener Baumarten gegenueber Immis-

sionen von SO₂, Hf and Magnesitstaub). Air Pollution Proc.

First European Congr. Influence Air Pollution Plants and

Animals, Wageningen, Netherlands 1968. p. 371-377. Translated

from German. Belov and Associates., Denver, Colo., 10p., Oct.

13, 1970.

Investigations were conducted to determine the degree of growth inhibition in various forest trees exposed to hydrogen fluoride emissions alone or to simultaneous emissions either of hydrogen fluoride and sulfur dioxide or sulfur dioxide and magnesite dust. Trees susceptible to SO₂, and Mg are, in increasing order of susceptibility, larch, pine, spruce, fir, and

beech. Trees susceptible to SO₂ and HF art; in increasing order of susceptibility, aspen, ash, beech, maple, spruce, pine, and larch. Susceptibility to HF increases in the order pine, spruce, fir. Unlike spruce trees, pines show no noteworthy individual differences in resistance to air contaminants. Resistance in spruce is affected by factors such as location and water and nutrient supply. The need to develop resistant strains of spruce is indicated by the importance of the tree for the European forest economy.

CHANGES OF PLANT CULTURES ON AREAS IN REGION OF THE INFLUENCE OF FLUORINE EMISSIONS. (Zmeny fytocenoz natrvalych plochach voblasti posobeni:j fluorovych exhalatov). Text in Czech. Ochrana Ovsdusi, vol. 11-12:177-181, 1969. 12 refs.

The results of a study of qualitative and quantitative changes of plant cultures in the area of fluorine emissions from an aluminum plant are presented. Emissions considered included hydrogen fluoride, carbon tetrafluoride, and solid fluorides as well as carbon monoxide, sulfur dioxide, and similar toxic compounds. The circular experimental surface areas (r equals 2.5m) placed at 100-200 m intervals in 3 directions from the emission source were regularly investigated. As criteria of change sociability coverage, coefficient of relationship, and domination were used. The number of plant species changed in an irregular fashion with the distance from the emission source and with length of exposure to emissions with the exception of a route going through an even flat terrain. Trie coefficient of relationship behaved in a similar manner. The total coverage decreased towards the epicentrum and with the; length of exposure to emissions. An exception was trifolium rubens, which is a species resistant to fluorine emissions. The frequency and coverage of certain species of the Daucaceae and Asteraceae family also increased. Qualitative changes of plant cultures on varying terrain thus occur irregularly, while on even terrain they bear a certain relation to the distance from the emission source. The changes so far observed were of a quantitative nature. Within a few years, extensive qualitative changes are expected in the area with deposits higher than 500 kgf/square km per year.

FLUORINE ANALYSIS OF ITALIAN PRUNE FOLIAGE AFFECTED BY MARGINAL SCORCH. Phytopathology, vol. 38:30-37, 1948. 30 refs.

A new non-parasitic disease of Italian prune trees characterized by marginal scorch and leaf spot appeared in certain areas of western Washington. In an investigation of the cause of the condition, it was shown by chemical analysis that leaves from trees grown in the affected areas were abnormally high in fluorine, as compared with leaf sampler collected from other localities where this condition does not occur. The analyses from six samples collected 90 miles or more from an aluminum factory ranged in fluorine content from 6 to 15 ppm, while 76 samples from areas within 20 miles of an aluminum factory varied between 30 and 1400 ppm of iluorine. Within a given area the amount of marginal scorch was approximately

<xref image="2000WVKQ.TIF|V3|2006:09:28:01:38:18.00|119715|0"> image: </xref>

proportional to the fluorine content of the leaves. The fluorine content of the prune leaves returned to near normal and marginal scorch of the leaves did not appear during the growing season following the closure of the two aluminum factories in Tacoma and Troutdale, Oregon. The evidence indicates that some fluorine is stored in dormant twigs, but is not translocated to any great extent into the growing leaves (Author summary)

Hill, A. C., L. G. Transtrum, M. R. Pack, and A. Holloman, Jr.

FACILITIES AND TECHNIQUES FOR MAINTAINING A CONTROLLED FLUORIDE ENVIRONMENT IN VEGETATION STUDIES. *J. Air Pollution Control Assoc.* 9(1):22-27, May 1959. 14 refs. (Presented at the Air Pollution Control Assoc., 51st Annual Meeting, Philadelphia, Pa., May 25-29, 1958.) Facilities were designed primarily for studying the effects over a long period of time of the low gaseous fluoride concentrations that may be found in certain atmospheres. The air circulating through each of three greenhouses is first drawn through lime-coated orlon bags to remove fluorides, while the air enters each greenhouse at 7 sites equally spaced along the base of one side. It is exhausted through 7 ducts located beside the inlet ducts, which tends to give the air a circular motion. Rapid air circulation is essential for the maintenance of the atmospheric fluoride concentrations as well as for the control of temperature and humidity. The greenhouses are cooled for circulating cold water through banks of finned coils in the air inlet ducts, and they are heated during the winter months by circulating hot water through the coils. Portable chambers of two different sizes are used for placing over crops growing in the greenhouses. These chambers are made of transparent vinylite sheeting, attached to aluminum frameworks with hardwood strips. Air flow measurements are discussed, as well as the method of injecting gaseous fluoride into the air stream. Very complete measurements have been made to evaluate the effects of hydrogen fluoride treatments on plants. These include photosynthesis measurements and periodic observations of the chlorophyll content and respiration rate of the leaves of several plant species.

Leone, Ida A., E. Brennan, and R. H. Dames
ATMOSPHERIC FLUORIDE: ITS UPTAKE AND DISTRIBUTION IN TOMATO AND CORN PLANTS. *Plant Physiol.*, 31(5):329-333, 1956. 13 refs.

Soil grown tomato and corn plants were subjected to hydrogen fluoride administered at various time-concentration levels designated as long-low, intermediate, and short-high fumigations, with the purpose of tracing the fate of the fluoride accumulated within the plants. Injury appeared more severe when the fluoride gas was administered in a short-high concentration dosage than when this same amount of gas was administered over a more protracted period. Corn was the more sensitive of the two species. As the fumigation level was increased, there was an increased fluoride accumulation. Tomato has a fluoride accumulating capacity approximately twice that of corn under all circumstances. Mature leaves accumulated greater quantities of fluoride than did younger leaves as a result of the more protracted fumigations. At the shorter higher level fumigations, the ratio of fluoride in mature to that in young corn leaves decreased to a certain point and then leveled off, whereas in tomato the ratio continued to decrease as fluoride concentration was increased. Washing the foliage removed even more fluoride than did natural diffusion. (Author summary)

Compton, O. C., L. F. Remmeri, and G. R. Spencer
SUMMARY REPORT OF FLUOROSIS INVESTIGATIONS IN

THE SAUVIE ISLAND ARE IN OREGON FROM DECEMBER 1, 1951 TO JUNE 30, 1953. Washington Stat Coll., Pullman, Coll. of Veterinary Medicine and Oregon State Univ. Corvallis, Agricultural Experiment Station, 38p., Dec. 1953. 7 refs. An investigation was made from December 1951 to June 1953 to determine if fluorine emanations from an aluminum reduction factory at Vancouver, Washington, were impairing the functioning or health of livestock on Sauvie Island, Oregon. The study included physical examinations of cattle and fluorine analyses of bones, teeth, soft tissues, and urine. The fluorine contents of pasture herbage, hay, silage, grain concentrate feeds, and drinking waters were determined to permit an estimate of total fluorine intake by cattle and a comparison with results from control areas. In addition, the relative fluorine contamination of the atmosphere was studied through use of indicator plants. The fluorine content of pasture herbage was not high enough to be considered deleterious to livestock; fluorine contamination of the atmosphere on Sauvie Island was of low magnitude and short duration. In most instances, grain concentrate feeds contributed a high percentage of total fluorine intake by cattle. There appeared to be no impairment of animal health from fluorosis, all symptoms of the disease being traced to other causes. (Author summary modified)

Shupe, James L.
FLUOROSIS OF LIVESTOCK. American Petroleum Inst., New York, Div. of Environmental Affairs, No. 69-4, 29p., Feb. 1969. 30 refs.

Various factors such as the level and duration of fluoride ingestion, type and solubility of fluoride ingested, age of animal, level of nutrition, stress factors, and individual biological response govern the reactive processes of animals ingesting fluorides. Fluorine has beneficial effects when ingested in small amounts, but toxic and adverse effects when ingested in excessive amounts. One must be aware of variables and conversion factors in the application of data from one species to another, or one age group to other age groups within a species and of the hazard of interpreting data only at the clinical level without correlating it with tissue and cellular levels. Fluorosis in livestock can be prevented and controlled but only when the complexity of the disease is realized and the symptomatology, pathogenesis, and lesions are properly correlated, interpreted, and evaluated. The tooth classification and the amount of fluorine in bone can be used to predict the extent of fluorosis with a high degree of accuracy. When properly interpreted, unanalyses can be an aid in diagnosing fluorosis and can be useful in roughly estimating current fluorine intake. Tolerances of fluorine for young and matured livestock under various conditions have been established and a comprehensive guide has been developed and compiled to facilitate diagnosing and evaluating fluorosis. Recommended standards are presented tabularly. Fluorine in stack emissions and ambient air should be determined so that these data may be correlated insofar as possible with the degree of fluorosis observed in livestock. (Author summary modified)

Phillips, Paul H. and John W. Suttie
THE SIGNIFICANCE OF TIME IN INTOXICATION OF DOMESTIC ANIMALS BY FLUORIDE. A.M.A. Arch. Ind. Health, 21(4):343-345, April 1960. 9 refs.

<xref image="2000WVKR.TIF|V3|2006:09:28:01:38:20.00|126055|0"> image: </xref>

A considerable body of evidence indicates that there is a time interval between the initiation of a significant increase in the ingestion of fluoride by domestic animals and the onset of intoxication by fluoride. This interval has been aptly referred to as the 'lag' or latent period in the toxic syndrome. Three physiologic mechanisms tend to protect the soft tissues against a significant rise in the concentration of fluoride. They are excretion through the kidneys, prompt deposition in the skeletal structures, and the voluntary refusal by the animal of feeds contaminated with fluoride. Inhibition or retardation of either or both urinary excretion and skeletal deposition leads to increased concentrations of fluoride in the soft tissues. Hence, a reduction in the rate of these mechanisms of soft tissue protection, to the point of insufficiency, provides the basis for the development of fluoride intoxication. Data are presented which show the relationship between time and dose in the development of intoxication following the finding of fluoride. The lower the dose, the longer is the time; conversely, the higher the dose, the shorter the time required to induce intoxication. (Author summary modified)

DARMOUS. SPONTANEOUS FLUOROSIS OF PHOSPHATED

AREAS. (Le darmous. Fluorose spontanee des zones phosphatees). Text in French. Arch. Inst. Pasteur Alger., 10(1):41-118, March 1932. 50 refs.

The Arabic name of Darmous is given to a disease of domesticated animals that occurs in certain sections of the North African countries of Algeria, Tunisia, and Morocco. The occurrence of the disease is most frequent in areas where there is an abundance of phosphates, and is characterized by dental dystrophy, which appears just after the weaning of young animals. On the basis of a series of observations and testing, the author's conclude that the disease is a fluorosis, since fluorine is almost always present in phosphate mineral deposits. The disease is considered dangerous to humans, since the meat of sheep raised in these areas, when fed to white rats, increases their mortality.

EFFECTS OF ATMOSPHERIC FLUORIDE ON THE RESPIRATION RATE OF BUSH BEAN AND GLADIOLUS

LEAVES. Plant Physiol., 32(2):121-124, 1957. 17 refs.

Bush beans and gladioli were exposed to known concentrations of atmospheric fluoride and the respiration rates of their leaves was measured manometrically. Fumigation resulted in an increase in leaf respiration of bush bean plants after a minimum of eight days at 30 ppb atmospheric fluoride concentration. Middle-aged and old leaves showed a greater increase in respiration than young leaves. Gladiolus leaves fumigated at 2.4 ppb for 25 days showed a high degree of stimulation of respiration of the chlorotic tissue next to the scorched area, and a lower but significant stimulation of respiration on tissues 5 cm from the dead area. Liming the leaves of gladiolus plants did not affect their respiration rate, and did protect them against fluoride damage. (Author summary modified)

EFFECTS OF AIR POLLUTION ON PLANTS. In: Air Pollution. Arthur C. Stern (ed.), Vol. 1, New York, Academic Press, 1962, Chapt. 8, p. 255-281. 38 refs.

Visible injury symptoms on the leaves of plants attributable to air pollution can be considered in three general categories, not necessarily mutually exclusive: leaf tissue collapse, chlorosis or other color changes, and growth alterations. In many of the cases the injury pattern developed is highly characteristic of the toxic agent, but while characteristic, the pattern is by no means specific for the agent. Disease, insects, nutrition, and

other factors can produce leaf patterns very similar to those produced by air pollutants. Problems of diagnosis are considered. Symptoms are discussed for injury due to sulfur dioxide, fluorides, ozone, oxidant smog, and several other pollutants, such as ethylene. Significant points in the symptomatology of air pollution on vegetation are summarized for these compounds. These include leaf markings, similar markings, concentration levels, and the sensitivity of indicators. Hidden injury and physiological effects are also considered. Field surveys are discussed.

National Academy of Sciences?National Research Council,

Washington D. C., Subcommittee on Fluorosis 1^blems

THE FLUOROSIS PROBLEM IN LIVESTOCK PRODUC-

TION. NAS-NRC-Pub-381, 25p., Sept. 1955. 105 refs.

Present information on fluorosis is reviewed with respect to its appearance in livestock. The recognized sources of fluorine which may affect livestock are mineral feed supplements; water contaminated by fluorides; forage contaminated by soil particles of high fluorine content; or forage contaminated by atmospheric fluorides from industrial plants. The development of fluorosis in livestock depends on the availability and level of the ingested fluorine; the length of time of exposure; skeletal storage; the age of the animal; physiological stress; and the effectiveness of defense mechanisms. Excretion by the kidney, deposition in the bones, and limitation of intake by loss of appetite all contribute to protect the animal body from fluorine toxicosis. The most definitive quantitative measurement of fluorosis is the extent of retention of fluorine in bones and teeth. The tolerance of the animal to ingested fluorine is increased by consumption of green forage, by supplementing the ration with certain soluble aluminum compounds, by including high levels of calcium in the ration, and by adequate nutrition.

ACCUMULATION OF FLUORIDE BY FORAGE CROPS.

Contrib. Boyce Thompson Inst., 24(7):165-166, 1969. 5 refs.

Portions of mixed timothy and red clover exposed to hydrogen fluoride that averaged 7.0 micrograms F/cu m over a 14-day period rapidly accumulated F, attaining a concentration of more than 100 ppm within three days and about 400 ppm by the end of exposure. The plants showed severe HF-induced foliar symptoms. Forage exposed continuously to a HF concentration that averaged 1.6 micrograms over the 14-day period accumulated 37 ppm F by the end of exposure. In contrast, forage exposed intermittently to a 14-day mean concentration of 1.9 micrograms F/cu m accumulated 101 ppm F after only 1-day of exposure. However, there were no discernible differences in the extent and severity of foliar injury following continuous low and intermittent HF exposures. Presumably the intermittent nature of the exposure provided sufficient time for the detoxification of the absorbed F. These data suggest that F accumulation by forage is at best a poor indicator of fluoride pollution, except when used for the protection of livestock or confirmation of suspected fluoride-induced foliar symptoms.

RESISTANCE OF SOME GRASSES TO FLUORINE. In:

American Institute of Crop Ecology Literature. Effects and Symptoms of Air Pollutes on Vegetation; Resistance and Susceptibility of Different Plant Species in Various Habitats, in Relation to Plant Utilization for Shelter Belts and as Biological Indicators. M. Y. Nuttonson (ed.), Vol. 2, Silver Spring, Md., American Institute of Crop Ecology, 1969, p. 56-59, 4 refs. (Also: Okhrana Prirody na Urale, 1966:45-47.)

Experiments were set up in an aluminum plant to select some grasses resistant to fluorine. Test plots were located near the electrolysis shop where the concentration of fluorine was 0.612 mg/cu m, while the control plots were located at a distance some 2000 m from the source of pollution. Additional experiments were conducted in chambers where the plants were fumigated for 8 hours with concentrations of 0.8 and 0.03 mg/cu m. The species planted were as follows: meadow fescue, red fescue, Kentucky bluegrass, perennial ryegrass, meadow foxtail, timothy grass, reedtop, awnless brome, meadow brome, and roegneria. Observations were recorded regarding damage to the leaves, and the plant height was noted in relation to the fluorine concentration. The water retention ability of leaves was studied, and the quantity of oxidizable substances was determined. At the end of the growing period, injury to the meadow foxtail, awnless brome, meadow brome, and roegneria was 50-60%. The least injury (25-35%) was noted with Kentucky bluegrass and red fescue. Compared with the control plants, the plants grown at the aluminum mill were smaller. The species having the greater water retention capacity were least injured. Determination of oxidizable substances in the cell content showed that meadow fescue has the least amount of them, whereas reedtop the largest. Meadow fescue, red fescue, and Kentucky bluegrass are recommended as suitable for planting in the industrial areas having the highest fluorine concentrations.

EFFECTS OF FLUORINE ON AGRICULTURE. Preprint, Air

Pollution Control Assoc., Pittsburgh, Pa., 14p., 1970. 32 refs.

(Presented at the Air Pollution Control Association, Annual Meeting, 63rd, St. Louis, Mo., June 14-18, 1970, Paper 70-154.)

Certain effects of fluorine on plants can be regarded as objective since they have been derived from laboratory experimental data, field observations, and the body of botanical knowledge. Agricultural effects, on the other hand, are to a great extent hypothetical and subjective. The three general classes of possible effects of fluorine on agriculture are decreased commercial value of the product, increased cost of production, and decreased value of farming facilities. While experimental data cannot be used to predict all the fluorine effects that might occur in the field, experimental procedures do permit the identification and prevention of agricultural effects. The latter can then be the subject of limited field trials and surveys.

Krueger, E.

DETECTION OF FLUORINE IN PLANTS DAMAGED BY

SMOKE. (Ueber den Nachweis von Fluor in rauchbeschädigten Pflanzen). Text in German. Metall u. Erz, 38(11):265-266, June 1941. 5 refs.

Fluorine damage caused by emissions of smelting plants, super-phosphate factories, and a chemical factory was investigated by anatomical studies of plant leaves, stems, and blooms. The differentiation between plant damage caused by fluorine and sulfur dioxide was found to be difficult and unreliable. Microchemically, fluorine was detected by the ammonium molybdate method and by the sodium fluosilicate method;

the latter was more reliable. In cases where fluorine was detected in undamaged plants the fluorine was actually in the dust covering the plants. To ascribe plant damage to fluorine emissions is easy where one isolated source of fluorine exhalations exists; where fluorine is emitted together with SO₂ from several sources the fluorine test is not conclusive. In such cases an experienced expert must consider all pertinent factors and form a judgment.

Bingham, F. T., R. C. McColloch, G. F. Liebig, and A. P. Vanselow
FLUORIDE INJURY TO CITRUS. Calif. Agr., vol. 8:12, 15,
May 1954.

Foliage from approximately 130 citrus groves was sampled for fluoride analysis. Approximately 1 ppm F was found in areas considerably removed from industrial centers. In the Los Angeles area, a gradual increase in leaf fluoride concentrations took place with the approach to the heavily industrialized district in and around Sante Fe Springs, Whittier, and San Gabriel. Fluoride levels as high as 57 ppm F were found. The largest source of airborne fluorides affecting vegetation in the San Bernardino Valley appeared to be a steel plant. There was a greater increase in fluoride during the July to October interval than from January to March. Foliar concentrations of fluoride increased very little once the winter rains began.

Nikolaevskiy, V. N.
INDICATORS OF GAS RESISTANCE OF ARBOREAL
PLANTS (ACCORDING TO INVESTIGATIONS CONDUCTED
IN THE CITY OF KRASNOURAL'SK). In: American Institute
of Crop Ecology Survey of USSR Air Pollution Literature. Vol.
3, Silver Spring, Md., American Inst. of Crop Ecology, 1970, p.
70-94. 30 refs. (Also: Tr. Inst. Bid. Ural. Filial Akad. Nauk
USSR., vol. 31:59-79, 1963.)

Two hundred trees in an industrial city heavily contaminated with sulfur dioxide and fluorine compounds were studied for their degree of gas resistance. The trees included aspen, balsam poplar, box elder, crab apple, and white birch. The studies were made in the summer and covered the following physiological processes: photosynthesis, respiration, transpiration, activity of the stomas, quantity of easily oxidizable substances, water holding capacity of the leaves, cell pH content, concentration of dry matter in leaves, and anatomical features of leaf structure. Intensity of the basic physiological processes was, to a significant extent, connected with the functioning of the stoma apparatus, reduction of the stoma apertures decreasing the rate of gas exchange. The gas-resistant box elder was characterized by smaller stoma apertures and by low intensity of photosynthesis and respiration during the growing period. In contrast, intensity was high in the greatly susceptible birch and crab apple. Although the highest transpiration intensity was found in the box elder, transpiration does not appear to be a reliable index of gas resistance. Total leaf water content correlated well with susceptibility to gas damage. Gas resistant species were also characterized by a smaller amplitude of fluctuations of the amount of oxidizable matter and by smaller amounts of this matter, by lower concentrations of dry matter, and by less decrease in cell pH content.

STATUS AND REDIRECTION OF RESEARCH ON THE ATMOSPHERIC POLLUTANTS TOXIC TO FIELD GROWN CROPS IN SOUTHERN CALIFORNIA. J. Air Pollution Control Assoc., 11(31):12S-128, March 1961. 31 refs. (Presented at the Air Pollution Control Association Annual Meeting, 53rd, Cincinnati, Ohio, May 22-26, 1960.)

Atmospheric pollutants in the Los Angeles area toxic to vegetation are becoming more clearly defined and their vegetational susceptibilities determined. Ozone and peroxyacetyl nitrate (PAN), each with a high oxidizing and phytotoxic potential, are now known to be toxic to vegetation. Further, it is becoming obvious that these oxidants are essentially reaction products of atomic oxygen formed by photolysis of nitrogen dioxide with a wide range of hydrocarbons. Whether sublethal or subnecrotic concentrations of fluorides cause economic damage in sensitive plants remains to be determined, as do the effects of the other phytotoxicants on crops under field conditions. These are the objectives of the Agricultural Air-Research Program of Southern California, which will conduct field evaluations of the effects of PAN, ozone, and fluorides on yields, growth, and quality of fruits and other agricultural products. Hopefully, the field studies will be implemented by the development of refined sampling and recording techniques for oxidants and fluorides.

Strong, Forrest C.

TOXIC GASES EFFECT ON PLANT LIFE. Am. Foundryman, 19(3):55-57, March 1951. 9 refs.

If the coal or coke in foundry cupola operations is not properly combusted, sulfur dioxide may be produced in such concentrations as to cause acute or chronic injury to plants under conditions of intense daylight, high humidity, and high temperature, especially when there is slow movement of the air. Plant species vary in their relative susceptibility to SO₂ injury, e.g., pine is injured by 2 ppm, beech by 33 ppm, and roses by 2-4 ppm. Dusts may cause clogging of the leaf pores, preventing normal air exchange, or cover the leaf surfaces to such an extent as to reduce photosynthetic activity. Fluorine compounds will escape as effluents when fluorspar and cryolite are used as fluxing materials, accumulating in the tissues of the leaves and causing severe injury especially during dry periods. Injury to plant tissues appears in the form of marginal leaf burning, that is, a killing of the tissues with resultant browning, followed by unseasonably early leaf fall. The normal processes of plant photosynthesis and respiration are reviewed. (Author summary modified)

Weinstein, Leonard H. and Delbert C. McCune

EFFECTS OF FLUORIDES ON VEGETATION. Preprint, Air Pollution Control Assoc., Toronto, Ontario Section, Air Pollution Control Assoc., Pittsburgh, Pa., TR-7 Agricultural Committee, and Ontario Dept. of Energy and Resources Management, Toronto, Air Management Branch, 31p., 1970. 99 refs. (Presented at the Impact of Air Pollution on Vegetation Conference, Toronto, Ontario, April 7-9, 1970.)

Fluorides are emitted in both gaseous and particulate forms in the manufacture of phosphate fertilizers, brick, ceramics, glass, enamel frit, beryllium, aluminum, steel, nonferrous metals, and from other sources. Hydrogen fluoride and silicon tetrafluoride are the predominant gaseous forms and represent the most important form of fluoride injurious to vegetation. Symptoms induced by atmospheric fluoride on broad- and narrow-leaved plants are described, and effects on growth, yield, and reproduction are discussed. Other important factors influencing symptom expression and growth effects, such as stage of development of the plant, specific and varietal differences, environmental effects, concentration of fluorides in

the atmosphere, and duration and frequency of exposure, are also reviewed. Enforcement of an air quality standard for fluoride will require sampling not only of air but also of native or economically important vegetation. Methods of concentration, separation of gaseous and particulate forms, and determination are noted. (Author abstract modified)

Cormis, Louis de

EFFECT OF INDUSTRIAL AIR POLLUTION ON VEGETATION.

(Effet sur les vegetaux de la pollution de Pair d'origine industrielle). Text in French. Ann. Mines (Paris), no. 11:15-20, Nov. 1970.

The two major pollutants of plants are sulfur dioxide and fluorine compounds. SO₂ causes necrosis of leaves but the vegetation resumes after the pollution wave has subsided. The killing of tree or of shrubs has never been observed. Under conditions of maximal photosynthesis and of high relative humidity, the noxious effect of SO₂ is at its peak. At a sub-necrotic level of SO₂, plants absorb SO₂, then re-emit part of it as SO₂, another part as hydrogen sulfide, and absorb a third part which appears in sulfates, proteins, and in sulfonated aminoacids. The absorption of SO₂ and its reduction by the plant is tied to the photosynthetic activity of the plant. Fluorine compounds in the atmosphere cause leaf necrosis at 10 to 1000 times lower levels than SO₂. In contrast to SO₂, necrosis develops slowly from the periphery to the center of the leaves. Fluorine ions do not participate in plant metabolism at any level. Since some highly necrotic leaves exposed to fluorine contain only traces of F (20 to 40 ppm) while leaves of other plants contain up to 1000 ppm F without signs of necrosis, analytical findings are of no use in the determination of the effect of fluorine on vegetation. A high level of fluorine in the atmosphere will kill plants. Effects of pollutants on vegetation cannot be predicted because they depend, in each case, on crop, locality and growth season.

Pack, Merrill R.

EFFECTS OF HYDROGEN FLUORIDE ON BEAN

REPRODUCTION. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 20p., 1970. 12 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 63rd, St. Louis, Mo., June 14-18, 1970, Paper 70-1.54.)

Tendergreen bean plants were grown from planting to seed maturity under continuous exposure to hydrogen fluoride at fairly uniform concentrations averaging 10.5, 9.1, and 2.1 micrograms F/cu m. Progeny of these plants and of comparable control plants were grown in a clean atmosphere to determine if subsequent generations were affected by HF treatment of the parents. The F-1 generation progeny of the HF treated plants were less vigorous than control plant progeny, as shown by later emergence, smaller primary leaves, and slower stem growth. This probably was a consequence of the lower starch content of the seed of the HF treated plants. The primary leaves of some of the HF treatment F-1 progeny were severely stunted and distorted. This also may have been due to the low starch content of the seed, or perhaps it resulted from damage to the plumules in shrivelled, distorted seed produced in the HF treatment. Some of the first trifoliate leaves of many F-1

<xref image="2000WVKU.TIF|V3|2006:09:28:01:38:30.00|121015|0"> image: </xref>

generation progeny of the HF treated plants were abnormal in the separation and number of their leaflets. This abnormality apparently was heritable, for in the next (F-2) generation it occurred most frequently among plants whose parents were abnormal. However, few F-3 generation plants had abnormal trifoliolate leaves, indicating rapid reversal to normal form. (Author abstract)

Schmidt, H. J., G. W. Newell, and W. E. Rand
THE CONTROLLED FEEDING OF FLUORINE, AS SODIUM
FLUORIDE, TO DAIRY CATTLE. Am. J. Vet. Res., vol.
15:232-239, April 1954. 27 refs.

Dairy cattle were fed fluorine as sodium fluoride on a daily basis for a three-yr period and periodically examined for the influence of fluorine on lactation, weight, teeth, general health, and bones and tissues. The daily ingestion of fluoride levels as high as 2.5 mg/kg of body weight did not significantly reduce milk production nor cause a depression in weight. There was no evidence in the cows of diarrhea, rough coat, lapping of water, or elongation of the toes which might be attributed to prolonged ingestion of fluorides. The fourth incisors of cows fed 2.0 and 2.5 mg fluorine showed marked mottling, staining, and wear. At the 1.5-mg fluorine level these effects were less apparent. Only slight mottling and staining, with no wear, was evident in cows fed 1 mg fluorine. Third incisors were less effected by fluorine, while first and second incisors remained free of any changes. Slight exostosis developed in three of four cows fed 2.5 mg fluorine but not in cows fed lower levels. The relative intake of sodium fluoride by the animals was consistently reflected in the urinary excretion of fluorine. (Author summary modified)

Newell, G. W. and H. J. Schmidt
THE EFFECTS OF FEEDING FLUORINE, AS SODIUM
FLUORIDE, TO DAIRY CATTLE--A SIX-YEAR STUDY. Am.
J. Vet. Res., 19(71):363-376, April 1958. 21 refs.

A six-year study was carried out to determine the effects of prolonged feeding of fluorine to dairy cows, beginning with two-yr old heifers, under conditions of practical dairy management and practice. Fluorine, as sodium fluoride, at levels as high as 2.5 mg/kg of body weight had no adverse effect on milk production or growth rate. The inseminations per conception, days in gestation, and percentage of live births were uninfluenced by the levels of fluorine used. Regardless of fluorine treatment, birth weights of calves were all within the normal ranges. The degree of dental fluorosis observed depended on the length of time on experiment, the amount of fluorine fed, and age on cow when sodium fluoride was first administered. Although the general health of the herd remained high, frequent unthriftiness and roughened coats were seen in cows fed 2.0 and 2.5 mg fluorine. Exostoses occurred on the metatarsal bones of two cows fed 2.5 mg fluorine and one of these animals subsequently exhibited lameness in walking. These results suggest that the boundary level at which toxicosis may be expected to occur over periods of prolonged ingestion is 2.0-2.5 mg fluorine. The most reliable indicator of the levels of fluorine ingested was found to be fluorine deposition in bone and cartilage.

Rand, W. E. and H. J. Schmidt
THE EFFECT UPON CATTLE OF ARIZONA WATERS OF
HIGH FLUORIDE CONTENT. Am. J. Vet. Res., 8(46):50-61,
Jan. 1952. 14 refs.

Observations of cattle that have been continually ingesting and absorbing fluoride from drinking water and from forage provide a direct confirmation of conclusions that have been derived from a study of the literature. Levels of soluble

fluoride in the diet can be tolerated as high as 1 mg per kilogram of body weight per day over a long period of time with no ill effect, except possible slight mottling and wear of the teeth. A level of soluble fluoride in the diet of the order of 2 mg per kilogram of body weight per day may result in mottling and severe wear of incisor teeth that form during the period of ingestion, as well as lameness and stiffn emaciation, and general unthriftiness. Conditions as observed in the Phoenix, Anz., area substantiate conclusions previously drawn from the literature with respect to fluorine content of urine and bones as criteria of damage. The fluorine content of urine must be well above 10 ppm to indicate current consumption of fluorine in damaging amounts, while the fluorine content of the metacarpus must be above 4000 ppm to indicate an accumulated amount that would have any effect other than some slight mottling or wear of the incisor teeth. (Author summary modified)

Schmidt, H. J. and W. E. Rand.

A CRITICAL STUDY OF THE LITERATURE ON FLUORIDE TOXICOLOGY WITH RESPECT TO CATTLE DAMAGE.

Am. J. Vet. Res., 8(46):38-49, Jan. 1952. 68 refs.

A critical study of the literature was undertaken to establish the best field method for the diagnosis of fluorosis in cattle, to determine the borderline between amounts of ingested and absorbed fluorine that will be damaging and nondamaging over an extended period, and to establish the best biochemical checks for support of the diagnosis. Since there is usually no reason for examining cows' teeth, the first noticed symptoms of fluorosis in cattle may be bilateral lameness and stiffness, often accompanied by palpable exostoses on the long bones, lower jawbone, and ribs. However, prior to these first-observed symptoms, the incisor teeth will exhibit ineradicable mottling and abnormal wearing, in those cases where the teeth were formed during the period of abnormal fluoride ingestion. In pronounced or advanced cases of fluorosis, cattle may exhibit dryness and stiffness of the hide, poor condition of the coat, diarrhea, impaired appetite, decreased weight gain, lowered milk yield, emaciation, cachexia, and anemia. Bones from animals that have been damaged by fluorosis will analyze more than 3000 to 4000 ppm of fluorine, while no damage from fluorosis has been found unless the urine continuously analyzes well in excess of 10 ppm. Because of the differing ability of various forages to accumulate fluoride, and because of seasonal and other variables, a comprehensive and long term sampling and analytical program is necessary to determine total amounts of fluorides ingested. Fac. Agr. Kagawa Univ.), 21(48):74-83, March, 1970. 16 refs.

Ten species of plant leaves were collected July through Sep-

tember, 1969, at the western part of Goslukidai in Kagawa

Prefecture. PH values of the cell sap obtained from ground

<xref image="2000WVKV.TIF|V3|2006:09:28:01:38:34.00|124232|0"> image: </xref>

plant leaf tissues were determined in situ with a portable pH-meter with specially designed electrodes. The electric conductivity of the water extracts of the same plant leaves was measured with a portable electric conductometer in the laboratory. Wind direction and velocity were monitored at 18 observation stations in the area with Mori's apparatus. The effects on the pH values and specific electric conductivity of the plant leaf cell sap of the wind direction and velocity at each observation station were studied to determine the effects of sea wind. Plant cell sap samples from the observation stations affected by the sea wind showed higher pH values than others. The specific electric conductivity, on the other hand, showed no definite tendency. The duration of water extracting affected the specific electric conductivity to an extreme degree. No marked effects of air pollution on plants were determined except some minor effects of sea wind and fog. When the air pollution due to acidic gases, such as sulfur dioxide and fluorides, is enhanced by sea wind or fog, the effects on plants is expected to be serious.

EFFECTS OF FLUORIDES ON FARM ANIMALS. Preprint,
Air Pollution Control Association, Toronto, Ontario Section,
and Ontario Dept. of Energy and Resources Management,
Toronto, Air Management Branch, 29p., 1970. 31 refs.
(Presented at the Impact of Air Pollution on Vegetation Conference, Toronto, Ontario, April 7-9, 1970.)
If animals ingest quantities of fluorides above their safe tolerance level for prolonged periods of time, fluorine toxicosis or fluorosis may result. Acute fluorosis toxicosis usually arises from accidental ingestion of extremely high levels of fluorine compounds in water, vegetation, or other feeds. Chronic toxicosis (fluorosis) is the type of fluorine poisoning most frequently observed in livestock; it is characterized by certain clinical manifestations or pathological lesions. Where fluorosis is suspected, proper sampling and chemical analysis of vegetation may give early indications of the source and extent of the problem. The degree of fluorosis can be determined with a high degree of accuracy by taking into account the amount of fluorine in bone and the tooth classification. Fluorine tolerance limits have been established for various animal species and are summarized in tabular form.

Navara, Jan
A CONTRIBUTION CONCERNING EFFECT OF FLUORINE
ON SEED GERMINATION IN RELATION TO THE NATURAL
CONTENT OF ASH AND SOME BIOGENIC ENDS.
(Prispevek k ucinku fluoru na knicenie semien vo vzťahu k prirodzenemu obsahu populovin a niektorých biogenných prvkov). *Biologia*, 19(8):589-596, 1964. 9 refs. Translated from Russian. Belov and Associates, Denver, Colo., lip., Jan. 2, 1971.
The effects of low and high concentrations of fluorine on the germination of seeds of peas, barley, white mustard, kohlrabi, and carrots were studied in relationship to the mineral content of the seeds. Fluorine was applied by soaking seeds for 20 hrs in various concentrations of sodium fluoride. High concentrations of fluorine inhibited germination of pea and barley seeds and, to a lesser extent, mustard and kohlrabi seeds. Seeds of poppies and carrots were relatively unaffected. For the most part low concentrations of fluorine had a stimulating effect that was apparent in speed of germination and overall ability to germinate, as well as root growth and the growth of coleoptiles. Increasing the calcium content of seeds by the application of $\text{Ca}(\text{NO}_3)_2$ decreased the inhibiting effects of fluorine on the germination process. The levels of other mineral elements in seeds appeared to have no correlation with tolerance to fluorine.

THE EFFECT OF FLUORINE AND OF BETA-INDOLACETIC ACID ON THE RESPIRATION OF ROOT TISSUE. (Action du fluor et de l'acide beta-indolylacétique sur la respiration des tissus radiculaires). Text in French. Rev. Gen Bot., 71(836): 12-21, 1964. 23 refs.

The effect of various concentrations of BIAA and of fluorine in the form of sodium fluoride on the growth of apical root fragments of *Lens culinaris* was studied. At all concentrations BIAA inhibited the elongation of the root fragments, fluorine had the same effect at high concentrations but at low concentrations had a stimulatory effect on the growth of the root fragments. BIAA was found to stimulate respiration mildly at low concentrations while it inhibited the absorption of oxygen at higher concentrations. Acting in combination no additive effect was noted. At concentrations stimulating respiration, fluorine was found to reduce the acceleration effect caused by BIAA. Thus fluorine and auxine acted as antagonists in their effect on the respiration of root fragments of *Lens culinaris*.

INFLUENCE OF AIR POLLUTION ON PLANTS. (De invloed van luchverontreiniging op planten). Text in Dutch. Neth. J. Plants Pathol., 73(4):129, 1967.

The history of plant poisoning from gaseous air pollutants in the Netherlands goes back 60 years; the first incident of this kind was damage caused by fluorine in the vicinity of a superphosphate plant. The effects of hydrogen fluoride, sulfur dioxide, and peroxyacetyl nitrate (PAN) are briefly summarized. Hydrogen fluoride, when present in quantities as low as a few parts per billion, can cause damage to the leaves of plants. Lichens are so sensitive to sulfur dioxide that they cannot exist in the vicinity of large cities and industrial centers where the SO₂ concentration is higher than 35 parts per billion. PAN, sometimes known as photochemical smog, was considered an American phenomenon until October 1965, when abnormal weather conditions in western Europe caused serious damage from this pollutant to spinach and lettuce. Damage to the leaves of certain species and varieties of plants makes them valuable as indicators (their sensitivity exceeding that of the human senses), but they are less accurate than chemical analyses, due to the fact that the 'symptoms' are not entirely specific for higher concentrations. The mechanism of plant damage from air pollutants is not completely understood, although it is known for certain that fluorine, ozone, and PAN act at the level of the cells, functioning as inhibitors of the plant enzymes. Fluorine affects the metabolism of carbohydrates; enolase is especially sensitive to this gas. A combination of PAN and ozone strongly inhibits the synthesis of cellulose. Liquid and solid particles in the air can also cause damage directly or indirectly to plants, especially by limiting the incidence of sunlight.

FLUORINE, A DYNAMIC TRACE ELEMENT FOR CORN.

(Le fluor, oligo-élément dynamique pour (e maïs). Text in French. C. R. Acad. Sci. Paris, Ser. D, vol. 269:1767-1769, Nov. 3, 1969. 7 refs.

<xref image="2000WVKW.TIF|V3|2006:09:28:01:38:36.00|121563|0"> image: </xref>

Corn plants grown in an artificial medium containing 0, 0.5, 1, 2, and 4 mg sodium fluoride yielded after 64 days 19, 30.8, 31.4, 39.6 and 27.3 g dry weight of vegetable matter respectively. A graphic analysis of the growth curve of corn under given experimental conditions yielded 1.8 mg NaF/l as the optimal growth-promoting quantity of NaF for corn. In the presence of aluminum salts and of 0, 0.5, 1 and 4 mg sodium fluoride, after 65 days corn plants yielded 18.6, 43.26, 11.4 and 10.54 g dry weight of vegetable matter. Fluorine in trace quantities is necessary for the optimal growth of corn in an artificial medium; at higher levels, however, fluorine is toxic and inhibits growth. The toxicity of fluorine can be attenuated by an excess of aluminum in the solution as a result of the probable formation of aluminum fluoride. The optimal concentration of fluorine varies from 250 to 800 microgram/1 g depending on the concentration of aluminum in the medium.

THE EFFECT OF CERTAIN COMBINED BORON FERTILIZERS ON THE ACCUMULATION OF FLUORINE IN

VEGETABLES. (Influence de certains engrais combines boriques sur l'accumulation du fluor dans les vegetaux). Text in French. Revue Suisse de Viticulture et Arboriculture (Lausanne), 1(2):30-33, March-April 1969. 7 refs.

Tests with grapevines, apricot trees, and forage plants performed on field lots, in potted plants, and in the laboratory disclosed that the use of certain combined fertilizers resulted in an accumulation of fluorine in the plant tissues, particularly in leaves. The fertilizers in question were manufactured by direct solubilization in a strong acid of a mixture of crude phosphates, of a potassium salt, and of a boron compound. An analysis of three different types of these fertilizers disclosed the presence of potassium fluoborate which as a result of its solubility is absorbed by the plant roots and accumulates in plant tissues. This accumulation was greatest at elevated temperatures, under strong illumination, and at low relative humidity and drought conditions, probably as a result of accelerated evapotranspiration. The manufacturers of the fertilizers in question were advised of these findings and the objectionable method of manufacture discontinued.

ATMOSPHERIC POLLUTION AND ITS EFFECT ON THE

PLANT. (Die Verunreinigung der Atmosphaere und ihr Einfluss auf die Pflanze). Text in German. Schweizerische Gaertnerzeitung (Zurich), 73(19): 233-236, May 1970.

Sulfur dioxide penetrates into the interior of leaves more readily at higher temperatures, under bright light, and at high humidity than in cold and dry weather and in darkness. The plant has a defensive mechanism in that it oxidizes the sulfite ion to a sulfate ion 30 times less toxic. Fluorine emissions from aluminum works, glass works, brick factories, ceramic factories, phosphate fertilizer plants, and from the manufacture of hydrofluoric acid can be controlled by the Harding-Desbaumes device which absorbs not only gaseous fluorine compound's but partly also solid fluonne compounds in dust and in aerosol. Fluorine is absorbed by plants principally through leaves, and only to a small degree through root from the soil. Its distribution in the plant is uneven, with content high in roots, leaves, and stems. Fluorine compounds cause plasmolysis of the cell content and thus the death of cells manifested by necrotic plant tissue. Chlorine and hydrochloric acid, which cause burns in plants, now contaminate the atmosphere only rarely; ammonia has a similar effect. Dust from cement factories and metallic oxide dust cause plant necrosis. Of automobile exhaust pollutants, saturated hydrocarbons, nitrogen oxides and organic acids are less phytotoxic, while

ozone, nitro-derivatives, and peroxyacetyl nitrate are more so. Lead emissions do not seem to cause severe damage to plants even at high levels but are dangerous indirectly to animals and humans.

THE EFFECTS OF AIR POLLUTION ON PLANTS. (Effete de la pollution de Pair sur les plantes). Text in French. In: Probleme der Luftverunreinigung durch die Industrie. Switzerland, Vogt-Schild S. A., 1969, p. 1-19. 126 refs.

A review is presented of sources of SO₂, methods of measuring it in the atmosphere, maximal permissible SO₂ levels, its mode of action on plant tissues, contributory factors, sensitivity of species and plant organs and methods of evaluating damage caused by SO₂, including inspection, air analysis, analysis of the affected tissues, microscopic examination, and turbidimetric tests. Some of the same subjects are also discussed for fluorine emissions. Damage from these and other pollutants, including chlorine, hydrochloric acid, ammonia, hydrogen sulfide, zinc oxide dust, dust from cement plants, compounds of arsenic and molybdene, coal tar fumes, automobile emissions, ozone, peroxyacetyl nitrate, and smog, to a variety of plants is described.

THE EFFECTS OF SULFUR DIOXIDE AND OF FLUORINE COMPOUNDS ON VEGETATION. (Action de l'anhydride sulfureux et des composés fluores sur la végétation). Text in French. Poll. Atmos. (Paris), vol. 7:381-391, 1965. 20 refs. (Presented at the Conference Internationale des Arts Chimiques, Paris, France, 1965.)

The study of the effects of SO₂ and HF pollution on crops and vegetation grown around the industrial city of Lacq, France, which has daily emissions of 400 tons SO₂ and 150 kg of fluorine, disclosed that in humid and cold years (1961, 1963) plant damage from SO₂ predominated while in hot and dry years fluorine damage predominated. While SO₂ causes burns immediately upon interaction with plant tissues, necroses produced by HF are slow in developing. Plants were the more susceptible to damage by SO₂ the closer external factors came to achieving optimal photosynthetic activity. The sensitivity of luzerne to SO₂ doubled when relative humidity was raised from 40 to 100%. Fruit trees manifested enormous differences in sensitivity as did grapevines. While the Petit Mauseign grapevine strain had an SO₂ sensitivity threshold of 2.5 ppm, the Tannat strain's threshold was 15 ppm. Fluorine damage is best assessed on apricot trees, which are quite immune to SO₂. The sensitivity threshold of plants to fluorine is 10 microg/cu m air. Analyses of sulfur and fluorine levels in plant tissue were of little help in diagnosing the cause of damage, in the case of sulfur because it is a major element of metabolism, and in the case of fluorine because some plants with a high fluorine content do not manifest damage while other plants with low fluorine content do. The various hypotheses of the mechanisms of damage by the two pollutants are discussed.

EXPERIENCE WITH LEAF ANALYSIS IN SMOKE DAMAGE

TESTS. (Erfahrungen mit der Blattanalyse bei Rauchscha-
denuntersuchungen). Text in German. Angew. Botan., vol. 34:33-37,
1960. 3 refs.

The role of chemical analysis in examining plant material for damage caused by smoke is discussed. Most difficult is the diagnosis of SO₂ damage, even in case of leaf discoloration, because this symptom is not specific. An increased content of sulfur in leaves can be an indication of damage by SO₂ but this proof is not reliable, since plants can manifest elevated sulfur levels through intake from the soil. A quantitative micromethod for the detection of SO₂ in fresh leaves has been developed by G. Bredemann and H. Radeloff. Hydrochloric acid and chlorine can also be detected by a micromethod (Ag-NO₃) but it is no proof of damage because the natural chloride content in plants fluctuates widely. The same holds for NO₂ and NO₃. Ammonia can be detected microchemically with great reliability; fluorine can also be detected microchemically and positive tests usually indicate the cause of damage, but the fluorine test is not always reliable. A sensitive and reliable microchemical test also exists for asphalt and tar vapors. Thus, if the circumstances of the damage and local conditions are known, microchemical leaf analysis is useful as an auxiliary method in attributing damage to a specific agent. But leaf analysis by itself does not constitute conclusive proof.

Wentzel, K. F.

SENSITIVITY AND DIFFERENCES IN RESISTANCE OF

PLANTS TO POLLUTION. (Empfindlichkeit und Resistenzun-
terschiede der Pflanzen gegenueber Luftverunreinigung). Text in
German. Forstarchiv, 39(9): 189-194, Sept. 1968. 27 refs.

Until 1940 the SO₂ concentration threshold beyond which damage to vegetation could be expected was considered to be 2 ppm. Recent experiments in chambers with controlled atmosphere show that the true threshold is around 0.2 ppm; and field experiments show that the most sensitive plants manifest deleterious effects from a median long-term exposure level of 0.02 ppm SO₂. The sensitivity thresholds for hydrogen fluoride are even lower. These data help explain the wide extent of emission damage in old coniferous stand as well as the occurrence of such damage at distances 10-30 km from the source. The resistance of plants to pollution varies with a whole complex of factors, primarily with type of emission, growth conditions, the developmental stage of the plants, and nature of the exposure. The combination of these factors will govern the difference in resistance of a plant species. A distinction must be drawn between experimental and field resistance, the former judged by leaf sensitivity, the latter by livability and yield impairment. No sequence of plants can be compiled in their order of resistance that would be valid under all conditions. Generally, the danger to vegetation from pollution increases in the order of cereal crops, deciduous trees, horticultural crops, fruit trees, fodder crops, ornamental plants, and conifers.

Spielings, F.

STUDY OF THE EFFECTS OF FUMES THROUGH FUMIGA-

TION EXPERIMENTS. (Untersuchungen von Raucheinwirkun-
gen (lurch Begasungsversuche). Text in German. Forschung und
Beratung, Reihe C, Wiss. Ber. u. Diskussionsbeitr. (Muenster),
vol. 5:56-63, 1963.

Fumigation experiments with controlled atmospheres of hydrogen fluoride and sulfur dioxide involving a number of grasses, plants, bushes, and trees, performed at the Institute voor Plantenziektenkundig Onderzoek in Wageningen (Hol-
land), are described. These experiments were undertaken because of the damage from these pollutants to tulip and

gladiolus crops. Experimental results with HF in the case of gladioli were in agreement with observations in the field both as to symptoms of damage and differences in resistance of various strains, but this was not the case with SO₂ where laboratory and field results differed. HF was found to cause much greater damage than SO₂ and some strains of both tulips and gladioli were found to be more pollution-resistant than others. The concentration range in the experiments for HF was from 0.015 to 0.2 ppm, for SO₂ from 0.75 to 3.50 ppm. HF damage in ornamental monocotyledons can be quantitatively expressed by the injury index indicating the percentage length of the leaf rim where damage can be observed. SO₂ damage is largely manifested by spots which are not easily measured. The degree of damage was expressed by the color difference between healthy and damaged leave in tomatoes, spinach, and endives, and was determined colorimetrically on alcoholic solutions of leaf pigments. Thus a 6-hr exposure of spinach to 0.5 ppm SO₂ resulted in 14% damage, exposure to 1 ppm SO₂ in 27% damage.

Baumeister, Walter and Helmut Burghardt
THE PHYSIOLOGICAL EFFECT OF FLUORIDE ON TOMATOES AND SPINACH. (Untersuchungen ueber die physiologische Wirkung von Fluorid bei Tomaten und Spinal). Text in German. Flora (Jena), vol. 144: 213-228, 1956. 23 refs. The effect of various concentrations of sodium fluoride on tomatoes and spinach was studied under conditions of hydroponic cultivation. The nutrient medium was a solution of 3 salts with Mn, B, Zn, and Fe as additives. In concentrations of 25 and 100 mg F/l for spinac and of 50 and 150 mg F/l for tomatoes, the effect was in all cases deleterious. The weights of the sprouts and roots, apparent CO₂ assimilation values, and pigment contents decreased while respiration intensity rose. Leaves yellowed at the tips; their rim dried up or curled up. At the higher concentration levels the plants died after about 4 weeks. At lower concentrations of 1, 5, 10, and 25 mg F/l no effect on apparent CO₂ assimilation, respiration, and pigment content was noted. But while in the case of spinach the live weight of the plant was reduced by up to 40%, the weight of tomato plants increased by up to 60% and did not fall off sharply until a 50-mg F/l concentration was reached. In tomatoes the roots, and in spinach the leaves, were most affected. The difference in the reaction of both species may be due to the circumstance that the tomato is free of fluorine while spinach is one of the fluorine-rich plants. Thus, at least on some plants, fluorine seems to have the effect of a trace mineral.

Cormis, L. de
ABSORPTION OF FLUORINE SOLUTIONS AND MIGRATION OF FLUORINE IN THE TOMATO. Ann. Physiol. Veg., 10(3): 155-169, 1968. 20 refs. Translated from French. 28p. Studies were made to determine whether fluorine absorbed by the leaves of tomato plants can be displaced toward the roots and whether the fluorine contained in the soil can be absorbed by the roots and then displaced toward the leaves. In the first part of the study, fluorine was introduced to the aerial parts of tomato plants, either by soaking the leaves or the leaf stalks
<xref image="2000WVKY.TIF|V3|2006:09:28:01:38:44.00|123455|0"> image: </xref>

with a hydrofluoric acid solution of 4 g/l of fluorine in two tests, the first lasting 2 minutes, the second, 4 minutes. The soaked leaves were rinsed twice in distilled water and their fluorine contents were measured and proved to be, respectively, 319 and 409 ppm, indicating that absorption of the fluorine ion is rapid. In the second part of the experiment, tomato plants were grown in various cultivation environments to which fluorine solutions were added. Tabulated data for both parts of the experiment revealed that fluorine moves normally from the leaf stalk of absorption to the leaflets, the stems serve essentially as a passage area, an appreciable quantity of fluorine is still found in the stem at the time of collection, there is practically no passage of fluorine to the roots, and that if the cultivation environment contains a large quantity of fluorine, the latter is not noticeably displaced toward the leaves even if it is absorbed in small parts of the roots.

Hasegawa, Toshio, Yoshiaki Yamazaki, Hideo Hayashi, and Masaaki Takahashi

ON THE ATMOSPHERIC FLUORIDE POLLUTION. PART

III. (Fukkabut.su ni yoru taiki osen chosa. Dai-3-po). Text in Japanese. Taiki Osen Keiikyu (J. Japan Soc. Air Pollution), 5(1):225, 1970. (Proceedings of the Japan Society of Air Pollution, Annual Meeting, 11th, 1970.)

The effects of hydrogen fluoride and sulfur dioxide emitted from a hydrofluoric acid plant in Suita, Osaka Prefecture, were investigated. Samples of the surrounding atmosphere, agricultural crops (rice plants), and soil were analyzed for fluorine and sulfuric acid ions. In addition, the wind speed and wind velocity were measured. Fluorine was analyzed by the alizarine complex method, and sulfuric acid ions by the barium chromate method. The fluorine content of rice plants was 340-379 ppm for those badly damaged, 200-210 ppm for those mildly damaged, and 42-76 ppm for those not damaged at all. The concentrations also tended to decrease with distance from the factory. In soil, the fluorine concentration was 12-38 ppm, and there was not much difference between the polluted and the control areas. The concentration of fluorine at the emission source, measured by dry-type cylindrical filter methods showed 86.2 mg of fluorine/400 sq cm/100 hr. The meteorological data showed that there is a relationship between the frequency of wind direction and the concentration of the pollutants downwind from the emission source.

National Academy of Sciences-National Research Council, Washington, D. C., Subcommittee on Fluorosis Problems

THE FLUOROSIS PROBLEM IN LIVESTOCK PRODUCTION.

Pub.- 824, 29p., 1960. 135 refs.

Colored photographs provide definitive diagnostic criteria for determining the incidence and severity of fluorosis in livestock. The development of fluorosis depends on the total fluorine intake, which varies with physiological phenomena such as growth, heavy lactation, and pregnancy. Sources of fluorine which may affect livestock are mineral feed supplements, water contamination, forage contaminated with soil particles from road dust or as a result of close grazing, forage containing an elevated F content induced by atmospheric fluorines from around industrial plants, and feed concentrates. The tolerance level from a soluble source is 30-50 ppm in the ration for a lactating dairy cow. Rock phosphate fluorine, however, would be tolerated up to 60-100 ppm. Tolerance levels for swine and poultry are higher. The most definitive quantitative measure of the degree of fluorosis is the extent of retention of fluorine in the skeleton. The most sensitive biological reaction to fluoride is that of the developing tooth. Suspected fluorine toxicosis may be diagnosed tentatively by the general health and condition of the herd. Clinical diagnosis supported by chemical analysis can positively identify fluorine

toxicosis. The tolerance of an animal to ingested fluorine is increased by consumption of green forage, by supplementing the ration with certain soluble aluminum compounds, by including high levels of calcium in the ration, and by adequate nutrition. Tolerance to fluorine varies with species, and the level tolerated depends upon the form of the fluorine ingested.

Rohmeder, Ernest and Alexander von Schonborn
THE BREEDING OF SPRUCE WITH INCREASED RESISTANCE TO EXHAUST GAS. International Union of Forest Research Organizations, Proc. Congr. Intern. Union Forest Research Organizations, 14th, Munich (West Germany), 1967, 5(Sect. 24):556-566. 8 refs. Translated from German, 12p. Thirty-six spruce of average age were selected from stands severely damaged by smoke in West Germany; the chosen trees remained somewhat healthy and productive in spite of severe exposure to smoke. About 7000 shoots were obtained by means of grafts from the selected trees. In greenhouse fumigation experiments with exactly measured concentrations of sulfur dioxide and hydrogen fluoride, the grafts displayed considerably more resistance than grafts whose shoots stemmed from spruce living more than 100 years in the high mountains. It was demonstrated that the characteristic of heightened resistance to exhaust gas is based in the genetic spectrum. The resistant grafts were even less damaged by SO₂ and HF, and by fumigation mixtures, than were other kinds of conifers and deciduous trees. Only the oak tolerated even higher SO₂ and HF concentrations than did the resistant grafts. The greenhouse fumigation experiments clarified which environmental factors influence the smoke resistance of forest trees. It was found that the higher the relative humidity, the higher the light intensity, or the higher the assimilation intensity, the greater the damage to forest trees. During the winter, forest trees contain higher concentrations of components such as SO₂ than in the summer. Optimally nourished plants endure higher concentrations than do plants cared for with insufficient nutrients. (Author summary modified)

Huff, Paul B.
DAMAGE TO CITRUS BY FLUORINE AIR POLLUTION IN CENTRAL FLORIDA. Citrus Ind., 40(3):12, 14, 16, 33, March 1959. 1 ref.
In the spring and summer of 1949 a number of groves north of Bartow in Florida began to show tip burning, excessive leaf drop, and a chlorosis in the foliage that was not common to Florida citrus. Then it was noticed that a foggy, pale white, yellow smoke was coming from a new triple-superphosphate plant only about seven-tenths of a mile away. Another such plant went into operation in Polk County, and two citrus groves within three-fourth of a mile South-West of this plant were showing leaf tip burn, leaf drop, and the peculiar chlorotic pattern on the leaves. Losses are indicated. Analysis revealed that fluorine was present in the leaves. As each new triple-superphosphate plant opened and went into operation, the people noticed the native vegetation begin to die. The cattlemen noticed that calves were born too early, and often dead. Liberation of fluorine is discussed, as each ton of raw rock phosphate contains 60 pounds or more of fluorine. An experiment was conducted with Ruby Red Grapefruit trees to prove the cause.

THE INVISIBLE INJURY THEORY OF PLANT DAMAGE. J.

Air Pollution Control Assoc.. 5(4):205-208, Feb. 1956. 8 refs.

(Presented at the Air Pollution Control Association, Annual Meeting, 48th, Detroit, Mich., May 22-26, 1955.)

A summary is presented of the present state of knowledge of sulfur dioxide, hydrogen fluoride, coal smoke, and smog in relation to invisible plant injury. The latter is defined as interference with growth, photosynthesis, respiration, reproduction, or enzymatic function, or demonstratable increase in susceptibility to disease. The evidence relating to physiological activity seems definite that invisible injury due to the reducing conditions that characterize sulfur dioxide fumigations is a second-order effect at the most. No observations have been recorded to suggest that the gas makes plants more susceptible to disease. The oxidizing conditions in smog seem to be more effective in causing invisible injury, possibly because the normal reductive processes in the leaf are less intensive than the oxidative process. Toxic fluoride ions have to be disposed of by rather slow mechanical means like translocation and volatilization and, therefore, permit some invisible injury when threshold concentrations are exceeded. Toxic organic compounds in smoke are more difficult to characterize, because their identity has not been definitely established. Presumably they represent a wide spectrum of compounds which would have to be inactivated primarily by chemical means. They might, therefore, interfere appreciably with the normal reactions in the leaf and cause some invisible injury. (Author summary modified)

Wander, I. W.

EFFECTS OF POLLUTANTS ON VEGETATION (WITH SPECIAL REFERENCE TO THE EFFECT OF FLUORINE ON

CITRUS). Fla. Eng. Ind. Expt. Sta. Bull., Eng. Progr. Univ.

Florida Bull. Ser., no. 10(9):14-16, Sept. 1956. 20 refs.

Following the construction of severe' triple-superphosphate manufacturing plants in Polk County, Florida, a unique chlorotic pattern developed on citrus leaves, particularly grapefruit. The condition differed from known chloroses resulting from nutritional deficiencies or toxicities and was eventually traced to the fluorine being released by the phosphate plants. The fluorine content in the chlorotic leaves ranged from 370 ppm to a low of 48 ppm. These findings are noted to contradict a California study which reported no instances of chlorosis in citrus leaves that were found to contain up to 211 ppm fluorine. The fact that chlorosis develops in Florida may be due to the higher humidity under which the leaves mature.

CHROMOSOMAL CHANGES IN MAIZE INDUCED BY

HYDROGEN FLUORIDE GAS. Can. J. Genet. Cytol. (Ottawa),

12(3):614-620, Sept. 1970. 18 refs.

Twelve corn plants were placed in growth chambers and fumigated for four to ten days with about 3 micrograms/cu m of hydrogen fluoride (HF). Following treatment, the plants showed no visible symptoms of fluoride injury. However, microsporocyte smears from the plants revealed chromosomal aberrations that included asynaptic regions, translocations, inversions, and bridge plus fragments or fragments by themselves. These abnormalities are considered due to the physiological effect of HF causing chromosome to become sticky and/or to the occurrence of chromatid breakage followed by reunion to form structural changes. These findings indicate that HF is a mutagenic agent. (Author abstract modified)

AMBIENT AIR QUALITY CRITERIA FOR
HYDROFLUORINE AND FLUORIDES. VDI (Ver. Duet. Ing.)
Ber., no. 164:23-31, 1971. 25 refs.

Air quality criteria (or standards) for fluorine are determined by fluorine's effects on vegetation, animals including man, and physical property. Fluorine's effects on vegetation are the most serious. The uptake of fluorine by plants can result in excess fluorine intake by animals, and cattle are the most sensitive animals. Cattle can tolerate up to 100 ppm of fluorine for up to 30 days. Responses are reduced feed intake, changes in dentition, and fluorine build-up in the skeleton. Knowledge of dietary limits in vegetation is less precise than in the case of animals. Fluorine can cause visible injury and growth effects. Different species have different sensitivities, but generally sensitivity depends on the amount of fluorine content in the tissue. Highly sensitive plants develop symptoms of injury when the tissue level of fluorine is less than 50 ppm. Sensitive plants show injury when fluorine content is 50 to 200 ppm, while tolerant varieties show no symptoms of injury until fluorine exceeds 200 ppm. The relationship between air pollution and fluorine in the soil is debatable, however some correlation exists for the following dose-rate relation: increase in fluoride content of vegetation over normal values expressed in ppm (ΔF) equals an atmospheric concentration constant (K) times the average concentration of gaseous fluoride in the atmosphere (C) times exposure time in days (T). Vegetation analysis is difficult to translate back to an emission rate of a source. Criteria based on vegetation levels are most useful in defining a goal for an area and confirming that control is or is not adequate.

DAMAGE CAUSED BY FLUORINE NEAR RHEINFELDEN
AND MOEHLIN. (Fluorschaeden bei Rheinfelden und Moehlin).
Text in German. Leben und Umwelt (Aarau), 12(3):69-71, Dec.
1955.

In 1952 the widespread dying of bees was for the first time attributed to the fluorine in flue gases of the aluminum plant in Rheinfelden-Baden. The bees contained from 5 to 112 mg fluorine in 100 g dry substance while the norm is 0 to 4 mg. In 1953 damage was noted for the first time in vegetation in the form of marbling and peripheral damage to leaves. Leaves curled up and assumed a spoon-like shape. More severe damage was manifested by necrosis proceeding from the leaf tip along the rims. Conifers exhibited similar symptoms and some complete defoliation occurred. Especially afflicted were cultures of clover, all cereal crops, and various grasses. The harvest was reduced by 50%. In 1955 cows were afflicted by a peculiar disease; they began to tremble, lost weight, and manifested pain in legs and joints. They often broke ribs and other bones. The fluorine content in cow bones was 6-10 times higher than the norm. These animals, suffering from fluorosis, either recovered spontaneously or died; administration of vitamins did not have any effect. Domestic animals not fed with green fodder or hay were unaffected, as were humans. The milk and meat of the diseased animals did not contain excessive levels of fluorine. Elevated levels of fluorine were detected in vegetation to a distance of 6 km from the factory.

CASUALTIES IN PLANTS BY FLUORIDES IN EXHAUSTIVE GAS OF GLAZED TILE MANUFACTURING FACTORY.

(Yuyakugawara seize kojo haigasuchu fukkabutsu ni yoru shokubutsu higai ni tsuite). Text in Japanese. Hyogo-ken Eisei Kenkyusho Kenkyu Hokoku (Rept. Environ. Sci. Inst. Hyogo Prefect.), no. 2:11-17, March 1971. 9 refs.

The cause of crop damage around a glazed tile manufacturing factory was determined by a survey of raw materials, fuel exhaust gas, environmental air, and damaged plants. During the period from May to August 1969, two ceramics with two tunnel kilns (the amount of exhaust gas per one tunnel kiln was 2700 - 2800 N cu m/hr) were tested. The change in fluorides in the tiles by calcination was measured and 296 - 306 ppm of the fluorides were found before the calcination and 208 - 214 ppm after it. The volatilizing amount of fluorides in the exhaust gas was about 45 ppm. On the other hand, the amount of fluorides contained in the exhaust gas in the fire flue was 1.7 - 4.4 ppm. This was perhaps caused by the condensation and adhesion of produced fluorides in the remaining heat kiln and in a fire flue. According to the JIS (Japanese Industrial Standard) K 0105 analysis method, the amount of fluorides in the exhaust gas was 0.020 - 0.043 ppm. Also, according to the Lime Treated Filter Paper method by Miller, the highest value in the place where the damage was the most distinctive was 258 micrograms F(-)/100 sq cm/3 days. The damaged plants included carnations, moist-land rice plants and onions. When the fluorides in the leaves were compared with those in healthy leaves, they showed: in carnations, where the amount of fluorides was the highest, the value of the damaged leaves was 52.3 ppm and that of the control leaves was 22.4 ppm; for the onions, the result was 42.1 ppm in the control leaves and 52.3 ppm for damaged leaves; for bamboo grass growing near the kilns, the amount of the fluorides was more than 12 times that of control leaves. Also, research was made on copper and sulfur oxides, and the obtained value was small in both cases. So the damage to crops is considered to be due to the fluorides.

ON DAMAGE TO PLANTS BY FLUORIDES IN EXHAUST GAS FROM TILE MANUFACTURING FACTORY. (Uwagusu-

rigawara seize kojo haigasu chu fukkabutsu ni yoru shokubutsu higai ni tsuite). Text in Japanese. Hyogo Prefecture, Kobe (Japan), Environmental Science Inst., Rept. 2, p. 11-16, Feb. 1971. 9 refs.

Crop damage occurred in the limited vicinity of glazed tile manufacturing plants in Hyogo Prefecture. The material clay for the tile contained fluorides, and damage to the carnation and rice plants was chiefly the withering of the leaf tips. Fluorides in the material clay, exhaust gas from the firing kiln, the atmosphere around the factories, and the damaged plants were examined. Fluoride in the material clay was 296-306 ppm. About 30% of the fluoride in the clay volatilized during the baking process. Also, the fluoride in the baked tile was about 208-214 ppm and in the exhaust gas was 1.7-4.4 ppm. Fluoride was 0.020-0.043 ppm in the environmental atmosphere, 52.3-54.3 ppm in the injured carnations and 179.3 ppm in the onions. The metal content in the exhaust gas was also analyzed, since the pigment used with about 80% of the manufactured tiles was copper oxide. The copper volatilizing during the baking process was measured as 10.6-66.8 microg/N cu m. Assuming it becomes diluted to 1 to 200 by atmospheric diffusion (about 200 m away from the source), the density will be about 0.05- 0.34 microg/N cu m, which can hardly affect the plants. Unlike lead, copper does not accumulate in living tissues, so it does not cause chronic poisoning. Total sulfide in

the stack gas was estimated at 4.8-5.9 ppm. Taking into account the dilution of sulfide by atmospheric diffusion, the density is too low to adversely affect the plants. Therefore, the primary cause for damage to the plants was fluoride. However, possible geometric or arithmetic effects of various air pollutants may have to be further studied in connection with plant damage.

METABOLIC EFFECTS OF ATMOSPHERIC FLUORIDES

ON PLANTS. Environ. Pollut., 1(3):169-174, Jan. 1971. 25 refs.

(Presented at the First International Congress of Plant Pathology, London, England, July 1968.)

The metabolic effects of atmospheric fluorides on plants are reviewed. Studies of enzyme activity in vitro provided most of the information on the nature of fluoride-sensitive sites and the possible mechanism of fluoride inhibition. There are many fluoride-sensitive enzymes; therefore, the possibility of multiple sites of fluoride action exists. Isolated tissues have been used to study the effects of fluoride on metabolic systems in vivo. It has been shown that many metabolic pathways may be affected by fluoride and that the presence or type of effect depends on which pathways are operative. Several metabolic effects are associated with leaf necrosis. The rate of oxygen uptake was increased in beans and gladiolus exposed to hydrogen fluoride. Fluoride-induced inhibitions of O₂ uptake have also been reported and the type of effect depended on the age of the plant, duration of exposure, nutrient status, and fluoride concentration. The concentrations or pool sizes of various metabolites are also affected by fluoride. Changes in keto acids, organic acids, amino acids, free sugars, DNA-RNA phosphorus, and starch and non-starch polysaccharides have been found in HF-fumigated plants. The effects of gaseous fluorides on glucose catabolism indicate that the pathways of respiration, monosaccharide interconversion, or polysaccharide synthesis are the most likely sites of fluoride activity. The biochemical effects induced by fluoride, not associated with chlorosis or necrosis, are diverse and suggest that many different areas of metabolism can be affected.

Quellmalz, E.

PROBLEMS OF FLUORINE EMISSION MEASUREMENTS.

(Problematik der Fluor-Emissionsmessung). Text in German.

VDI (Ver. Deut. Ingr.) Ber., no. 164:77-83, 1971.

The correct interpretation of measurements of the fluorine content in air presents some difficulties. The effect of the fluorine can vary depending on the type of compound in which it is present. Biologically, plants are most strongly affected by hydrofluoric acid, animals by free ions of fluorine. In addition to free hydrofluoric acid, other gaseous fluorine compounds can be present in the air, some of which are harmless, whereas others can undergo subsequent reactions and become harmful. It may be assumed that fluorine compounds penetrate the plant surface both in the form of gas and aerosols. The usually ill effects of fluorine compounds in plant food on animals can often be completely neutralized by feeding the animals simultaneously with fodder containing minerals. Emissions of fluorine from industrial sources can have different effects as air pollutants, depending on the industrial process involved. For instance, emissions from blast furnaces containing fluorine carrying dust are more harmless if alkaline sub-

<xref image="2000WVL1.TIF|V3|2006:09:28:01:38:54.00|132790|0"> image: </xref>

stances, particularly lime, are prevalent in the dust. If acidic substances prevail, the fluorine emission becomes far more noxious.

THE EFFECTS OF LOW LEVEL FLUORINE POLLUTION

IN A MOUNTAIN VALLEY. (Consequences d'une pollution fluoree de faible importance dans une vallee de montagne). Text in French. Tribune Cebedeau, (Centre Beige Etude Doc. Eaux), 24(327):62-66, Feb. 1971. 8 refs.

The effects of fluorine pollution from a phosphoric acid plant discharging daily 20 kg fluorine into the atmosphere of a mountain valley were studied. Ten % of the fluorine was emitted as dust, 25% was contained in aerosol form and in condensation on water and 65% in a gaseous state as SiF₄ and HF. In an area of 15.2 sq km, fluorine concentration between 0 and 10 mcg/cu m were recorded over a period of 10 years. Cattle fodder was found to contain between 20 and 50 ppm fluorine contents in the jaws of cattle, signs of dental decay and dental enamel discoloration. This latter symptom was found in cattle living in the polluted zone for 3 years. Occasional lameness was observed in cattle living in the polluted zone for five years and feeding on fodder with a fluorine content of 50 ppm. Exostosis was not observed. While it is difficult to set a fluorine level for fodder which would never cause pathological changes in cattle because of contributory meteorological, ecological, nutritional and physical-chemical factors a maximal permissible level of 20 ppm should be considered a safe level.

FLUORINE CONCENTRATION OF THE AIR AND PLANTS

IN THE VICINITY OF A BRICK KILN. (Fluorgehalte von Luft und Pflanzen in der Umgebung einer Ziegelei). Text in German. Staub, Reinhaltung Luft, 31(5):206-208, May 1971. 11 refs.

Brick kilns emit fluorine in the form of hydrogen fluoride and silicon fluoride. This is particularly true when the crude material contains many fluorine and few alkaline components. Emission measurements were taken with impingers in the vicinity of a brick kiln. In the period from May to August, 49 air samples were taken and the fluorine content was determined. Average concentrations of 1.4 to 6.9 microgram /cu m were determined. In 1968, Bergerghoff units were set up in which gaseous fluorine and fluorine-containing particles were collected. In rural areas the fluorine concentration amounted to 0.1 mg/sq m/day; a maximum concentration of 7.44 mg/sq m/day was found in the vicinity of the brick kiln. Examination of grape leaves revealed that the fluorine concentration rose gradually during the growing season, from 4.2 mg/100 g dry substance on the first of July to 23.5 mg/100 g dry substance on the last day of October. In leaf samples from rural areas. the concentration was 1.2 mg/100 g dry substance. In the foliage of peas and string beans, a 10-fold fluorine concentration was found, in spinach a 9-fold, and in lettuce, a 20-fold concentration of that found in the rural areas. No direct correlation between the fluorine content of the leaves and the leaf injuries could be determined.

AIR POLLUTION AND THE QUALITY OF WINE. (Luftverunreinigung und Weinqualitaet). Text in German. Muench. Med. Wochenschr. (Munich), 113(23):901, 1971.

Emissions of sulfur dioxide and halogens such as hydrogen chloride, chlorine, fluorine, and hydrogen fluoride stemming from factories and refuse burning produce damage or retarded maturation in grape vines. The maturing fruit is injured by intake of the pollutants through assimilation and through the fine

wax layer that coats the berries. The taste of the berries may be spoiled by smoke, mineral oil vapors, asphalt, and tar. Following use of freshly tarred wooden supports for the vine, the taste of tar was transferred through the roots. Dust and soot deposits on the plants also slow the ripening process and impair the taste. Vines within 300 m of highways are polluted by lead. Fortunately, vineyards in Germany are rarely located near highways.

McCune, Delbert C. and Leonard H. Weinstein

METABOLIC EFFECTS OF ATMOSPHERIC FLUORIDES

ON PLANTS. Environ. Pollut., no. 1:169-174, 1971. 25 refs.

The metabolic effects of atmospheric fluorides on plants are reviewed. Results of studies on the effect of the pollutant on individual enzymes in vitro, isolated plants or plant parts, enzyme activities, pool sizes of various metabolic intermediates in fumigated plants, or physiological processes such as photosynthesis or respiration in plants exposed to atmospheric fluorides are discussed. Each approach yields important information, but the results must be interpreted in the light of the characteristics and limitations of the systems employed. Fluorides may act as metabolic inhibitors in a process in which the pollutant reacts with a metabolically active site to render it inactive. Presumably this site is in enzyme, although coenzymes or activators may be targets of the pollution. The inhibition of the enzyme results in an inhibition of the reaction mediated by that enzyme. The degree of inhibition depends on the concentration of the inhibitor at the active site, and this in turn depends on the amount and distribution of the inhibitor within the cell. Scholl, G.

IMMISSION RATE OF FLUORINE IN PLANTS AS A QUANTITATIVE BASIS FOR AN IMMISSION LIMITATION. (Die

Immissionsrate von Fluor in Pflanzen als Masstab fuer eine Immissionsbegrenzung). Text in German. VDI (Ver. Deut. Ingr.)

Ber., no. 164:39-45, 1971. 16 refs.

The accumulation of fluorine in organs of plants which grow above ground, such as leaves and needles, represents an important criterion for the evaluation of the effect of phytotoxic fluorine compounds on vegetation. The quantity of fluorine absorbed depends on the sensitiveness and absorption capacity of the plants, and on the fluorine concentration in the surrounding air. Fluorine concentrations of less than 0.5 micrograms/cu m air can already cause an accumulation in the course of one growth period of more than 50 mg fluorine in 100 g dry leaf substance. With increasing concentrations of hydrofluoric acid in the air, enrichment of fluorine occurs in tomato leaves, grasses, clover, and other fodder plants. Based on the close connection between fluorine concentrations in the fodder and the fluorine intoxication of cattle, standards of fodder quality are suggested for the protection of domestic animals, particularly cattle and sheep. Since the fluorine content fluctuates with the seasons, a maximum yearly average of 4.0 mg fluorine in 100 g dry substance (DS) based on one analysis per month is proposed, maximum 6.0 mg F/100g DS within two consecutive months, and maximum 8.0 mg f/100 G DS in any individual month. Standardized grass cultures, grown in portable containers under controlled conditions of seed and soil have been developed as measuring devices for

<xref image="2000WVL2.TIF|V3|2006:09:28:01:38:58.00|122007|0"> image: </xref>

fluorine air pollution. They are being exposed to the open air for 14 days, then washed, dried, and pulverized to obtain the required condition for analysis of the fluor content.

Guderian, R.

FINDINGS FROM GASSING EXPERIMENTS FOR DETERMINATION OF PLANT - DAMAGING HF CONCENTRATIONS.

(Ergebnisse aus Begasungsexperimenten zur Ermittlung pflanzenschädigender HF-Konzentrationen). Text in German. VDI (Ver. Deut. Ingr.) Ber., no. 164:33-37, 1971. 2 refs.

Extensive experiments have been conducted to determine the effect of hydrofluoric acid gas concentrations on plants. The experimental set-up consists of miniature greenhouses in the form of chambers with walls made of plastic sheet, into which rarefied HF-air mixtures are brought from a generating room via plastic piping mounted below ground. Atmospheric air enters through the roofs of the chambers, drawn in by the suction effect of the piped-in mixture. A change of air is thus effected 100 times per hour, and the fluctuations in temperature and humidity inside the chamber follow those of the outer air. The experiments were made with HF concentrations between 0.85 and 25 micrograms/cu m of air. Among the forest cultures, some varieties of fir, spruce, ash, and beech show already after ten days of exposure to average gas concentrations of 1.3 micrograms/cu m of air such distinct damage to needles and leaves that one has to expect drastic retardation of growth in case of exposure for several months or years. The symptoms of damage observed were necrosis on needle tips and blade edges. Fodder plants, particularly varieties of grass and clover, were tested after 16 days exposure to gas of 0.85 and 2.60 micrograms HF/cu m air, respectively. The ensuing enrichment of fluorine in the plants was up to 9 mg F per 100 g dry substance with the weaker HF concentration, and up to 22 mg F per 100 g dry substance with the stronger HF concentration. Visible damage on the clover leaves occurred in the form of chlorosis and in rarer cases necrosis of leaf parts. A table of resistivity of a number of tree, plant, flower, and vegetable varieties to HF effects is shown comprising the very sensitive ones, the sensitive and the less sensitive species. Lasting damage to plants can be caused already by very low HF concentrations in the atmosphere in case of long exposure.

30299

Spienngs, F. H. and H. G. Woltmg

INFLUENCE OF VERY LOW HF CONCENTRATIONS OF THE LENGTH OF THE DAMAGED BLADE-TIP REGION AND ON THE BULB YIELD WITH THE TULIP VARIETY PARIS.

(Der Einfluss sehr niedriger HF-Konzentrationen auf die Laenge der Blattspitzen-Schaedigung und den Zwiebelertrag bei der Tulpenvarietaeet Paris). Text in German. VDI (Ver. Deut. Ingr.) Ber., no. 164:19-21, 1971.

In a gardening area outside of Amsterdam, damage to tulips and gladioli by hydrofluoric acid emission from an industrial plant located 8 km away was noted. The same symptoms occurred inside of hothouses where tulips were grown already early in the year. Since HF concentrations inside of hothouses are normally considerably less than in the outside air, long-term tests were made with the tulip variety Paris which was known to be very sensitive. Inside a larger glass building, four specially designed exposure chambers, each of 30 cu m inside volume, were used for these experiments. For producing the noxious mixture of air and HF, air saturated with water vapor was forced through heated hydrofluoric acid, and then combined with a stream of purified outside air. Purification of the latter was effected by filtering for dust removal and passing through shell lime for absorption of gaseous impurities. The mixture thus obtained was equalized in a suspended nylon bag, and then admitted to the four chambers, where a change of atmosphere was taking place three times a minute. The outer air

was either sucked in continuously, or alternatively a condition was established where nine tenths of the air was being circulated and one tenth drawn in. The HF concentration in the chambers was checked by sample taking in two three-hour periods each day, using an impinger for subsequent analysis. Graphs of damage to the plants were plotted for conditions of 0.5, 0.7, 1.4, and 4.3 micrograms HF/cu m, with number of weeks of exposure on the abscissa, and damage to blade points in cm on the ordinate. The increase of damage as a function of time was very small at 0.5 micrograms, but became very pronounced at the higher HF concentrations. A study on changes in the yield of bulbs in dependence of HF concentration revealed 100% yield up to 0.3 micrograms HF/cu m, falling off gradually to 55% at 4.0 micrograms HF/cu m air.

Garber, K.

INTRODUCTION AND SURVEY. (Einfuehrung und Ueberblick). Text in German. VDI (Ver. Deut. Ingr.) Ber., no. 164:7-10, 1971. 23 refs.

In 1959, a sub-commission of the Association of German Engineers (Verein Deutscher Ingenieure, VDI) was formed to take care of the preparatory work for establishing guidelines concerning effects and maximum permissible values of fluorine compounds in the air. Since available data at that time were insufficient, an extensive research program was started to reduce the various known methods of fluorine analysis to one or two recognized ones and to clarify important questions in the areas of veterinary medicine and botany. The research work carried out since then yielded many interesting data, for instance relations between fluorine content in the air and the analytically determined F-content of plants. One example of reported figures refers to grass where at average F-content in the air of 1.4 to 1.7 micrograms F/cu m air, the accumulation of F in the grass amounted to 1.5 to 16.6 milligrams/100 g dry grass substance. The results of tests made inside of chambers where plants were exposed to air mixed with hydrofluoric acid under controlled conditions for about 14 days were comparable with open-air observations. The extent of damage to the plants was not only dependent on the F-content in the air, but also on other factors such as humidity, light, temperature, and conditions of growth and nourishment of the plants. An important factor for the absorption of fluorine by plants is rainfall. Measurements made in the vicinity of a phosphate plant showed 10.0 mg F/l of rain water as yearly average in locations in the main wind direction, and in the same location an average accumulation of 185 mg F/100 g dry plant substance. The results from a measuring station located in the opposite direction were 1.85 mg F/l of rain water and 205 mg F/100 g dry plant substance.

Fukushima Prefectural Government (Japan), Agricultural Experiment Station

PHOTOGRAPHS FOR ESTIMATING SMOKE INJURY; RICE

PLANT. (Engai hantei zuhan). Text in Japanese. 36p. Dec. 1969. 19 refs.

Rice plants at different stages of growth were subjected to high concentrations of sulfur dioxide, hydrogen fluoride (100, 500 ppm), and chlorine (50, 100 ppm) for 30 minutes to study the plant injuries caused by waste gases from chemical factories in the Fukushima Prefecture. Symptoms of plant injury

<xref image="2000WVL3.TIF|V3|2006:09:28:01:39:02.00|127209|0"> image: </xref>

were shown by colored photographs. Leaf blades showed brown spots after SO₂ gas exposure; these spots changed to yellowish-white with increasing gas concentration. Rice plants were sensitive to HF gas and a symptomatic dark greenish-brown coloration, like that of sheath blight disease, was observed in the panicle and leaf tip after exposure to low concentrations. At high concentrations of HF, the leaf blade turned grey and became fragile. Dark brown spots appeared on the leaf blade and leaf sheath following exposure to Cl₂. Damage to plant growth occurred with SO₂ having the greatest effect and Cl₂, the least effect. Damage at different stages of growth occurred in the following decreasing order: young panicle formation period, tillering stage, booting stage, heading stage and milk-ripe stage. The dry weight of the plant also decreased, with HF having the greatest and SO₂, the least effect. According to gas exposure, nitrogen and phosphorus increased in absorption rate, potassium and silicon decreased, and calcium, magnesium, iron, and manganese differed according to the stage of growth. However, the amount of nutrient absorption decreased in every case. Tests on lime-emulsion spraying and OED-lime emulsion mixture spraying were also conducted as preventive measures for smoke injury. Spraying which preceded gas fumigation was effective. Lime emulsion-OED mixture was most effective against HF gas and a little less effective against SO₂ gas. However, respiratory injury resulted from the spraying and plant growth was inhibited.

Brandt, C. Stafford and Walter W. Heck
EFFECTS OF AIR POLLUTANTS ON VEGETATION. In: Air Pollution. Arthur C. Stern (ed.), Vol. 1, 2nd ed., New York, Academic Press, 1968, Chapt. 12, p. 401-443. 99 refs.
The visible injury symptoms on leaves attributable to air pollution fall within three categories: leaf tissue collapse with necrotic patterns, chlorosis or other color changes, and growth alternations. Continual chronic exposure to low levels of sulfur dioxide will produce a diffuse chlorosis in the leaves of many plants. Continual exposure to ozone causes necrotic lesions through the leaf and eventually collapsed areas. Peroxyacetyl nitrate damage is usually seen as a cross-leaf banding; the typical symptoms can be seen around the edge of the tissue collapse area. Nitrogen dioxide injury develops as bifacial lesions in mature leaf tissue. Fluorides appear to act as cumulative poisons to the plant. When the toxic concentration is reached, the internal cells of the leaf collapse; the result is a characteristic tip and marginal burn, leading to necrosis. Plants sensitive to ethylene may show epinasty, chlorosis, necrosis, leaf abscission, bud abscission, or failure of flowers to open properly. The effects of chlorine, hydrogen sulfide, hydrochloric acid, ammonia, missile propellants, mercury, and herbicides on plants are also given. Factors affecting the response of vegetation to pollutants, such as genetic factors, concentration-time relations, and environmental and growth factors are discussed in detail. The use of plants as pollution indicators has long been accepted. Monitoring programs have included field surveys, bioassay of ambient pollution, and the bioassay of pollutant mixtures produced under laboratory conditions. Injury to plants can be reduced by breeding programs, cultural and management practices, land use, and air quality control.

Suketa, Y., A. Endo, and T. Yamamoto
EFFECT OF FLUORIDES ON AGRICULTURAL CROPS BY AMBIENT FLUORIDES. (Kichu fukkabutsu no kankyo nodo to nosakubutsu e no eikyo). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 5(1): 159, 1970. (Proceedings of the Japan Society of Air Pollution, Annual Meeting, 11th, Tokyo, Japan, 1970.)
The relationship between the fluoride concentration in the atmosphere and the distance from the source was examined. The

atmosphere at polluted area A, 0.5 km from the emission source, contained an average of 10 F (counting the F of unpolluted area as one). The F in dust particles varied from 0.49 to 3.25 micrograms/cu m, and showed the highest concentration at the distance of 1.0 km from the emission source. One-year old orange leaves at area A showed 227.0 ppm F content, and two-year old leaves had 571.3 ppm F. One-year old leaves had 165.7 to 203.3 ppm F at the distance 1.0 to 3.5 km from the emission source, and two-year old leaves had 365.3 to 391.0 ppm. The F in the air captured by alkali filter paper decreased in proportion to the distance, but the ratio did not coincide with that of F content in leaves and the distance, which seemed to signify an effect of F on metabolism. The F content and visual damage on taro potatoes was compared in area B in 1969 and 1970. Leaves with visible damage 0.5 km from the emission source contained 74.4 ppm and 69.4 ppm F, and those with no visible effect had 40.9 ppm. This contrasted with the F content in the plants in the control areas (distances of 10 km or more) which varied from 9.4 to 18.9 ppm.

Takahashi, R., Y. Suketa, and T. Yamamoto
EFFECT OF ATMOSPHERIC FLUORIDE ON PLANT
METABOLISM. (Kichu fukkabutsu ni yoru shokubutsu taisha e no eikyo). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 5(1):160, 1970. (Proceedings of the Japan Society of Air Pollution, Annual Meeting, 11th, Tokyo, Japan, 1970.)
The influence of fluoride on glycolysis phosphoric acid enzyme of gladiolus, especially on beta glycerophosphatase action was observed. Bulbs of gladioli were cultured for three weeks in Hoagland culture solution. They were then exposed to HF of a given concentration and temperature in fumigation chambers for one, five, and 10 days. Changes in beta glycerophosphatase action, protein content, chlorophyll content, and appearance of the leaves were observed. The glycerophosphatase actions in the gladiolus leaves exposed in HF 11.7 micrograms/cu m and 20.9 micrograms/cu m were both lower than those of the control plants. The leaves affected by 20.9 micrograms HF functioned at 55% of the normal activity. Tests also revealed that gladiolus was much more susceptible to HF' damage than crocus or iris. The protein content of the leaves and bulbs of gladiolus exposed to 20.9 micrograms/cu m HF showed a 42.5% decrease. Chlorophyll content in the leaves at 11.7 micrograms/cu m was 88% of that in the control plants. It decreased further to 69% in 20.9 micrograms. A significant effect of atmospheric f on plant metabolism was deduced.

Suketa, Yasunobu and Takeo Yamamoto
EFFECT OF ATMOSPHERIC FLUORIDE ON PLANT
METABOLISM. (Kichu fukkabutsu no shokubutsu daisha e no eikyo). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 7(5):427-434, May 1971. 30 refs.
Leaf scorch, or foliar burn, is a common symptom of plant injury caused by atmospheric fluoride. Chlorosis is another symptom of fluoride injury. The density is atmospheric fluoride and its accumulation in a living plant, the effect of fluoride on plant metabolism, and the hereditary effect of the fluoride on plants are discussed. Studies on the relationship
<xref image="2000WVL4.TIF|V3|2006:09:28:01:39:04.00|126441|0"> image: </xref>

between the exposure factor and foliar deposition of the fluoride, or foliar burn, was introduced briefly. The value of the exposure factor is about the same for cases of both the high concentration (890 micrograms/cu m) and low concentration (40 micrograms/cu m). It also shows a similar distribution of the fluoride deposition, in high or low concentration, if the exposure factor gives the same value. Photosynthesis is adversely affected by the atmospheric fluoride. The photosynthesis of a strawberry deteriorated by 50% when the strawberry was exposed to 48 ppb hydrofluoric acid for one hour. The effect of fluoride on the respiratory organs of plants was also reported. Soy beans exposed to 0.03 ppm HF had metabolic abnormalities. The total sugar quantity of its leaves decreased from 242-253 mg/100 g to 111-141 mg/100 g and the non-reduced sugar/reduced sugar ratio decreased from 4.6-8.7 to 0.8-1.6. For the hereditary effect of fluoride on plants, is also discussed.

Oelschlaeger, W.

FLUORIDE IN FOOD. Fluoride, 3(1):6-11, Jan. 1970. 4 refs. The results of fluoride assays in food, in the vicinity of fluoride-emitting factories and under normal conditions, are presented. Lettuce and spinach contain more fluoride than other vegetables; sweet cherries more than other fruits. In peas, 200 times more fluoride was found in polished than in unpolished peas. The fluoride content of polished rice was 50 times higher than that of unpolished rice. Food derived from animals was higher in fluoride than that which originated from plants. The largest amounts were found in fish. A person eating an average daily diet would consume between 0.3 and 0.4 mg of fluoride. The addition of polished peas and rice, tea, and fish may raise the daily average intake to above two milligrams. Foods from areas near fluoride-emitting factories has much higher fluoride levels than the uncontaminated areas. Near a hydrofluoric acid factory, milk contained 5.7 ppm, compared with 0.05 ppm fluoride in non-contaminated areas.

Pack, Merrill R.

RESPONSE OF STRAWBERRY FRUITING TO HYDROGEN FLUORIDE FUMIGATION. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 16p., 1971. 12 refs. (Presented at the Air Pollution Control Association Annual Meeting, 64th, Atlantic City, N. J., June 27- July 2, 1971, Paper 71-102.) Strawberry plants were grown throughout flowering and fruiting under continuous, long-term exposure to hydrogen fluoride gas at fairly uniform concentrations averaging 0.55, 2.0, 5.0, and 10.4 micrograms/cu m. At 0.55 micrograms fluoride/cu m, there was a small but significant increase in fruit deformation, predominantly at the apical end of the fruit, which was associated with lack of development of some seeds and the adjacent receptacle tissue. In the higher HF treatments, deformities were proportionately more prevalent and severe. At 2.0 micrograms F/cu m and higher, the average fruit weights were also significantly lower than in the control atmosphere; and at 5.0 and 10.4 micrograms F/cu m, the proportion of the flowers that developed into fruit was smaller. None of the HF treatments significantly influenced the number of flowers produced. There were no fluoride injury symptoms on the foliage at 0.55 micrograms F/cu m and only very mild, uncertain symptoms at 2.0 micrograms F/cu m. Therefore, the effects of HF on strawberry fruiting seemed to be independent of visible injury to the foliage and to result from inhibition of seed development. (Author abstract modified)

Hill, A. Clyde

VEGETATION: A SINK FOR ATMOSPHERIC POLLUTANTS. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 37p., 1971. 26 refs. (Presented at the Air Pollution Control As-

sociation, Annual Meeting, 64th, Atlantic City, N. J., June 27-
July 2, 1971, Paper 71-66.)

The possibility of vegetation being an important sink for gaseous air pollutants was investigated. Plant pollutant uptake measurements were made utilizing a typical vegetation canopy and chambers that were designed specifically for gaseous exchange studies. An alfalfa canopy was indicated to remove gases from the atmosphere in the following descending order: hydrogen fluoride, sulfur dioxide, chlorine, nitrogen dioxide, ozone, peroxyacetyl nitrate, nitric oxide, and carbon monoxide. The absorption rate of NO was low, and no absorption of CO could be detected by the methods used. In the typical ambient concentration range, uptake increased linearly with increasing concentration except for O3 and C12 which caused partial stomatal closure at the higher concentrations. Wind velocity above the plants, height of the canopy, and light intensity were shown to affect the pollutant removal rate. A relationship between the absorption rate and solubility of the pollutant in water was also shown. (Author abstract)

Daessler, Hans-Guenther and Hans Grumbach
WASTE-GAS DAMAGE TO FRUIT IN THE VICINITY OF A
FLUORINE PLANT. Arch. Pflanzenschutz, 3(1):59-69, 1967. 10
refs. Translated from German. Sanzare Assoc., Inc., Philadelphia, Pa., 14p.

The effects of fluorine emissions on certain species and varieties of fruits are described. During periods of high humidity, slowly moving emission clouds form to cause acute damage with severe leaf necrosis. High pressure weather conditions lead to chronic damage which becomes apparent during harvest time. The behavior of vegetation to fluorine emissions depends, to a large degree, upon what stage the vegetation is in and its physiological activity. Signs of fluorine damage on sweet cherries, plums, apples, and pears are described. The resistivity of plants can be influenced by the application of certain hormones and by spraying the plants with time to reduce the sensitivity to hydrogen fluoride.

Raay, A. van
THE USE OF INDICATOR PLANTS TO ESTIMATE AIR
POLLUTION BY SO2 AND HF. Council of Europe, Committee
of Experts on Air Pollution, Air Pollution Proc. First European
Congr. Influence Air Pollution Plants Animals, Wageningen,
Netherlands, 1968, p. 319-328. (April 22-27.)

Indicator plants can be used to estimate damage to crops by air pollution, although they can never give an absolute measure. An indicator plant must be sensitive to a certain contaminant, and it must react with clearly visible specific symptoms, preferably at low concentrations. Sulfur dioxide and hydrogen fluoride pollution may be detected with plants that accumulate the contaminant or with simple measuring devices. Both symptoms and chemical analysis must be used to trace the source, the rate, and the extent of contamination. Indicator plants with a different reaction to SO2 and HF allow distinction in areas where both pollutants occur. Endive, lucerne, clover, buckwheat, and barley may be used to detect SO2, and gladioli and freesias for HF. By using these plants in many small plots it is possible to mark the polluted area. The advantages of this method are low cost and immediate and easy

<xref image="2000WVL5.TIF|V3|2006:09:28:01:39:08.00|123644|0"> image: </xref>

indication of the pollution. The disadvantages are the possible non-specificity of symptoms and losses of the pollutant from the plant. Gladioli are being studied for a possible correlation between the fluorine content of leaves, or tipburn injury, and the fluorine concentration of exposed sticky papers. (Author abstract modified)

Spielings, F. H. F. G.

A SPECIAL TYPE OF LEAF INJURY CAUSED BY HYDROGEN FLUORIDE FUMIGATION OF NARCISSUS AND NERINE. Council of Europe, Committee of Experts on Air Pollution, Air Pollution Proc. First European Congr. Influence Air Pollution Plants Animals, Wageningen, Netherlands, 1968, p. 87-89. (April 22-27.)

The studies of injuries to monocotyledonous ornamental flowers growing near a steel factory west of Amsterdam, gladioli and tulips artificially fumigated with hydrogen fluoride showed the same order of sensitivity as in the field. Tests in a fumigation chamber with different concentrations of HF resulted in the following order of decreasing sensitivity: *Ixia*, *Freesia*, *Crocus*, *Sparaxis*, *Fritillaria*, *Chionodoxa*, *Scilla*, *Muscari*, and *Galanthus*. The symptoms of injury were an ivory-colored necrosis of leaf tips, or, in freesias, a marginal ivory-colored necrosis. *Narcissus* and *Nerine bowdenii* showed different symptoms; after the appearance of the ivory-colored leaf tip, the injured part of the leaf slowly extended and a yellow discoloration started close to the original necrosis. This area may stretch several times further than the injured tip. (Author abstract modified)

Robak, H.

ALUMINIUM PLANTS AND CONIFERS IN NORWAY. Council of Europe, Committee of Experts on Air Pollution, Air Pollution Proc. First European Congr. Influence Air Pollution Plants Animals, Wageningen, Netherlands, 1968, p. 27-31. (April 22-27.)

Quantities of fluorine emitted from aluminum plants polluting the air in Norway vary from 8-10 to 27-30 kg/hr. Natural pine forests in the neighborhood of all plants are notably damaged, in three cases even completely destroyed. Visible injury is observable at up to 32 km. The current year's needles of badly damaged trees usually show a fluorine content above 40 ppm. Damage to spruce forests has occurred in a 100-200 ha area within which the fluorine content of the current year's needles exceeds 15-20 ppm and that of the last year's needles 24-35 ppm. Because the outlook for preventing fluorine-induced conifer damage by technical means does not appear promising, a switch should be made to more resistant conifer species. Field observations and experimental plot studies show that *Larix decidua* and *L. leptolepis* are remarkably free from damage, even under unfavorable weather conditions.

32289

Ender, F.

THE EFFECTS OF AIR POLLUTION ON ANIMALS. Council of Europe, Committee of Experts on Air Pollution, Air Pollution Proc. First European Congr. Influence Air Pollution Plants Animals, Wageningen, Netherlands, 1968, p. 245-254. 12 refs. (April 22-27.)

The most important problem concerning damage to animals by air pollution is the poisoning of domestic animals by fluorine in smoke, gas, or dust from various industries. The extent of the problem is illustrated by evidence from the international literature and studies conducted in Norway, where the postwar growth in aluminum production has produced a tremendous rise in livestock fluorosis. The total quantity of fluorine in gases emitted by an aluminum plant is roughly 20 kg/ton of aluminum produced. Emitted with the smoke and other damaging compounds such as gaseous hydrofluoric acid and fluosil-

ic acid, dust-containing cryolite, and aluminum- and calcium-containing fluorides. The geographic location as well as topographic conditions near the aluminum factories have a striking influence on the fluorine contamination of soil and vegetation in the surroundings. The risk of fluorine injuries in neighboring valley districts is far greater with factories located at the bottom of deep, narrow, U-shaped valleys than with those on open, unsheltered ground. Despite installation of gas purification procedures, it is impossible to completely prevent the escape of fluorine-containing gases from doors, ducts, and windows in electrolysis halls. With respect to the defluorination of forage, good results have been obtained by treating contaminated grass with a mixture of diluted sulfuric acid and hydrochloric acid, or by using formic acid.

Stamatovic, S. and D. Milic
PROBLEMS OF AIR POLLUTION IN YUGOSLAVIA. Council of Europe, Committee of Experts on Air Pollution, Air Pollution Proc. First European Congr. Influence Air Pollution Plants Animals, Wageningen, Netherlands, 1968, p. 255-258. (April 22-27.)

The expansion of the nitrogen and phosphate fertilizer industries in Yugoslavia has caused an increase in fluor emissions, endangering plants and domestic animals. In affected areas, fluorosis has been observed in horses, cattle, sheep, and goats. Its occurrence is explained by the quantities of fluor measured in hay, straw, wheat, maize, and sunflower seeds. The intensity of the poisoning varies according to geographic location, climate, and animal species. Under normal conditions, damages are restricted to a distance of about 5 km from the factories. A lead foundry has created the problem of lead accumulation in soil, water, and animals, particularly in ruminants. Lead poisoning has been observed in lambs but so far not in sheep. Sheep milk in the affected area contains an average of 132 gamma/100 g lead. About the same concentration is found in milk from cows, though no lead poisoning has been observed in cattle.

Donaubauer, Edwin
SECONDARY DAMAGE IN REGIONS OF AUSTRIA EXPOSED TO POLLUTION. DIFFICULTIES IN DIAGNOSIS AND ASSESSMENT. (Sekundaerschaden in Oesterreichischen Rauschschadensgebieten. Schwierigkeiten der Diagnose und Bewertung). Text in German. Polska Akademia Nauk, Zaklad Badan Naukowych Gornoslaskiego Okregu Przemyslowego, Mater. Miedzynarodowej Konf., Wplyw Zanieczyszczen Powietrza na Lasy, 6th, Katowice, Poland, 1968, p. 277-284. 10 refs. (Sept. 9-14.)

Secondary damage from pollution most frequently occurs through sunburn on peripheral susceptible tree stands in clearings of wooded areas. Such trees, damaged by the sun, attract pests and die. This applies especially to pine stands. In the pollution-exposed areas of Aichfeld near Judenburg and Gailitz-Arnoldstein, needles of mature pine stands suddenly turned brown in 1963 following the appearance of an additional pollutant (hydrofluoric acid) into the already sulfur dioxide-polluted atmosphere (first area) and intensification of SO₂ emission (second area). A contributing factor was an ex-

<xref image="2000WVL6.TIF|V3|2006:09:28:01:39:12.00|118307|0"> image: </xref>

ceedingly cold winter with temperatures 4 to 5 C below the long-term average. Pollution-exposed stands are more susceptible to infestation with the fungus *Armillaria mellea* which causes great damage in Austria to pine, spruce, and deciduous tree stands. Other pests which proliferate in pollution-damaged stands are *Pissodes piceae*, *Cryphalus piceae*, *Ips typographus*, and *Pissodes harcyniae*. Generally it is not easy to prove a causal relationship between emission and secondary damage: detection of damage in a pollution-exposed area is not sufficient proof. The task is easier where identical or similar stands in unpolluted areas are available for comparison.

FLUORINE-INDUCED POLLUTION AND PLANT DAMAGE

IN THE VICINITY OF A METAL ENAMELING PLANT. (Die durch Fluor hervorgerufene Luftverunreinigung und die Pflanzenbeschädigung in der Nähe eines Emailierwerkes). Text in German. Polska Akademia Nauk, Zakład Badan Naukowych Gornoslaskiego Okregu Przemyslowego, Mater. Miedzynarodowej Konf., Wplyw Zanieczyszczen Powietrza na Lasy, 6th. Katowice, Poland, 1968, p. 117-125. 4 refs. (Sept. 9-14.) Fluorine-induced damage observed on fruit trees and garden plants at distances of 200-500 m from a metal enameling plant initiated measurements of fluorine emission at 0.5 and 2.5-3 m above ground and of fluorine content in plant life. The tests were performed by exposing filter paper saturated with calcium hydroxide to the atmosphere for 3.5 and 10 hours and for 30 days respectively from October 1967 to February 1968. Leaves were completely destroyed on 10-year old five-m high fruit trees, and of peripheral leaf necrosis and light grey to brown spots occurred on ornamental plants and *Phaseolus vulgaris*. The median monthly atmospheric fluorine level in the area of greatest damage (200 m from source) was 2.649 mg F/100 sq m with a maximum of 3.029 mg F/100 sq m at 2.5 m above ground and 2.004 mg F/100 sq m at 0.5 m above ground. The pollution level at 2.5 m above ground was everywhere greater than at 0.5 m above ground. The fluorine content in leaves of bean plants at 1.5 to 2 m above ground was 285 m from the source, two to three times that of plants growing close to the ground. Fruit trees were more susceptible to damage than horticultural and crop cultures.

32343

Kisser, Josef

THE PHYSIOLOGIC EFFECT OF POLLUTION ON

VEGETATION. (Physiologische Probleme der Einwirkung von Luftverunreinigungen auf die Vegetation). Text in German. Polska Akademia Nauk, Zakład Badan Naukowych Gornoslaskiego Okregu Przemyslowego, Mater. Miedzynarodowej Konf., Wplyw Zanieczyszczen Powietrza na Lasy, 6th, Katowice, Poland, 1968, p. 27-43. 18 refs. (Sept. 9-14.) The observations that individual plants in a monoculture react differently to air pollution, that gladioli strains differ in their resistance to pollutants, and that resistance of a plant to hydrofluoric acid does not coincide with its resistance to sulfur dioxide lead to the conclusion that generally there are no pollution resistant plants or strains but only increased resistance to a certain chemical compound. The major part of damage to vegetation can be attributed to gaseous components of smoke emissions which penetrate into leaf tissues by gas diffusion. The degree of damage to leaf cells depends basically on the quantity of gas that penetrates into the leaf tissues and on peak concentrations, if the leaf pores are open during the emission period. Exposure of plants to hydrochloric acid caused a depression of the water balance while exposure to SO₂ caused an initial rise, indicating that the effect on the pore opening mechanism can differ from gas to gas. Higher osmotic pressures and greater diffusion in peripheral regions

and leaf tips were found in all plants examined, where leaf damage is initially manifested. In some cases the distribution of leaf damage is also determined by leaf veins.

Jung, Erwin

CHANGES IN AFFORESTATION OF THE POLLUTED REGION OF RAUSHOFEN. (Bestandesumwandlungen im Rauchschadensgebiete von Ranshofen). Text in German. Polska Akademia Nauk, Zaklad Badan Naukowych Gornoslaskiego Okregu Przemyslowego, Mater. Miedzynarodowej Konf., Wplyw Zanieczyszczen Powietrza na Lasy, 6th, Katowice, Poland, 1968, p. 407-413. (Sept. 9-14.)

An aluminum plant in Raushofen is the source of fluorine and tar containing emissions polluting 800 ha of an almost entirely wooded countryside of spruce and white pine with some fir and beech trees. Of this area 120 ha were either completely destroyed by pollution or so heavily damaged that reforestation with more resistant species became necessary. Sixty ha were planted with birches and alders 5 to 6 m high; while they are not a crop-yielding culture they form, because of their high resistance to heavy concentrations of pollutants, and excellent protective belt around the aluminum plant. Only in the close vicinity of the ovens did the alder not take hold. There, willow (*Salix caprea*) was planted which, while only 1.5 to 2 m high, does contain the heaviest pollution emitted from the ovens. The alder belt is about 600 m deep. The remaining 60 ha furthest from the plant were replanted with larch trees. Two ha were planted experimentally with fir. Parcels of the remaining woods were classified according to a five-point scale with the fifth point denoting the highest degree of pollution damage. Reforestation is ordered when a parcel incurs 40% damage (2.5 on the point scale).

Knabe, Wilhelm and Karl-Heinz Guenther

CONTRIBUTIONS OF FORESTRY TO THE ENVIRONMENTAL PROTECTION IN NORTH RHINE WESTPHALIA. (Forstwissenschaftliche Beitrage zum Umweltschutz in Nordrhein-Westfalen). Text in German. AHg. Forstz., 26(24):503-506, 513-514, June 1971. 28 refs.

The contribution of forestry to environmental protection consists primarily of observations of the effects of air pollutants on trees and plants. The results from indoor exposure test (in greenhouses) do not always reflect the true situation. In open air exposure experiments, young spruce trees grown from seeds were less resistant than scions, whose needles had all the characteristics of those of an old tree. In outdoor gasification experiments, spruces, set up at different levels above the ground, were exposed to the emissions from an aluminum plant. The higher elevated plants were exposed to more fluorine because of greater air ventilation. Tall old trees were injured while young ones growing next to them were seemingly healthy. Although more fluorine was absorbed by the plants, it was eliminated again after some time. In North Rhine Westphalia, forests with an average sulfur dioxide concentration of more than 0.08 mg/cu m during the growing season over three quarters of all measurement years were unsuitable for the growth of any coniferous trees with the exception of *Pinus nigra* Arn.

NECROSES ON APRICOTS: CASING EXPERIMENTS WITH HYDROFLUORIC ACID. (Necroses sur abricots: essais de gazage au niroyen d acide fluorhydrique). Text in French. Revue Suisse de Viticulture et Arboriculture (Lausanne), 3(3):78-81, May-June 1971.

Necroses on apricots were frequently observed in the alpine valleys where certain chemical and metallurgical industries, particularly aluminum factories, were emitting fluorine into the atmosphere. Casing experiments were conducted with various concentrations of hydrofluoric acid on apricot trees and picked fruit. Meteorological conditions of temperature, humidity, and precipitation were observed. Exposure to hydrofluoric acid caused necroses to appear on the leaves and the apricots similar to the necroses on the fruits affected by industrial fluorine emissions. A dry climate, high temperature, fine precipitation followed by long periods of sunny weather, followed in turn by more dry spells were favorably correlated to the appearance of necroses.

Bolay, A., E. Bovay, G. Neury, J. P. Quinche, and R. Zuber

DAMAGE TO APRICOTS AND OTHER FRUITS CAUSED BY FLUORINE COMPOUNDS. (Degats causes aux abricots et a d autres fruits par les composes fluores). Text in French. Revue Suisse de Viticulture et Arboriculture (Lausanne), 3(3):82-92, May-June 1971. 49 refs.

Stone fruits (apricots, peaches, plums, and cherries), pears, and apples grown in the alpine valley (Valais, South Tirol, and Savoy) were examined for fluorine-induced damages. Climatic conditions, particularly temperature, humidity, and precipitation, were observed and correlated. Symptoms of fluorosis on the stone fruits were characterized by well-delimited brown-black necroses, sometimes surrounded by a reddish aureole. The necroses were deep and reached to the stone on very young fruits and were rather superficial on fruits approaching maturity, which were most sensitive to fluorine. Pears gave similar results. Fluorosis on apples appeared as a reddening of the epidermis and rifts appearing around the apex or on the most exposed side. The apples were deformed. Damage symptoms were identical regardless of the origin of the fluorine: atmospheric pollution, fluorine salts sprayed on the fruit, or absorption by the roots from fertilizers containing fluoborate compounds.

Bolay, A., E. Bovay, J.-P. Quinche, and R. Zuber

AMOUNTS OF FLUORINE AND BORON IN THE LEAVES AND FRUITS OF FRUIT TREES AND VINEYARDS, FERTILIZED BY CERTAIN BORON- AND FLUORINE-CONTAINING FERTILIZERS. (Teneurs en fluor et en bore des feuilles et des fruits d arbres fruitiers et de vignes, fumes avec certains engrais composes, boriques fluores). Text in French. Revue Suisse de Viticulture et Arboriculture (Lausanne), 3(3):54-61, May-June 1971. 14 refs.

Various orchards and vineyards were examined for absorption of fluorine and boron from the atmosphere and certain fertilizers by the fruits and leaves. Apricot trees grown in the orchards of Rechy were affected by fluorine emissions from certain aluminum factories. The amount of fluorine in the leaves was proportional to the age, regardless of the fertilizer. Young leaves, that emerged in the hot summer months, were most damaged by the fluorine emissions but contained the least fluorine. Conversely, the youngest leaves were richest in boron content. Apricot orchards in Bieudron and Fey, areas of minimal air pollution, had very few appearances of necroses. The fluorine content in the leaves remained in the range of 17-28 ppm. A stronger application of fertilizer increased the fluorine content but had no notable effect on the boron content or chemical composition of the apricots. Comparable

results were gathered in one of the apricot orchards in Martigny. The other, exposed to fluorine emitted by an aluminum factory, had a higher fluorine content in the leaves. The treatment of apricot trees by a fungicide containing fluorine had no effect on the fluorine content. The boron content was clearly increased upon application of the boron-containing fertilizer, but the fruits did not absorb the fluorine of the fertilizer. Tests on orchards in Marceh'n and Changins, areas virtually free of fluorine in the atmosphere, determined an increase in fluorine content in the leaves and of necroses due to the fertilizer. Plum and pear trees examined under similar conditions gave comparable results, with slight variations for different variables of pollution and fertilizer. Vineyards were also tested in Valais. General results indicated that the combined boron-containing fertilizers determined an evident accumulation of fluorine in the leaves of the plants but had no effect on the fluorine content in the fruits, which was proportional to the degree of pollution by industrial fluorine emissions in the atmosphere.

Dziubek, Tadeusz

HARMFUL INFLUENCE OF INDUSTRIAL DUSTS UPON PLANTS AND ANIMAL ORGANISMS. (O ujemnych skutkach pylow fabrycznych na roslinnosc i organizmy zwierzecze). Text in Polish. Zesz. Probl. Postepow Nauk Rolniczych (Warsaw), no. 74:195-197, 1967.

Contamination of the atmosphere near aluminum and copper foundries and phosphate fertilizer plants is caused mainly by fluorine compounds. The contamination damages plants, meadows, and pastures adjacent to factories or situated in the vicinity and has an indirect effect on domestic animals fed with fodder from such grasslands. Grassland vegetation 100-3000 m from the factories were investigated by measuring the quality and quantity of dust; 0-30 mg% fluorine compounds were found. Changes in cattle tissue (teeth and bones), a decrease in lactation, and a stunting of young animal growth were noted. A considerable decrease in the hemoglobin in the animals investigated also occurred.

Feriancova-Masarova, Zora and Eva Kalivodova

THE EFFECT OF EXHALATIONS FROM THE ALUMINUM PLANT IN ZIAR N/HRONOM ON THE SPECTRUM OF BIRD SPECIES IN THE VICINITY OF THE PLANT. (Vplyv exhalatov hlinikarne v Ziari nad Hronom na druhoze zlozenie vtakov v okoli). Text in Slovak. Biologia (Bratislava), 20(2): 109-121, 1965. 28 refs.

Composition of the bird population composition was studied for three years in five biotopes (woods, orchards, fields, streams, and villages) situated in three geographic zones contaminated with varying fluorine concentrations and in one uncontaminated zone. The zones formed concentric belts around an aluminum plant. Severe fluorine damage to conifers, fruit trees, and various deciduous species caused a change in the biotopes which in turn affected the nesting habits of birds. These changes were significant in the wooded area villages, in the other biotopes the changes seemed unrelated to fluorine levels. The number of bird species nesting in woods (first biotope) was 8, 6, 17, and 22 respectively in the four zones;

<xref image="2000WVL8.TIF|V3|2006:09:28:01:39:20.00|122451|0"> image: </xref>

the number of transient bird species in the respective zones was 15, 8, 7, and 9. These counts indicate that the number of nesting species was lowest in the zone with the maximal fluorine level. The same result was obtained when the numbers of nesting species in the four zones were compared without regard to biotope. Thus a shift of nesting species away from the source of pollution is in progress.

Kostolanska, Anna and Eugen Hluchan

THE EFFECT OF EXHALATIONS FROM AN ALUMINUM

PLANT ON THE FLUORIDE CONTENT IN BONES OF

FROGS. (Vplyv exhalatov z hlinikarne na obsah fluoridov v kostiach ziab). Text in Slovak. *Biologia (Bratislava)*, 20(12):916-919, 1965. 5 refs.

The effect of emissions from an aluminum plant on the calcium fluoride content in bones of *R. temporaria*, *R. dalmatina*, and *R. esculenta* living in the vicinity of the plant was determined and compared with respective fluoride contents in uncontaminated frogs. The fluoride levels found in 100 g dry bones fluctuated between 51.5 and 488.4 mg F compared with 21.6 and 69.6 mg F in uncontaminated frogs, a tenfold increase in fluoride content. Stagnant water near the plant contained 10.9 mg F/liter. Surface soil samples contained 91 mg F/100 g soil. The high fluorine content caused reduction of the phosphorus content in frog bones.

PLANT DAMAGE BY AIR POLLUTION. (Taiki osen ni yoru shokubulsu higai). Text in Japanese. *Anzen Kogaku (J. Japan Soc. Safety Eng.)*, 10(4):189-196, Aug. 1971. 2 refs.

Plants were exposed to sulfur dioxide, chlorine (hydrogen chloride), fluorine (hydrogen fluoride), ozone, peroxyacetyl nitrate (PAN), and nitrogen oxides (nitric oxide and nitrogen dioxide) and observed for symptoms of plant damage. The effects of exposure to sea winds, frost, and SO₂ appeared as round spots around the leaf edge or between the leaf veins. The spots increased with strong sunlight. Damage due to HCl, large irregularly shaped spots, was limited to small areas of the leeward side, but was sometimes severe. Symptoms of damage by HF were similar to those of Cl₂; the damage and healthy parts of the plant were clearly distinct with HF damage. Apricot trees and gladiolus were very sensitive to HF exposure and effected by concentrations of 0.1 ppb and less. The HF content of the damaged leaf attained 50%. Damage due to ozone, caused by factory and automotive exhaust gases, was most severe in June and July. Among the nitrogen oxides, NO₂ and NO caused most damage and inhibited plant growth. PAN, the product of a photochemical reaction, caused reduction of the photosynthetic function when damage was chronic; in cases of acute damage, it affected the protoplasm and produced cavity formations on leaves.

LEAD POISONING IN HORSES. *Arch. Environ. Health*, vol. 23:185-197, Sept 1971. 13 refs.

Five elements (lead, zinc, fluorine, arsenic, and cadmium) were investigated in the vicinity of a smelter; excessive amounts of lead in ingested forage were considered to be the primary cause of a chronic debilitating disorder in six horses. The high lead levels in forage were related to the presence of lead in surface soil accumulated from emissions of a nearby smelter. Young horses were found to have a significantly higher susceptibility to the effects of lead than older horses and cattle. The role played by high concentrations of zinc in local grasses is not fully understood. The possibility of a synergistic effect of zinc and other trace elements on animal

health deserves further study. While elevated fluoride content in some of the grasses tested was evident, fluorosis was ruled out as a cause of illness in the affected animals. Testing of local ambient air and drinking water for all five elements studied showed values to be well within acceptable limits. The same applied to the testing of most locally produced foods of animal and vegetable origin. A few species of leafy vegetables were the only human foodstuffs in which, occasionally, significantly elevated contents of lead and some of the other trace elements studied were found. However, the possibility of any health hazard related to their consumption was considered extremely remote. Human urine specimens and cattle were also studied.

EFFECTS OF HYDROGEN FLUORIDE FUMIGATION ON ALFALFA AND ORCHARD GRASS: A SUMMARY OF EXPERIMENTS FROM 1952 THROUGH 1965. Contrib. Boyce Thompson Inst., 24(14):363-385, Jan.-March 1971. 22 refs.
The results of experiments on controlled hydrogen fluoride fumigation of alfalfa and orchard grass are presented. Alfalfa was relatively tolerant to HF with respect to the production of foliar lesions. Chlorosis appeared prior to necrosis or was induced at lower concentrations of fluoride. The symptoms were most intense along the margins of immature expanded leaflets of the leaves near the tips of main or axillary shoots. Mature leaves were more resistant. The most severe symptoms developed on alfalfa exposed for nine days to the highest dosage of HF (5.20 micrograms F/cu m). The tolerance of orchard grass was comparable. The high dosages of HF which induced foliar markings did not reduce the yield of crops harvested immediately after the fumigation or subsequently. Effects on growth, when determined, amounted to an increase in the fresh or dry weight of the plants. For each day of exposure to HF at 1 microgram F/cu m, the fluoride concentration of alfalfa tissue increased by 2-4 ppm, and that of orchard grass increased by about 1 ppm. During the post-fumigation period (8-22 days), the concentration of fluoride in alfalfa tissue decreased by 50%. (Author summary modified)

Arndt, U.
AIR POLLUTION-INDUCED LEAF PIGMENT CONCENTRATION CHANGES. A CONTRIBUTION TO THE DISCUSSION OF PIGMENT ANALYSIS. (Konzentrationsänderungen bei Blattfarbstoffen unter dem Einfluss von Luftverunreinigungen. Ein Diskussionsbeitrag zur Pigmentanalyse). Text in German. Environ. Pollut., 2(1):37-48, July 1971. 41 refs.
The value of pigment changes is discussed as an early indication of the effects of air pollution on plants. Wheat, oat, and rye plants were exposed to the effects of hydrofluoric acid, of sulfur dioxide, and of hydrochloric acid for varying periods of time and until necrosis set in; then chlorophyll A, chlorophyll B, and beta-carotene were extracted from exposed and control plants and analyzed chromatographically and spectrophotometrically. Control plants exhibited a dependence of the pigment concentration on plant strain, age, and on ecological conditions prevailing prior to and during the experiment. While the content of both chlorophyll A and B was not affected by ex-

<xref image="2000WVL9.TIF|V3|2006:09:28:01:39:24.00|124876|0"> image: </xref>

posure to the pollutants, the content of beta-carotene decreased by 20 to 35% in plants exposed to SO₂ and HCL. In plants exposed to HF, the drop was less significant. Results of this study do not warrant the use of changes in pigment content as an early indicator of the effect of pollution on plants but the question should be pursued in the case of the yellow chloroplast pigments.

DETERMINATION OF FLUORINE-IMMISSIONS BY MEANS OF STATIC ABSORPTION APPARATUS (MODIFIED HARDING METHOD). (Determination des immissions fluorees au moyen d appareils d absorption statique, type Harding modifie). Text in French. Revue Suisse de Viticulture et Arboriculture (Lausanne), 3(3):75-77, May-June 1971.

A modified Harding apparatus was used to determine the correlation between fluorine in the air and in plant leaves. The device consists of a galvanized armature attached to a pole, a group of superimposed discs holding filter paper, and a conical roof protecting the device from rain and bird droppings. The fluorine content was determined by the Belcher and West method modified by Sulzberger after the calcination of a one gram filter paper sample with calcium hydroxide. Measurements were taken near an aluminum factory and near a fertilizer plant. The fluorine content in the filters was directly proportional to the duration of exposure and inversely proportional to the distance from the source of the fluorine. The absorption of fluorine by filter paper is much less than by plant tissues because of respiration and evapotranspiration.

DAMAGES AND DISCOMFORTS CAUSED BY INDUSTRIAL POLLUTION OF THE ATMOSPHERE. (Skador och obehag orsakade av industriell fororening av atmosfaren). Text in Swedish. IVA (Ingenioersvetenskapsakad.) Tidstr., 26:141-163, 1955. 85 refs.

An extensive review is made of the literature of the effects on humans, livestock, and plant life of the various types of gaseous and particulate air pollutants, including sulfur oxides, hydrogen sulfide, fluorine compounds, chlorine, hydrogen chloride, nitrogen oxides, ammonia, organic compounds, and dust. Of these, the most extensive treatment is given to the effects of sulfur compounds and aldehydes. The effects of sulfur dioxide on plants is discussed in great detail. The effect of low concentrations of sulfur compounds in the atmosphere on plant life are being studied in Sweden at the agricultural school in Ultima.

Went, Frits W.
PLANTS MONITOR AIR POLLUTION. Sci. Citizen, 7(10):6-9, Oct. 1965.

The effects of photochemical smog on plants and the use of plants as indicators of air pollution are discussed. Experiments have shown that there are at least two effects of smog which do not give any immediately visible symptoms. One is a general growth retardation. This was shown only in seedlings; it is not certain whether mature plants also show this. The second effect is a closing of the stomata of the leaf, which will decrease the rate of photosynthesis. Plants are more sensitive to smog than animals or humans, and can be used as warning devices. When signs of damage begin to appear in plants, concentrations of air pollutants which may be poisonous to animals and man are being approached. If the lower surface of spinach, beet, or swiss chard leaves show a silvery or bronzed appearance, the leaves of annual blue grass show white banding, or petunia leaves show white discolored areas, photochemical smog is indicated as cause for the damage. By observing which leaves show this damage, the date when the

smog was present can be approximated, since the leaves are most sensitive during the period of expansive growth. If the leaves show a general ivory-white bleaching, or bleaching between the veins, the toxicant was probably sulfur dioxide. A brown burn around leaf edges, spotting on corn leaves, or white or yellow discoloration of the tips of gladioli indicates the presence of hydrofluoric acid. Plants in cities can constitute a vast air pollution monitoring network if many more persons are trained in the recognition of plant damage and sent throughout the country to monitor toxic air conditions.

SOME COMMON DISEASES OF ORNAMENTAL PLANTS IN THE LOS ANGELES AREA. *Lasca Leaves*, 21(2):36-45, June 1971.

Common diseases of ornamental plants in the Los Angeles area were studied and correlated to unfavorable environmental conditions, e.g., exposure to industrial emissions of sulfur dioxide, ozone, peroxyacetyl nitrate, nitrogen oxides, fluoride, and ethylene gas; nutritional disorders, e.g., lack of water, poor drainage, soil alkalinity, lack of organic matter, and salt buildup; and parasitic organisms (bacteria, fungi, viruses, phanerogamic and nematodes). Specific causes and characteristics of certain diseases, the plants they attack, and possible cures are examined.

FLUORINE POISONING FROM WASTE GASES AND DUST EMITTED BY A SUPERPHOSPHATE PLANT: DETERMINATION OF F CONTENT FROM DEPOSITS IN PLANTS, DRINKING WATER, FORAGE, AND BONES. (Fluoor-vergiftiging door rook-gassen en stof van een superphosfaatfabriek). Text in Dutch. *Chem. Weekblad*, vol. 38:585-593, 1941. 101 refs.

An extensive review is given of the literature on detrimental effects caused by fluorine in plants, animals, and humans, as well as the literature on methods of determining trace amounts of fluorine in water, air, and various other locales. A report is given of an original study of fluorine determination in plants, rainwater, drinking water, plant life consumed by cattle, and the bones of cat!e. Results obtained in the immediate vicinity (distances of 4 or - 100 m and + or - 300 m from the fertilizer factory) were compared with control results from other locales. The water, grass, and hay consumed by the cattle contained high amounts of fluorine, and that the bones of cattle that died with the symptoms of fluorine poisoning contained a higher fluorine level than other cattle.

Thompson, C. R., O. C. Taylor, and B. L. Richards

EFFECTS OF AIR POLLUTANTS ON L. A. BASIN CITRUS. *Citrograph*, 55(5):165-166, 190-192, March 1970. 5 reis.

Commercially producing lemon and orange trees were enclosed in plastic-covered greenhouses to which filtered or ambient air was introduced. Various air treatments were applied to test for the effects of total pollutants in ambient air (fluoride, ozone, peroxyacyl nitrates, and nitrogen oxides). The

<xref image="2000WVLA.TIF|V3|2006:09:28:01:39:26.00|114564|0"> image: </xref>

photochemical smog complex reduced the rate of water use, apparent photosynthesis, and yield of fruit in trees receiving ambient air. Fluoride levels in the atmosphere were too low to cause detectable effects. Leaf drop was significantly less in lemons receiving carbon-filtered air than in those receiving ambient air. A similar trend occurred in navel oranges. Fruit drop in navel oranges was also significantly less in carbon-filtered air. Yield of mature fruit is reduced in some cases by as much as 50%. (Author summary modified)

Quinche, J. P., R. Zuber, and E. Bovay
A METHOD FOR THE DETECTION OF FLUOROBORATE IN FERTILIZERS. (Un precede de detection du fluoborate dans les engrais). Text in French. *Revue Suisse de Viticulture et Arboriculture* (Lausanne), 3(3):71-74, May-June 1971. 6 refs.
The presence of fluoborate in commercial fertilizer can be detected by growing young *Coleus* plants in a hydroponic solution to which a small amount of the fertilizer has been added. The plants are grown for two weeks in a glasshouse or in a climatic chamber, then the leaves are plucked and dried, and fluorine and boron are determined. An abnormal and simultaneous increase of both fluorine and boron levels compared to the respective levels in control plants grown under identical conditions, but without the addition of the fertilizer, is proof of the presence of KBF_4 in the fertilizer. The method is sensitive down to a fertilizer concentration of 0.1% KBF_4 .

AIR POLLUTION EFFECT TO THE AGRICULTURE AND FORESTRY. (Norin sakumotsu ni oyobosu taiki osen no eikyo). Text in Japanese. *Ryusan* (J. Sulphuric Acid Assoc., Japan), 24(6):22-36, June 1971. 34 refs.
Influences of sulfur dioxide, agricultural chemicals, nitrogen oxides, and hydrogen fluoride on plants and agricultural produce are discussed. A common damage of SO_2 is chlorosis and withering of red pines. The mechanism of damage has not been explained satisfactorily, but it is clearly caused by SO_2 oxidation reduction. A plant in its budding stage has a large respiratory capacity and a small photosynthesis ability; as leaves grow, the latter increases and the former decreases, thereby increasing production and accumulation of carbohydrate. The quantity of SO_2 absorption increases with the increase in the surface area of leaves, yet a plant's SO_2 absorption capacity has little to do with its respiratory capacity; it is more influenced by the tree's respiratory capacity; it is more influenced by the tree's photosynthetic capacity. This is supported by the fact that an orange tree shows the same amount of resistance when exposed to 30 C and 95% humidity in middle March and forced to bud, as it does during winter. Respiration of a tree in winter will increase in high temperature and humidity, but metabolism does not increase. When metabolism is small, the influence of SO_2 is small. Spraying trees with glutathione is effective against oxidant damage but it enhances the SO_2 damage. The reason might be that glutathione increases photosynthesis or impairs SO_2 's reduction of photosynthesis, thus causing the tree to absorb more gas.

Paluch, Jan and Irina Schalenkowa
AIR POLLUTION BY FLUORINE IN POLAND AND ITS TOXIC EFFECT ON HUMANS, ANIMALS AND PLANTS. (Die Luftverunreinigung durch Fluor in Polen und ihre toxische Wirkung auf Menschen, Tiere und Pflanzcn). Text in German. *Wiss. Z. Humboldt Univ. Berlin Math. Naturw. Reihe*, 19(5):489-492, 1970.
The major sources of the emission of fluorine compounds to the atmosphere are aluminum phosphorus fertilizer manufacturing plants. In Poland, the superphosphate industry alone

produces a fluorine emission of some 4000 to 5000 tons annually, the aluminum industry some 2000 tons. Fluorine has a toxic effect on plants and animals, generally in an area within a radius of 1.5 to 3 km. External symptoms on plants are necrosis of leaf borders which can lead to destruction of their metabolic system and eventual plant death. Some plants, like cabbage, are more resistant than others in this respect. Peach leaves, for instance, are extremely sensitive to fluorine concentrations. The plants in general absorb the fluorine through their leaves and store it; such afflicted plants represent a danger to animals and human beings if taken in as food. The biological and clinical symptoms of fluorosis are due to changes in the calcium and iodine balance in the human or animal organism. Typical externally noticeable symptoms in animals are deformations of long bones, ribs, and joints, followed by lameness. Young animals show disturbances in growth and changes on their teeth. In humans, the most well-known effects are those brought about by fluorine in drinking water. Acute fluorine poisoning can be caused by intake of food which has been contaminated by fluorine compounds. These occur in some insecticides and in some plant sprays.

RELATIVE SUSCEPTIBILITY OF SEVEN GRAIN SORGHUM HYBRIDS TO HYDROGEN FLUORIDE. Contrib.

Boyce Thompson Inst., 24(12):241-244, July-Sept. 1970. 4 refs.

Fumigation of seven grain sorghum hybrids with gaseous hydrogen fluoride resulted in necrosis of the leaf tips and chlorotic mottle of subtending tissue. One-third of the plants were fumigated with HF at an average concentration of 7.0 micrograms F/cu m, one-third received an average of 3.9 micrograms F/cu m, and the remaining one-third received filtered, preconditioned air only. HF-induced injury to foliage was first apparent in plants exposed to the higher concentration on the fifth day of fumigation. Physiological age of the leaves influenced the appearance of foliar symptoms. The youngest (expanding) leaves were not affected by fumigation with HF, whereas the two subjacent leaves were most susceptible. No HF-induced necrosis was observed on basal leaves but mild chlorosis, similar to that which accompanies senescence, was present. Severity of injury was variable: DeKalb C44C and RS 608 were most resistant to HF-induced necrosis, whereas Northrup King 222A, Pioneer 846, RS 610, RS625, and RS 671 were more susceptible. There was no relationship between the tissue accumulation of F and the relative susceptibilities of the seven hybrid lines. Differences in accumulation were affected only by the HF concentration during fumigation. (Author summary modified)

THE EFFECT OF FLUORINE ON PLANTS. (Vliyaniye flora

na rasteniya). Text in Russian. Polska Akademia Nauk, Zaklad

Badan Naukowych Gornoslaskiego okregu Przemyslowego,

Mater Miedzynarodowej Konf., Wplyw zanieczyszczen powietrza

na lasy, 6th, Katowice, Poland, 1968., p. 95-99. (Sept. 9-14.)

The effects of fluorine on certain physiological processes oc-

ccurring in plants are summarized. Peas and cabbage are among

the most susceptible while carrots, tomatoes, and poppy-seeds

<xref image="2000WVLB.TIF|V3|2006:09:28:01:39:30.00|123457|0"> image: </xref>

are the most resistant species to fluorine, even when applied at doses as high as 3-6 g f/1. The effect of calcium, magnesium, or phosphorus on the accumulation of fluorine in pea tissues decreases in this order. The dicotyledoneous plants are more sensitive than the monocotyledoneous plants to fluorine when applied in the substratum. The disruption of the plant growth processes under these conditions is due to a decrease in the assimilation of such nutritive elements as magnesium, phosphorus, and potassium, whereby maximum fluorine accumulations occur in the plant roots. The fluorine-induced alterations in plant metabolism are manifested mainly by alteration in the water balance of the plant tissues when exposed to concentrations of 0.07 mg/cu m of fluorine in the ambient air.

Leonard, C. D. and H. B. Graves, Jr.
SOME EFFECTS OF AIR-BORNE FLUORINE ON GROWTH
AND YIELD OF SIX CITRUS VARIETIES. Proc. Florida State
Horl. Soc., vol. 83:34-41, 1970. 6 refs.

Young Hamlin, Pineapple, and Valencia orange, Orlando tangelo, Dancy tangerine, and March grapefruit trees were grown for 28 months in fine sand in 76-by 29-ft pots at six locations, five of which were exposed to different levels of airborne gaseous fluorine compounds. Variable but significant reductions in yield of the six citrus varieties occurred when the spring flush leaves sampled in May 1969 contained from 20-40 ppm fluorine. These leaf fluorine contents resulted from exposure for 11 weeks to air averaging 0.23 to 0.38 ppm fluorine. In most cases, the spring flush leaves sampled in October contained two and a half times as much fluorine as those sampled in May. This increase in leaf fluorine was closely related to the mean fluorine content of air from May to October and to the additional exposure time. There were also highly significant yield reductions from dilute hydrofluoric acid (HF) applied to bearing orange trees only during the spring blooming season. This fact and the negative correlation between fluorine content of spring flush leaves sampled in May and yield strongly suggest that most of the fluorine-induced injury occurs in the spring bloom period. However very high levels of leaf fluorine accompanied by severe chlorosis can reduce yields the next year even in the absence of fluorine exposure during the period of bloom and fruit set. Only Valencia orange showed a significant reduction in growth.

Liebenow, H.
BEARINGS OF IMMISSIONS ON PLANTS AND
LIVESTOCK. (Die Bedeutung der Immissionen fuer Pflanzen-
und Tierbestaende). Text in German. Monatsh. Veterinaermed.,
26(3):106-111, Feb. 1, 1971. 10 refs. (Presented at the Probevor-
lesung anlaesslich des Habilitationsverfahrens, Sektion Tier-
produktion und Veterinaermedizin, Jan. 20, 1970.)
Plant and livestock damage from sulfur dioxide, fluorine and
its compounds, ozone, and dusts is discussed. The threshold
sensitivity limits for plants are 0.3 mg/cu m SO₂, 0.01-0.03
mg/cu m fluorine, and 0.2 mg/cu m ozone in ambient air. Pine

and fir are among the most sensitive tree species and the sugar beet appears to be the most susceptible plant to these pollutants. Macroscopic damage to plant species from SO₂ includes reddish brown color of the coniferous needles and brown spots on the leaves; chlorophyllous alterations and damage of cytoplasmic organelles appear on the microscopic level. A concentration of 0.15 mg/cu m SO₂ reduces the daily milk performance in cattle by 9% and the milk fat content by 8%. Aluminum and superphosphate plants are the main sources of fluorine pollutants. Fluorine and its compounds cause the blackening of needle and foliage tips and chloroplast decay in plants. Dental fluorosis is the most common fluorine-induced disease in livestock. Fluorine produces impairment of calcium and phosphorus metabolism as well as alterations in cellulose digestion processes. The bean species appears to be the most sensitive plant to ozone. Ozone causes death from lung edema in livestock and the incidence of lung and skin cancer appears to be twice as high in ozone-polluted areas than in unpolluted air. Arsenic-bearing dusts produce the most damaging effects on livestock following ingestion of dusty feed, and accumulation of dusty layers on plant surfaces hinders normal metabolism.

Kerin, D.

DELIMITATION OF INDUSTRIAL EMISSIONS BY MEANS OF PLANT ANALYSIS. *Protectio Vitae*, 16(5):201-202, Oct. 1971. 13 refs.

Vegetation damage in areas surrounded by metallurgical and industrial plants are mainly caused by sulfur dioxide and fluorine compounds. Plants are much more sensitive than humans or animals to SO₂. Many plant varieties show signs of damage at a concentration of 0.3 ppm SO₂. Fluorine and its compounds are particularly injurious to cherries, grapes, plums, various ornamental plants, and vegetables. The Ontario variety of apples is very susceptible. Visible damage to buildings is also caused by this group of pollutants. For determination of the effect of the above pollutants on vegetation, needle samples were taken in September and October in polluted areas and compared to needle samples from unpolluted regions. First and second year needles were separated. Average samples were taken from 100 grams dried needles. Sulfate, lead, zinc, iron, and manganese were determined. Plants taken from the immediate vicinity of a glass work were heavily contaminated with fluorine. Concentrations of 4.0 to 25 mg F/kg dried basis were measured. The sulfur concentration was between 0.50 to 1.5% (natural concentration is 0.20%). The lead concentration ranged from 24 to 1.136 mg Pb/kg (natural concentration is 3.0 mg Pb/kg dried needles). The zinc content ranged from 136 to 495 mg Zn/kg dried needles; in unpolluted areas it is 28 to 75 mg Zn/kg.

H. EFFECTS-PLANTS AND LIVESTOCK

409

The smoke lesions caused by various gases such as sulfur dioxide, sulfuric acid mist, chlorine, hydrogen chloride, hydrogen fluoride, oxidant, and nitrogen dioxide are reviewed. Experiments were conducted on the effect of SO₂ on black pines; the increase of sulfur content in the leaves per day (approximately seven hours of exposure) was 0.004%. This figure imposed on a standard mature black pine forest (dry leaves one kg/sq m) means that the forest theoretically has a capacity for absorbing 40 mg of sulfur (80 mg SO₂)/sq m/day. The accumulation of dusts on leaf surface and the necessity of green buffer areas in cities are discussed. The amount of green area required per person was calculated by the amount of oxygen discharged and carbon dioxide absorbed by photosynthesis of trees as against the O₂ consumption and CO₂ emission by human respiratory activities. An adult requires approximately 30 to 40 sq m of wooded area for living. These matters are to be taken into consideration in the future city planning.

Oelschlaeger, Walter

THE PROBLEMS OF EMISSION MEASUREMENTS OF FLUORINE CONCERNING THE EFFECTS ON PLANT AND

ANIMAL. (Problematik der Inunissionsmessungen von Fluor hinsichtlich der Wirkungen auf Pflanze und Tier). Text in German. Staub, Reinhaltung Luft, 31(11):457-459, Nov. 1971. 27 refs.

The fluorine content of the ambient air can be determined by two methods: either the gaseous fluorine compounds are determined or the gaseous F compounds plus the F compounds contained in the fly ash are determined. Plant damage is almost exclusively caused by the gaseous F compounds in the atmosphere. Industries emit mostly hydrogen fluoride and silicon fluoride. These gases are easily absorbed by plants through the stomata. The damage caused by fluorine compounds found in fly ash on plants is minimal. This can be confirmed by experiments with apple, pear, and cherry trees and with lilac. The soil in which the plants grew contained 1.5 g/kg fluorines and the fly dust applied to the leaves contained 12 g/kg and 132 g/kg. After weeks of application, no injuries could be observed. Apart from the gaseous F compounds in the atmosphere, resistance, water metabolism, nutrient supply, relative humidity, and light intensity must be taken into consideration. Cattle are most sensitive to higher fluorine intakes. Fluorine compounds are either ingested with food or drinking water or inhaled. Cattle's tolerance limit for fluorine intake with the fodder is 30 to 40 ppm referred to dry substance, which is less than one mg/kg body weight. Experiments have shown that higher F concentrations in hay hardly raised the F content in bones above that in cattle receiving sodium fluoride. The same is true for the F intake from fly dust adhering to grass. Therefore it is better to use only the measurement of gaseous emissions for any evaluation of the injurious effect of fluorine. The F content on and in plants should be separately determined by the carbon tetrachloride method.

PHYSIOLOGICAL-BIOCHEMICAL PRINCIPLES OF THE

GAS RESISTANCE OF PLANTS. In: American Institute of Crop Ecology Survey of USSR Air Pollution Literature. Gas Resistance of Plants with Special Reference to Plant Biochemistry and to the Effects of Mineral Nutrition. M. Y. Nuttinson (ed.), Vol. 9, Silver Spring, Md., American Institute of Crop Ecology, 1971, p. 1-27. 126 refs. Translated from Russian. (Also: Uch. Zap., no. 222:5-33, 1969.)

Principal advances in research pertaining to the gas resistance of plants are reviewed. The influence of toxic compounds on the anatomical-morphological structure of leaves and the physiological-biochemical characteristics of plants is considered. Also, the species of plants resistant to various com-

pounds in different physico-geographical zones have been ascertained. Investigators have undertaken detailed studies of the chemistry of injuries to plants by acid gases, as well as the chemical mechanism of transformation of sulfur dioxide in plants and its influence on the metabolism of carbon compounds, with the aid of isotopic techniques. Considerable attention has been given to the development of methods for studying gas resistance of plants. Of major importance for a successful diagnosis and study of the gas resistance of plants is the establishment of direct indicators characterizing the degree of plant resistance. The effects of ammonia, mercury, acids, fluorine, chlorine, and other pollutants on plants are described.

SMOKE INJURIES OF VEGETATION. HANDBOOK FOR DIAGNOSING AND EVALUATING SMOKE INJURIES. (Die Beschädigung der Vegetation durch Rauch. Handbuch zur Erkennung und Beurteilung von Rauchschaeden). Text in German. Leipzig (East Germany), Gebrueder Borntraeger, 1903, 412p. 124 refs.

Smoke generation, characteristics and progression of smoke injuries, causes of necrotic changes in plants, and comparisons of smoke injuries with normal processes in plants are investigated. The effects of sulfurous and sulfuric acids, chlorine, hydrochloric acid, hydrofluoric acid, nitric acid, acetic acid, ammonia, hydrogen sulfide, bromine, tar and other organic substances, asphalt, and methane on plants were determined. Sulfuric acid content of the soil was not increased by acute and continuous exposure to gases containing sulfur dioxide; even an increase in soil sulfate content would not damage plants. Plant damage due to SO₂ effects on leaves was examined. Injuries due to SO₂ included depression of transpiration; exposure to hydrochloric acid impaired assimilation. Metal compounds, introduced into the soil through fly ash, could affect plant roots. Mercury vapor emissions were very damaging to plants, resulting in black spots and fading. The value of plant and soil studies, sampling techniques, chemical analyses, botanical studies, and preventive measures were discussed.

Dreher, K. von

POISONING OF BEES BY FLUOR. (Fluorvergiftungen bei bienen). Text in German. Bull. Apic. Doc. Sci. Tech. Inform. (Nice), 8(2):119-128, 1965.

In order for laboratories analyzing bees for fluorine compounds to obtain comparable results, the average of fluor per bee should be established and the bees should be washed before analysis to eliminate exogenous impurities. Analysis of healthy bees in industrial areas showed that the percentage of fluor is lower in wintering bees than in summer bees. Bees from an experimental apiary near an aluminum factory contained an average of 9.85 micrograms per bee, with an average of 15-25 micrograms for poisoned bees. Sensitivity varies with age for healthy bees. A toxicity threshold of 10 micrograms is suggested. When different parts of the body were examined, 91% of the fluor was found in the abdomen and 83% in the middle gut.

FRICITION WITH FLORIDA FARMERS. Chem. Week, 76(14):28, April 2, 1955.

Gladioli and tomato growers in the Tampa area claim that stack gases from a local phosphate plant are damaging their crops. As compensation for the alleged damage, 22 agricultural firms and individual farmers are seeking judgements against the company totaling nearly \$1.5 million. The plant maintains that it has installed the most modern air-pollution control equipment, while the state Board of Health believes that the pollutant in question comes from putrefaction of waters in Tampa Bay and not from phosphate plants. One theory holds that crop damage from phosphate plants may be due to a fluorine compound formed in treating phosphate rock.

LeBlanc, Fabius, Gilberte Comeau, and D. N. Rao
FLUORIDE INJURY SYMPTOMS IN EPIPHYTIC LICHENS
AND MOSSES. Can. J. Botany, 49(9):1691-1698, 1971. 22 refs.

To study in situ the effects of fluorides on lichens and mosses, lichen- and moss-bearing bark discs were cut from trees in an unpolluted area of Arvida, Quebec, and transplanted in groups of six onto trees in an area polluted by an aluminum factory. Fifteen sites, in addition to a control site, were selected in different directions from the factory. At each site, two boards on which the bark discs were fixed were nailed to a tree. One board was removed after four months exposure and the other after 12 months. The lichens and mosses in both control and polluted areas were compared with respect to color, external morphology, plasmolysis in algal cells, loss of green color, nature of reactions toward neutral red and 2,3,5-triphenyl-2H-tetrazolium chloride, absorption spectra of chlorophyll, and fluoride concentrations. Results indicate that fluoride pollution affects moisture balance, causes chlorophyll damage, and produces other symptoms of injury which could lead to the ultimate death of these organisms. At the end of 12 months, lichen fluoride concentrations ranged from 134 ppm at 15 km NE of the factory to 990 ppm at one km E. Moss fluoride concentrations were always lower than lichen concentrations. (Author abstract modified)

Scholl, G.

INFLUENCE OF PHYTOTOXIC EMISSIONS ON THE
GROWTH OF HORTICULTURAL AND AGRICULTURAL

CROPS. (Einfluss phytotoxischer Immissionen auf das Wachstum landwirtschaftlicher und gaertnerischer Kulturen). Text in German. Landwirt. Forsch. Sonderh., no. 19:166-176, 1965. 20 refs.

The effect of emissions from a metallurgical plant, including sulfur dioxide and fluorine derivatives, on plant growth was investigated during a three-year period. The 12 month average SO₂ content ranged from 0.24 to 0.30 mg/cu m above the two experimental lots. The damaging effects were focused on the leaves and consisted in color alteration and necrosis. Plant growth and yield effects varied according the climatic conditions, species, and stage of growth. Winter rye and leek appeared to be the most emission-resistant species. Highest yield losses were produced in certain bean species, spinach, and summer barley. Barley accumulated the highest amount of sulfur which increased from 0.54 to 0.83% (dry matter) in the leaves at the end of the third year of the experimental period. Fluorine content ranged from 3.0 (spinach) to 26.2 (summer barley) mg/100 g dry matter during the second year of the experiment.

EXTENSION GROWTH IN SEEDLINGS AS A BIOLOGICAL
TEST OF SOILS CONTAMINATED WITH FLUORINE EX-

HALATES. (Verlaengerungswachstum der Keimlinge als biologischer test von durch Fluorexhalate intoxicierten Boeden). Text in German. *Biologia*, 24(10):728-737, 1969. 19 refs. Biological tests based on measurements of pea and barley seedling root extension growth to evaluate the toxicity of fluorine exhalates from an aluminum plant were carried out. The aluminum plant is located in the Hron River Valley and exposed to northwest and north winds with a hilly background on its southern side; the location is characterized by 30% still days/year. Soil located varying distances from the emission source and control soil treated with known amounts of dust from the fusion electrolysis shop of the factory were used for the seedling growth experiments. Lowest growth rates of pea seedling roots appeared on the soil exposed to the highest amounts of fluorine contamination as affected by meteorological and topographic interactions. Inhibition of pea seedling root growth was well correlated with the amounts of fluorine-contaminated dusts added to the control soils. Pea seedlings can be utilized as a biological testing species for the evaluation of fluorine contamination of soils exposed to this pollutant. Barley seedlings elicited irregular reactions and, thus, were rejected as unsuitable for similar tests.

Wentzel, K. F.

THE EFFECTS OF INDUSTRIAL AIR POLLUTANTS AND LIME FERTILIZERS ON SMOKE-EXPOSED GROUNDS.

(Zur Bodenbeeinflussung durch industrielle Luftverunreinigungen und Duengung in Rauchsadenslagen, insbesondere mit Kalk.) Text in German. *Forst-Holzwirtschaft*, 14(8):178-182, 1951. 31 refs. (Presented at the Bezirksgruppentagung des Bundes Deutscher Forstmaenner, Muenster, West Germany, Jan. 22, 1959.)

While air is only a temporary carrier of industrial pollutants, the soil is the final site of their absorption. Sulfur dioxide and fluorine compounds are the main smoke constituents and metal oxides and silicic acid are the main dust constituents absorbed by soil. Sulfur dioxide containing smoke elicits an acid pH. Conversion of SO₂ into sulfurous or sulfuric acid which is then conveyed into the ground by rain or snow increases soil acidity. The available free bases of the soil are then converted into insoluble sulfates, depriving the plants of an important nutritional requirement. Forests are the most susceptible to damage from smoke because of their poor buffering properties and their initial low base contents. Metallurgical processing, cement, and electric power producing plants are the main dust emission sources. Dusts may elicit acid, neutral, or alkaline pH, according to their chemical composition. Dust fall inflicts severe damage to soil structure. Application of fertilizers such as lime would prevent the acidifying effects from smokes and would improve plant resistance against noxious agents. Fertilizer application would also provide a means for the protection of soil structure.

THE EFFECT OF HYDROGEN FLUORIDE AND CRYOLITE DUST UPON PLANTS AND ANIMALS NEAR A HYDROGEN FLUORIDE FACTORY. *Fluoride*, 4(1):21-24, Jan. 1971. 3 refs.

(Presented at the International Society of Fluoride Research Conference, 3rd Annual, Vienna, Austria, March 22-25, 1970.)

<xref image="2000WVLE.TIF|V3|2006:09:28:01:39:42.00|120242|0"> image: </xref>

To clarify damage due to fumigation by hydrogen fluoride and cryolite (sodium aluminum fluoride) dust, studies were carried out on fruit trees, agricultural plants, vegetables, and ornamental plants in the vicinity of a hydrofluoric acid factory. The development of toxic symptoms, differences in sensitivity between plant species, and extent of leaf and fruit damage are described. Plants resistant to F(-) pollution were sour cherries, raps, sugar beets, potatoes, cabbage, asters, and roses. In fruit trees, the sensitivity of leaves did not parallel that of fruit. Fumigation experiments with HF in air mixtures produced results that agreed closely with the field observations. Fluoride intoxication in milk cows near the factory was manifested by reduced milk production. The bee population suffered substantially from F(-) emissions. (Author abstract modified)

Woltz, S. S., W. E. Waters, and D. C. Leonard
EFFECTS OF FLUORIDES ON METABOLISM AND VISIBLE
INJURY IN CUT- FLOWER CROPS AND CITRUS. Fluoride,
4(1):30-36, Jan. 1971. 11 refs. (Presented at the Conference of
the International Society of Fluoride Research, Annual, 3rd,
Vienna, Austria, March 22-25, 1970.)

Experiments were conducted to determine the susceptibility of horticultural crops grown in Florida to damage from fluorides. Atmospheric fluorides were considered, as well as fluorides derived from soil and water. Fluoride taken up by gladiolus roots caused foliar damage only when soil pH was low and F(-) containing superphosphate was applied in relatively excessive amounts. The damage to leaves occurred more to leaf interior than to margins and tips as in F(-) fumigation. Fluoride in leaves moved passively with the transpiration stream of water and accumulated at the terminus of translocation. Rose and gladiolus cut flowers were damaged by low F(-) concentrations in vase water, while chrysanthemums were less affected. De novo chlorophyll synthesis in Vigna sinensis seedling leaves was inhibited by F(-) absorbed by detached seedling tops. The yield of Valencia orange fruit was depressed by airborne F(-). Valencia leaves were reduced in size, had decreased photosynthetic rates, and had decreased chlorophyll content in response to increasing levels of airborne F(-). (Author abstract modified)

Rippel, A.
EFFECT OF FLUORIDE EMISSION ON ANIMAL
PRODUCTS. Fluoride, 4(2):89-92, April 1971. 8 refs. (Presented
at the International Society of Fluoride Research Conference,
Annual, 3rd, Vienna Austria, March 22-25, 1970.)

Fluoride assays were made over a 3-year period of milk and eggs produced by animals raised within 100 m of an aluminum smelter. Milk from eight cows, 4 to 9 yrs old, averaged 0.6 mg fluoride/l. Milk produced in the morning contained an average of 0.5 mg F, while evening milk contained 0.7 mg F/l. The highest fluoride, content, an average of 0.94 mg/1 for 18 months, was noted in the milk of a young heifer. The F(-) in the yoke of chicken eggs averaged 1.2 ppm. This value was only slightly higher than that of the controls (1.1 ppm). However, the fluoride content of egg shells in the exposed area was nine times higher than in the control eggs. The differences in the fluoride content of milk and eggs confirms the fact that poultry are relatively more resistant to fluoride emissions than cattle. (Author abstract modified)

Oelschlaeger, W.
FLUORIDE UPTAKE IN SOIL AND ITS DEPLETION.
Fluoride, 4(2):80-84, April 1971. 6 refs. (Presented at the International Society of Fluoride Research Conference, Annual, 3rd,
Vienna, Austria, March 2-25, 1970.)

The magnitude of fluoride uptake by soil from artificial fertilizers was determined. The values were compared with the

amount of F(-) removed through harvesting crops and through seepage water. Fertilization of cereals, potatoes, grass, fodder, beets, and sugar beets with superphosphates added from 8-20 kg F(-)/ha to soil. On the other hand, these plants, when harvested, contained only 5-80 g F(-)/ha or 0.1-0.4% of the added F(-). The F(-) accumulation in soil containing 200 ppm F(-) (a general average) after fertilization with superphosphate was 1.3-4.5% annually. Removal of F(-) from soil by seepage water was estimated at 30 widely separated agricultural and wooded areas. Fluoride loss through seepage water averaged 52-208 micrograms/l, depending on levels of clay and lime in the soils and on the marked relation between the F(-) content of the water and the runoff. From 0.5-6% of the yearly added increment was thus removed. In a nonpolluted area, therefore, considerable amounts of F(-) accumulate in soil from fertilizers. In some instances, they constitute up to 90% of the amounts which are added to the ground. (Author abstract modified)

Rao, D. N. and D. Pal

A VOLATILE FLUORIDE GENERATOR FOR FUMIGATING

PLANTS. Fluoride, 5(1): 18-21, Jan. 1972. 5 refs.

A simple apparatus for generating volatile fluoride in controlled amounts is described. A polyethylene reservoir is mounted over an atomizer and a feeder cup containing a solution of hydrofluoric or hydrofluorsilicic acid as a source of volatile fluoride. A syphon tube, fitted with a flow regulator, connects the reservoir to the feeder cup. The atomizer, consisting of a capillary tube, a compressed air nozzle, and a basal tube, converts the fluoride solution into a mist of fine droplets which pass into a heating tube and are converted to gas. Heavier droplets condense on the atomizer cover, and the resulting liquid is returned to the feeder cup. Due to the solution returning from the atomizer and the fresh solution coming from the reservoir, the level of liquid in the feeder cup remains more or less constant. This arrangement helps to maintain a constant concentration of the atomizing solution. The equipment is portable and can be used to fumigate plants at any location. It can be used to test plant damage from fluorides or absorption of fluoride under controlled conditions.

PLANT-DAMAGING HYDROGEN FLUORIDE CONCENTRA-

TIONS. (Pflanzenschaedigende Fluorwasserstoff-Konzentrationen). Text in German. Umschau (Berlin), 71(21):777, 1971. 2 refs.

Because of increased emissions of fluorine-containing gases from plants manufacturing aluminum, copper, superphosphate, glass, or cement, tests were conducted to determine the effect of various concentrations of atmospheric hydrogen fluoride on a variety of plants. Varying harmful effects were noted with concentrations of 0.85-4.2 micrograms/cu m in air, but no definite conclusions regarding allowable concentration limits were reached.

EFFECTS OF AIR POLLUTANTS ON AGRICULTURAL

PRODUCTS. (Zur Wirkungsweise von Luftverunreinigungen auf landwirtschaftliche Erzeugnisse). Text in German. Biol. Zentralbl., 90(5):611-619, Sept./Oct. 1971. 12 refs.

With the aid of simplified graphs, the specific effects of sulfur dioxide, fluorides, and indifferent and toxic (lead, zinc, and arsenic containing) dusts on agricultural plants in the German Democratic Republic are shown. Continuous and long-term exposure to low SO₂ concentrations impair the photosynthesis (carbon dioxide assimilation), which in turn affects the quantity and quality of plant products. Most characteristic is the reduction of crop yield. Moreover, the SO₂ intake raises the sulfate level in plants. Relatively high SO₂ concentrations cause the death of cells, photosynthesis does not take place any more in necrotic tissue. Exposure to fluorine-containing emissions and to dusts leads to an accumulation of these pollutants in the plants to an extent which might be harmful to animals. Exposure of plants to non-toxic dusts such as fly ash and soot causes considerable changes of the plant metabolism. Toxic dusts inactivate ferments and retard root growth.

McCune, D. C.

PROBLEMS INVOLVED IN DEVISING AIR QUALITY

CRITERIA FOR THE EFFECTS OF FLUORIDES ON

VEGETATION. (Am. Ind. Hyg. Assoc. J.), 32(10):697-701, Oct. 1971. 14 refs.

Air quality criteria function as guidelines to acceptable air quality which requires that they should be complete, accurate, and useful presentations of the evidence. The problems for presenting accurate data for air quality criteria for effects of fluoride on vegetation are discussed. The available information is insufficient in depth and scope to allow unequivocal statements about the effect of fluorides on plants. The variety of effects, receptors, and conditions necessitate a number of simplifying assumptions if data are to be collated. Also, unless some desired air quality objective and the conditions for achieving it are given, the body of information in the criteria may not be presented in its most effective or useful form. Illustrations for the problems include studies on the effects of hydrogen fluoride on alfalfa. (Author abstract modified)

MacIntire, Walter H.

AIR VERSUS SOIL AS CHANNELS FOR FLUORIC CON-

TAMINATION OF VEGETATION IN TWO TENNESSEE LO-

CALES. Interdepartmental Committee on Air Pollution, Washington, D. C., Air Pol I lit., Proc. U. S. Tech. Conf., Washington, D. C., 1950, p. 53 - 58. 2 refs. (May 3-5, Louis C. McCabe, ed.)

Long-term (20-year) field and experimental studies are reported of the processes through which forage vegetation may acquire an abnormal fluorine content; the work was initiated in response to complaints that fluorine emissions from nearby industry were causing damage to plants and livestock. Results indicate that soils possess distinctive capacities to fix additive fluorides against rain-water leaching and against migration of the fluorine ion into above-ground forage crops, and that such migration is repressed in soil systems that contain adequate supplies of calcium. Abnormal fluorine content in the vegetation of certain locales in Blount County (eastern Tenn.) is attributed to direct contamination from the hydrofluoric acid that is emitted to the atmosphere through the manufacture of aluminum. In the absence of fluorine dusts and without mechanical pollution from phosphatic soils, fluorine contamination of forage vegetation in Maury County (middle Tenn.) apparently comes directly from the fluorine effluents present in that atmosphere, rather than through uptake of fluorides from the soil. (Author summary modified)

Phillips, Paul H.

FLUOROSIS IN LIVESTOCK. Interdepartmental Committee on Air Pollution, Washington, D. C., Air Pollut., Proc. U. S. Tech. Conf., Washington, D. C., 1950, p. 123 - 126. 1 ref. (May 3-5, Louis C. McCabe, ed.)

Gaseous effluents from industrial activities may be important contributors to chronic fluorine poisoning in livestock. The three principal symptomatologic features are described in the order in which they occur: effects on the dental structures, the skeletal system, and the protoplasmic mass. Experimental feeding of raw rock phosphate fluoride to cattle resulted in an intake of 2 mg/day/kg body weight with safety; 4 mg was an unsafe level. Conversion of the results of these studies to the fluorine equivalent of the more soluble NaF would mean that 41-45 ppm NaF would not affect growth or milk and butter fat production; 75-87 ppm would affect milk production but not growth. A laboratory analysis of the fluorine level in the long bones of the legs provides an essential check in diagnosing fluorosis, since some of the symptoms are non-specific. The normal fluorine content in these bones is 200-1000 ppm, and no growth retardation or reduced yield of milk or butter fat occurs unless the average concentration exceeds 5000 ppm.

Davidsson, Ingolfur

INCREASED FLUORINE POLLUTION. (Vaxandi fluormen-gun). Text in Icelandic. Freyr, 67(7/8): 167-168, April 1971. General problems of air pollution are outlined with special regard to fluorine. Damage caused by fluorine was observed in coniferous forests near Ragnars Peturssonar during the second part of the vegetation period. Red to brown spots appeared on the needles in August. In November, whitening of the needle edges was observed, which was followed by necrosis. Fluorine concentrations up to 193 ppm were measured in this area. Coniferous forests were damaged by fluorine-bearing dusts in concentrations of 10-20 ppm in Norway.

38412

Hornvedt, Richard

EFFECTS OF AIR POLLUTION ON FORESTS. (Virkninger av luftforurensninger pa skog). Text in Norwegian. Norsk Skogbruk, 17(1):3-4, 1971.

Direct and indirect effects of air pollution and related investigations for a glass-fiber plant are described. Direct damage caused by gaseous and particulate pollutants has a local character. Damage to forests was observed around a glass-fiber processing plant emitting fluorine and sulfur dioxide in amounts of 3 kg and 20 kg/hr, respectively. Knowledge of meteorological data such as wind speed, stability, and stack height, and emission volume allow correct forecast of concentrations at different distances. The respective thresholds applied for HF and SO₂ were 1 microgram/cu m and 0.5 micrograms/cu m. With neutral stability, HF concentrations exceeding the above threshold could be anticipated at a distance of 5 km in wind direction. Synergetic effects of HF and SO₂, and a minimum exposure time of 10 days were considered. The proliferation of insects and the reduced resistance to drought

<xref image="2000WVLG.TIF|V3|2006:09:28:01:39:50.00|119084|0"> image: </xref>

and frost are some of the indirect effects of air pollution. Increasing soil acidification due to SO₂ is also a general phenomenon. A pH value of 4.7 was measured in 1967 against pH of 5.3 in 1957. The increase in acidity was calculated as 1.5 %/yr.

38417

Largent, Edward J.

THE EFFECTS OF AIR-BORNE FLUORIDES ON LIVESTOCK. Interdepartmental Committee on Air Pollution, Washington, D. C., Air Pollut., Proc. U. S. Tech. Conf., Washington, D. C., 1950, p. 64 - 72. 12 refs. (May 3-5, Louis C. McCabe, ed.)

Fluorides carried through the air and deposited on pastures and fields of forage pose a hazard of chronic fluorosis to livestock fed on these plants. Previous reports on the mechanism and symptoms of fluorosis occurring in livestock near factories are reviewed. An investigation is described in which cattle kept on a farm in the vicinity of a rock phosphate plant developed clinical fluorosis. The results of measurements of fluoride concentrations in the atmosphere over the farm, in samples of vegetation grown on the farm, and in the tissues of the exposed cattle are given. Fluoride levels in both air and vegetation decreased as the distance from the factory increased. Concentrations of fluoride in the bones of affected animals were abnormally high.

Massey, L. M.

SIMILARITIES BETWEEN DISEASE SYMPTOMS AND CHEMICALLY INDUCED INJURY TO PLANTS. Interdepartmental Committee on Air Pollution, Washington, D. C., Air Pollut., Proc. U. S. Tech. Conf., Washington, D. C., 1950, p. 48 - 52. 13 refs. (May 3-5, Louis C. McCabe, ed.)

Plant effects induced by sulfur dioxide and hydrogen fluoride are used to illustrate the difficulties in diagnosing cases of suspected injury from phytotoxic gases. Disease (i.e., injury) caused by such chemicals is a continuing process paralleling disease caused by living organisms, with chemical analysis of plant tissue used instead of microscopic examination and culture of the living organism to identify and confirm the diagnosis. Despite extensive knowledge of the characteristic symptoms produced by SO₂, field diagnosis is often complicated by the wide variety of markings caused by such factors as drought, frost, winter injury, insects, disease, and various physiologic disorders. Thus, some knowledge of the conditions of exposure, weather factors, and the reaction of susceptible indicator plants is necessary. Sulfur dioxide and hydrogen fluoride produce symptoms that are similar in certain respects and difficult to distinguish. Problems in using color values, tip burn, and foliage injury to conifers as diagnostic symptoms are discussed.

38568

Treshow, Michael

FLUORIDES AS AIR POLLUTANTS AFFECTING PLANTS.

Ann. Rev. Phytopathol., vol. 9:21-44, 1971. 91 refs.

The pathological effects of fluorides on plants are reviewed with respect to fluoride sources, symptomatology, environmental influences, host-parasite relations, injury control, and air quality standards. The major sources of fluoride emissions are producers of aluminum, ceramics, phosphate, and occasionally steel. Toxic concentrations of fluoride are largely air-borne and absorbed by the leaves. Fluorides occur naturally in soils, but soil contamination may occasionally also provide an index of corresponding air contamination. Toxicity is influenced primarily by fluoride concentration, duration of exposure, and sequence and frequency of exposure, but may be modified by climate, e.g., temperature and humidity, soil factors, synergistic effects of other pollutants, and biological fac-

tors. Visible symptoms of fluoride damage, e.g., chlorosis, necrosis, and tip burn, metabolic and cytogenetic effects, and effects on growth and production are considered. The effects of fluorides on host-parasite interaction are also discussed. Fluoride injury controls include the application of protective chemicals, the development of resistant species, and basic elimination of the pollutant. For the highest degree of control, air quality standards are best based on the atmospheric fluoride concentrations capable of injuring the most sensitive plant species.

Dybczynska, Krystyna

POLAND S FORESTS HIT BY AIR POLLUTION. (Luftfororenning hot mot polska skogar). Text in Swedish. Tek. Tidskr., 101(20):30-31, Dec. 1971.

Gaseous emissions amount to about three million tons yearly in Poland, with sulfur dioxide predominant. Precipitation adds 100 kg of sulfuric acid to one ha yearly. Dust is emitted in an amount of five million tons/yr. Forests near industrial areas are attacked by sulfur dioxide and nitrogen gases. One half of all trees are more or less seriously damaged in a total forest area of 300,000 ha which accounts for 3.5% of the total forest area. Thermal power plants consuming coals with 0.5-4% sulfur represent a major danger. Chemical plants, emitting primarily sulfur dioxide, pollute the air in a radius of 15 km; 500 ha of forest was destroyed, 700 ha damaged, and 4000 more ha affected by a chemical plant producing nitrogen-containing fertilizer, for example. The metallurgic industry is the source of 7% of the total SO₂ emission, and dust and metal fluorides emissions are not negligible. While there are no resources available, a law for the protection of the atmosphere was enacted in 1966. In the period from 1971 to 1975 an increase of investments for pollution control by 150% is planned.

Tomatsuri, Masaru

EFFECT OF HYDROGEN FLUORIDE ON PADDY RICE.

(Suito ni oyobosu fussoka suiso no eikyo). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 6(3):336-342, Dec. 1971. 2 refs.

The effect of low concentrations of hydrogen fluoride on paddy rice was investigated with respect to HF toxicity and threshold value. Paddy rice was exposed to 2-5 ppm HF gas for 10-40 days. The fluorine content of the leaf blade and fluorine concentration in the air were positively correlated but there was no visible injury to the plants. Even under conditions of 40-day exposure to 5 ppb of HF gas, there was no difference between the fluorine content of the hulled rice, the weight of 100 grains, and the weight of straw of the exposed rice plants and the control plants.

FLUORIDE INHIBITION OF THE HILL REACTION IN

BEAN CHLOROPLASTS. Atmos. Environ., 6(4):267-273, April 1972. 21 refs.

The Hill reaction (oxygen evolution) of bush bean chloroplasts was inhibited by potassium fluoride within a pH range of 4.8-

<xref image="2000WVLH.TIF|V3|2006:09:28:01:39:52.00|113555|0"> image: </xref>

5.7. No inhibition was detected at higher pH s, and no inhibition occurred at pH 5.6 if the potassium fluoride was injected into a chloroplast preparation with a solution of magnesium chloride or sulfate already added. However, if the magnesium chloride or sulfate was added to a preparation that already contained potassium fluoride, then there was no alleviation of the inhibition. Magnesium appeared to act by reducing fluoride concentrations in reaction mixtures. A decrease in fluoride inhibition at 5.6 occurred when the concentration of potassium chloride was increased. Sodium monofluoroacetate was not as effective as potassium fluoride in inhibiting the Hill reaction. (Author abstract)

Rippel, A.

FLUORIDE INTAKE FROM FOOD. Fluoride, 5(2):89-91, April 28, 1972. 3 rets. (Presented at the International Society for Fluoride Research, Annual Conference, 4th, the Hague, Netherlands, Oct. 24-27, 1971.)

In order to evaluate the safety of food grown near a Czechoslovakian aluminum smelter, grain and vegetables were assayed for their fluoride content at varying distances from the smelter during a 10 year period. The fluoride content of green parsley leaves was 11.57 ppm (control 0.66); the roots contained 0.08 ppm (control 0.03) and the outer surface of root contained 0.12 ppm (control 0.03). Relatively little fluoride was found in potatoes. At a distance of 80-130 m in the area of the prevailing winds, the fluoride content of the grain varied within 6.34-19.64 mg/kg. At a distance of 500 m, the fluoride levels of grain were reduced to about 35% and at 1 km to about 15% of these values. Grain cultivated in a circular area with a diameter of 2 kilometers from the source of emission should not be consumed locally but can be exported for use in uncontaminated areas, and fluoride should not be added to drinking water in the vicinity of a fluoride-emitting factory. (Author summary modified)

Bossavy, J.

THE ACTION OF GASEOUS FLUORINE COMPOUNDS ON FOREST SPECIES. (Action des fluorures gazeux sur les especes forestieres). Text in French. National Society for Clean Air, London (England), Item. Clean Air Congr. Proc., London, England, 1966, p. 193-196. (Oct. 4-7, Paper VI/13.)

Fluorine pollution-induced damage on woody species and measures to be taken to prevent such damage are reviewed. In leaf-bearing trees, fluorine migrates to the boundary portions of the leaf and produces tip or marginal necrosis as soon as the toxicity threshold is reached. Leaf necrosis is produced in certain species by 0.025 ppm fluorine concentrations in the air. Continuous accumulation of fluorine contents by coniferous species is illustrated by data accumulated during 1963-1965 in France. Thus, one year old needles had 277 mg fluorine/kg dry matter at 900 m altitude, 138 at 1300 m altitude, and 47 at 1520 m altitude; two year-old needles had 635, 200 and 85 mg fluorine/kg dry matter at the corresponding forest sampling points located six to ten km distance from the polluting source. Leaf-bearing trees show a tendency to accumulate fluorine within the same season to a higher extent than the coniferous species. Thus, beech tree leaves may accumulate up to 970 mg fluorine/kg, maple leaves may accumulate up to 675 mg/kg, and oak leaves may gather up to 421 mg fluorine/kg within one season. Despite such elevated concentrations, premature leaf fall seldom occurs. Apparently, the annual leaf fall prevents the accumulation processes occurring in the coniferous species. Long term effects of fluorine pollution lead to soil alterations which may hamper large forest areas. Accumulation of fluorine bearing dust particles on the ground surface and their further infiltration by rain and snow waters may produce chemical alterations of the superficial soil layer. These alterations include increased acidity which modi-

fies the bacterial flora and produces impairment of calcium and nitrogen mobilization within the vital soil layer. Soil treatment with appropriate salt or alkaline additives as well as continuous fertilizer treatment to increase plant resistance against air pollutants are considered among the essential measures to be taken to prevent these damaging effects. Experimental studies show only partial benefits, limited mainly to young populations, from the application of such procedures. Reference is made to new protective procedures adapted in the USA and Germany, which promise new perspectives for the future.

39190

Hoericht, W.

FOREST DEVASTATION FROM SMOKE. (Waldverwuestung durch Rauch). Text in German. Kranke Pflanze, vol. 15:90-92, 1938.

The chief sources of gases (sulfur dioxide, sulfuric acid, hydrochloric acid, and hydrofluoric acid) that poison forests are domestic heating, cellulose, and other industry plants. The damages caused to trees by these gases are very different, so no diagnosis can be established. Due to their exposure, lasting for many years, pine woods are more sensitive to sulfur dioxide and other poisonous gases contained in air than deciduous trees. The symptom of the damage is, in general, the reddening of the leaves and needles. Even if the air does not contain harmful gases, the dust and soot deposited on leaves and other organs reduce the respiration activity of the plants. Employing species more resistant to smokes cannot be regarded as a genuine solution to the pollution problem in forestry.

Haul, Hans van

ANALYSIS OF SEVERAL AIR POLLUTION COMPONENTS WITH KALE (BRASSICA OLERACEA ACEPHALA) AS INDICATOR PLANT. (Nachweis mehrerer Luftverunreinigungskomponenten mit Hilfe von Blaetterkohl (Brassica oleracea acephala als Indikatorpflanze)). Text in German. Staub, Reinhaltung Luft, 32(3):109-111, March 1972. 18 refs.

Kale (brassica oleracea acephalia) was used for identification of fluorine, chlorine, sulfur, and lead air pollutants. The plants were exposed to the atmosphere at various sites in the Ruhr valley. Plastic boxes with 60 l volume were used for growing the plants. The fluorine concentration was determined by the electrometric method developed by Reusmann and Westphalen, the chloride concentration by the familiar method of potentiometric titration, and the sulfur concentration by the microanalytic method by Stratmann. The lead concentration was determined by inverse-polarographically. For the determination of these components by the mentioned methods only 5 g dry substance are needed. The plants, five in a pot, were exposed over several successive years from the beginning of August to the middle of November. Control plants were exposed outside the Ruhr valley in an entirely emission-free area. The F-level in the plants was in all cases above (with one exception) that of the control plants. It ranged from 4.1 to 20.1 mg/100 g dry substance. In washed leaves, the F concentrations were lower by 15 to 30%. The chloride concentration in the plants from the polluted area was four times the concentration in the control plants, the lead concentration was ten times the concentration in the control plants. The highest sulfur dioxide was 1.83% versus 1.33% in the control plants. The

<xref image="2000WVLI.TIF|V3|2006:09:28:01:39:56.00|123658|0"> image: </xref>

results show that kale serves well as an indicator for the mentioned pollutants, as well as for a number of polycyclic hydrocarbons, including the carcinogenic benzo(a)pyrene.

Wei, Ling-ling and G. W. Miller

EFFECT OF HF ON THE FINE STRUCTURE OF
MESOPHYLL CELLS FROM GLYCINE MAX, MERR.

Fluoride, 5(2):67-73, April 28, 1972. 8 refs. (Presented at the International Society for Fluoride Research, Annual Conference, 4th, the Hague, Netherlands, Oct. 24-27, 1971.)

The effects of hydrogen fluoride on soybean leaves fumigated with 40-50 ppb HF were examined. In the cytoplasm the presence of small vacuoles was the first noticeable initial change. The fragmentation of the vacuolar membrane occurred either simultaneously or followed immediately. Lipid-droplet-like globules and numerous vesicles occurred subsequently in the cytoplasm and increased as the injury became more severe. There was a decrease in polysomes and a detachment of ribosomes from the rough endoplasmic reticulum. Free ribosome concentration also decreased as the injury became severe. Mitochondria! modifications involving dilation of outer and cristae membranes followed by reduction of both cristae number and matrix electron density and the disappearance of mitochondrial granules were observed in the chlorotic leaves. Electron dense inclusions accumulated in some mitochondria. The first noticeable change observed in the chloroplast was the presence of clusters of phytoferritin granules within the stroma after only 1 days of fumigation. Alterations in nuclear structures were observed in later stages of injury. Numerous small electron dense particles were found on various types of membranes in cells of severely chlorotic leaves. They were distributed on outer mitochondrial membranes, endoplasmic reticula, dictyosomes, tonoplasts, plasmalemma, nuclear envelopes, and disintegrating organelles and vesicles, but were never observed on membranes of chloroplasts and microbodies. SMOKE DAMAGES OF FOREST FROM THE BIOLOGIC

STANDPOINT. (Forstliche Rauchschaeden aus der Sicht des Biologen). Text in German. Mitt. Forst. Bundesvers., no. 73:7-48, 1966. 67 refs. (Presented at the Symposium on Smoke Damage to Forests in Austria, Vienna, Austria, Nov. 9-11, 1965.)

The biological aspects of smoke damage are reviewed with special regard to forests. Due to long exposures, smoke is more harmful to forests than to farm plants. Forest damage is termed as injuries and disfunctions causing economic losses. Invisible physiological damage due to protoplasm lesions is counteracted by the regenerative effect of certain enzyme systems. Insoluble solid emissions reduce both light and assimilation, while soluble particles may penetrate the plant or soil, causing changes in the vegetation. Damage caused by soot and photochemical smog is detailed. Sulfur dioxide and hydrofluoric acid are two basic gaseous pollutants damaging forests. The importance of the damage is primarily determined by concentration and duration of exposure, with emphasis on concentration. In high concentrations, the substances are dissolved in the mesophyll cell wall fluid, causing point-like necrosis. Low concentrations lead to necrosis on the ends and edges of leaves and needles. The basal and end parts of the needles show different osmotic pressures. Due to disturbances in the water supply, the necrosis starts from the top part of the tree. Intervals between intermittent exposures lessen the damage. Damage is also influenced by climatic factors. The assimilation is dependent on light intensity and duration. Transpiration and consequently sensitivity to SO₂ are dependent on relative humidity. A sharp increase in sensitivity can be ob-

served from 60 to 90% relative humidity. There is no direct connection between transpiration rate and assimilation performance. High transpiration coefficients are characteristic of dry climates. There is no relation between transpiration and sensitivity, while any factor affecting the cuticular openings influences the extent of the damage. Resistance to smoke cannot be improved in forests by means of fertilizers. Different resistances of various species and individual trees as well as problems of breeding smoke-resistant species are discussed.

Blakemore, F.

INDUSTRIAL FLUOROSIS OF ANIMALS IN ENGLAND.

Proc. Nutr. Soc., vol. 1:211-215, 1944. 6 refs.

Industrial fluorosis was studied in stock in pastures near certain brickworks in England. The sources of fluorine were determined from the examination of the flue gases, detection of fluorine in the atmosphere, and evidence of surface contamination of plants. The severity of the symptoms depended upon the degree to which the herbage was contaminated. The chief symptom of severely affected cattle was lameness. The main histological features were extensive atrophy of the bony tissue and the presence of excessive amounts of osteoid. The fluorine content of the bones ranged within 6000-16,000 ppm. The amount of fluorine in the urine was most valuable in assessing damages.

Wislicenus, H.

THE ASSESSMENT AND CONTROL OF SMOKE DAMAGE.

(Zur Beurtheilung und Abwehr von Rauchschaeden). Text in German. Z. Angew. Chem (Weinheim), 14(28):689-716, 1901. 16 refs.

The assessment of smoke damage in a given case involves the gathering of evidence that the damage has indeed been caused by smoke, the rendering of proof of such damage, evaluation of its extent, and the estimation of damage for purposes of indexing. A methodology of smoke damage assessment on crops must include examination of the spot, consideration of other contributory factors (frost, mismanagement), laboratory tests, differentiation between acute and chronic damage, determination of the contributory share of several pollution sources, and the calculation of the actual damage accrued. Normal and abnormally high concentrations of pollutants (carbon monoxide, sulfur dioxide and trioxide, hydrogen chloride and fluoride, chlorine, carbon disulfide, cyanide, ether, gasoline vapors, hydrogen sulfide, and ammonia) in emissions from acid manufacturing plants, glass works, lime kilns, fertilizer plants, brick kilns, ceramic works, paper mills, dye works, sugar mills, the manufacture of explosives, and from railroad locomotives are tabulated, and the physiological effects of the various pollutants on plant tissues, on chlorophyll formation, and on assimilation in crops, deciduous trees, and conifers, and sampling and the analytical detection of sulfur and of fluorine in the samples are reviewed. One way of controlling smoke damage is to desulfurize coal by coking and to recover the sulfur by washing coking gas in an alkaline bath. Another way is to achieve a greater dispersion of emissions in the atmosphere by modifications in furnace and smokestack construction.

CHRONIC FLUORINE POISONING FROM FOOD. (Intoxication chronique d'origine alimentaire par le fluor). Text in French. Compt. Rend. Soc. Biol. (Paris), 1925:139-141, 1925. 1 ret.

Studies on the toxic action of fluorine contaminated feed on domestic animals are reviewed. Chronic intoxication of cattle raised in fluorine-emitting industrial areas were mistaken for osteomalacia due to spontaneous fractures. The symptoms also persisted with balanced feed. Consequently, the symptoms were caused by fluorine instead of by deficiency of minerals. Fluorine contents above normal were revealed in the bones of cattle poisoned by fluorine. Fluorosis and fluorine cachexia occurring in fluorine-emitting industrial areas could be simulated by means of experimental doses. Minimum doses are required to cause toxic effects, and the time required for the development of cachexia is in proportion to the amount of the doses. Depending on the dose, times of a few weeks or months are required for lethal cachexia to occur. Fluorine concentrations of 1/1000 to 1/10,000 in hay are capable of producing death within a couple of weeks or months.

Sette, Nicola

NOTE ON FLUOROSIS. (Note sur la fluorose). Text in French.

Compt. Rend. Soc. Biol. (Paris), no. 98:1094-1096, 1928.

Symptoms of fluorosis, observed on bovine animals raised in a superphosphate manufacturing plant area, were simulated on guinea pigs. Also sulfuric and nitric acids were produced at this plant. The symptoms were most serious in cattle kept in a stable near the superphosphate store. The guinea pigs fed with the same feed as the cattle died in an interval of 20-50 days after the start of the treatment. The investigations revealed brittle bones, intense congestion in liver, kidney, and adrenal glands, as well as increased volume of the latter. The lesions were primarily characteristic of intense liver congestion. Single inflamed mononuclear cells with congestion and hemorrhagic suffusions were found. The symptoms observed were primarily caused by vapors of sulfuric and nitric acids rather than by fluorine. The bone lesions represented one of the symptoms of acid poisoning only and not the disease proper.

MISTLETOE, INDUSTRIAL FUMES AND THE MAURIENNE

FORESTS (SAVOIE). (Gui, fumées industrielles et forêts de

Maurienne (Savoie)). Text in French. Rev. Geog. Alp., no.

59:326-342, 1971. 23 refs.

Attention is drawn to the dramatic situation of the fluorine-damaged Maurienne forests. The first damage of these mistletoe forests, consisting of 90% coniferous trees, were observed in 1910 when nearby aluminum production started. The upper limit of the fluorine damage rose successively to altitudes of 1600 and 2200 m, while the attack of mistletoe was unimportant above 1000-1400 m. Now, a forest area of nearly 10,000 ha is affected. The damage caused to mistletoe aggravated by the severe damage due to hydrofluoric acid. The losses due to smoke damage show an increase of 58% in the period 1956-1968, compared to the period 1950-1955. At the same time, production by the nearby aluminum plants increased from 43,000 t/yr in 1954 to 92,000 t/yr. The total fluorine emission is 1820 t/yr. Gas cleaning should be introduced. Irrespective of such steps, however, experiments are being carried out with American smoke-resistant *Thuja plicata* in a 75 ha-area. Measures by the newly-established Department of Environmental Protection are anticipated.

EXPOSURE CHAMBER PROCEDURES IN THE DETECTION

OF PHYTOTOXIC POLLUTANT COMPONENTS. (Testkam-
merverfahren zum nachweis phytotoxischer immissionskom-
ponenten). Text in German. Environ. Pollut., 3(2):123-132,
April 1972. 12 refs.

Portable exposure chambers were developed to identify the presence of phytotoxicants in the air, particularly in areas with several pollutants, by plant reactions to filtered and unfiltered air. An experimental unit includes two chambers, each consisting of a plexiglass cap covering the plants to be exposed and a box below containing air filter, blower, and watering system. Ambient air is filtered before entering the control chamber or is passed directly into the experimental chamber. By comparing the plant reactions in both chambers, the effects of the pollutants are accurately identified; combinations of indicator plants with differing resistance levels and special filtering systems determine the individual pollutants. A filter material coated with silver and silver oxide is used to remove the most important phytotoxicants, i.e., sulfur dioxide, hydrogen fluoride, and hydrogen chloride. The exposure chambers can be used for fumigation experiments in the field and in climatic chambers and for the testing of pesticides.

Sertz, H.

ON THE EFFECTS OF HYDROFLUORIC ACID AND
FLUOSILICATE ON LIVING PLANTS. (Ueber die Wirkung
von Fluorwasserstoff und Fluorsilizium auf die lebende Pflanze).
Text in German. Tharandter Forstl. Jahrb., vol 72:1-13, 1921.
Smokebox tests were carried out on fir and spruce trees to in-
vestigate the effects of hydrofluoric acid and fluosilicate in
two different concentrations. Both types of trees showed signs
of acute poisoning from tests where smoke with a concentra-
tion of 1:10,000 of either compound was applied for 1 hr each
day. In another test, where the trees were treated with a con-
centration of 1:250,000 of either compound for three 1-hr
periods per day to indicate chronic effects, firs showed higher
resistance to fluor than did spruces. Hydrofluoric acid and
fluosilicate are extremely harmful to living plants even in very
low concentrations. Damage symptoms are similar to those ob-
served in sulfurous acid tests. The material damaged by smoke
was analyzed for fluor content.

39895

Slagsvold, Lars

FLUORINE POISONING. (Fluorforgiftning.) Text in Norwegi-
an. Nord. Veterinaarmed., vol. 36:2-16, 1934.
Investigations were carried out into possible connections
between disease symptoms occurring in domestic animals and
fluorine air pollutants from nearby aluminum plants. Dust sam-
ples from the aluminum works area contained 14.05% fluorine
and 25% fluorides (cryolite, magnesium fluoride, aluminum
fluoride). Feed experiments were performed on domestic
animals with small doses of cryolite and sodium fluoride (1 g
each daily). The animals showed signs of fluorosis (exostosis,
weight loss, anemia, paralysis, irritations or inflammations in
digestive organs, drop in red blood cells, lachrymation, bone
porosity or brittleness). Symptoms observed in the experimen-
tal animals were similar to those of animals who became sick
under natural conditions. Ashed bone samples of poisoned
<xref image="2000WVLK.TIF|V3|2006:09:28:01:40:02.00|118100|0"> image: </xref>

animals contained fluorine, with levels in teeth always lower than in bones. Bone was the most affected of all tissue. The effect of fluorine compounds rises with increasing solubility

Bursche, Eva-Maria

VEGETATION DAMAGE BY FLUORINE. (Vegetationsschaeden durch Fluor). Text in German. Schriftenreihe Ver. Wasser Boden Lufthyg. (Berlin), no. 10:39-83, 1955. 43 refs. Laboratory tests were carried out to elaborate methods for recognizing and diagnosing plant damage produced by fluorine smoke. Brown to black ends and discolored edges were observed on leaves from open-air and artificially smoke-exposed plants. The resistances of different plants were investigated. Microscopic observations revealed slightly creased epidermis and badly creased parenchyma. The cell content formed a homogeneous brown mass in badly damaged leaves. Coloration due to fluorine and natural processes were separated in tissue investigations. Plasmolytic experiments were carried out for diagnosing chronic, acute, and invisible damage with NaF and NaCl. In *Fontinalis antipyretica*, 0.03% NaF-solution constituted the threshold limit while NaCl was much less harmful. No influence of the toxic effects of NaF and NaCl on the rate of plasmolysis could be revealed. Cells damaged by NaF (separation of protoplasts from the cell walls and slight plasmolysis) were regenerated after the normal conditions were restored. Hydrofluoric acid was more harmful than sodium fluoride. *Elodea densa* was damaged by a 0.0008% hydrofluoric acid solution. A special spectrophotometric method that permits determination of a typical acid effect only is explained. Chlorophyll extracts from damaged leaves showed a band of 535 micromicron, of different intensities depending on the actual fluorine content. Experiments were carried out to detect fluorine in plants by means of the methemoglobin method. A minimum of 0.01% of NaF in pure NaF solution could be satisfactorily detected. The method for dissolving the leaf material for fluorine detection is not sensitive enough. The characteristic fluorine-methemoglobin-hemoglobin band could be obtained for leaf material artificially damaged by 40%-HF, and ashed.

FLUORIDE POSIONING DUE TO EXHAUST GASES AND DEPOSITS FROM A SUPERPHOSPHATE FACTORY.

(Fluor-vergiftiging door rookgassen en stof van een superphosphaatfabriek). Text in Dutch, ("hem. Weekblad, no. 38:585-593, 1941. 101 refs.

Fluoride poisoning of cows, caused by emissions from a superphosphate factory, was investigated. Fluoride levels in bones were determined by quantitative methods, and the fluoride contents of rain and sluice water were measured. A method of sample preparation is described, and measured values of bone ash from different cities are tabulated. Results indicate that the affected animals were exposed to soluble fluoride in sluice water and to large quantities of fluoride in gases and hay fodder. Fluoride poisoning in humans, experiments on damaging effects to plants and animals, and problems of quantitative determination are discussed, and a literature survey of fluoride toxicity in cows is included.

Schmitz-Dumont, W.

TESTS ON THE EFFECTS OF ATMOSPHERIC

HYDROFLUORIC ACID ON PLANTS. (Versuche ueber die Einwirkung von Fluorwasserstoff in der Atmosphaere auf Pflanzen). Text in German. Tharandter Forstl. Jahr., vol. 46:50-57., 1896.

Smokebox tests were carried out on 3-year-old trees to investigate the effects of hydrofluoric acid introduced in the

form of NaHF in two different concentrations. Smoke was applied once a day. At a concentration of 1:10,000, spruce showed a much lower resistance than oak, the most resistant, and Norway maple. Ashes from oak leaves treated with hydrofluoric acid gas outdoors contained 0.125% fluor while those from untreated leaves were free of fluor. Applications of smoke with hydrofluoric acid in a concentration of 1:300,000 revealed the harmfulness of this substance to plants, even in this low concentration, when the exposure is for a period. Oak and Norway maple again showed higher resistance than spruce case. Brown and red discoloration of the leaves and needles are the most conspicuous symptoms of fluorine damage.

Schneider, R. E. and D. C. MacLean
RELATIVE SUSCEPTIBILITY OF SEVEN GRAIN
SORGHUM HYBRIDS TO HYDROGEN FLUORIDE. Contrib.
Boyce Thompson Inst., vol. 24:241- 243, 1970. 4 refs.
The relative susceptibility to gaseous hydrogen fluoride of seven grain sorghum hybrids of commercial importance in Texas was investigated. Fumigation resulted in necrosis of the leaf tips and chlorotic mottle of subtending tissue. Necrosis was generally limited to the second and third youngest leaves. The severity of injury was variable: DeKalb C44C and RS 608 were most resistant to HF-induced necrosis and Northrup King 222A, Pioneer 846, RS 610, RS 625, and RS 671 were more susceptible. There was no relationship between foliar injury and F accumulation. (Author abstract modified)

Huffman, W. T.
EFFECTS ON LIVESTOCK OF AIR CONTAMINATION
CAUSED BY FLUORIDE FUMES. Interdepartmental Committee on Air Pollution, Washington, D. C., Air Pollut., Proc. U. S. Tech. Conf., Washington, D. C., 1950, p. 59-63. 16 refs. (May 3-5, Louis C. McCabe, ed.)
Chronic fluorine toxicosis in livestock can be caused by aerial contamination of forage with fluorine effluents from nearby industry, principally phosphate and aluminum processing plants, although cement plants and enameling works may also be involved. The extent of the area involved is governed by the volume of fluoride effluents, the form in which they occur, and meteorologic factors. Effects on livestock depend on the level of intake, duration of the feeding period, the class of animals involved, and feeding and management practices. The symptomatology is described; dental fluorosis and bone lesions are prominent. Normal and threshold levels of fluorine in bone tissue and normal and excess urinary levels are noted. Dairy cattle appear more susceptible to fluorosis than beef breeds, but neither meat nor milk from affected animals is likely to be injurious. Complicating factors unrelated to fluorosis should be considered, since most of the symptoms may be present in a variety of diseases. Disease control requires reduction of emissions to the point where nearby forage contains a safe level of fluoride.

Pollution, Washington, D. C., Air Pollut., Proc. U. S. Tech. Conf., Washington, D. C., 1950, p. 127-139. 30 refs. (May 3-5, Louis C. McCabe, ed.)

Studies of the effects of low concentrations (0.1-0.2 ppm) of sulfur dioxide on alfalfa under different conditions of temperature, water, and nutrient supply; sulfur content of nutrients; and age of plants showed that resistance to SO₂ at 40 F or below is greater than at higher temperatures. Drying the soil to a point that causes wilting also increases resistance to the gas. Plants tend to recover between treatments if enough time elapses. Plant susceptibility during treatment increases with light up to full sunlight. Young plants are more resistant than old plants, while middle-aged leaves are most susceptible. The susceptibility of various species and the characteristic symptomatology are described. The results of experimental fumigations of plants with 0.05 to several ppm hydrofluoric acid gas in air are detailed, and similar studies of the effects of chlorine, hydrogen sulfide, ammonia, mercury vapor, ethylene and carbon monoxide, and the vapors of 2,4-dichlorophenoxyacetic acid and other hormone-like herbicides are reported.

Grzywacz, Andrzej

THE INFLUENCE OF INDUSTRIAL AIR POLLUTION ON PATHOLOGICAL FUNGI OF FOREST TREES. (Wplyw przemyslowych zanieczyszczen powietrza na grzyby chorobotworcze drzew lesnych). Sylwan, 15(6):55-62, 1971. 28 refs. Translated from Polish. Scientific Translation Service, Inc., Santa Barbara, Calif., 13p.

The reaction of pathological fungi to the presence of air pollution is a function of the chemical nature of the pollutants, their concentration, the frequency of diurnal and seasonal changes in concentration, the duration of action, the composition of floras, the degree of damage by phytotoxins in the pollutants, the topography of the terrain, climatic conditions, the character of the forest site, and the sensitivity of the pathogens. The most important pollutants and their sources are reviewed, including sulfur dioxide, fluorine compounds, smog, and ozone formed from nitrogen oxides. The toxic action of SO₂ with respect to fungi depends on the temperature and relative humidity of the air, increasing with an increase in relative humidity. The occurrence of pathological fungi in forests with polluted air, the effect of air pollution on certain vital processes of fungi, and the mechanism of action of the air pollutants on the fungi are considered.

NEW TASK FOR THE RESEARCH INSTITUTE: ENVIRONMENTAL HYGIENE. (Neuer Aufgabenbereich der Forschungsanstalt: Umwelthygiene). Text in German. Chem. Rundschau (Solothurn), 25(16):450, April 1972.

A new department for environmental hygiene of the Swiss Research Institute for Agricultural Chemistry deals with health aspects of air pollutants on domestic animals with the effects of air pollutants on agricultural crops. The department tests the fodder, plants, fruits, as well as bones, and urine of animals from the vicinity of fluorine emitting industries as to the fluorine concentration. In all cases the method with the ion specific fluoride electrode was found most suitable for the analyses. Measurements of the lead concentration along street and highways by atomic absorption spectrophotometry revealed that plants and grass carried lead concentrations of up to 170 ppm 1-3 m from the street curb. They decrease slowly to a distance of about 50 m. In some cases lead residues were still measured as far off as 100 to 200 m. The various types of plants accumulate the lead in different ways. Rain and tap water wash out the metal to half of the original concentration. The sulfur dioxide concentration of the air is presently being determined by the Ultragas unit. Measurements of other pollutants such as ammonia, chlorine, the ox-

ides of nitrogen, dust, unburned hydrocarbons, oil, rubber, and asbestos shall be the target of future studies.

VEGETATION TESTS AND ANALYTICAL WORK IN THE
LABORATORIES. (Vegetationsversuche und analytische Arbeit
in den Laboratorien). Text in German. Chem. Rundschau
(Solothurn), 25(15):425-427, April 1972.

Since the important quantities of refuse from mass-stock farming and the various types of sludges are reused in Swiss agriculture, vegetation tests were carried out by the Swiss center for agricultural enemies in order to examine the compatibility of the matter used as manure. Vegetation tests were also done to investigate the influence of exhaust gases from motor cars, fluoride, and sulfur trioxide on plants. The Swiss research center used an air-conditioned vegetation hall where the tests were made during the whole year. The necessary sun light was simulated by fluorescent strip lamps of 20,000 Lux. Plants to be tested were put into special zinc pots filled with 5 l of mineral soil and were exposed.

POTENTIAL ATMOSPHERIC POLLUTION FROM THE IN-
VERGORDON INDUSTRIAL COMPLEX. Scot. Forest., vol.
24:270-273, Nov. 1971. 5 refs.

The main atmospheric pollutants from the Invergordon complex will be fluorine and hydrogen fluoride from the aluminum smelter and sulfur dioxide and hydrocarbons from the oil refinery. Both acute and chronic tree damage is expected. The effects of F and SO₂ on the trees via the soil is expected to be insignificant. Acute tree damage results from high concentrations of pollutants as a result of meteorological conditions or industrial cleansing failure. Chronic tree damage results from long term low level pollution. Broad leaved trees are not regarded as susceptible to chronic pollution. All the conifers are susceptible. Clean air sampling has begun in order to provide before and after comparison. Foliage samples will be taken for a radius of 16,000 M. A survey of lichens has been completed. Lichenology may assist in discrimination between F and SO₂ injuries.

479

posed to hydrofluoric acid gases develop fluorosis, but with very small concentrations, death may occur only after a year or more. Cows afflicted with this disease due to fodder harvested in fluorine-infested areas show initial symptoms of lameness of one or more legs, stamping by the animal, resting on one leg and then the other, inability to rise, and spontaneous sprains and bone fractures occurring in the stable. After several months, the animal gradually grows thin with a dry, hard hide and eventually dies. Experiments with corpses of animals who died of fluorosis have shown that their bones are more brittle than those of normal healthy animals.

EFFECTS OF ATMOSPHERIC FLUORIDE AND SULFUR
DIOXIDE ON SERICULTURE. (Fukka suiso oyobi nisanka io
no kuwa oyobi kaiko ni oyobosu eikyo). Text in Japanese. Taiki
Osen kenkyu (J. Japan. Soc. Air Pollution), 6(1):155, 1971.
(Presented at the National Council Meeting of Air Pollution Studies, 12th, Nagoya, Japan, Oct. 27-29, 1971.)
The effects of hydrogen fluoride and sulfur dioxide on mulberry and, subsequently, on silkworm administered with the mulberry leaves were studied. Potted plants of mulberry were placed in a gas contact chamber for 4-72 hours in a hydrogen fluoride atmosphere of 30 ppb or for 2-8 hours at 200 ppb, and in sulfur dioxide atmosphere of 2 ppm for 8-72 hours. The silkworms were administered with the leaves continuously for the three stages of growing. From about 1/4 hours in 0.03 ppm HF or 2 hours in 0.2 ppm, the external appearances of the leaves started to show discoloration, and approximately 120 to 160 ppm HF were accumulated on the leaves. Silkworms administered mulberry leaves containing 35 to 70 ppm HF showed chronic symptoms such as malacosis, and died with leaves containing more than 90 ppm HF. Two ppm of SO₂ for 72 hours caused spot browning of the leaves, and 0.8% of the SO₂ was accumulated. Silkworms administered with the leaves died from loss of appetite, malacosis.

Gruender, H. D.
PREVENTION OR REDUCTION OF FLUORIDE EFFECTS
IN CATTLE. Fluoride, 5(2):74-81, April 28, 1972. 6 refs.
(Presented at the International Society for Fluoride Research, Annual Conference, 4th, the Hague, Netherlands, Oct. 24-27, 1971.)
Fluoride uptake in plants, animals, and humans is determined by the sum total of fluoride in the soil, water, and air due to both natural and emission sources. To prevent or reduce the damaging effects of fluoride on cattle, in particular, the maximum emission concentration must be limited to 1 microgram/cu m of air to be further supplemented by a reduction in the daily fluoride uptake by animals from feed below the tolerance limit; a limitation of the period of emission; and inhibition of the rate of fluoride absorption into the animal tissue. Based on studies in two emission areas, methods concerning the production, maintenance, and feeding technique are suggested. A supplementary feeding regime with a low fluoride forage (below 20 ppm) will reduce the daily fluoride uptake per kilogram of dry food substance on an average by 8%. During a two year experiment on 24 milk cows in a polluted area near an aluminum factory, administration of a low fluoride food mixture containing 3% aluminum sulfate and chloride in equal parts reduced fluoride uptake and absorption per kilogram dry substance by about 15%. (Author summary modified)

EFFECT OF AIR POLLUTION ON PLANTS. (Oddzialywanie
zanieczyszczen powietrza na rosliny). Text in Polish. Wiad. Bot.,
14(2):91-102, 1970. 157 refs.
Some aspects of sensitivity of plants of phytotoxic agents (sul-

fur dioxide, fluorine and chlorine compounds, ozone, pollutants of an oxidative character) and of the changes in intensity of vital plant processes are discussed. Discussion is based on literature documentation. The role of ecological factors (atmospheric and soil humidity, sun-light conditions, temperature, and content of minerals in soil) in modification of susceptibility of plants to phytotoxic pollution of the atmosphere and in modification of effect of these pollutants on biological processes in plants is shown. The age of foliage also modifies in plant sensitivity to pollution with foliage on middle age being most sensitive. Some gaseous phytotoxic compounds accumulate in leaf cells (SO₂, fluorine and chlorine compounds). The changes in intensity of plant physiological processes, especially in photosynthesis, are a measurable and sensitive indicator of plant reaction of pollution. The disturbances in enzymatic processes, i.e., changes in activity of a number of enzymes caused by SO₂, ozone, fluorine compounds, and substances of photochemical origin, are discussed.

THE ACTION OF AIR POLLUTANTS ON PLANTS. (Wirkungen von Luftverunreinigungen auf Pflanzen). Text in German. In: Ullmanns Encyklopaedie der Technischen Chemie. Vol. 2/2, 3rd ed., Berlin, Urban and Schwarzenberg, 1968, p. 349-356. 9 refs.

Sulfur dioxide and hydrogen fluoride are the main industrial pollutants causing widespread damage to plants; nitrogen oxides, ammonia, hydrogen sulfide, chlorine or hydrochloric acid, bromine, and iodine produce effects limited to the industrial area. Hydrophyte mineral acid vapors such as sulfuric or nitric acid exhibit their action within the area close to the emission source. Depending on the concentration of pollutants and on the duration of their action, plant damage can be acute, chronic, or latent. Acute damage is produced by high air pollutant concentration following short-time exposure; leaf necrosis, general weakening of plant vitality, reduced growth, and sometimes plant death are its main effects. Chronic plant damage occurs in areas exposed to long-lasting low pollutant concentrations and includes chloroplast damage associated with inhibition of photosynthesis and overall impairment of metabolism. Latent damage is considered a precursor of chronic damage. Alterations of the structure, pH, and nutritional quality of soil from the cumulative action of pollutants cause indirect damage to plants. Diagnosis of plant damage from air pollutants can be made visually, by chemical analysis of air and plant samples, and by biological tests. Experimental evaluation of pollutant action on plants in special exposure chambers or in the free field should constitute one of the basic tools of research in this field. Included are descriptions of such experimental facilities are described and prevention of plant damage from pollutants by special soil treatments is discussed.

THE VALUE OF AIR AND NEEDLE ANALYSES FOR SMOKE DAMAGE DETERMINATION. (Der Werf von Luft- und Nadelanalysen fuer die Rauchsadensfeststellung). Text in
<xref image="2000WVLN.TIF|V3|2006:09:28:01:40:14.00|123123|0"> image: </xref>

German. Mitt. Forst. Bundesvers., no. 73:91-99, 1966. 9 refs. (Presented at the Symposium on Smoke Damage to Forests in Austria, Vienna, Austria, Nov. 9-11, 1965.)

For air analyses, quantitative and qualitative long-term methods, rapid methods, continuous and intermittent, and recording methods can be applied. Qualitative long-term analysis does not reveal the actual time the emission occurred and the frequency of toxic concentrations. The rapid and recording methods deliver data on the absolute concentration and the frequency of toxic concentrations. The latter methods should, however, be preceded by a general survey, applying long-term methods. Formulae for determining stack height only apply to plain areas with no forests. Threshold values cannot be regarded as fully reliable. The threshold of 0.5 mg/cu m for sulfur dioxide may be too high for certain plants. For sulfur dioxide, leaf analyses are not fully reliable due to the inherent SO₂ content and the lack of a direct relationship between emission intensity and leaf SO₂. Fluorine analyses yield, however, unambiguous results. The samplings should be completed within a relatively short period, and in the same vegetation periods for analyses extending over a number of years. Due to different sensitivities and influencing factors, the intensity of the damage cannot be determined from SO₂ and fluorine analyses. Consequently, representative forest age and comparable test areas are principal sampling criteria. While air and needle analyses unambiguously reveal the fact of emission, the actual damage can only be determined from growth measurements.

Daessler, H. G.

THE EFFECT OF HYDROGEN FLUORIDE AND CRYOLITE DUST UPON PLANTS AND ANIMALS NEAR A HYDROGEN

FLUORIDE FACTORY. Fluoride, 4(1):21-24, Jan. 1971. 3 refs.

(Presented at the International Society for Fluoride Research, Annual Conference, 3rd, Vienna, Austria, March 22-25, 1970.)

Some of the findings obtained from 11 test stations situated near a hydrofluoric acid factory are reviewed. Studies were conducted on forestry, agricultural, and horticultural plantings in the emission area. In the immediate vicinity of the factory, HF induced necrotic lesions on vegetation and fluoride accumulation in the foilage of fruit trees. The leaves of fruit trees showed necroses on the side of the plants facing the factory. The margins of leafy plants reached fluoride values of up to 80 mg in dry, hot weather. At a 6 km distance, necrotic areas were found on fruit without visible damage to the foilage, particularly in pears, sweet cherries, apples, plums, and tomatoes. Fruit development decreased when HF levels were high at blossoming time. Only the fruit of pears is sensitive; the leaves and fruit of plums are equally susceptible to damage. Resistant plants include sour cherries, winter rape, sugar beets, potatoes, cabbage, asters, and roses. Results of fumigation experiments showed that although most evergreens, walnut, and maple trees should not be considered for cultivation near fluoride pollution, field corn, common oak, and lilac can be planted. Forage near the factory contained 76-120 mg fluoride/100. This caused reduced milk production, yellow stains on teeth, motor disorders, and bone changes in dairy cows. Bee populations were also affected. A decrease in fluoride pollution was accomplished by the installation of control equipment.

Pfeffer, Anton

INSECT PESTS ON FIRS IN AIR POLLUTION AREAS. (Insektenschaedlinge an Tannen im Bereich der Gasexhalationen).

Z. Angew. Entomol., vol. 51:203-207, 1962/1963. 9 refs. Translated from German. Scientific Translation Service, Inc., Santa Barbara, Calif., 7p.

The effect of fluorine emitted into the air on insect pests in fir groves was investigated in center Czechoslovakia. Before the

first signs of injuries, an attack of dark beetles often appeared along with occasional snout beetles. Weak damage from the larvae of the fir leaf roller could also be observed. The fir bark lice appeared only in isolated instances. In the course of several years, the fir trees slowly sickened and died. Primary monophagous bark beetles of the genus *Pityokteines* Fuchs disappeared. Only small numbers of *Pissodes piceae* Ill. and the bark beetle species living in twigs (*Cryphalus piceae* Rtzh., *Cryphalus abietis* Rtzb., and *Pityophthorus pityographus* Rtzb.) were observed. In contrast, *Dreyfusia piceae* Rtzb., *Dreyfusia nuesslini* C.B., and the polyphagous wood wasp living in the wood (*Paururus juvenicus* I,.) increased in population. (Author summary modified)

Zieger, Erich

SMOKE-INDUCED DAMAGE TO FORESTS. (Rauchschaeden im Walde). Text in German. *Wiss. Z. Tech. Hochsch. Dresden*, 3(2):271-280, 1953-1954. 22 refs.

Problems of smoke-induced damages and appropriate control measures are reviewed. Fly ash and waste gases are the pollutants involved in forest damages. Fly ash depositing chiefly in zones of 100-600 m around high stacks turns the soil gradually sandy. Sulfur dioxide is the most dangerous of all waste gases, followed by sulfuric acid, hydrofluoric acid, nitric acid, fluorine compounds, ammonia, hydrogen sulfide, and tar vapors. Both the character and the measure of the damages are determined by such factors as distance from the emission source, dilution, and season. Regarding damages due to etching, different species show different degrees of resistance, conifers being highly sensitive. Damages due to disturbed assimilation are most important in humid weather and in old needles. The sensitivity increases with increased assimilation activity. The incrustation damages caused by dust build-up on leaves and needles are of a local character. The pollutants also affect the soil, turning it acid, and changing its physical and chemical properties. The control measures should be applied at the emission source proper. The fine fractions of the fly ash, amounting to 50-75%, are hard to retain, and high stacks cannot be regarded as an adequate solution. Various methods of dust separation are discussed. There are no adequate methods for sulfur dioxide control available. The breeding of smoke-resistant stands, the plantation of shelter woods, and liming are some of the steps to be taken by forestry.

Wentzel, K. F.

METHODS IN TREATING FOREST IMMISSION DAMAGES IN GERMANY. (Erfahrungen bei der Bearbeitung forstlicher Immissionsschaeden in Deutschland). Text in German. *Mitt. Forst. Bundesvers.*, no. 73:237-247, 1966. (Presented at Symposium on Smoke Damage to Forests in Austria, Vienna, Austria, Nov. 9-11, 1965.)

Problems and experiences regarding emission damages are outlined. Following World War II, increased growth was observed in coniferous forests damaged formerly by emissions. Domestic heating and traffic have no negative effects on forests, but changeovers to central heating stations may cause damages. In coniferous forests in highly industrialized areas, sulfur dioxide concentrations exceeded a threshold of 0.5 mg/cu m in 6% and

<xref image="2000WVLO.TIF|V3|2006:09:28:01:40:18.00|124441|0"> image: </xref>

less than 1% of the winter and summer seasons, respectively. Leaf and needle analyses are the best method to determine damages, as air analyses have indicative character only. Needle analyses deliver more reliable data than leaf analyses for SO₂ and HF. Two year old needles are best for analyses. Rates of growth should be measured in vertical rather than radial direction, as vertical growth is most affected by emissions. The test plant methods have no value for forestry, while test trees can be used to evaluate damages to arm plants. Emission damages should be prevented at their sources, i.e., in industry, by using effective pollution control techniques or less harmful raw materials. Increased stack heights can enlarge the emission-affected area, particularly in hilly regions. In industrialized areas with high emissions, forest maintenance costs rise, and an increasing number of forest properties are sold as a consequence.

Huber, H.

EFFECT OF AIR POLLUTION ON PLANTS. (Ueber die Einwirkung von Luftverunreinigungen auf die Pflanzen). Text in German. Mitt. Schweiz. Landwirtschaft., 19(1):7-18, Jan. 1971. 1 ref.

Effects of different air pollutants on plants are described, with special regard to sulfur dioxide and fluorine. Daily averages of 0.2 cu cm and 0.3 cu cm SO₂ are specified for summer and winter seasons, respectively. After attacking the chlorophylls, sulfur dioxide is metabolized into sulfates and other compounds in plants. Lasting exposures to low concentrations are less harmful than limited exposures to high concentrations. Different species and plant parts show different degrees of resistivity to SO₂. Young plants and coniferous trees are most sensitive. Blossoms are less sensitive than green parts. Fluorine concentrations of 0.005-0.018 ppm were measured in industrial areas in Switzerland. Though a threshold of 0.01 ppm/cu m is specified, necrosis can be observed at concentrations of 0.0001 mg/cu m in certain species. Concentrations of 0.003-0.004 mg/cu m result in reduced crops. The toxic effects of fluorine compounds are dependent of their respective solubilities. Fluorine attacks auxins, and inhibits both assimilation and respiration processes. Both high relative humidity and temperature, and nitrogen shortage enhance hazards. Old needles show decreased susceptibility. Different species show different rates of absorption for fluorine. Pale green or yellowish coloration and peripheral necrosis of leaves and needles are conspicuous symptoms of fluorine-induced damage. Other air pollutants exercise mostly local and transitory effects. Chlorine and hydrochloric acid lead to total necrosis, while hydrogen sulfide is harmful in high concentrations only. The effects of metals, metallic oxides, metalloid anhydrides, dust, and tar vapors are not negligible. Lead compounds in exhaust gases are very harmful, particularly for vegetables for human consumption. Ethylene is harmful in a concentration of 0.01 ppm. Among photochemical oxidants, ozone and peroxyacetyl nitrates as found in smog are highly phytotoxic. Spinach, tobacco, tomatoe, and cereals show increased sensitivity against ozone.

Maeno, M.

EFFECTS OF AIR POLLUTION ON TREES (IX) FLUORINE IN LEAVES OF STREET TREE. (Jumoku ni taisuru taiki osen no eikyo (Daikyuh) Cairo juyo no fusso kanryo). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 6(1): 154, 1971. (Presented at the National Council Meeting of Air Pollution Studies, 12th, Nagoya, Japan, Oct. 27-29, 1971.) The fluoride contents of street trees in various areas were studied. Fluorines were mainly discharged as hydrogen fluoride and silicon tetrafluoride. The tolerance threshold of plants to fluorides was as low as 1-10% of tolerance to sulfur dioxide.

Fluoride content in leaves of paulownia sampled in May 1967 was highest value at 1600 ppm and averaged at 409 ppm. The average concentration in leaves of the maidenhair tree was 193 ppm; that of the willow was 97 ppm. Average concentrations in leaves of trees in commercial and residential areas were as low as 10-30% of concentrations in industrial areas. Fluoride concentration slightly increased in the residential area from 1967 to 1970 but remained unchanged in commercial areas and decreased in industrial areas. High fluoride content was also measured in the soil of industrial areas.

ATMOSPHERIC POLLUTION AND BOTANICAL GROUP GROWING. (Taikiosen to Shokubutsu Gunraku). Text in Japanese. Kankochō Kogaisenmon Shiryo Public Nuisance Gaz.), no. 3:58-64, April 1972.

A botanical index for the evaluation of atmospheric pollution is examined. Plants can be affected by sulfur dioxide, fluorides, chlorine, nitrogen oxides, ozone, hydrogen sulfide, ethylene, dust, and peroxyacetyl nitrate. Type of damage in plants depends on the difference in pollutants. The Science and Technology Agency has investigated four kinds of deciduous trees and five kinds of evergreens. The period of the investigation was from last part of July to last part of August, and for the investigation of defoliation, after the first part of October. Surveyed areas were six spots 2, 4, and 6 km to the west, 12 km to the west-northwest, and 12 and 25 km to the northwest of the seaboard industrial belt area. The relationship between distance from the industrial belt area and degree of damage is given. The relationship between concentration of sulfur oxides in the air according to the lead dioxide method and sulfur content in ginkgo leaves is a close correlative relationship. Use of the botanical index for evaluation of atmospheric pollution has a bright future, and in order to get the widely spread information, it is necessary to patternize and computerize the subjects of investigation. The specific gravity of each of the investigation items should be compared with the comprehensive plant vitality.

NOTES ON THE DUST DAMAGE OF TREE. (Jumoku to jinai ni kansuru shiken). Text in Japanese. Fukuoka-ken Ringyo Shikenjo Jiho, (Bull. Fukuoka-Ken Forest Expt. Station), no. 22:31-35, March 1972. 1 ref.

Sulfur dioxide, chlorine, and fluorine affect trees. Eleven kinds of young trees were planted in April 1969. The fly ash and cement dust were spread three times/month through 17 months on the trees of the test groups which were compared with the trees of control groups. There was no visible negative effect of the ash and the dust on the development of trees. The developmental index for each kind of the tree was measured and is shown on a graph. The pH of the soil of each group was measured and is shown on a table.

4(1): 148, 1969. (Presented at the Japan. Society of Air Pollution, Annual Meeting, 10th, Tokyo, Japan, 1969, Paper 146.)

A glass factory in East Osaka has a history of damaging agricultural produce in the area. A sodium hydroxide absorbent analysis of flue gas from the factory was conducted and a filter paper cylinder measurement of the concentration distribution was taken. Settling particulates were measured by a simple soot collection jar. Samplings of agricultural produce were burned to ashes and a perchloride analysis was given. The fluorine emission at the time of melting of raw material was 9.2 to 229.6 F mg/N cu m Hydrogen fluoride concentration near the furnace was 0.71 to 2.25 ppm. The maximum fluoride content in settling particulates near the boundaries of the factory premise was 1.54 F mg/sq m/day. This last figure was no higher than the average concentration of nonpolluted areas. The F concentration in the lee of the factory was higher than other directions, and this corresponded with the fact that the farms with produce damages were southwest of the factory, and that the wind was mainly northeasterly in this area. Heavily damaged leaves of rice and soybeans in these farms had several hundred times higher fluoride content than those in undamaged leaves.

Nielsen, S. W.

ENVIRONMENTAL POLLUTANTS PATHOGENIC TO ANIMALS. J. Am. Vet. Med. Assoc., 159(9):1103-1107, Nov. 1, 1971.

Veterinary diagnostic laboratories have detected a number of disease problems caused by environmental pollution. The pollutants and the resulting disease conditions are in many forms. Air pollution due to industrial and automotive exhaust fumes causes damage to the lungs of man and lower animals that closely share his environment, namely, the dog and the cat. Lung lesions caused by prolonged fume or dust inhalation range from anthracosis, emphysema, and fibrosis to lung cancer. Dogs and cats in London have a much higher incidence of oro-pharyngeal cancers than in any other area in the world. Radioactive fallout from the testing of nuclear devices has caused chronic radiation dermatitis and precancerous lesions in cattle, mules, and other animals grazing near test sites. Fluorosis has been observed in cattle and deer on pastures surrounding factories processing clay or other raw products with high fluoride content. Other environmental pollutants which are toxic to animals include nerve gas, chlorinated hydrocarbons, polychlorinated biphenyls, lead, and mercury. Tasks for the veterinary pathologist with regard to the identification and examination of environmental compounds causing pathogenesis are outlined.

Yu, Ming-Ho, Gene W. Miller, and C. James Lovelace

GAS CHROMATOGRAPHIC ANALYSIS OF FLUOROORGANIC ACIDS IN PLANTS AND ANIMAL TISSUE. International Union of Air Pollution Prevention Associations, Proc. Int. Clean Air Congr., 2nd, Washington, D. C., 1970, p. 156-158. 15 refs. (Dec. 6-11, Paper MB 4E.)

Studies to develop gas chromatographic techniques for the determination of organic, specifically fluoroorganic, acids in tissue, and to determine organic acid changes induced by fluoride injury are reported. A gas chromatograph was used with a flame ionization detector. Analyses were carried out on dual columns using helium carrier gas. Tissues were obtained from soybean plants fumigated with approximately 60 ppb of atmospheric hydrogen fluoride for 4 days. Leaves from soybean plants grown in a chamber fumigated with ambient air were used as controls. Kidneys and hearts from cows and horses suffering severe fluorosis were used in further studies. Results indicate that several organic acids and other volatile compounds in the fluoride treated tissue changed in concentrations compared to control tissue. Cis-aconitate, citrate, and ox-

alate were not determined. Malate, malonate, and succinate increased markedly in concentration when plants were exposed to hydrogen fluoride.

42923

EFFECT OF AIR POLLUTION ON VEGETATION. In: Air Pollution Manual. Part I. Evaluation. Detroit, American Industrial Hygiene Assoc., 1960, Chapt. 5, p. 49-61. 18 refs. Local meteorology, industrial operations, type of fuel in general use, incinerator practice, motor fuel consumption, and other factors all contribute to the individual character and extent of the pollution produced and the resulting damage to vegetation. Gas exchange by the plant takes place largely by diffusion through the many breathing pores or stomata, thereby permitting the entry of gaseous phytotoxicants into the leaf. Light, temperature, humidity, soil moisture, fertility conditions, and stage of growth all play a part in controlling gas absorption by the plant. Plant injury due to sulfur dioxide, fluorides, oxidants, chlorine, hydrogen sulfide, ammonia, mercury vapor, and ethylene are considered. The use of plants in measuring and evaluating air contaminants is discussed, as well as the inspection of plants in making a field survey.

42924

EFFECT OF AIR POLLUTION ON FARM ANIMALS. In: Air Pollution Manual. Part I. Evaluation. Detroit, American Industrial Hygiene Assoc., 1960, Chapt. 6, p. 63-71. 97 refs. The susceptibility of animal species to air pollutants will vary according to the specific contaminant in question. In addition to different species susceptibilities, individual animal variations also exist within each species. The lesions produced by air pollutants depend on the toxic property of the pollutants, the dosage rate, the duration of the exposure, and the susceptibility of the animal. Criteria are listed for the diagnosis of injury by air pollutants. It is important in investigating the effects of air pollutants on farm animals to ascertain whether any abnormal condition found is the result of the pollutants in question or some other stress Nutritional disorders, metabolic diseases, mineral deficiencies, and accidental poisoning are considered. Adequate information is needed on the dosage range of the contaminants to which the animals are subjected, and a careful meteorological study of the area should be included. Tissue samples may provide an important source of data when animal injury has resulted from specific known pollutants. The effects of arsenic, fluorides, lead, molybdenum, and sulfur dioxide on farm animals are discussed, including threshold limit values and toxic tolerances.

DETERMINATION OF F IN VEGETATION WITH F SELECTIVE ION ELECTRODE. Preprint, American Inst. of Mining, Metallurgical and Petroleum Engineers (ATME), New York, N. Y., p. 489-495, 1971. 1 ref. (Presented at the American Institute of Mining, Metallurgical and Petroleum Engineers, Annual Meeting, 100th, New York, Feb. 26- March 4, 1971.)
<xref image="2000WVLQ.TIF|V3|2006:09:28:01:40:24.00|116897|0"> image: </xref>

Preliminary work of the Boyce Thompson Institute was evaluated and some modifications were made. In the modified method, the fluorine is leached out of the ground vegetation using perchloric acid. The sample is then filtered and the filtrate is made up to 100 ml with a buffer containing sodium carbonate, sodium chloride, and sodium citrate. The sample solution should now have a pH of approximately 5.5 and is ready to be read after calibration of the meter with suitable standards. The results of electrode analysis (potentiometry) of 140 vegetation samples with values ranging from 3 to 500 ppm compared to automated analysis shows a correlation of 0.993 and the regression equation indicated a slope of 1 and an intercept of 1.7 ppm. The procedure as modified uses more HClO₄ than does the Boyce Thompson method. Also, the application of a wetting agent to both the acid and buffer solutions gives better solution contact with the finely ground sample, yielding a more efficient extraction of fluoride.

AIR POLLUTION - FOREST SITE FACTOR OR EVIL
WHICH CAN BE KEPT OFF? - RECOMMENDATIONS FOR
THE DETECTION AND CONTROL OF FUME DAMAGE EV

A FOREST-RANGE. Forstarchiv, 42(8/9):172-179, 1971. Translated from German. 29p.

Ways in which the forest ranger can assess the effects of fumes on the forest trees are suggested. In judging these effects three cases must be distinguished: single sources, congested areas, and long-range effects. The plant damage that may result from each of these cases is described in detail. Three field methods to clarify suspicion of fume damage in a forest range are described. The first of these involves testing the needles of pine branches for the degree of needle foliage, degree of pollution, needle color, and distribution of damage to the needles. Evaluation of the lichen vegetation on tree bark can also provide information about fume damage. Lichens are killed off by very small concentrations of sulfur dioxide, hydrogen fluoride, and hydrochloric acid. The third field method involves determining the pH value of precipitation. The following values are given to aid in evaluating the pH readings: 2.0-3.0 - suspicion of strong effects from acid fumes; 3.1-4.0 - suspicion of slight effects from acid fumes; 4.1-6.0 - no indication for acid or alkaline fumes; 6.1-7.0 - suspicion of slight effects from alkaline fumes; and 7.0 - suspicion of strong effects from alkaline fumes. It is noted, however, that the most reliable proof of fume damage is a matter of scientific investigation by trained experts.

Daines, Robert H., Ida Leone, and Eileen Brennan

THE EFFECT OF FLUORINE ON PLANTS AS DETERMINED BY SOIL NUTRITION AND FUMIGATION STUDIES.

Interdepartmental Committee on Air Pollution, Washington, D. C., Air Pollut., Proc. U. S. Tech. Conf., Washington, D. C., 1950, p. 97-105. 4 refs. (May 3-5, Louis C. McCabe, ed.)

Results of experimental studies of fluorine toxicity and mechanisms of action in various plant species are reported, indicating that plants absorb F from both the atmosphere and soil, thereby accumulating the abnormally high F content that causes development of typical toxic symptoms. A means of distinguishing between F from the air or from the substrate was determined, since atmospheric F results in a high leaf and low root F content, whereas soil F causes a high leaf and even higher root content. Plant species vary in their threshold concentrations that cause visible injury, in capacity for uptake of F, and in the relation between F content and the extent of injury. Plants grown with optimum supplies of nitrogen, calcium, and phosphorus are more susceptible to F injury from the soil and, to a less extent, from the atmosphere than plants with unbalanced nutrition. As the soil pH increases, F toxicity and the

amount of F absorbed are minimized High atmospheric humidity, turbidity of the plant, and wetting of the plant surfaces are conducive to a greater degree of injury and F absorption. A loss of F in plant leaves following an exposure to F in solution or in the atmosphere is being studied. (Author conclusions modified)

AIR POLLUTION RESEARCH NEEDS WITH ANIMALS.

Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 31p., 1972. 107 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 65th, Miami Beach, Fla., June 18-22, 1972, Paper 72-153.)

Based on published reports, air pollution problems relating to livestock are identified. These are discussed under two categories: pollutants from industrial-urban sources affecting livestock, and pollutants originating from animal production units. The available knowledge concerning these problems is briefly described. Air pollution from industrial sources affecting farm livestock is usually the result of accumulation of the pollutant on forage in a localized area surrounding the source, and the animals affected are primarily herbivores. Specific pollutants discussed in this regard are fluorine, lead, molybdenum, cadmium, and arsenic. In the second category, available information on specific pollutants identified as arising from various livestock production systems is presented. In any animal production system, volatile compounds from decomposing manure may be released into the atmosphere. In some cases, these gases may have adverse effects on the animals in the housing unit, or they may possess such odors as to be considered a public nuisance. Gases present in poultry, swine, and cattle housing units are identified. Of all problems identified, extensive information is available only for fluorosis, and in all cases the knowledge to assess the situation completely is lacking. (Author abstract modified)

Garber, K.

STUDIES AND EVALUATION OF SMOKE DAMAGES. (Un-

tersuchung und Begutachtung von Rauchschaeden). Jahresber. Staatinst. Angew. Bof., Hamburg, vol. 76/78:119-127, 1961. 13 refs. Translated from German. 12p.

A summary is presented of 666 studies and evaluations conducted in the field of smoke damage to vegetables, ornamental plants, fruit and other trees, and bushes. A large number of plants are categorized based on their individual sensitivity to hydrofluoric acid and sulfur dioxide gases. Depending on their chemical composition, dusts can have damaging effects on both plants and soil fertility. The calcium oxide content in soil in the vicinity of a cement plant was studied. Plant damage is traced to chlorine-containing fumes in conjunction with ammonia from a zinc extrusion plant and to sulfur-containing exhaust gases from warm slag used to repair sidewalks. High amounts of molybdenum in plants can be toxic to ruminants.

<xref image="2000WVLR.TIF|V3|2006:09:28:01:40:26.00|121750|0"> image: </xref>

Forschung). Landwirtsch Forsch., no. 20:116-118, 1966. 6 refs. Translated from German. 5p.

The increased fluorine content in plants in regions of fluorine emission was investigated to ascertain whether this increase might also be due to absorption from the soil. The fluorine content in different plant types in different soils, the effect of single or split application of fluorine on the growth and F content of plants and the extent of increased F content in the soil on plants was researched. The findings proved that the F content in plants does not run parallel to the natural F content of the soil. Fine, sandy, marshy and clay soils were tested. Bush beans were the experimental plants. Jamrich, V.

IS CHLOROPHYLL STABILITY A FACTOR IN THE

POWER OF RESISTANCE AGAINST FUMES? (Je stability

chlorofylu faktorom odolnosti proti dymu?). Zbornik Vedeckych Prac Lesnickej Fakultv Vysokej Skoly Lexhickej a Drevarskij Vo Zvolene, vol 1:7-14, Oct. 1968. 14 refs. Translated from Czech. 14p.

The relationship between the intensity of the effects of gaseous fluorine compounds, in the form of industrial emissions, and the degree of chlorophyll destruction in two species of trees was studied. *Alnus glutinosa* was selected to represent the resistant species, and *Quercus patraea* to represent the species of low resistance. Each species was exposed to a definite amount of fluorine, and the degree of depigmentation was expressed in terms of the differences in the total chlorophyll and the differences found in the components, chlorophyll a and chlorophyll b. The degree of chlorophyll destruction is directly proportional to the intensity of exposure to fluorine; the degree of depigmentation is also dependent on the strength of the chlorophyll bonds in the plastid structures. Depigmentation is continuous with changes in the ratio of chlorophyll components, and chlorophyll b is relatively more stable than chlorophyll a. (Author summary modified)

Oelschlager, W.

DETERMINATION OF FLUORIDE STANDARDS FOR

VEGETATION AND ANIMALS. Fluoride, 5(3):111-114, July

1972. 1 ref.

In determining fluoride emission standards with respect to possible damage to vegetation, better results are obtained if gaseous fluoride is considered exclusively. However, in evaluating damage to animals, fluoride uptake in gaseous or through respiration is negligible compared with uptake through forage, soil, and fly ash. Soil and fluoride, emitted with fly ash near factories, is attached to raw forage such as grass, clover, and alfalfa. Since the amount of fluoride in soil is approximately 20 to 150 times as high as the fluoride content of forage and that of fly ash is more than 1000 times as high, the question arises as to whether or not the solid particles should be considered when measuring emissions. When nearly identical supplements of fluoride, namely 72 ppm, in the form of soil, sodium fluoride, and fly ash from an aluminum factory smelter, were administered to cattle, the fluoride uptake from

soil was 0.7 times, from fly ash 1.4 times, and from sodium fluoride 3.0 times as high in the experimental animals as in those which received the fluoride supplement. The utilization of fluoride derived from soil in ruminant animals is highly variable depending on the origin of the soil. The fluoride from soil and fly ash is more or less available, although at lower magnitudes, than fluoride contained in forage. However, if for establishing emission standards, particulate fluoride in addition to gaseous fluoride is being considered, values can be obtained which are not in accord with the possible damage to animals. Thus, damage to health may be more extensive with a relatively low gaseous emission than with a high level depending on the proportion of fluoride in the gaseous and particulate form. As a maximum value for fluoride content of forage, 40 ppm/dry is being considered for high productive cattle. This value, however, is not only reached, but occasionally substantially exceeded, in non-polluted areas, because of the permissible fluoride levels in phosphate-containing feed.

EFFECT OF FLUORIDE AIR POLLUTION ON FLORIDA

CITRUS. Fluoride, a(3):145-163, July 1972. 15 refs.

The effect of different concentrations of fluorides in the leaves on the yield and quality of Valencia and Hamlin oranges and Marsh seedless grapefruit was studied. Under Florida conditions, exposure of citrus trees to relatively high levels of airborne fluorides during spring bloom period is believed to cause the greatest losses in fruit production. This is indicated by the significant reduction in yield of Hamlin oranges by each of three different concentrations of hydrogen fluoride sprays applied only three different times during the 1967 bloom period. Where the concentration of airborne fluorides is high enough during the bloom period to cause extensive leaf chlorosis, leaf burn, dropping of young leaves, and excessive dropping of bloom and small fruit, the mechanism causing yield reduction is obvious. Heavy drop of young leaves, bloom, and small fruit as a result of exposure to high levels of airborne fluorides, however, has occurred in relatively few Florida citrus groves. These symptoms of acute or severe fluoride toxicity did not occur on the trees in greenhouse experiments. In spray experiments, leaf burn and dropping of young leaves occurred only moderately when the highest concentration of HF sprays was applied while the trees has an extensive new flush of immature leaves. No dropping of young leaves nor excess dropping of bloom and small fruit occurred during the bloom period in the first three years of the spray experiments. Decrease in photosynthetic activity due to smaller leaf size and inhibition of chlorophyll synthesis probably accounts for much of the decrease in yield. The addition of urea to high manganese sprays for greening of fluoride-chlorotic leaves appears to increase the absorption of Mn by the leaves over similar high Mn sprays with urea.

ATMOSPHERIC POLLUTANTS: THEIR EFFECTS ON

VEGETATION. (Les polluants atmospheriques. Leurs effets sur

<xref image="2000WVLS.TIF|V3|2006:09:28:01:40:30.00|119599|0"> image: </xref>

la vegetation). Text in French. Rev. For. Fra., 22(5):533-543, 1970.

After a 10-year period of observations in France on the effects of industrial wastes on vegetation, an in-depth examination was conducted on symptoms of fluorine and sulfur dioxide pollution, on certain measurement methods, on types of studies conducted over a 3-year period in the Alps, and on the principal features of the territory where damage information was gathered. Measurements were made using lime-impregnated paper to determine concentration of fluorine deposits on vegetation. It was established that fluorine not metabolized by vegetation penetrates the cells of the parenchyma of leaves and is transferred and retained in the extremities of edges of the limb. Depending upon the vegetation, fluorine damage (burns) is evident on leaves in the form of various tints such as light brown, black, or brick red. Caution is recommended in order that late frost damage not be confused with pollution damage. Ozone damage is characterized by small brown spots on the upper surfaces of leaves; photochemical smog produces silver-white spots on the bottom of leaves. Peroxide acetyl nitrate produces a vitreous or metallic silver-white tint on the bottom of leaves. Little is known about the effects of nitrogen oxides. Research findings are described and discussed according to specific effects of pollutants on specific types of vegetation by regional measurements. (Author abstract modified)

Gisiger, L.

ON THE FLUORINE CONTENT OF SOILS AND ITS ABSORPTION BY PLANTS AND ANIMALS. (Ueber den Gehalt der Boden an Fluor und dessen Aufnehmbarkeit durch Pflanze und Tier). Text in German. Schwiez. Landwirt. Monatsh., 44(6):221-230, June 1966. 3 refs.

Soil samples in Fricktal in the Canton of Aargau, Switzerland, were studied to determine if a fluorine increase on the soil surface was traceable to the emissions of an aluminum plant. Guided by the literature and a similar study made in 1962 to investigate the influence of the clay content of soil on its F content, the soil was examined in accordance with the dominant wind direction from the aluminum plant. Soil was studied at depths of 0. to 2.5 cm and 2.5 to 10 cm. Examination of F content in representative vegetation evidenced no recognizable dependence from 26 to over 100 mg% of the soil samples studied. Among the many results of the research discussed and presented in tabular format are the findings involving feeding hay to sheep and determining F retention and absorption by analyzing their urine and excrement. Fluorine toxicity of the soil yielded a sodium fluoride equivalence of approximately two-thirds. The specific phases of the research discussed are: solubility of F in soil, absorption of F by plants in soils of differing F content, and F resorption through pollution as measured in ruminants. Largent, Edward J.

FLUORIDE DAMAGE TO PLANTS. In: Fluorosis. The Health Aspects of Fluorine Compounds. Columbus, Ohio State Univ. Press, 1961, Chapt. 10, p. 94-100.

The reactions of various plant species have not been found to be consistent with respect to the effects of fluorides, sulfur dioxide, and some other materials that injure plant tissues. Distinguishing between damage caused by SO₂ and that caused by fluorides can be difficult and complicated. The effects of hydrofluoric acid on certain broad, flat leaves include injury to and death of marginal areas or of the tips of the leaves, and some spotting and killing of scattered areas of interveinous tissue. Another type of flat leaf exposed to HF in air showed injury at the tips, streaking, spotting, and mottling. Tips of the needles of pine trees first turn yellow and then

brown as a result of exposure to HF. Certain plant species appear to be sensitive to very low concentrations (below 5 ppb) of HF in air while others appear to be quite insensitive to HF, with only slight injuries being noted at concentrations of greater than 10 ppb. In general, the accumulation of fluoride is smallest in the fruit and greatest in the leaves; stems and twigs occupy an intermediate position. When fluoride enters a plant through its roots, it injures the leaves in much the same manner as does air-borne HF. Deposition of particulate fluorides on leaf surfaces is usually not injurious to the leaves or other parts of the plant.

Garber, K.

EFFECTS OF AIR POLLUTANTS ON PLANTS. (Auswirkungen von Luftverunreinigungen auf Pflanzen). Text in German. Mitt Deut. Landwirtschaft. Ges. (Frankfurt), 84(20):673-674, 1969. Effects of different air pollutants on plants are described. The influence on plants of air pollutants can be determined through analyses of the air, precipitation, plant parts, and soil samples. Trees are hit harder by emissions than agricultural plants, and the resistance against pollutants can be increased by lime and nitrogen doses. Gaseous pollutants usually penetrate plants through the stomata of leaves. Sulfur dioxide, mainly causing intercostal necrosis of leaves, is more dangerous during the daytime and in humid weather than at night and in dry weather. A small proportion of SO₂ incorporated is converted into sulfates, and elevated sulfur levels in leaves due to the effect of emissions can be detected. Lettuce, spinach, and bean were found to be particularly sensitive to SO₂. The acidification of soils is another consequence of SO₂ emissions. Fluorine, in the form of hydrofluoric acid, deposits in the points and edges of leaves, and also soluble fluorine salts can be absorbed by leaves. The background concentrations range from 0.5 to 1.8 mg/100 g of dry substance. Hydrochloric acid, having a shorter action radius than SO₂, causes necrotic edges on leaves, and can be detected in the form of chlorides. Nitrogen oxides cause largely the same symptoms as SO₂. Plant damages due to ammonia near fertilizer, urea manufacturing plants, and largely poultry farms were observed. Tar vapors cause dark brown to silver coloration of leaves. Dusts, though less dangerous than gaseous pollutants, may cause damages by coating leaves and penetrating into the soil. Reduced production due to zinc and lead containing dusts was determined in experiments.

Bennett, Jesse H. and A. Clyde Hill

ABSORPTION OF GASEOUS AIR POLLUTANTS BY PLANTS: INVESTIGATIONS INTO POLLUTANT CONCENTRATION PROFILES IN A STANDARDIZED CANOPY.

Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 22p., 1972. 17 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 65th, Miami, Fla., June 18-22, 1972, Paper 72-156.)

Concentration profiles for hydrofluoric acid, sulfur dioxide, ozone, nitrogen dioxide, and nitric oxide generated in a standardized alfalfa canopy are presented. Wind, light, temperature, and carbon dioxide profiles, pollutant uptake, and canopy data are given. Canopy pollutant concentration profile characteristics of major air pollutants were studied to evaluate

<xref image="2000WVLT.TIF|V3|2006:09:28:01:40:32.00|122296|0"> image: </xref>

their potential for penetrating into canopies. The study was conducted in an environmental growth chamber which allowed automatic control of environmental conditions and gaseous exchange. The steady state HF profile showed the greatest displacement within the canopy. Hydrofluoric acid, SO₂, and NO₂ profiles suggested that these gases may be removed efficiently by the upper portion of the canopy as well as the immediate subsurface vegetation. The steady state NO profile was not substantially displaced within the canopy. The meager uptake rate of NO by plants was too slow in comparison with gas transport and mixing within the canopy to materially affect the internal profile. Ozone appeared to be readily deposited on the surface tissues, but the lower tissues had less effect on the concentration profile. Data are presented which show the relationship between the NO₂ concentration within the canopy and changes in the air concentration above the vegetation. The NO₂ concentration was oscillated (between 9-11 pphm) above the canopy. The amplitude of oscillation was damped within the canopy in proportion to the depression in mean concentration at that level. (Author abstract modified)

THE PROBLEM OF AIR POLLUTION. (Das Problem der Luftverunreinigung). Text in German. *Angew. Bot.*, no. 37:299-311, 1964. 10 refs. (Presented at Muenster University, West Germany, Botanical Institute, Jan. 8, 1963.)

The general problem of air pollution-induced plant damage and morphological and physiological alterations in damaged plants are reviewed. The effects of air pollutants on plants are dependent on and modified by climatic, orographic, edaphic, and biotic factors; the synergism of pollutants; and differences in the sensitivity of individual plants and species. Sulfur dioxide and fluorine are the most dangerous pollutants for plants, but ammonia, hydrogen sulfide, nitrogen oxides, nitric acid, chlorine, hydrochloric acid, bromine, iodine, hydrocyanic acid, ethylene, carbon monoxide, hydrocarbons, mercaptans, asphalt and tar vapors, mercury, and selenium can also inflict damage. Young leaves, sensitive to H₂S, nitrogen oxides, Cl, HCl, HCN, mercaptans, Hg, and sulfuric acid, are more resistant to SO₂, gaseous F compounds, ethylene, and selenium than older leaves. Damage is most serious when pollutants enter leaves simultaneously or alternately through epidermis and stomata. Solution of the cellular matter due to SO₂, H₂S, nitrogen oxides, HNO₃, Cl, HCl, mercaptans, and selenium was observed. The yellow-to-brown coloration of leaves is usually a result of the precipitation of tannin. Plasmolysis is caused by SO₂, gaseous F compounds, ammonia, nitrogen oxides, HNO₃, Br, asphalt and tar vapors, while photosynthesis is stimulated by traces of ammonia, HNO₃, and saturated hydrocarbons. Increased dissimilation and respiration due to diverse pollutants, increased transpiration due to SO₂ and HCl, and elevated permeability and osmosis due to SO₂ were observed. The stomata are choked by dust, soot, and fly ash buildups.

Forest Service, Atlanta, Ga. Environmental Protection and Improvement

AIR POLLUTION AND TREES. 13p., 1971. 14 refs.

The most common pollutants injuring trees are sulfur dioxide, fluorides, oxidants, and minor air pollutants such as ammonia, chlorides, and ethylene. The sources of sulfur dioxide are coal burning (60%); refining and combustion of petroleum products (21%); smelting of ores (7%); and minor amounts generated by natural gas production, refining and utilization of sulfur, and manufacturing and utilization of sulfuric acid. Fluoride injury to plants in the United States became widespread after World War II, when the aluminum and other industries grew rapidly. Ozone, a naturally occurring oxidant existing in the upper atmosphere, may be brought to earth by turbulence during

severe storms, and small amounts are formed by lightning. Most other oxidants come from the emissions of automobiles and industries which mix in the air and undergo photochemical reactions in sunlight. Oxides of nitrogen are formed by combustion at high temperatures in the presence of two natural components of air, nitrogen and oxygen. Automotive exhaust is the largest producer of nitrogen oxides. Ethylene comes from the manufacture of illuminating gas, automobile exhausts, combustion of various fuels or any organic substance, petroleum refining, and manufacturing of polyethylene. Hydrogen chloride and chloride originate from refineries, glass-making plants, incineration, accidental spillage, and burning of polyvinyl chloride plastics. Ammonia injury to plants and plant products is caused by refrigeration gas escaping in cold storage rooms, from fertilizer tanks, or during various manufacturing processes utilizing or making ammonia. The injury caused to plants, including symptoms is described. Symptoms may be chronic or acute. A general yellowing of needles occur. Growth is impeded. Leaf margins begin to die. Tips of conifer needles turn brown and die. In the case of broadleaved trees, leaves turn yellow, or get small flecks of dead or pigmented tissue on the upper leaf-surface. Air pollution may injure trees many miles away from pollution source, especially during inversions, when pollutants are trapped and concentrated close to the ground. Air pollution is also responsible for retarding growth and weakening trees to attack by various insects and diseases. Air pollution problem to forestry is a near-future problem, and will depend upon population growth, engineering technology, willingness of private individuals and industry to become involved, and issuing adequate laws controlling the situation. Bohne, H.

INJURIES FROM DUSTS OF CEMENT WORKS ON THE FOREST STANDS. (Schaedlichkeit von Staub aus Zementwerken fuer Waldbestaende). Text in German. Allg. Forstz., 18(7):109-111, 1963. 4 refs.

Investigations of forest damages due to dust emissions from cement works are described. Tree leaves were covered by whitish-gray dust deposits, often in the form of a hard film, and many dead trees, mostly conifers, were found. Dust sedimentation measurements over one year revealed sedimentation rates of 1.7 g/sq m/day as a monthly average, while weekly averages reached 3.8 g/sq m/day. The dust contained 30-40% lime, 15-20% silicic acid, 5-45% sulfur, about 1% potash, up to 0.15% fluorine, and traces of iron and aluminum. The pH values ranged from 8 to 12. The dust, of high binding ability, resembled cement in its behavior in the presence of humidity. The dust deposits reduced the assimilation, and, due to being highly alkaline and containing hydroxyl ions and water-soluble salts, damaged or destroyed the cell matter. Also lenticels in the bark were affected. Measurements of annual ring widths revealed considerable reduction in growth, parallel to the increase in the cement production. The annual rings in a poplar were 8.5 mm wide during the period 1925-1930, as against 3.8 mm in the period 1951-1960. The width of the annual rings in conifers decreased from 2.1-2.5 mm in the period 1911-1920 to 1.4 mm during 1951-1960.

Houten, J. G. ten

AIR POLLUTION AND PLANT HEALTH. OEPP/EPPO Bull.,
no. 4:65-77, 1972. 20 refs.

Plant injury due to chemical air pollutants (sulfur dioxide, hydrofluoric acid, ethylene, ozone, and peroxyacetyl nitrate) is a well-known phenomenon in densely industrialized and urbanized areas. Several studies on the physical, chemical, and biotic influences of pollutants are reviewed. Little is known about the influence of air pollutants on the development of parasitic plant diseases and insect pests, and only in a few cases has the effect of the presence of certain pathogens in plant leaves on symptom-expression resulting from chemical air pollutants been investigated. In some instances, virus-diseased plants are less susceptible to air pollutants. In exceptional cases, air pollutants may reduce plant diseases. Some pollutants may inhibit spore germination of certain pathogens, whereas other pathogens are not influenced at all or may even be stimulated.

William, A.

AIR, PRIMORDIAL FACTOR OF THE ENVIRONMENT. (L
air, facteur primordial de l'environnement). Text in French.
Ann. Gembloux, 77(2):11M20, 1971. 9 refs.

A historical review is given of air pollution, and studies on plant damage due to air pollutants such as sulfur dioxide, hydrogen fluoride, hydrochloric acid, nitric acid, nitrous acid, ammonia, hydrogen sulfide, bromine, and mineral oils are summarized. The relative sensitivities of certain plants for air pollution are given. Atomic oxygen may react with nitrogen oxides and saturated hydrocarbons, forming peroxyacetyl nitrates and peroxypropionyl nitrate. Sulfur dioxide present in air may be oxidized by ozone to sulfur trioxide to form finally sulfuric acid. Plant leaves develop whitish or brown spots within a few minutes on the action of ozone in concentrations of 0.1-0.2 ppm. Epiphyte plants and lichens are regarded by many scientists as the best pollution indicators. Territorial development plans for different regions of Belgium are reviewed with regard to air pollution prevention.

Schucht, F., H. H. Baetge, and M. Dueker

SOIL INVESTIGATIONS IN THE OKER METALLURGICAL
PLANT AREA (HARZ MOUNTAINS, GERMANY). (Ueberbodenkundliche Aufnahmen im Rauchschaengebiet der Unter-
harzer Huettenwerke Oker). Text in Gern.an. Landwirt. Jahrb.,
vol. 76:51-98, 1932. 39 refs.

Soil investigations were carried out in a smoke-damaged forest area around the Oker metallurgical plant in the Harz mountains. The damages were primarily due to sulfur dioxide which formed sulfur trioxide and then sulfurous acid. Other pollutants, such as carbon dioxide, nitrogen oxides, and dusts containing copper, zinc, arsenic, lead, and traces of cadmium as well as traces of hydrofluoric acid and chlorine, were also detected. Soil samples showed increased soil sulfate contents around the metallurgical works, and an irregular decrease of sulfate levels with distance. The lime contents decreased due to the effect of sulfurous acid, as did magnesia and potassium concentrations. The soil pH ranged from 6.7 to 7.5. Copper contents of 0.04-0.007%, decreasing irregularly with distance, were measured, while both the zinc and lead contents, 0.16% and 0.14-0.0007%, respectively, were highest in the immediate proximity of the plant due to rapid sedimentation. Dusts containing arsenic had the largest action radius, and it was possible to determine the extension of the smoke damage area from the soil arsenic levels. Since copper, zinc, lead, and arsenic were present in the form of water-insoluble salts in soils with adequate lime contents, damages due to these metals were not probable, and soil acidification due to SO₂ could be coun-

teracted by proper fertilization.

Bohne, H.

INVESTIGATION OF AIR POLLUTION-INDUCED PLANT DAMAGES. (Untersuchung von Pflanzenschaeden durch Luftverunreinigung). Text in German. Mitt. Deut. Landwirtsch. Ges. (Frankfurt), 80(20):684-685, 1969.

The investigation of air pollution-induced plant damages is described, with special regard to the production of evidence for legal proceedings. Dead trees near industrial plants, asymmetric growth, and yearly recurring coloration, appearing during spring or early summer, are the general symptoms of the influence on vegetation of industrial activity. The chemical analysis of plant samples delivers usually unambiguous evidence. The problem is complicated by the presence of several industrial plants emitting different pollutants in the affected neighborhood. While fluorine contents in leaves decrease with increasing distance of the suspected emission source, chlorine and hydrofluoric acid are carried away from leaves by plant fluids. Repeated pollutant concentration measurements, preferably at different distances of the emission source, are necessary. The plant damage area should be divided into a number of zones according to the degree of the damage.

Ryder, Edward J.

SELECTION AND BREEDING OF PLANTS FOR INCREASED RESISTANCE TO AIR POLLUTANTS. Preprint, American Chemical Society, Washington, D. C., 1971. 35 refs. (Presented at the American Chemical Society, National Meeting, 161st, Los Angeles, Calif., March 28 - April 2, 1971.)

A few crops, ornamental plants, and forest plants were investigated for variations in reaction to air pollution. Evidence for a genetic basis for resistance to pollutants was found in several species. Plant breeding techniques and current breeding programs are listed. The effects of the following toxicants are reviewed: ozone, fluoride, oxidants, sulfur dioxide, nitrogen dioxide, and peroxyacetyl nitrate. Future needs and prospects are discussed. Breeding new varieties of plants, resistant to the toxicants, which can be successfully grown in a polluted atmosphere is considered.

PLANTS THAT WILL WITHSTAND POLLUTION AND

REDUCE IT. In: Landscape for Living. Washington, D. C., Government Printing Office, 1972, p. 16-22. GPO

Ozone, peroxyacetyl nitrate, sulfur dioxide, nitrogen dioxide, fluorides, and ethylene are pollutants that singularly or in combination can cause damage to plants in the form of lesions, tissue collapse, discoloration, defoliation, premature aging, and necrosis of leaf margins and tips. The concentration of these pollutants is high enough in some areas to result in economic losses. The sensitivity of the plants can be used to detect the presence of these pollutants and to augment monitoring instruments. Trees and other plants also play a role in removing gaseous pollutants and particulates from the atmosphere and in reducing noise. The ginkgo and the Ailanthus are two species

<xref image="2000WVLV.TIF|V3|2006:09:28:01:40:40.00|117651|0"> image: </xref>

which have been grown successfully in urban areas. Natural selection will result in more resistant plants, but the cultivation of particular species is desirable.

Wood, Francis A.

AIR POLLUTION RESEARCH NEEDS ESI FORESTRY.

Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 20p., 1972. 10 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 65th, Miami, Fla., June 18-22, 1972, Paper 72-152.)

Research needs with respect to the effects of air pollution on forests are presented. The principal difference between research needs pertaining to forests in comparison with those pertaining to herbaceous plants is a function of the perennial nature of forests. Research areas that need attention in the future include: a determination of the impact of air pollution on forests, the effects of pollutant interactions, the effect of pollutant-biopathogen interactions, an examination of changes in the nature of air pollution problems associated with applications of control technology, the development of additional field diagnostic techniques, and the use of chemicals and resistant plant materials to minimize air pollution effects. The effects of specific air pollutants, such as sulfur dioxide, hydrogen fluoride, ozone, peroxyacetyl nitrate, and hydrogen chloride, at the cellular, whole plant, and plant community levels need to be elucidated. (Author abstract modified)

ENVIRONMENTAL POLLUTION BY FLUORIDES IN

FLATHEAD NATIONAL FOREST AND GLACIER NA-

TIONAL PARK. Forest Service, Missoula, Mont., Forest Insect and Disease Branch, 62p., Oct. 1971. 27 refs.

The major cause of vegetation injury and damage on forested lands near the Anaconda Aluminum Company was studied. Research took the form of studies of visual burn, chemical analysis, histological analyses, aerial photography of area, and entomological (insect) sampling. Fluorides generated by the Anaconda Aluminum Company were determined to be the primary cause of the injury and damage to vegetation in the surrounding area. Highest fluoride concentrations, up to 1000 ppm, in foliar tissue were found near the Anaconda aluminum plant. Data indicated the fluorides were carried by air movement from the aluminum plant through a saddle in Teakettle Mountain to Glacier National Park, following the pattern of the prevailing winds in the area. Elevated fluorides (greater than 10 ppm) were found in vegetation on Columbia Mountain and Teakettle Mountain, in vegetation near the towns of Columbia Falls, Hungry Horse, and Coram, Montana, and in the southwest portion of Glacier National Park. Varying degrees of visible fluoride injury were found on vegetation over more than 69,120 acres. Although fluoride emissions were reduced during the summer of 1970, fir and spruce trees continued to accumulate fluorides at the same rate as in 1969. Definite histological reactions to elevated fluorides occur in conifer needle tissue, including hypertrophy of parenchymatous cells. Fluorides also accumulated in insect tissue. All groups of insects studied contained high fluoride levels. Pollinators possessed the highest, up to 406 ppm. Cambium feeders contained in excess of 52 ppm, indicating that fluoride must be translocated in the cambium of trees. Predatory insects had fluoride counts over 53 ppm, showing fluoride is passed along the food chain. Insect population samples indicated that elevated fluoride levels in pine needles lead to a buildup of the pine needle scale. During the summer of 1971, evaluations of possible timber growth losses and pasture grazing lands should not be utilized due to fluoride were evaluated. Environmental damage can be stopped only by installation of pollution abatement equipment to limit fluoride emission to 0 lb/day, which is impossible, or by closing the plant,

which is also impossible. The only possibility left is installing a permanent system to monitor fluoride pollution. (Author conclusions modified)

Compton, O. C., F. W. Adams, Stanley Elliott, Jack H. Wood, D. W. Claypool, and R. K. Marsh
FLUORINE LEVELS IN PLANTS OF THE WARRENTON AREA, 1968-1970: CULTIVATED AND NATIVE WOODY AND HERBACEOUS PLANTS PRIOR TO ALUMINUM FACTORY OPERATIONS. Oregon Agricultural Experiment Station, Corvallis, Rept. 335, 30p., July 1971. 32 refs.
The fluorine level of plants in an area intended for construction of an aluminum plant was studied to supply reference data in anticipation of pollution after start of plant operation. Cultivated and native plants within 6 mi of the factory site were sampled. Pasture herbage contained an average of 0.8-3.2 ppm fluorine, with only 11% of the samples exceeding 3.4 ppm. The fluorine content of each of the other six species averaged 2.9 ppm, with the exception of spruce needles containing 4.2 ppm. Five improved strains of pasture grasses maintained in pure strands were consistently and uniformly low in fluorine content. Within the area, differences in terrain, river valley, or distance from projected factory site produced no trends in fluorine concentrations. (Author summary modified)

Heggstad, H. E.
HOW PLANTS FIGHT MAN-MADE POLLUTION. Sci. Teach., 39(4), 4p., April 1972. 22 refs.
Various investigations concerning the response of plants to polluted environments are reviewed. Removal of ozone by plants is regulated by the same factors that control the exchange of water vapor between the leaves and the atmosphere. Depending on the species, ozone concentration, and other factors, uptake of ozone by leaves often results in acute injury, premature aging, and plant senescence. Sulfur absorption by plants is least when the concentrations of sulfur dioxide are highest. Sulfur accumulation may occur even under pollution conditions which do not depress plant yield or the quality of plant products. The initial uptake rate of nitrogen dioxide by alfalfa and oats is directly proportional to concentration in the range of 0 to 24 ppm. Alfalfa removes gaseous pollutants in the following order: hydrogen fluoride most rapidly, followed by sulfur dioxide, chlorine, nitrogen dioxide, ozone, peroxyacyl nitrate, and nitric oxide. The absorption rate of nitric oxide is very low, and it is not possible to detect any absorption of carbon monoxide. There is a close relationship between the uptake of these pollutants by plants and their solubility in water. The action of various woody plants on SO₂ removal is described. Soil organisms, including fungi, yeast, and bacteria, also play an important role in air purification, especially for gases such as CO and ethylene, which are not absorbed by green plants, soil also acts as an effective sink for SO₂ and NO₂. Trees, shrubs, and tall grass make effective sound barriers and thus reduce noise pollution. Removal of particulates by plants has little, if any, effect on the vegetation itself, but plant removal of gaseous pollutants, such as ozone, PAN, sulfur dioxide, and chlorine, may cause injury to plants.

Zietzschmann, Otto

CONTRIBUTION TO FLUORINE NOXIOUSNESS IN CATTLE. (Zur Frage der Schaedlichkeit des Fluores beim Rinde). Text in German. Deut. Tieraerstl. Wochschr., no. 39:203-204, 1931.

Observations on the effects of fluorine on cattle are described. Grazing cattle kept in a pasture near a chemical plant emitting hydrofluoric acid lost weight and showed symptoms of osteomalacia but never those of fluorine cachexia. The symptoms rapidly receded during winter when the animals were fed only little hay from the chemical plant area. Fluorine in grass and hay was detected, and vegetation damages in the form of reddish-brown spots on leaves and leaves turning yellow in summer were observed. In another case loss of weight and symptoms of osteodystrophy were observed in cattle grazing near a plant which discharged fluorine bound in air borne dust. Osteodystrophy failed, however, to appear in tests in which cattle were fed 2.3 g/day of sodium fluoride and sodium fluosilicate, which indicates the possibility of the indirect action of fluorine.

MacLean, D. C, L. H. Weinstein, D. C. McCune, R. H., and A. E. Hitchcock

A STUDY TO ASSESS THE IMPACT OF TOXIC PROPELLANTS ON KSC ECOLOGY. (FINAL REPORT). Boyce Thompson Inst. for Plant Research, Inc., Yonkers, N. Y. and TRW Systems, Cape Canaveral, Fla., Florida Operations, NASA Contract NAS 10-3147, 92p., Dec. 1966. 3 refs. NTIS: N67-35193

The impact of toxic propellants on plant species near the Kennedy space center was studied. Nitrogen tetraoxide, which is currently used as an oxidizer, and hydrogen fluoride, which would be the toxic vapor from a fluoride-based oxidizer, were the propellants studied. The study was concerned only with high vapor concentration, short duration exposures which might result from launch operations. The vapors of both propellants caused plant damage in proportion to the vapor concentration and exposure time. Boundary conditions for damage by nitrogen dioxide varied from 25 ppm for 4 hr to 250 ppm for 15 min. Boundary levels for hydrogen fluoride ranged from 15 ppm for 2 hr to 8 ppm for 4 hr. The minimal effects of both vapors on plant tissue resemble the symptoms produced by environmental stresses, insects, and diseases. The maximum effects observed included complete defoliation, abscission of flowers and fruits, and necrosis of terminal shoots. Vapor concentrations and/or exposure time significantly above the maximum levels studied in this program could be expected to produce complete necrosis of plants. Hydrogen fluoride was approximately 20 times more effective on a concentration basis than NO₂ in inducing plant damage. Plant damage induced by HF can be distinguished from that induced by NO₂ on the basis of the species affected, type of tissue injured, pattern of symptom development and expression, and chemical analyses. Injuries to plants observed in this study ranged from marginal effects through complete defoliation. The visible expressions of injury are described for a number of citrus varieties and ornamental species.

AIR POLLUTION AND TREES. In: Man's Impact on Terrestrial and Oceanic Ecosystems. William H. Matthews, Frederick E. Smith, and Edward D. Goldberg (eds.), Cambridge, Mass., MIT Press, 1971, Chapt. 7, p. 116-129. 31 refs. Coniferous trees, bearing the same foliage year-round and often for several years, are notable victims of air pollution. There is much variation among tree species in sensitivity to toxic airborne gases and great variation from tree to tree

within the same species. Thus, some sensitive white pine trees are being propagated to provide a clonal line useful in monitoring air pollution, while other neighboring resistant white pines have permitted the production of clonal lines of trees that can withstand field levels of certain toxic gases. The main air pollutant gases toxic to trees are sulfur dioxide, fluorides, ozone, peroxyacetyl nitrate, and oxides of nitrogen. Today the main damage to forest and shade trees results from the stack gas from coal-burning power plants and from the photochemical toxicants in urban smog. When trees were killed over thousands of acres around a smelter, the climate of the area was definitely altered adversely. Trees help screen out polluting industries and serve as fixed monitors of dangerous pollution levels. Trees have also been considered as sometimes contributing to atmospheric haze through photochemical combinations involving their aromatic hydrocarbons such as terpenes. Wisely used, trees can help in many ways in the struggle against air pollution. (Author abstract modified)

CERTAIN ASPECTS OF THE EFFECT OF AIR POLLUTION BY INDUSTRIAL FLUORINE COMPOUNDS UPON FORESTS. (Niektóre zagadnienia wpływu na lasy przemysłowych 7, anieczyszczeń powietrza związkami fluoru). Text in Polish. *Sylvan*, 108(6):45-54, 1964. 27 refs. A brief review is given which emphasizes that the content of fluorine compounds in air, soil, and plants differs in different areas depending on the distance from industry (especially metallurgical aluminum, and fertilizers industries). The signs of the adverse effects of fluorine pollution are described in detail. Resistance of plants differs in different species. Of the evergreens, the most sensitive are the pine (75-85%), spruce (26-75%), and fir (3-12%), and least sensitive is the larch (less than 1%). Of deciduous trees, the most sensitive is the beech tree, while maple, oak, and plane trees are much more resistant. Different methods for determining the cause of damage (chemical, botanical, biometric, and histochemical) and methods of plant protection (spraying with lime or special oil emulsions) are briefly described. The need for better control of sources of fluorine pollution is stressed.

AIR POLLUTION AND PLANTS. In: *Man's Impact on Terrestrial and Oceanic Ecosystems*. William H. Matthews, Frederick E. Smith, and Edward D. Goldberg (eds.), Cambridge, Mass., MIT Press, 1971, Chapt. 6, p. 101-115. 33 refs. Air pollution problems caused by gaseous and particulate pollutants on cultivated plants are reviewed. Agricultural losses due to air pollution are an estimated \$500 million annually and are increasing. Most of the loss is due to growth suppression or to chronic injury as indicated by relative growth of plants in ambient air containing pollutants and carbon-filtered air with most oxidants and some other pollutants removed. Photochemical oxidants such as ozone and peroxyacetyl nitrate are considered, as well as ethylene, sulfur dioxide, fluoride, nitrogen dioxide, and other pollutants. The combined effect of two or more gases is discussed, and the significance of environmental factors is reviewed. Research needs are summarized.

SOURCE, DISPERSION AND EFFECT OF CHEMICAL AIR

POLLUTANTS. (Herkomst, verspreiding en effect van chemische luchtverontreinigingen). Text in Dutch. Inst. of Phytopathological Research, Wageningen (Netherlands), 16p., 1972. 32 rets. (Presented at the Aerobiology Symposium, Wageningen, Netherlands, Jan. 1972.)

The effects of general and specific air pollutants on plants are reviewed. The air pollutants enter into plants through the stomata of the leaves and may cause serious metabolic disorders on a cellular level. Sulfur dioxide causes necrosis of intercostal tissues without affecting the nerves. It has no cumulative effect as it is metabolized into harmless sulfates. Lichens were highly sensitive for SO₂. Examples of plant damage and action radii in different areas are given. Ethylene, originating from automotive exhaust, causes epinasty in stomata in a concentration of 0.1 ppm. Nitrogen dioxide in a concentration of 0.25 ppm damages tomato. The effects of ozone formed in photochemical reactions on *Pinus ponderosa* were detected at a distance of 100 km from the source. Hydrofluoric acid emissions from a aluminum plant caused total destruction of conifers and needle damage up to a distance of 32 km. Cement dust and other solid particles may serve as condensation nuclei for other air pollutants. Reduced virulence of phytopathogenic fungi due to SO₂ was observed; 0.5-1 ppm ozone concentrations, maintained over a few hours had a similar effect on *Fusarium oxysporum*, *Colletotrichum lagenarium*, *Verticillium albo-atrum* and *V. dahliae*. The growth-stimulating effect of acetaldehyde on *Sclerotium rolfsii* was observed. An air pollution monitoring network of 250 sampling stations, designed to measure SO₂ and NO₂, nitric oxide, and ozone concentrations is under construction in the Netherlands.

INVESTIGATION OF THE SUSCEPTIBILITY OF WOODY

PLANTS FOR SO₂ AND HF. (Onderzoek naar de gevoeligheid

van houtige gewassen voor SO₂ en HF). Text in Dutch. Groen, 1972:1-12, Jan. 1972.

The equipment for fumigation of woody plants in the field developed by Spiennings was improved by mounting feelers to the fumigation gun in order to measure climatic conditions. The data from these feelers is registered automatically on instruments situated in a van and worked out by a computer. The equipment is used for short-time fumigations in the field. Short-time fumigations were also carried out in the laboratory. The data and symptoms of damage to the trees and shrubs caused by low concentrations of sulfur dioxide and hydrogen fluoride are discussed. In a fumigation experiment with a concentration of 2.41 ppb HF applied during 4 months, trees and shrubs showed a great difference in susceptibility to and capacity for uptake of HF.

THE DETECTION OF HIDDEN F-INJURY OF FOREST

TREES BY A SIMPLE COLORIMETRIC DETERMINATION

OF PEROXIDASE ACTIVITY. (Der Nachweis unsichtbarer

(physiologischer) Fluor-Immissions-schädigungen an Waldbäumen

durch eine einfache kolorimetrische Bestimmung der Peroxidase-Aktivität). Eur. J. Forest Pathol., 1(1):6-18, 1971. 26 rets.

Translated from German. 21p.

A simple routine method is described for colorimetrically determining peroxidase activity in foliage of forest trees, including conifers. Peroxidase activity increases with aging of tissues. Fluoride emissions add to this natural tendency, thus leading to premature senescence; the increased fluoride content in assimilation organs is associated with increased peroxidase activity. External dust influences peroxidase activity only after several hours, while peroxidase activity is very little

affected by variations in tissue water content. An analysis of potted plants exposed at varying distances from an aluminum plant and fluoride emissions indicates that peroxidase activity and the fluoride content of foliage increases with decreasing distance. Increased peroxidase activity may occur without or before symptoms of visible fluoride injury develop. (Author summary modified)

DETECTION OF AIR POLLUTION BY THE TRANS-
PLANTED FOLIOLIC LICHEN, PARMELIA PHYSODES.
(Zur Nachweis von Luftverunreinigungen durch die transplan-
tierte Blattflechte Parmelia physodes). Zentralbl. Bakteriol.,
Parasitenk. Infektionskr. Hyg.:Abt. 1:Orig., Reihe B,
212(2/4):3S6-3S7, Feb. 1970. 1 ref. Translated from German. 2p.

Open air and fumigation studies indicate that the foliose lichen Parmelia physodes reacts to ground level concentrations of sulfur dioxide and hydrogen fluoride, and that it can be measured by the withering of individual thallus parts. Reactions were photographically recorded at predetermined time intervals. An investigation conducted in the vicinity of an aluminum plant ascertained that Parmelia physodes is a quantitatively reacting biological indicator.

Wentzel, Karl Friedrich
INSECTS AS EMISSION-RELATED PESTS. (Insekten als Imis-
sionsfolgesschaedlinge). Naturwissenschaften (Berlin), 52(5): 113,
1965. 3 refs. Translated from German. 3p.

An appraisal was made of the degree of conifer foliation in eight test areas lying end-to-end in a radiating pattern from a brick kiln factory and to a distance 1020 m East and Northeast, as well as the accompanying degree of infection from spruce gall lice. Close relationships were found between the degree of damage to the trees and the gall infection. Hydrogen fluoride emissions from the brick kiln can effect a shift in the disposition of the host plants, thus providing conditions for the development of spruce gall lice.

VARIATIONS IN THE INTENSITY OF TRANSPIRATION
AND DAMAGE TO PLANTS CAUSED BY FLUORINE
PRESENT IN THE ATMOSPHERE. (Zmeny v intenzite trans-
piracie a poskodenie rastlin pri posobeni fluoru z ovzdušia).
Text in Slovak. Biologia (Bratislava), 27(7): 545-559, 1972. 30
refs.

The effect of various atmospheric fluorine concentrations on transpiration intensity and the health of leaves of 10-day-old plants of *Pisum sativum* was studied under conditions of continuous and periodic fumigation. Transpiration intensity was determined gravimetrically by a special apparatus. Low fluorine concentrations (50 ppb), following a temporary drop in water transpiration, resulted in a marked increase in transpiration. Following the attainment of maximal increase, transpiration decreased again to end up shortly before the appearance of visible leaf damage at lower intensity than control plants unexposed to fluorine. Higher concentrations (100-150
<xref image="2000WVLY.TIF|V3|2006:09:28:01:40:48.00|113579|0"> image: </xref>

ppb) led immediately to a gradual drop of transpiration intensity which continued throughout the stage of invisible and visible leaf damage. Lower and higher fluorine concentrations also affected the appearance of leaf damage. Leaf necrosis appeared sooner at higher, later at lower, fluorine concentrations. At lower concentrations, upper ontogenically younger leaves turned light brown which was followed by peripheral necrosis on fully developed leaves. Concentrations of 150 ppb caused a different type of damage: after one day of fumigation, the leaves began to wilt. Transpiration intensity at high fluorine concentrations dropped more markedly in plants growing at relatively lower humidity, at higher relative humidities the effect of fluorine was less noticeable. Periodic fumigation disclosed that at night plants were more sensitive to the effect of fluorine than during the day: transpiration intensity dropped more.

CONSEQUENCES OF SMALL FLUORIDE POLLUTION IN A MOUNTAIN VALLEY. (Consequences d'une pollution fluoree de faible importance dans une vallee de montagne). Text in French. Tribune CEBEDEAU (Centre Beige Etude Doc. Eaux), 24(327):62-66, Feb. 1971. 8 refs.

Fluoride content in the air and forage were determined, and symptoms of chronic fluoride poisoning in cattle raised in a mountain valley accommodating a phosphoric acid production plant were studied systematically over 10 years. The plant, processing phosphates with a fluoride content of 3.8%, emitted 20 kg of F daily. The atmospheric average F concentration ranged from zero to 10 micrograms/cu m, with 90% in the form of hydrofluoric acid and silicotetrafluoride, and 10% in the form of apatite. The fluorine content in forage, ranging from 20 to 50 ppm, and up to 164 ppm in one case, is responsible for pathological symptoms of fluorine poisoning in cattle. Fluorine content of about 30 ppm causes discoloration of the dental enamel in cattle fed such forage over more than 3 years, which corresponds to the fluorine residues of more than 1000 ppm in the jawbones. Periodic limping occurs in cattle fed forage with about 50 ppm of F over 5 years, corresponding to an F content of more than 4000 ppm. Such animals lose weight and yield much less milk than normal ones. Caries and loose teeth in cattle whose jawbones contain F residues of more than 3000 ppm are observed. Osteosis is, however, practically nonexistent. The urine F content, ranging from 2 to 20 ppm, was normal with less than 10 ppm in 60% of all animals. The results show an accumulation of F in bones, and suggest an F content of 20 ppm in forage as a safe limit.

Spinka, Josef

EFFECTS OF POLLUTED AIR ON FRUIT TREES AND LEGUMES. (Vliv znečisleneho ovzduší na ovocné stromy a zeleninu). Text in Czech. Živa, 19(1):13-15, June 1971. Plants undergo microscopic and macroscopic changes when exposed to atmospheric sulfur dioxide and chlorine concentration of 1 times 10 to the -6th power g/cu m. Soil quality also suffers from SO₂, Cl, fluorine, and other gases. All plant damage from atmospheric pollutants is intensified by high humidity. Plant damage can best be detected by microchemical methods. Detection of leaf damage from nitrogen oxides or ammonia is difficult because of the high content of other nitrogen compounds. Suspended dust reduces the amount of solar energy available for photosynthesis by reducing the intensity of solar radiation. Maximal short-term and median long-term concentrations tolerated by plants for SO₂, carbon monoxide, NO_x, Cl, hydrogen sulfide, soot, fluorine, arsenic, phenol, benzene, and ammonia are given. In Czechoslovakia a 12.5 g/sq m/mo dust fall with up to 20% free silicon dioxide is

permissible. Emissions of CO, hydrocarbons, NOx, and lead cause damage to crops and trees lining heavily travelled highways.

47286

Daessler, Hans-Guenther
PLANT DAMAGE FROM AIR POLLUTION. (Vegetationsschaeden als Folge der Luftverschmutzung). Text in German. Wiss. Z. Tech. Univ. Dresden, 20(4): 1171-1173, 1971. The problem of air pollution-induced plant damage in East Germany is outlined. Sulfur dioxide causes most of the damage in forestry and agriculture, followed by hydrofluoric acid and silicon tetrafluoride. Dust and soot emissions are less hazardous for forests, while they may cause damage to fruits and vegetables and unfavorably modify soil properties Arsenic, lead, copper, and zinc emissions are especially harmful since they may result in reduced crops. Invisible physiological, chronic, and acute plant damage due to pollution are distinguished. Exposures over a short time to high pollutant concentrations are generally more hazardous than long-term exposures to low concentrations. The total forest damage area in East Germany is estimated at 220,000 ha. Pollution induced damages of barley and flax, as well as livestock damages due to the consumption of contaminated forage have occurred repeatedly. As the proportion of fossil fuels among the energy sources steadily increases, no decrease in the SO2 level is expected. There are no effective means for controlling SO2 emissions, and the construction of high stacks constitutes no real solution to the emission problem.

Subido, P. S., P. A. Santamaria, E N. Alqueza, and A C. Pizarro
PLANTS INJURED BY AIR POLLUTANTS. Philippine J. Sci. (Manila), 98(3/4):323-328, Sept./Dec. 1969. 5 refs. The effects of emissions from a fertilizer factory on the plant life in the surrounding areas were examined. The typical symptoms and condition of the plants affected by corrosive sulfur dioxide and hydrogen fluoride gases included shrivelling, discoloration, and scorched leaves. Branches and twigs were covered with grayish deposits of fertilizer dusts and other particulates. Defoliation was common. The effect on sweet potato was even more devastating, on the average, a field was completely destroyed within three days. Plant growth of varied species was stunted in several cases. The magnitude of destruction was less near the source of pollution and more intense further away, corresponding to the dispersal of pollutants.

Wentzel, K. F.

FORESTRY MEASURES AGAINST IMMISSIONS. (Waldbauliche Massnahmen gegen Immissionen). Allgem. Forstztg., vol. 18:101-106, 1963. 12 refs. Translated from German. 32p. Forest damage can be prevented with certainty only by controlling toxic pollutants before they leave the factories. Thus, the protective measures against pollutants available to forestry are almost exclusively of a prophylactic nature. Their only objective is to prevent major destruction of a forest's structure and character and to maintain a certain capacity of yield and finally any growth at all in the vicinity of industries. Sulfur dioxide and hydrogen fluoride gases cause the most damage to forests. The countermeasures available to forest management are based on three hypotheses: that the tree species, as well as an individual specimen of one species, have different resistances to harmful emissions; smoke plumes dilute more quickly, the more they pass through obstacles and barriers in their path; the more favorable the general conditions of growth are, such as the soil, the more resistant the plant will be to attacks of smoke concentrations. Reforestation with more resistant species, some of which are cited, is discussed, as well as the arrangement of protective belts or smoke barriers and improving the conditions of growth. The selection of seeds and sapling is also considered. Economic problems involved with adapting a forest to the effects of pollution are mentioned.

STUDIES OF THE TOXIC EFFECT OF HAY ON CATTLE IN

SMOKE-INJURED AREAS. (Untersuchungen ueber toxische

Wirkungen von Heu aus Rauchschaedengebieten beim Rind).

Text in German. Z. Erzbergbau Metallhuettenwesen, 25(10):498-505, 1972. 21 refs.

In the vicinity of /me, lead, and sulfuric acid plants in Arnoldstem, Austria, the extent of injuries to the vegetation by the emissions from these plants was determined. The hay from the smoke-injured area was used for feeding experiments with seven test cows for determination of any possible intoxication through the higher lead, zinc, and fluorine intake with the fodder. With the exception of spots on the teeth of about 1/3 of the test cows, no symptoms of intoxication with these elements could be determined. The feeding experiment lasted 6 months. The lead and zinc concentration of the examined hay was above normal, but below the toxic limit. The fluorine concentrations were on the upper limit of the normal values. Clinical examinations including blood tests carried out at 2-week intervals were negative. The lead and zinc concentrations of blood, blood plasma, feces, urine, milk, and hair were below the toxic range. The fluorine concentration in the bones excluded any fluorine intoxication. The milk production of the test animals, however, was significantly lower by 0.64 l/animal/day (average over the total duration of the feeding experiments), compared to the control animals.

Haneda, Mikiko and Fumio Tsunoda
INDICATOR PLANT IN FLUORIDE AIR POLLUTION INVESTIGATION. (Fukkabutsu ni yoru taiki osen chosa no tame no shihyo shokubutsu ni tsuite). Text in Japanese. Nippon Kosho Eisei Zasshi (Japan. J. Public Health), 19(9):449-456, Sept. 1972. 20 refs.

Atmospheric fluoride accumulates in the leaves of some plant species, thus designating them as a fluoride air pollution index. Irises, gladioli, and pines as pollution indicators were tested around an aluminum factory. A very high concentration of fluorine was determined in the upper part of the iris leaf and was in proportion to the actual fluoride air pollution index. A fluorine content of 30-50 ppm (dry weight bases) or 10-20 ppm (wet weight basis) indicated that the air was polluted by fluorides. Similar results were determined for the gladioli and pines.

Stark, Nellie B. and Patricia F. Harris
STUDIES OF TRACE ELEMENTS IN SOILS AND PLANTS FROM THE FOUR CORNERS AREA OF NEW MEXICO. (FINAL REPORT). Nevada Univ., Reno, Center for Water Resources Research, Environmental Protection Agency Contract 68-02-0269, EPA-R4-72-007, Project Rept. 20, 94p., Sept. 1972. 24 refs. NTIS: PB 212561

The concentration of eleven trace elements in plants and soil in the Four Corners area of New Mexico was measured to develop background and preliminary data on the environmental effects of coal-fired power plants in the area and data on the potential buildup of each trace element. The elements included arsenic, beryllium, cadmium, chromium, fluoride, lead, manganese, mercury, molybdenum, nickel, and selenium and were chosen on the basis of the chemical makeup of the fly ash emitted by the power plants. Instrumentation, sample collection and preparation, testing procedures, and results are reviewed. Complete analytical data are presented. (Author introduction modified)

<xref image="2000WVM0.TIF|V3|2006:09:28:01:40:56.00|109617|0"> image: </xref>

In June 1969, damages by hydrogen fluoride to 25 boxes of silk worms (at 10 farms) and damages to mulberry trees covering three hectares of area were reported. The emission source was a glass fiber manufacturing plant in Fukushima City. The fluorine content in the raw material was measured and a maximum of 0.035% to a minimum of 0.002% was detected. The hydrogen fluoride gas was measured on a sunny day. A maximum of 23.3 ppm, a minimum of 19.1 ppm, and an average of 20 ppm of HF were detected. The mulberry leaves within 300 to 500 m of the plant contained 39 to 40 ppm of fluoride, in contrast to those in the control areas, which had 0.9 ppm. Recommendations are made for the planning an air quality monitoring system in relation to equipment, personnel, and information-obtaining method.

EFFECT OF FLUORINE ON FUNARIA HYGROMETRICA

AND HYPOGYMNIA PHYSODES. (Influence du fluor sur le

Funaria hygrometrica et 1 Hypogymnia physodes). Can. J.

Botany, 50(4):847-856, 1972. 23 refs. Translated from French.

24p., 1972.

Two species of cryptogams were fumigated with hydrofluoric acid to determine their degree of sensitivity to atmospheric fluorine by direct observations of symptoms of chlorosis and necrosis in the leaves; the extent of accumulation of fluorine in the plants and their capacity for recuperation after the fumigation process. The fumigation process consisted of treatment with 13, 65, and 130 ppb HF for 4, 8, and 12 hours and then 13 ppb for 36, 72, and 108 hours. At concentrations of 65 ppb/12 hr, the moss and lichen showed chlorotic spots; some of the chloroplasts started to disintegrate; and plasmolysis occurred. After three weeks of recuperation, the Funaria hygrometrica lost 26-36% and the Hypogymnia physodes lost 36-47% of the fluoride accumulated.

Bossavy, J.

AIR POLLUTANTS AND THEIR EFFECTS ON PLANTS. (Les

pollnants atmospheriques, leurs effets sur la vegetation). Ann.

Gembloux, no. 77:163-173, 1971. Translated from French. 14p.

The effects of air pollutants on plants are reviewed with respect to types of air pollutants, symptoms of damage, and species affected. Plant damage was surveyed in France, East and West Germany, Austria, Greece, the Netherlands, Norway, Poland, Rumania, Sweden, Switzerland, Turkey, and Czechoslovakia. The pollutants of greatest concern with respect to plant damage included fluorine compounds, sulfur compounds, especially sulfur dioxide, smoke, ethylene, and metal compounds. Some emission sources are also discussed.

48556

Kaneda, K., R. Sugai, Y. Fujieda, and E. Abe

ATMOSPHERIC POLLUTION BY FLUORIDE AND ITS IN-

FLUENCE ON PLANTS. (Fukkabutsu ni yoru taikiosen to

shokubutsu eikyo). Text in Japanese. Nippon Kosshu Eisei Zasshi

(Japan. J. Public Health), 19(10):423, Oct. 1972. (Presented at

the Japan Society of Public Health, General Meeting, 31st, Sapporo, Japan, Oct. 25-27, 1972.)

Atmospheric fluoride concentrations were measured from May 1969 to March 1972 for each month by the limus and alkali filter paper methods. The growth of potted gladioli at 11 spots near two factories (phosphate fertilizer and an aluminum refining factory) was measured in 1969, of rice at 30 spots in 1970, and of cedar trees at 38 spots in 1971. Gladioli growth was measured at 10 spots; at two spots with high fluoride concentration, the leaf color change, retardation of height and number of leaves, and other significant differences were observed. At 1 km from the factory, the plant growth rate decreased. Cedar trees, checked at 37 spots except for nine

contrasted spots, revealed some damage. Some correlation was found between atmospheric fluoride concentration and more fluorine quantity in the leaves.

48639

Yamazoe, Fumio

THE EFFECT OF AIR POLLUTION ON AGRICULTURE

AND FORESTRY. (Taiki osen ni yoru norin kogai). Text in

Japanese. Nogyo Oyobi Engei (Agr. Hort.), 48(1):133-138, 1973.

6 refs.

The effect of hydrogen fluoride on plants is stronger than on animals. The threshold value of indicator plants (gladioli) is 5-10 ppb/day. The HF can cause etiolation at the tip or fringe of leaves. Silkworms fed leaves polluted by over 30 ppm of HF became ill. Cows exhibit fluorosis effects in teeth and bones after HF exposure. Chlorine turns leaves yellow by causing decomposition of chlorophyll. Plant damage occurs after 2-4 hr of exposure to 0.05-0.07 ppm of ozone or after 8 hr of exposure to 0.05 ppm of peroxyacetyl nitrate. Ozone causes white or brown spots on the surface of leaves; peroxyacetyl nitrate causes silver or bronze spots.

Boertitz Siegfried and Horst Ranft

ON THE SUSCEPTIBILITY OF LICHENS AND MOSSES TO

SO₂ AND HF. (Die SO₂ und HF-Empfindlichkeit von Flechte

und Moosen). Text in German. Biol. Zentralbl., 91(5):613-623,

1972. 16 refs.

The assimilation of 20-25 different types of mosses and lichens exposed to sulfur dioxide and hydrogen fluoride containing air was studied. For the assimilation measurements with the carbon dioxide URAS, the samples were put into glass cuvettes. For a study of the externally visible injuries, the sample material was exposed for 36 hours to 3.5-5.5 mg SO₂/cu m air and for a period of 27 hours to 0.3-0.4 mg HF/cu m. During the four to five days of exposure the weather was cloudy with showers. The noon temperatures were between 6 and 10 C. A sunny afternoon at the end of the experiments accelerated the development of visible damages. The exposure to phytotoxic substances such as SO₂ and HF does not immediately produce visible injuries. These substances gradually are retained in the plant tissue; moreover they are capable of reversibly or irreversibly influencing the photosynthesis. The assimilation intensity diminished during fumigation and gradually picked up again afterwards, provided the assimilation apparatus was not irreversibly damaged. With several lichens and mosses the visible injuries did not correspond in any way to the damages of the assimilation organism. The physiological dynamics prior to the occurrence of visible damage showed no fundamental difference in lichens from higher plants affected by phytotoxic substances.

THE EFFECT OF AIR POLLUTION ON PLANTS-THE

FLUORINE CONTENT IN STREET TREES. (Jumoku ni taisu-

ru taiki osen no eikyo-Gairoju-yo no fusso ganryo). Text in

Japanese. Kanagawa-ken Taiki Osen Chosa Kenkyu Hokoku

(Tech. Rept. Air Pollution Yokohama-Kawasaki Ind. Area), no.

14:87-92, Feb. 1972.

<xref image="2000WVM1.TIF|V3|2006:09:28:01:41:00.00|115657|0"> image: </xref>

Leaves of street trees in Kawasaki and Yokohama cities were collected in 1967. The maximum value of the content of fluorine in the leaves was 1653 ppm, the minimum value was 22 ppm and the average value was 135 ppm. There was a regional difference in the fluorine content in leaves between an industrial area and a commercial or residential area. The fluorine content in leaves of an industrial area and a commercial or residential area was in the ratio 10 and 2 or 3. There was a mutual relationship between the value of sedimented dust in the air and the content of sulfur oxides in air and the content of fluorine in leaves. The relationship between the fluorine content and the sulfur content in leaves and the relationship between the fluorine content in leaves and insoluble substances stuck to the leaves was not clear. The fluorine content in the soil was between 108 and 504 ppm, and the average content was 240 ppm.

EMISSIONS AND THEIR EFFECTS ON CATTLE. (Immisionen und ihre Wirkung auf landwirtschaftliche Nutztierc). Text in German. Umweltforschung, no. 58:26-29, 1971.

(Presented at the Seminar on Environmental Research, Hohenheim University, Stuttgart, West Germany 1971.)

Cattle is mainly affected by two air pollutants, fluorine and lead. The fluorine emissions are largely under control due to regulations. With the number of automobiles increasing, the lead is increasing in the vicinity of highways. Although the lead concentration in fodder grown along highways is considerable, the concentration drops quickly with increasing distance from the highway. Cattle are not so much affected by this pollutant, since they are not fed with fodder of this kind all year round. The concentrations of these pollutants in living animals is still rather low so that there is no danger for humans ingesting the meat from such cattle. Milk could be an exception in this respect provided the animal was acutely exposed to lead.

CASE STUDY OF THE DISSECTION OF A CATTLE RAISED IN FLUORIDE POLLUTION FOR 30 MONTHS. (Fukkabutsu ni yoru taiki osen kankyoka ni sanjikkagetsu shiiku shita ushi no bokenrei). Text in Japanese. Japan Society of Air Pollution, Proc. Symp. Japan Soc. Air Pollut., 13th, 1972, p. 200. (Nov. 7-9, Paper 155.)

Cattle raised for 30 months in an environment polluted by average of 1 ppb of fluoride and feed containing 40-60 ppm fluorine were slaughtered and dissected. There were no visually detectable anomalies. The blood test conducted immediately before slaughtering showed no anomaly in blood chemistry; liver and kidney functions were also regular. Histopathologically, slight irregularities were recognized in teeth and bones, but the heart, lungs, trachea, brain, liver, kidneys, spleen, glands, and other organs had no abnormalities. The fluorine content in all the organs were normal; high F content was noted in urine, plasma, bones, and teeth. The fluorine content in the skull was 4984 ppm; jaw 5069-5311; vertebrae 4826 to 5629; ribs 3900 to 5163; bones of the lower limb 5142; and teeth 2653 to 4889. The bones of the cattle were in the process of chemical fluorosis or bone fluoridation, or in the process of bone mottling, had not developed into abnormal bone formation.

INDUSTRIAL FLUORINE EMISSIONS: THEIR EFFECTS ON PLANTS AND ANIMALS. (Les emissions fluorees industrielles: leurs effets sur les plantes et les animaux). Text in French. Pract. Environ. Control, Proc. Int. Congr. PRO AQUA-PRO

VITA, Basel, Switzerland, 1971, p. 163-184, 1972. 80 refs.
Emissions of fluorine compounds from metallurgical and chemical factories, particularly aluminum factories and phosphate fertilizer plants, are a source of pollution of a high grade of causticity with regard to vegetables, for very weak fluorine concentrations in the air, in the range of 1 microgram hydrogen fluoride/cu m of air. Some plants are even more sensitive to the effects of fluorine compounds, like apricot trees, vines, barberry, gladioli, the Liliaceous species in general, pine trees, Norway spruce, and other forest trees. These sensitive species form typical necroses on the edge or at the tip of the leaves for fluorine contents in the dry matter lower than 50 mg/kg. The topographic situation of the factories plays an important part in the diffusion of gases. Fluorine intoxication (fluorosis) of animals originates most frequently from the absorption of fluorine compounds in fodder which originate from volatile F compounds issued by certain metallurgical and chemical factories. The symptoms of fluorosis include mottling and wearing of teeth, osteofluorosis, high fluorine content of bones and urine, and secondary effects like limeness and reduced milk production. The fluorine content of the total daily diet of milk cows should not exceed 30 mg/kg dry matter. Factories emitting F have generally taken precautions to reduce these emissions to 10-15%; however, a larger reduction must be reached in areas with highly F-sensitive plants.

Sato, Y. and Y. Tsuji
FLUORIDES INFLUENCE ON FERTILIZATION AND APPEARANCE IN EARLY STAGES OF SEA URCHINS. (Uni-ran no jusei oyobi hassei shoki ni yaisuru fukkabutsu no eikyo). Text in Japanese. Nippon Koshu Eisei Zasshi (Japan. J. Public Health), 19(10):427, Oct. 1972. (Presented at the Japan Society of Public Health, General Meeting, 31st, Sapporo, Japan, Oct. 25-27, 1972.)

The eggs and spermatozoa of sea urchins were used to observe fluoride's influence on fertilization. Additions of 5, 10, 25, 50, 100, 125, 250, 375, and 500 mg (F concentration: 22.6, 45.2, 113.0, 226.0, 452.0, 565.0, 1130.0, 1695.0, and 2260.0 ppm, respectively) were made to normal sea water of 100 ml. They were used as test groups and were compared with a control group. The rate of fertilization and state of appearance were judged from photographs. The fertilization rate was near 100% in the 0-250 mg groups and below 10% in 375-500 mg groups. The difference in the deposition time of eggs which were laid in the testing liquid prior to fertilization did not seem to affect the fertilizing rate. Three hours after the fertilization, eight-cell-terms were the majority in the 25-250 mg groups and 4-cell-terms showed a high rate in the 50-250 mg groups. Normal pluteus appeared in the control group after 48 hours and were also seen in the 5 and 10 mg groups at 88 and 30% rates, respectively. But embryos in 25-250 mg groups which are supposed to grow to normal pluteus did not appear at this moment. After 72 hours from the fertilization, embryos which started forming born structure were seen in each of the 0, 5, and 10 mg groups, also the abnormal born structure appeared in each of those groups at 30, 8, and 11% rates, respectively. Further, abnormal embryos were observed in all groups, especially with an extremely high rate in the 25-125 mg groups. Mam stages of the process are shown in tabulations, graphs, and photos.

THE EFFECT OF AIR POLLUTION ON PLANTS. (Oddzia-
lywanie zanieczyszczen powietrza na rosliny). Wiad. Bot.,
13(4):239-248, 1969. 102 refs. Translated from Polish. Leo
Kanner Assoc., Redwood City, Calif., 16p., Nov. 1972.

The effect of air pollution on plants is reviewed. Pollutants
discussed included sulfur dioxide, hydrogen fluoride, fluorine
and its compounds, nitrogen oxides, ozone, chlorine and its
compounds, and ammonia. The sources of each of these pollu-
tants, their specific properties, and their effects are listed.
Plant damages elicited by air pollutants are divided into acute
damage, chronic damage, and invisible damage. Changes oc-
curring during plant injury are described.

Haertel, O.

ECOPHYSIOLOGY AND ANTHROPOGENIC ENVIRON-

MENTAL CHANGES. (Oekophysiologie und anthropogene Um-
weltveraenderungen). Ber. Deut. Bot. Ges., 84(9):497-506, 1971.
34 refs. (Presented at the Botanists Convention, Innsbruck, Aus-
tria, Aug. 31, 1971.) Translated from German, 17p.

The effects of human influences on the environment and their
results are discussed. Effects on the environment which are
becoming more perceptible are the results of two circum-
stances: concentration in preferred living areas; and the capa-
bility of Man to satisfy his civilizing demands in steadily in-
creasing measure, according to his technical capabilities. En-
croachments on the environment are direct and indirect: direc
through producing the necessary dwelling, cultural, and civic
areas; and indirect through waste products, and especially
through those of the technological civilization Man has
produced. The greater demand for soil, removal of vegetation,
the use of fertilizers and insecticides, and the depletion of soil
nutrients in relation to unbalancing the original state are con-
sidered. Harmful pollutants stemming from industry and the
increased use of motor vehicles, including sulfur dioxide and
fluorine compounds are reviewed. Photooxidation products
such as ozone, the main components of smog, carbon dioxide,
and their effects on plants are also reviewed.

CLINICAL ASPECTS OF FLUOROSIS IN HORSES. J. Am.

Vet. Med. Assoc., 1S8(2):167-174, Jan. 15, 1971. 12 refs.

Clinical aspects of fluorosis in horses are described. Horses
grazing in areas where cattle and sheep had developed severe
fluorosis were examined clinically. Major fluorotic lesions oc-
curred only when the horses ingested excessive amounts of
fluorine during the period of tooth formation. Dental fluorosis
with excessive premolar and molar abrasions, and
osteofluorotic lesions, such as porosis, sclerosis, hyperostosis,
osteophytosis, and malacia, were observed. Fluorosis was due
to the ingestion of vegetation contaminated with airborne par-
ticulates and gaseous affluents high in fluorine. Therapy is
described.

NATURE, EXTENT, AND VARIATION OF PLANT
RESPONSE TO AIR POLLUTANTS. Advan. Agronomy, vol.

23:111-145, 1971. 154 refs.

Nature, extent, and variations of plant response to air pollu-
tants are reviewed. The most common phytotoxic air pollu-
tants in the USA are ozone, sulfur dioxide, fluorides, perox-
yacl nitrates, ethylene, nitrogen dioxide, pesticides, chlorine,
heavy metals, acid aerosols, ammonia, aldehydes, hydrogen
chloride, hydrogen sulfide, and particulates, such as cement
dust. Ozone and SO₂ are widely distributed. In the USA,
ozone seems to be causing more plant damage than any other

air pollutant, but on a worldwide basis, SO₂ is more injurious than ozone. Air pollution problems have increased because of multiple sources and mixtures of pollutants. There is increased concern about chronic injury and reduced growth attributed to air pollutants, such as photochemical oxidants and sulfur oxides. Ozone causes small necrotic spots on the upper surface of the leaves, PANs induce undersurface leaf injury in the form of glazing, silvering or bronzing, and SO₂ exerts usually bifacial and interveinal attack with relatively large collapsed areas surrounding the larger green veins. Fluorides cause injury of leaf tip and margins. The effects of nitrogen dioxide resemble those of SO₂ in acute incident. Response to pollutants may be altered by many factors, such as genetic, environmental, cultural conditions, time-concentration relationships, and the presence of mixtures of pollutants. The identification and use of tolerant varieties, including resistant varieties developed by breeding, will help reduce losses and assure maximum agricultural production.

Shaw, W. C., W. W. Hech, and H. E. Heggstad
ROLE OF AGRICULTURE IN AIR POLLUTION AND CONTROL. Options Mediterr., no. 9:63-69, Oct. 1971. 12 refs. (Presented at the Agricultural Research Institute, National Academy of Sciences, Annual Meeting, 19th, Arlington, Va., Oct. 13-14, 1970.)

General problems of air pollution-afflicted damages to agriculture are described. The most important toxic air pollutants that originate primarily from nonagricultural sources and that affect agriculture include ozone, sulfur dioxide, peroxyacyl nitrates and other oxidants, ethylene and other hydrocarbons, fluoride, chlorine, hydrogen chloride, nitrogen oxides, heavy metals, particulates, acid aerosols, ammonia, aldehydes, hydrogen sulfide, carbon monoxide, pesticide and other chemical wastes, and radioactive chemicals. Annual damage to agricultural crops and livestock is estimated at more than 0.5 billion dollars, and it is increasing each year. Current agricultural research is concerned with the development of chemical and bioassay techniques to detect the kinds, and measure the quantities of chemical pollutants in the air. Effects of pollutants on plants and animals are being determined. Chemical air pollutants that are being investigated include ozone, sulfur compounds, ethylene, peroxyacyl nitrates, fluorides, nitrogen oxides, chlorine, and automobile exhaust mixtures. Sites of action, mechanisms of action, and the fate of pollutants in plants, animals, and the environment are discussed. Current emphasis is also on research to determine crop yield and quality reductions under field conditions, to understand the influence of climatic, edaphic, and genetic factors as they relate to plant and animal susceptibility, and to develop biological indicators of pollutants. The effects of airborne herbicides, defoliants, desiccants, growth modifiers, nematocides, fungicides, and insecticides on plant growth are also being studied.

STUDIES ON THE MEASUREMENT METHODS OF DAMAGE TO AGRICULTURAL PRODUCE BY AIR POLLUTION. (Taiki osen ni yoru norin sakumotsu higai no sokutei hoho ni kansuru kenkyu). Text in Japanese. Nogyo Gijutsu Kenkyusho Hokoku A, 1972:56-60, Sept. 1972. (Presented at the
<xref image="2000WVM3.TIF|V3|2006:09:28:01:41:06.00|120071|0"> image: </xref>

Conference on Agriculture, Forestry, and Marine Product Technology, Japan, 1972.)

Studies were made on the effects of air pollution on plants and agricultural produce, starting in 1968. In 1971, the research programs included the relationship between the absorption of toxic gases in plant leaves and the wind velocity, sunshine, and the conditions of the leaf surfaces; the distribution of sulfur in the plant which has absorbed sulfur dioxide; the morphological analysis by equipment of the damaged plants and radiochemical studies; the effects of sulfur dioxide on the growth of vegetables, fruit, and plants; the sulfur content in the leaves; the explanation of the damage mechanism and metabolic changes of plants exposed to SO₂; the analysis of plant damages by hydrogen fluoride and ozone and the distribution of these pollutants in the plants. The seasonal fluctuation of susceptibility of plants to pollutants varied by various species. The susceptibility of certain kinds of adhesive mosses proved useful in measuring the degree of air pollution. The distribution pattern of the moss proliferation throughout city was used as an indicator of SO₂ pollution, and a map was formulated. The plants do not respond to automotive exhaust gases as clearly as they do to SO₂.

INFLUENCE OF AIR POLLUTION WITH FLUORIDE ON

SERICULTURE. (Fukkabutsu ni yoru talki o sen no yosan ni oyobosu eikyo). Text in Japanese. Nihon Sanshigaku Zasshi (J. Sericult. Sci. Japan), 41(4):316-322, Aug. 1972. 86 refs.

The effects of fluoride on mulberry leaves and silkworms are reviewed. Fluorine emission sources are discussed. The damage symptoms of mulberry plants vary by degrees, but main characteristics include tip burn, chlorosis of leaves from the edges toward the center, withering, warping, and dropping of leaves. Mottling, banding, and the appearance of shininess or a white powder-like substances are some other symptoms. The normal F content in mulberry leaves is 10-20 ppm. When exposed in 1.5 ppb hydrogen fluoride for 118 hr, no visual damage appears; but further exposure for 212.6 hr will cause visual damages. For a slow accumulation of F, the leaves show a relatively high tolerance, and the F content in the leaves can be as high as 273 ppm when the damages begin to show. When exposed to 5 ppb gas for 40.6 hr, visual damages appear, and the F content can be as high as 213 ppm. A vast variety of damages and concentrations are reported. Silkworms can be damaged either by the consumption of high concentrations of the F in mulberry leaves, or by accumulation of F by consumption of low concentrations of F over a long period. The damage mechanism is not clear, but F seems to suppress the enzyme function and disrupt the respiration of the body system. An acute poisoning usually causes inactivity and death. Chronic effects can delay the growth of the silkworm, or cause lack of sleep, softening of the body, decrease of weight, formation of knots, black mottles, or virus. The tolerance of silkworms for F is usually in the range of 24 to 40 ppm (in dry mulberry leaves).

INJURY TO PLANTS EXPOSED TO FLUORIDES. (Fukkabutsu ni yoru shokubutsu higai to sono jittai).

Text in Japanese. Kogai to Taisaku (J. Pollution Control), 9(4):331-338, April 1973. 6 refs.

Fluoride emission sources, emission standards, plant damage, plant resistance, damage factors, damage characteristics and mechanisms, the evaluation method for F damage, and the control or attenuation method for F damage are discussed. Plant leaves which absorbed fluoride generally turn yellow on the tips and around the edges; when the roots absorb F, a slighter degree of discoloration and withering occur. Silicicolous plants such as rice and wheat form a compound of silicon and F

which is relatively insoluble, and calcicolous plants such as soybeans and colza seed form a compound of calcium and F which is also insoluble. These compounds stay in fixed locations. Toxic hydrogen fluoride solutions destroy the cell system and do not transfer to other locations. They usually damage the metabolism; evaporation of water increases temporarily and then decreases; chlorosis occurs and further develops into necrosis; respiration increases temporarily but gradually decreases; the assimilation of carbon and nitrogen decreases; and the balances of various elements are completely destroyed. The control or attenuation methods for F damages are: the use of an evaporation control agent such as water, lime emulsion, or OED; cultivation of other species with a greater resistance against F damages; improvements of fertilizer and care, avoiding nitrogen fertilizers and replacing them with potassium fertilizers; and planting a buffer area with smoke-resistant trees such as camellia, acacia, or phoenix trees.

FLUORINE CONCENTRATION IN ENVIRONMENTAL SAMPLES MEASURED BY IRRADIATION SYSTEM. (Kokaku hanno-ho ni yoru kankyo shiryo-chu no fussoryo). Text in Japanese. Kankyo Hoken Reporto (Environ. Health Rept.), no. 8:29-30, 1972.

Fluorine in plants and soil can be measured up to 0.005 ppm by an irradiation method with a + or - 8% precision rate. Fluorine is trapped with sodium hydroxide-sodium oxide, and an anion exchange method is used for pretreatment. Then a F(19)/F(18) reaction is used and the radioactivity of F(18) is measured by a gamma spectrometer.

50505

Yatazawa, M. and S. Ono
QUANTITATIVE MEASUREMENT OF FLUORINE BY IRRADIATION SYSTEM. (Kokaku hanno ni yoru fusso no teiryoho). Text in Japanese. Kankyo Hoken Reporto (Environ. Health Rept.), no. 8:7-8, Jan. 1972.

An irradiation analysis of fluorine in plants and soils is described. The detection limits were 0.41 micrograms carbon(11), 0.17 micrograms nickel(13), 0.17 micrograms oxygen(15), 43 micrograms sodium(22), 0.069 micrograms chlorine(34), and 0.003 micrograms fluorine(18). The detection limit of chlorine is low compared to fluorine. Since chlorine can interfere with fluorine, isolation by gamma irradiation is required. This method can be used to determine small quantities of fluorine.

AUTOMATIC DETERMINATION OF LEAD, ZINC, CADMIUM AND COPPER IN PLANT MATERIALS BY STRIPPING

VOLTAMMETRY. (Automatische Bestimmung von Blei, Zink, Cadmium und Kupfer in Pflanzenmaterial durch Inversvoltammetrie). Text in German. Z. Anal. Chem., 264(2): 165-167, 1973. 4 refs. (Presented at the Tagung Euroanalysis I, Heidelberg, West Germany, Aug. 8-Sept. 1, 1972.)

During the automatic determination of lead, zinc, cadmium, and fluoride in plants by stripping voltammetry, the ashed plant material is fused with sodium hydroxide. Afterwards hydrochloric acid and citric acid is added, and a pH value of 3.7 is adjusted. For the determination of copper, the sample is acidified with perchloric and citric acid. Then a pH value of 2.7 is adjusted. It is possible to carry out several determinations of lead in plant materials with only one drop of mercury. The limit of detection is 1-3 ppm.

ANALYSIS OF THE CONCENTRATION OF TRACE SUBSTANCES IN PLANTS IN THE FIELD OF ENVIRONMENTAL POLLUTION.

(Die Bewertung des Spurengehaltes der Pflanzen auf dem Gebiet des Umweltschutzes). Text in German. Proc. Simp. Int. Agrochim. Fitonutriz. Oligominerale, Punta Ala, Italy, 1972, p. 283-288. 5 refs. (Oct. 2-6.)

Plants and soil samples taken in the vicinity of metallurgical plants were analyzed by spectrophotometry and atomic absorption. The iron concentration in spruce and pine needles from the vicinity of a steel plant ranged from 200 to 700 mg Fe/kg dry substance. More than 40% of the examined samples had an iron concentration of 400 mg/kg or higher. The iron concentration in needle samples from a non-industrial area ranged from 65 to 190 mg Fe/kg dry substance. Iron and manganese concentrations of needle samples from the vicinity of a steel plant were considerably higher than from a non-industrial environment. The same is true for sulfur and fluorine. The lead concentration of pine needles from non-industrial area measured 3 mg Pb/kg. In the vicinity of a lead plant concentrations of up to 1100 mg Pb/kg were measured. The lead concentration of hay measured 1700 mg Pb/kg, in non-industrial areas the average concentration measured was 5.26 mg/kg. Other examples are discussed concerning zinc.

ATMOSPHERIC POLLUTION AND ITS EFFECTS ON

VEGETATION. (La pollution atmospherique et ses effets sur la vegetation). Ministere de la Protection de la Nature et de l'Environnement (Quebec) and Quebec Univ., Trois-Rivieres (Quebec), Joint Pub., 1972. 5 refs. Translated from French, Sip.

The effect of air pollution on vegetation and the air quality in the Canadian industrial regions of Shawinigan, Grand-Mere, Trois-Rivieres, and Cap-de-la-Madeleine were investigated. The major emissions in the areas were traced to their sources, and the industrial processes and controls were examined. Pollutants of greatest interest due to their toxic effects on vegetation were sulfur dioxide, fluorine and chlorine compounds, particulates, and hydrogen fluoride. The general effects of the pollutants on vegetation were reviewed, and damages to vegetation characteristic of each region were studied with respect to plants affected, sensitivity ratings, and symptoms of damage. The Shawinigan area was the most affected by air pollution, followed by Cap-de-la-Madeleine, Trois-Rivieres, and Grand-Mere. The major symptoms, detected in various degrees on the leaves and needles of trees, included necrosis, defoliation, burns, chlorosis, and spotting.

Garrec, J. P., R. Bligny, A. Bisch, and A. Fourcy
ACCURATE FLUORIDE DETERMINATIONS
THROUGHOUT POLLUTED FIR NEEDLES. Fluoride,
6(2):73-78, April 1973. 10 refs.

Fluoride analyses were made of the surface tissues of polluted needles of fir trees by using microanalysis by proton nuclear reaction. Two distinct peaks of fluoride accumulation were established. The first in the extreme tip of the needle is necrotic area, and the second in the narrow strip which separates the healthy from the injured tissue. The magnitude of these two accumulations and the distribution of fluoride throughout the needle is related to the age of the needle. The amounts of fluoride differ depending upon which side of the needle is measured, the upper surface takes up more fluoride than the lower one. (Author abstract modified)

Treshow, Michael
AIR POLLUTION AS AN ECOLOGICAL FACTOR. Clean
Air, 6(3):41-43, Aug. 1972. (Presented at the International Clean
Air Conference, 1972.)

The air environment is vital to the health and welfare of man and to the health of plants. Thousands of acres of forest watersheds in Europe and North America have been blighted by sulfur dioxide emissions from smelters and power plants. Fluorides, particularly from aluminum plants and the phosphate industry, have also been destructive to natural areas. The current threat to forests and crops alike is mainly from automobile exhausts. When acted on by ultraviolet light, the emissions react photochemically to form ozone and peroxyacetyl nitrate which are highly toxic to many plant species. In California, more than 150,000 acres of Ponderosa pine have been damaged by oxidants, while herbs that protect land from erosion and are vital to maintaining the nutrient balance of the soil may have been killed off. Desert ecosystems may also be sensitive to the pollutants emitted by high coal-burning power plants being built in the Southwest. If society is willing to take action and pay the price, the technology for reducing industrial emissions to harmless levels is available. The standards set

<xref image="2000WVM5.TIF|V3|2006:09:28:01:41:12.00|113551|0"> image: </xref>

and attainable are adequate to protect man and plants. However, two problems persist: control of emissions from transportation sources, and compelling the use of known control technology on a world-wide basis.

Cormis, L. de

ATMOSPHERIC POLLUTION AND VEGETATION. (Zanieczenie atmosfery a roslinnosc). Air Conserv. (English translation from Polish of: Ochrona Powietrza), 4(5):22-31, 1970.

(Presented at the French-Polish Symposium on Air Pollution Control, Paris, France, Nov. 17-21, 1969.) NTIS: TT 70-P55124/5

The effects of sulfur dioxide and fluorine compounds on vegetation were studied in two regions characterized by different topographies and climatic conditions. The relative susceptibilities of various plant species to SO₂ were investigated in a spacious valley, with little or no wind and a high frequency of fog, where the major emission source was coal and heavy oil combustion and natural gas refining. The effects of SO₂ were characterized by interveinal necrosis, blotches, and defoliation. The effects of fluorine compounds, particularly hydrogen fluoride, were observed in narrow valleys with shifting wind patterns where aluminum smelters were the major source of pollution. The essential feature of fluorine action was the progressive development of the necrotic zone. Plant indicators were discussed.

Carlson, Clinton E.

FLUORIDE IN VEGETATION NEAR A PHOSPHOROUS MANUFACTURING PLANT IN THE VICINITY OF BUTTE,

MONTANA. Insect Dis. Rep., no. 70-3:1-5, Feb. 1973. 2 refs.

The fluoride content of vegetation at seven sites near a Butte, Montana, phosphate facility was determined with a specific ion probe. Amounts ranged from 9.4 ppm in Douglas fir foliage to 74.2 ppm in crested wheatgrass foliage. All but two analyses showed more than 10 ppm fluoride, the control level established at Columbia Falls. The State standard of 35 ppm for fluoride in plants was exceeded at three sites within one mile of the facility. No visible symptoms of fluoride injury were observed on coniferous foliage.

51526

Bohn, Hmch L.

SOIL ABSORPTION OF AIR POLLUTANTS. J. Environ.

Quality, 1(4):372-377, Oct.-Dec. 1972. 79 refs.

The mechanism and rates of the absorption of various air pollutants by soil are reviewed with respect to particulate air pollutants, including nickel, cadmium, lead, arsenic, copper, beryllium, zinc, and mercury; and gaseous air pollutants, including sulfur dioxide, carbon monoxide, nitrogen oxides, oxidants (chlorine, ozone, and peroxyacetyl nitrate), hydrogen sulfide, mercaptans, aldehydes, hydrocarbons, fluorine compounds, phosphorus compounds, and acidic gases and mists (hydrogen chloride, sulfuric acid, phosphoric acid, nitric acid, and hydrogen fluoride). Soils absorb organic gases faster and in greater amounts with increasing molecular weight and increasing number of nitrogen, phosphate, oxygen, and sulfur groups in the compound. The absorption of lower molecular weight and less-substituted organic gases depends on the buildup of an appropriate microbial population. The absorption of inorganic air pollutants is primarily by chemical and physical means and involves oxidation and other chemical reactions. (Author abstract modified)

Kanagawa Prefecture Agricultural Experiment Station (Japan)

COOPERATIVE STUDIES ON THE EFFECTS OF AIR POL-

LUTANTS ON GARDEN PLANTS (I). (Taiki osen busshitsu ga

engei sakumotsu nado ni kansuru kenkyu seisekisho (I)). Text in Japanese. 136p., Feb. 1972.

Cooperative studies were conducted on the general effect of air pollution throughout Kanagawa Prefecture. Studies included periodical measurement of pollutants, plant damage examinations, evaluations of plant indicators, and measurement of sulfur, heavy metals, and fluorine. Gingko and pine were chosen as general plant indicators, and as area representatives, mulberry leaves from the north, pear and grape leaves from the center, and orange leaves from the western part of the Prefecture were selected. Gingko and pine samplings in Kawasaki were extremely unhealthy in appearance, compared to those from suburban Kawasaki, and the northern, central, western, and coastal areas. The S content in leaves was extremely high in Kawasaki, and a particularly high ratio of non-soluble S was noted. In all categories of metals, samples from Kawasaki had the highest content, but other than that, generally leaves from the western part of the Prefecture had high counts of iron, zinc, copper, nickel, lead, and manganese. The average fluorine content in leaves was 135 ppm, 22 ppm minimum, and 1653 ppm maximum. The differences by locations and tree specimens were extremely high. If the F index of leaves in the industrial area is considered to be 100, those in commercial, residential, and agricultural areas were less than 20-30. There was a correlation of 0.711 between F and S content of gingko trees. There was an extremely close correlation between the F content of leaves and the amount of settling particles and sulfur oxides concentration in the air. The F content in the leaves increased with the season; at the peak, it reached three to eleven times the amount in new leaves in May.

Gerdes, Raymond Allen
EFFECT OF ATMOSPHERIC HYDROGEN FLUORIDE
UPON DROSOPHILA MELANOGASTER. Texas Agricultural
and Mechanical Univ., College Station, Dept. of Genetics, Thesis
(Ph.D.), Ann Arbor, Mich., Univ. Microfilms, Inc., Aug. 1967,
57p. 33 refs.

The effects of gaseous hydrogen fluoride on *Drosophila melanogaster* (flies) were investigated. The populations were exposed to different concentrations of HF for various treatment periods, and the effects on fecundity, hatchability, fertility, longevity, and generation time were studied. All of the parameters except generation time responded significantly to the HF treatment, with a range of responses from lethality to relatively no effect. The lethal concentration varied with strains but was very low for all the strains. In sublethal concentrations, the major treatment response was a function of treatment duration. Sublethal concentrations (less than 7.5% HF) caused measurable deleterious effects in the traits exhibited in the two strains, Oregon-r and yw, at the treatment levels and durations studied. Inst. for Policy Sciences (Japan)
PROGRESS TOWARD AN ECOLOGY SYSTEM DESIGNED
TO HARMONIZE INDUSTRIAL ACTIVITIES AND NATURE.
(Sangyo katsudo to shizen to no chowa no tame no ekoroji shisutemu e no sekkin). Text in Japanese. 509p., March 1972. 47 refs.
<xref image="2000WVM6.TIF|V3|2006:09:28:01:41:16.00|112837|0"> image: </xref>

Sulfur dioxide emitted mostly from factories is believed to be responsible for most of the plant injuries. Although there are differences of the resistances toward this particular gas, most of the plants die in a few hours after being exposed to 0.4 to several ppm of sulfur dioxide. The injured plants generally show gray or brown spots on veins of leaves which eventually fall. The SO₂, when washed by rain into soil, reacts with calcium and consumes the nutrients. Carbon monoxide and hydrocarbons of low molecular weight cause the destruction of chlorophyll and the abnormal falling of leaves. Other air pollutants that inhibit the growth and damage the plants include nitrogen oxides, smog, hydrogen fluoride, chlorine, hydrogen chloride, and airborne particulates.

FLUORINE CONTENT OF PLANTS AND ANIMALS.

(Doshokubutsu-chu no fusso ni (suite - shizen to osen). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 9(6):613-619, June 1973. 19 refs.

The fluoride content in the air can be measured by plant indicators, either by the extent of plant damage or by the cumulative fluoride content in the plant. The latter seems to be more effective when dealing with fluorine in the air, since a considerable amount of F accumulation in the plant sometimes does not manifest itself in damage. Leaves of gladioli are often used as indicators, but experiments have shown that the leaves of wild iris and flags are just as susceptible to F in the air. The pine and cedar needles and tulip and orange leaves are also sensitive indicators. The measurements of soluble fluorine in the air were taken for the past 5 years by the lime treated filter paper method and a dust meter in seven polluted areas, and the cumulative F content in the leaves of iris in these areas were compared with iris leaves in control areas. By the characteristic translocation of F, the tips and edges of leaves had much higher F content than other parts of the same plant. Approximately 1/3 of the measurements in those parts could be considered as a pollution index. The leaves taken from the most polluted areas showed approximately 80 times over the leaves from control areas in dry weight. Even 1/3 of the actual measurements was 100 ppm in dry weight, 30 ppm in raw weight. The produce in air polluted area has 5-10 ppm F content in polished rice and green vegetables. If the daily consumption of rice is 308 g/capita, 3.08 mg of F is taken daily into the human body.

Maeno, Michio

AIR POLLUTION AND PLANT COMMUNITY. (Taiki osen to shokubutsu gunraku). Text in Japanese. In: Data on Pollution, No. 34: Environmental Protection Bureau, Yokohama City?Special Series City Environment and Biological Index. Yokohama Municipal Office (Japan), Environmental Protection Bureau, p. 21-28, April 1972.

The threshold of plant damages by pollutants such as ozone, peroxyacetyl nitrate, nitrogen dioxide, sulfur dioxide, hydrogen fluoride, chlorine, and ethylene, the general damage symptoms, the location of damages on plants, and vulnerable parts in plant structure are discussed and presented in a table. The external appearance of plant damage can be used as an index for air pollution. With some fluctuation by tree types, trees such as zelkova, ginkgo, and plane follow certain curves formed by damage indexes and the distances from the industrial areas. Also, the relationship between sulfur oxide concentration in the air and the sulfur trioxide content in the leaves of ginkgo forms a linear graphic relationship. The effect of SO₂ on the general deterioration of trees and the sulfur content of tree leaves seem to have a certain relationship. Most of SO₂ gas absorbed through the leaves into plants is accumulated as inorganic sulfuric acid ion, and very small amount

changes into organic sulfur. The degree of sulfur degradation in plants are clearly different by the geographical locations of the plants, and in heavily polluted areas, the sulfur content in ginkgo leaves increase as time passes and reaches as high as 1.4% before the leaves drop. The portion that increases is soluble sulfur, and insoluble organic sulfur seems to remain at the same level. There is not much geographical difference in the amount of organic sulfur. Therefore, as an air pollution indicator, soluble sulfur, or the ratio of soluble sulfur to the total sulfur content in the tree should be considered.

Fujiwara, Takashi

DAMAGE TO PLANTS BY COMPLEX POLLUTION OF THE ATMOSPHERE. (Taiki no fukugo oxen ni yoru shokubutsu no higai). Text in Japanese. Shokubutsu Boeki (Plant Prot.), 27(6):233-236, June 1973. 19 refs.

Plant damage caused by secondary pollutants such as peroxyacetyl nitrate or ozone are discussed. Several pollutants can cause a different effect on plants than an individual pollutant acting alone, these include sulfur dioxide plus ozone, SO₂ plus nitrogen dioxide, NO₂ plus O₃, SO₂ and NO₂ plus O₃, PAN or SO₂ plus fluorides, O₃ plus fluorides, and hydrocarbons plus SO₂, NO₂, or O₃. There are additive, more than additive, or less than additive effects of coexistence. The specific effects of the synergistic action of two or more pollutants include necrosis and discoloration. In the case of SO₂ acting in conjunction with O₃, the lowest concentrations causing damage are 0.12/0, 0.1/0.01, and 0.05/0.05 ppm/ppm on green peas; no damage appeared at 0.1/less than 0.2; slight damage occurred at 0.2/0.1-0.2 ppm/ppm; and the addition of more O₃ gave no more damage. The effect of SO₂ and O₃ on radishes was additive or less than additive; the effect of SO₂ and O₃ on Satsuma oranges was additive.

THE RESPONSE OF POTATO (SOLANUM TUBEROSUM)

TUBER PHOSPHOGLUCOMUTASE TO FLUORIDE.

Biochem. Physiol, Pflanzen, 164(3):228-233, 1973. 12 refs.

Most research on the effects of fluoride ions in plants has been concerned with aerial parts. For observation of the response to underground tissues, potato tubers were fluoridated. At the same time in vitro studies on the effect of fluoride on phosphoglucomutase (PGM) from untreated tubers were made. Protein content was measured by Eaddell's method. Najjar's procedure was modified for enzyme activity tests. Phosphoglucomutase was partially purified from potato tubers and was relatively insensitive to the presence of fluoride ions in vitro. The enzyme was activated by magnesium(++) but not by manganese(++) ions, and was not inhibited by fluoride(-) in the presence of Mn(++). The enzyme was relatively insensitive to F(-) when Mg(++) was present, but the amount of inhibition was dependent on the level of Mg(++) and, more importantly, on the order of mixing the reagents prior to the assays. Peterson, P. J.

UNUSUAL ACCUMULATIONS OF ELEMENTS BY PLANTS

AND ANIMALS. Sci. Prog., Oxf., S9(236):50S-526, Winter 1971.

79 refs.

<xref image="2000WVM7.TIF|V3|2006:09:28:01:41:18.00|120567|0"> image: </xref>

The accumulation of certain elements to very high levels by plants and other organisms is outlined. In higher plants, the ability to accumulate elements and to survive on soils containing toxic quantities of various elements occurs sporadically throughout different species, but in lower plants a higher concentration of some elements is typical of a particular order. Elements accumulated by some higher plants include copper, strontium, calcium, zinc, rare earths (the hickory tree), aluminum, silicon, and nickel. Among lower plants, algae accumulate iodine and bromine dust; fungi, selenium and vanadium; mosses, copper, boron, and vanadium; lichens, yttrium, gallium, tin, and lead; horsetails, silicon and zinc; lycopods, aluminum; and ferns, yttrium and uranium. Copper, cadmium, arsenic, barium, and fluoride are accumulated by certain marine organisms. Mammalian accumulator tissues exist for many elements including iodine, titanium, aluminum, vanadium, zirconium, and selenium. Some of the mechanisms which may enable an organism to survive an accumulated element are: the toxic element is excluded or partially excluded from the cells; the element is confined to the cell wall; the element enters the cell and is metabolized to possibly inactive components or by binding with another compound.

MONITORING OF AIR POLLUTION USING PLANTS AS MONITORS. (Shokubutsu o shiyo to shita taiki o sen no kanshi). Text in Japanese. Shokubutsu Boeki (Plant Prot.), 27(6):259-260, 1973.

Plants can be used to monitor air pollution by measuring the characteristic visible damage and its degree, the defoliation and discoloration, the retention of pollutants by the leaf, and the effects on reproduction. Indicator plants should be very susceptible to one specific pollutant or equally susceptible to every pollutant by showing specified symptoms. Such plants should also constantly develop new leaves and be resistant to diseases and insects. Alfalfa and buckwheat are used to monitor sulfur dioxide. Pinus densiflora is susceptible to SO₂. Gladioli and turnips are susceptible to hydrogen fluoride. Apricot, plum, and grape are weak indicators of HF. Tobacco and morning glory can be used to measure ozone. Petunia shows specific damage due to peroxyacetyl nitrate. Buckwheat and tomatoes react to ethylene and propylene as if they were exposed to growth hormones at levels of 0.05 and 0.1 ppm, respectively. Measuring pollutant concentrations in leaves is used to measure chronic effects of low concentrations of pollutants, such as HF in citrus leaves. Sulfur is naturally contained in normal plants and the content varies with the season, however, S content in citrus leaves is unusually high when the plants are grown in a SO₂-rich atmosphere.

Bohne, H.

FLUORIDES AND SULFUR DIOXIDES AS CAUSES OF PLANT DAMAGE. Fluoride, 3(3):137-142, July 1970. 8 refs. Fluoride and sulfur trioxide levels were determined in three polluted industrial areas where the two pollutants had damaged vegetation. The appearance of the leaves was typical of fluoride injury with no indication of toxicity by sulfur dioxide. Chemical analyses of fluoride and SO_x contents of the injured plants supported these findings. Fluoride levels in gladioli ranged within 3.4-8.7 mg% whereas SO₃ levels ranged within 0.77-1.15%, thus showing that the greatest damage from combustion products was caused by fluoride compounds, primarily hydrogen fluoride. (Author summary modified)

Wheeler, Garland Laurin

THE EFFECTS OF FLUORINE ON THE CYCLING OF CALCIUM, MAGNESIUM, AND POTASSIUM IN PINE PLANTATIONS OF EASTERN NORTH CAROLINA. North Carolina State Univ., Raleigh, Dept. of Botany, Thesis (Ph.D.), Ann Ar-

bor, Mich., Univ. Microfilms, Inc., 1972, 72p. 66 refs.
The effect of fluorine emissions from ore processing plants in pine ecosystems, with respect to the points of accumulation and the effects on the cycling rates of calcium, magnesium, and potassium, was investigated in North Carolina pine plantations. The only visible damage occurred during the late winter and early spring and was characterized by a visible browning or necrosis of needles. Fluorine was associated with an increase in the return rate of Ca and K through leaf leaching and of all three nutrients, Ca, K, and Mg, by increasing the amount of litterfall. The Ca content of the litterfall increased with increasing F content. There was no detectable relationship between F or the three nutrients and net primary production. The sites of accumulation of F were in the needles, litter, and soil. The trees accumulated the greatest amount of Ca, followed by K and Mg in that order. (Author summary modified)

Fujii, Shintaro

THE STATUS QUO OF PLANT DAMAGE BY AIR POLLUTION IN OKAYAMA PREFECTURE. (Okayama-ken ni okeru taiki osen ni yoru Shokubutsu higai no genjo). Text in Japanese. Shokubutsu Boeki (Plant Prot.), 27(6):249-2S2, 1973. Plant damage in Okayama Prefecture includes grape damage caused by fluorine from a firebrick manufacturing factory and vegetable and fruit tree damage due to oxidants such as ozone. By regulating hydrogen fluoride concentrations to less than 5 ppb/hr, grape damage was eliminated. Ozone damage (withering) has occurred on taro, Japanese leek, and Japanese radish. Experimental exposure of plants to 0.4-0.5 ppm for 1.5-6.0 hr, 0.25-0.3 ppm for 4-7 hr, and 0.25 ppm of O₃ plus 0.1 ppm of sulfur dioxide for 2-2.5 hr caused deep green spots on taro, which developed into white or grey spots on the leaves. Japanese leeks had whitening of leaf tops when exposed to 0.5 ppm of O₃ for 2 hr, 0.25-0.3 ppm for 5-6 hr, 0.1 ppm for 14 hr, and 0.25 ppm of O₃ plus 0.1 ppm of SO₂ for 4.5 hr. Recently other plants have suffered damage such as insufficient growth, lack of fruit, defoliation, and dropping of fruit, which suggest damage due to ethylene. Sulfur dioxide is suspected of causing tip-withering of mat grass in the southern part of Okayama Prefecture.

PROBLEMS AND TASKS OF DIAGNOSIS OF FOREST INJURIES CAUSED BY AIR POLLUTION. (Probleme und Aufgaben der Diagnostik der durch Luftverunreinigung verursachten Waldschaeden). Text in German. Preprint, International Union Forest Research Organization, 10p., 1972. (Presented at the International Union Forest Research Organization Congress, Sopron, Hungary, Oct. 9-14, 1972.)
The tasks of diagnosing injuries from air pollution involve the determination of whether the observed injury does indeed stem from air pollution and which emission component caused the injury. The problems of diagnosis are manifold due to the different reactions of the plants to the various pollutants or to the absence of reactions. A brief review of direct and indirect effects of air pollutants is given. In cases of very mixed pollu-
<xref image="2000WVM8.TIF|V3|2006:09:28:01:41:22.00|118960|0"> image: </xref>

tion coming from many different sources, the decisive factors can be determined only through greenhouse exposure experiments. Leaf and needle analyses are valuable tools for diagnosis. Anatomic criteria, growth retardation, and harvest losses are not specific enough. Aerial photography also lacks specificity. Doubts still exist concerning the specific sensitivity of indicator plants. Some experts place the *Medicago saliva* plant among the sulfur dioxide indicator plants claiming that this plant is rather resistant to fluorine, while others group it with the fluorine indicator plants on the grounds that this plant reacts to very small concentrations of fluorine with minor but visible injuries. Widespread agreement seems to exist that lilies are particularly sensitive for fluorine, papilionaceae for SO₂. Lichens and mosses are obviously indicators of the general air pollution. The problem of injuries by indirect emissions which may spread over thousands of kilometers is discussed. For instance, sulfuric acid formed through oxidation of SO₂ and subsequent water intake renders strongly acid precipitation which particularly affects soils with a weak buffering capacity, and eventually all vegetation growing in such soils.

Carlson, C. E.

FLUORIDE POLLUTION IN MONTANA. *Fluoride*, 6(3): 127-137, July 1973. 6 refs.

An intensive study of the effect of airborne fluorides on vegetation was undertaken in 1970 in the vicinity of an aluminum production plant in northwestern Montana. Fluorides greater than control levels (10 ppm) were found in vegetation over a region of 214,000 acres, and visual fluoride injury to conifers occurred in an area comprising 69,000 acres. Histological reactions characteristic of elevated fluoride levels occurred in conifer needle tissue, including hypertrophy of parenchymatous tissue. Forest insects were found to accumulate fluorides. Analyses of predaceous insects for fluoride indicated that fluorides are likely to be carried through the food chain. Even though the company reduced fluoride emissions by 67% between 1970 and 1971, data collected in 1971 indicated that vegetation in Glacier National Park, 7 air miles distant from the source, was still accumulating abnormal amounts of fluoride. THE AIR-POLLUTANTS WHICH CAUSE PLANT DAMAGE.

(Shokubutsu higai no genin to naru taiki osen busshitsu). Text in Japanese. *Shokubutsu Boeki (Plant Prot.)*, 27(6):220-223, June 1973. 5 refs.

Ozone and peroxyacetyl nitrate and its homologues cause oxidative damage to plants. Sulfur dioxide, formaldehyde, hydrogen sulfide, and carbon monoxide cause reductive damage. Hydrogen fluoride, silicon tetrafluoride, hydrogen chloride, sulfur trioxide, sulfuric acid mist, and hydrocyanic acid cause acidic attacks. Ammonia causes alkaline attacks. Ethylene, propylene, soots, smokes, dusts, metal, metals oxides, and other particulates also cause plant damage. Pollutants are classified according to order of toxicity as follows: strongly toxic substances causing symptoms as the ppb level such as fluorine, chlorine, and PAN; moderately toxic substances causing symptoms at ppm levels such as sulfur oxides and nitrogen oxides; and fairly toxic substances which cause symptoms at levels between tens and thousands of ppm such as aldehydes, HCl, NH₃, HCN, H₂S, and CO. Recently, damage due to the synergistic action of two pollutants has been increasing (such as SO₂-HF, SO₂-PAN, and SO₂-O₃). Origin, toxicity, and damage mechanism of major pollutants are discussed.

Gruender, H.-D.

STUDIES ON THE EFFECT OF FLUORINE EMISSION ON CATTLE. (Untersuchungen ueber die Fluorimmissionswirkungen auf Rinder). Text in German. Deut. Tieraerztl. Wochschr., 79(7): 147-ISO, 1972. 3 refs.

Studies on the effects of fluorine emissions on cattle in the nearby of industrial plants emitting fluorine compounds are reviewed. Dental fluorosis, bone fluorosis with such manifestations of exostosis or hyperostosis, reduction of the elasticity of the bones with increased susceptibility to fracture, and reduction of the food uptake are among the principal consequences of daily fluorine intakes exceeding the normal value by 5 to 10 times. The effect of administering aluminum salt mixtures with the feed or drinking water to lower fluoride resorption was studied. Damage due to fluorine in cattle can be reduced by special management and feeding techniques.

Carlson, Clinton E.

MONITORING FLUORIDE POLLUTION IN FLATHEAD NATIONAL FOREST AND CLACFFIR NATIONAL PARK. Forest Service, Missoula, Mont., Forest Insect and Disease Branch, 27p., 1971 (?). 4 refs. (The same information described in this paper also appears in Carlson, Clinton E. and Jerald E. Dewey, Environmental Pollution By Fluorides, Forest Service, Missoula, Mont., Forest Insect and Disease Branch 62p., Oct. 1971. 27 refs.)

Measurements of fluoride pollution made in 1971 in Flathead National Forest and Glacier National Park, caused by fluoride emissions from the Anaconda Aluminum Company at Columbia Falls, Montana, are presented and compared with a similar study completed in 1970. Chemical analysis of vegetation indicated average fluoride concentration from 4% less, in Glacier National Park, to 77% less, close to the aluminum plant, when compared to 1970 data. Injury indexes dropped an average 45.8%. The total polluted area was 59 sq mi (34,560 acres) less than in 1970, and injury was found on 84 sq mi (53,920 acres) less than in 1970. Analysis of insect tissue indicated insects are still accumulating excessive fluorides. Above-normal fluorides are still accumulating in vegetation up to 12 miles from the Glacier National Park.

Dewey, Jerald E.

ACCUMULATION OF FLUORIDES BY INSECTS NEAR AN EMISSION SOURCE IN WESTERN MONTANA. Environ. Entomol., 2(2): 179-182, April 1973. 12 refs.

Four major groups of insects such as pollinators, predators, foliage feeders, and cambial region feeders were collected near an aluminum reduction plant and analyzed for fluorides. Collections were made in June, August, and October in 1970 and in August 1971. From 58.0 to 585.0 ppm fluoride was found among the pollinators, from 6.1 to 170.0 ppm among the predators, from 21.3 to 255 ppm among the foliage feeders, and from 8.5 to 52.5 ppm among the cambial region feeders. Fluoride levels among the control insects sampled ranged from 3.5 to 16.5 ppm. The relative high fluoride levels in the 100% predatory insects indicate fluorides are either accumulated by respiration or are passed along the food chain. (Author abstract)

CHLOROSIS PRODUCED BY FLUORINE ON CITRUS IN

FLORIDA. *Science*, vol. 123:933-934, May 25, 1956. 6 refs.

A unique chlorotic leaf pattern on citrus trees in Florida that is attributed to fluorine is reported. The chlorosis was first noted in Polk County in April 1950 and was associated with a triple superphosphate manufacturing plant that recently opened. The polluting condition was corrected, but as new triple superphosphate plants opened, chlorosis increased. Florida pebble rock phosphate contains 2-4% fluorine which is released during the production in triple superphosphate. Chlorotic leaves from affected groves ranged in fluorine content from 370 ppm to as low as 48 ppm. Chlorotic citrus leaves were observed up to 6 miles away from the nearest plant, but the leaves were not abnormally high in fluorine content. It appears that fluorine causes leaf chlorosis and is then dissipated by translocation. Normal appearing leaves away from the affected area contained from 12 to 30 ppm fluorine. In 1955 sprays of aqueous acids were applied at concentrations 0.1N to 4 year old Ruby Red grapefruit trees located 20 miles from the nearest triple superphosphate plant. Seven sprays of 1 l of solution each were applied during a 2-month period, and an identical chlorotic leaf pattern emerged in the trees sprayed with hydrofluoric and fluosilicic acid. Citrus trees in California that contained up to 211 ppm fluorine did not develop chlorosis and may be the results of differences in climatic conditions, primarily the higher humidity in Florida.

FLUOROSIS AND ENVIRONMENTAL HYGIENE. (Fluorosc

und Umwelthygiene). Text in German. *Tieraerztl. Umsch.*,

27(1):7-8, 10-12, 14-16, 1972. 54 refs.

A review of fluorosis in animals, as reported in veterinary medical journals, is presented. Although ubiquitous in nature in micro-quantities, fluorine is present in considerable amounts in the vicinity of aluminum foundries and other industrial plants which are responsible for its emission. The fluorine is taken up by plants and transmitted to animals in their fodder or in their drinking water. It has been established (in Germany) that the ingestion by animals of more than 1.0 mg of fluoride/kg body weight/day could result in fluorosis, with more than 1.5 mg, fluorosis is sure to occur. In chronic fluorine poisoning the most marked clinical symptoms are changes in the teeth and bones and characteristic lameness. The chronic absorption of slight quantities of hydrofluoric acid from the air constitutes the greatest threat to plants; the danger of fluoride uptake through plant roots from the soil is less likely. The effect of the poison in all organisms is enhanced by external factors such as humidity and temperature of the air. With more effective supervision to avoid the introduction of fluorine into plants and into the air, and with proper supervision of animal fodder, it is possible to prevent toxic effects.

Japan Society of Air Pollution, Research Committee

PHOTOGRAPHS OF PLANTS DAMAGED BY AIR POLLU-

TION. (Taiki osen shokubutsu higai shashin-shu). Text in

Japanese. 229p., March 1973. 17 refs.

Plant damage by air pollutants are displayed in hundreds of photographs. Pollutants such as sulfur dioxide, nitrogen dioxide, and ozone cause necrosis between veins of leaves, hydrogen fluoride causes necrosis at the edges of leaves. Oxidants such as aldehydes and peroxyacetyl nitrate (PAN) cause the formation of silver-grey color on the backs of leaves. At lower pollutant concentrations, chlorosis of leaves or invisible injuries such as plant growth retardation occurs. Plants weak in resistance to SO₂ are alfalfa, barley, cotton, marvel-of-Peru, rhubarb, cosmos, and sweet pea; those strong in re-

sistance are musk melon, citrus fruits, celery, and chrysanthemum. The resistance to SO₂ increases as the humidity decreases. The threshold value of HF was several ppb using gladiolus as the indicator plant. The resistances of plants to air pollutants depend not only on the plant and pollutant, but also on meteorological conditions and planting conditions.

Sekiuchi, Teruo, Kaku Kikuchi, and Hikaru Sone
QUICK QUANTITATION OF FLUORINE IN PLANTS, REPORT 1. (Shokubutsu- taichu fusso no jinsoku teiryō ni tsuite (daiippo)). Text in Japanese. Miyagi-ken Kogai Gijutsu Senta Hokoku (Miyagi Prefect. Pollut. Contr. Tech. Center Rep.), no. 1:36-40, May 1973. 4 refs.

In the Ishimaki area where a phosphate fertilizer manufacturing plant has damaged the grape and pear harvest by its fluoride emission in 1970, measurement of fluoride in the leaves is one method of assessing the plant damage. Presently, the Association of Official Agricultural Chemists (AOAC) method is generally in use, but it is complicated and time consuming. A simplified wet combustion or dry combustion-steam distillation method was examined in the lab, and the results were reported. The preparation of reagent (60% perchloric acid, acetone, silver perchlorate), preparation of samplings, wet combustion, dry combustion, distillation, and photoelectric colorimetry application are described. The fluoride loss during the distillation process was negligible. The fluoride loss during reflux was within 10%. The fluoride recovery rate was best during the third hour of reflux; therefore all the measurements were taken in the third hour. The recovery rates by the AOAC method ranged between 86.5% and 94.5%; the proposed method ranged 88.1% and 93.8%. The measurements of the both methods agreed very well. But the proposed method has the following advantages: it is simple and there is no F loss in the process; the time for analysis is shortened by half; the time and trouble for the preparation of milk of lime is eliminated and pollution by the muffle furnace is eliminated. The proposed method may present a problem with samples containing small amount of F, but it is considered appropriated for F quantitation of damaged plants.

Knabe, W.
POLLUTION AND ITS THREAT TO FORESTS IN THE RUHR. (Inunissionsbelastung und immissionsgefahrdung der Waelder im ruhrgebiet). Mitt. Forst. Bundesuers., no. 97/1:53-87, 1972. 30 refs. Translated from German, 36p. (Presented at the International Symposium of Forest Fume Damage Experts, 7th, Essen, West Germany, Sept. 1970.)
The effects of air pollution on the forests in the industrial areas of the Ruhr district are discussed. No older spruce and pine stands of yield classes I-V are found in the center of the Ruhr district. The remaining stands are characterized by a lower needle age, sparse crowns, reduced growth in height and diameter, as well as increased amounts of dead wood resulting from the additional action of secondary parasites. Concentrations of sulfur, fluoride, chloride, and lead are found in needles and leaves. Acute damage to broadleaved species is concentrated in the vicinity of certain industrial plants which emit fluorine and chlorine compounds. The causes of chronic pollu-
<xref image="2000WVMA.TIF|V3|2006:09:28:01:41:28.00|125041|0"> image: </xref>

tion damage are primarily sulfur dioxide, halogen compounds, oxidizing agents, and dusts. The extent to which heavy metals are causes for damage has not been determined. The danger of pollution to conifers is estimated in North Rhine-Westphalia in part of the basis of the SO₂ measuring program, with SO₂ being considered to be both a harmful substance and an indicator for general air pollution. The risks of cultivating conifers is estimated in part according to the frequency with which certain mean values for the growth season are exceeded. In the central area, the growth season mean value of 0.08 mg SO₂/cu m was as a rule exceeded in at least 3 of 4 years, in the border area it was reached or exceeded as a rule at least in 1 year. POLLUTION AND ITS CIRCUMFERENCE (IV): BIOLOGICAL USE AND ENVIRONMENTAL INVESTIGATION. (Kogai

to sono shugen 4, Seibutsu riyo to kankyo chosa). Text in Japanese. Kagaku to Yakugaku no Kyoshitsu (Chem. Pharm., Quart. J.), no. 40:6-11, 1973. 5 refs.

For measurement of traceable sulfur oxide, the use of microbiological quantitation of sulfate ions is reliable and convenient for treating a large amount of test material simultaneously. This method is also useful for examining bacterial proliferation inhibitors or inhibiting factors. Quantitation of sulfates in rain water by the colitis bacteria (*Escherichia coli*), and the relationship between inhibitors and toxic metals are discussed. The pattern of hydrogen fluoride damages was examined by gladioli and orange leaf experiments. The SO_x first damages the plant's spongy parenchyma and then the total system. The damages appear first in spots, and then turn into gray, white or yellow as the symptom advances. The HF can be absorbed in gas form through the stomata of the epidermis and damage spongy parenchyma and palisade, or water soluble compounds in HF can be absorbed into plant. Once absorbed, HF moves to the tips or edges of the leaves, and the accumulation causes graying or browning of the leaves. Traceable amounts of HF can damage agricultural produce visibly. In the area 1-2 km from the emission source, plants can have approximately 150 ppm, or five times the HF accumulation in a control area. Rats were raised at a street intersection to see the effects of automotive exhaust gas. An interesting and significant inhibition of weight increase was noted among one group of rats. The lead content in the atmosphere or the dust count did not show a significant difference from other exposure areas. In addition to exhaust gases, noise, light, and other conditions such as ventilation, temperature, and vibration seemed to have inhibited the growth of the rats.

FLUORINE-SEMIAUTOMATED METHOD. J. Assoc. Offic.

Anal. Chemists, 55(5):998-1003, Sept. 1972.

A semiautomated, colorimetric method for the analysis of fluoride in vegetation is presented. Dried and ground plant material is ashed, fused with alkali, and diluted to volume. Leaf samples may be washed with an aqueous solution containing 0.05% detergent and 0.05% tetrasodium ethylene diamine tetracetic acid salt. The digest and sulfuric acid are then pumped into microdistillation apparatus which is maintained at 170 C. A stream of air carries the acidified sample to a fractionation column where F and water are distilled into a condenser; the condensate passes into a small collector. The distillate is mixed continuously with alizarin F blue-lanthanum reagent, the colored stream passed through a tubular flowcell of the colorimeter, and the absorbance measured at 624 nm. Conditions must be carefully controlled since accurate results depend upon obtaining the same degree of efficiency of distil-

lation from samples as from standard F solutions used in calibration. The temperature must be maintained within plus or minus 2 C, and regulation of the acid concentration during distillation is achieved by taking plant samples in the 0.1-2.0 g range and by using specified amounts of calcium oxide and sodium hydroxide for ashing and fusion. Interfering metal cations and inorganic phosphate are not distilled, and organic substances are destroyed by ashing. Interference from remaining volatile inorganic anions is reduced with high concentrations of acetate buffer at the expense of some reduction in sensitivity. The method can detect 0.1 micrograms F/ml, and the normal range is 0.1-4.0 micrograms F/ml.

BIOLOGICAL ASPECTS OF AIR POLLUTION. (Biologische aspecten van de luchtverontreiniging). Text in Dutch. Chem. Weekblad, 69(26): 11-12, June 1973. 11 refs.

Studies on the effects of air pollutants, such as automotive exhaust components, sulfur dioxide, hydrofluoric acid, and ozone, on plants, animals, and humans are reviewed. Very high susceptibility of spinach and lettuce to ozone and peroxyacetyl nitrate was observed. Nitrogen oxides cause leaf burns in certain plants, while nitrogen dioxide interferes with growth processes in tomatoes in concentrations as low as 0.25 ppm. Ethylene in above-normal concentrations has similar effect on tomatoes. Necrosis of leaf tissues due to the action of SO₂ was observed. The acidification of the soil and of surface water bodies, a process most acute in Sweden due to SO₂, interferes with the lives of certain plant and animal species. Lichens were determined to be most sensitive to SO₂ of all plants. Leaf burns and inhibition of the cis-aconitase in *Fresia* and *Gladiolus* species due to hydrofluoric acid was evidenced. This pollutant also tends to reduce bee populations in polluted areas.

INFLUENCE OF SULFUR DIOXIDE AND HYDROGEN FLUORIDE AS A MIX OR RECIPROCAL EXPOSURE ON CITRUS GROWTH AND DEVELOPMENT. J. Air Pollution

Control Assoc., 22(9):710-713, Sept. 1972. 13 refs.

The influence of exposure to mixtures of sulfur dioxide and hydrogen fluoride on Koethen sweet orange, and alternate exposure to these gases on Satsuma mandarin, were tested using a rotating fumigation greenhouse. The concentration of SO₂ was effectively maintained at approximately 0.8 ppm or 2.3 mg/cu m during the experiment, but the HF concentration varied from approximately 2.5 ppb or 2.2 micrograms/cu m at the beginning of the experiment to approximately 13 ppb (11.6 micrograms/cu m) at the end. Effects of HF-SO₂ mixtures on linear growth and leaf area of Koethen orange were additive, not synergistic. No necrosis was observed on Koethen oranges exposed to HF, SO₂, or a mixture of HF and SO₂. Effects of the mixture on chlorosis of Satsuma mandarin foliage was also not synergistic. No significant difference in linear growth of Satsuma mandarin was found. Alternate exposure to SO₂ followed by HF produced no synergistic injury to Satsuma mandarin. Satsuma mandarin appeared more sensitive than Koethen orange to HF, SO₂, and mixtures of these two gases, using degree of chlorosis and leaf abscission as the criteria of sensitivity. If linear growth and leaf area were the principal

<xref image="2000WVMB.TIF|V3|2006:09:28:01:41:32.00|128955|0"> image: </xref>

criteria considered, Koethen orange would appear more sensitive. (Author abstract modified)

TOLERANCE OF BANANAS TO FLUORIDES AND

SULPHUR DIOXIDE. Alex J. Agr. Res., 18(1):115-118, 1970. 5

refs.

The sensitivity of banana plants growing near the superphosphate plant at Kafr-El-Zayat, U.A.R. to fluorides and sulfur dioxide was investigated. The growth of the fourth ratoon plants raised in this area was compared with that of plants raised in a non-industrial area (Alexandria). The results indicated that the plants from the two areas were similar in terms of height of the pseudostem, length of the bunches, average number of hands per bunch, number of fingers per hand, and average number of fingers per hand per bunch. The plants in Kafr-El-Zayat showed no visual symptoms of foliage lesions, severe chlorosis, or necrosis. Although the margins of the lamina were dry and scorched, the same observation was made of the plants in Alexandria. The air pollutants in the area at Kafr-El-Zayat are present in concentrations not injurious to banana plants grown in the area.

THE PHYTOTOXICITY OF PARTICULATE FLUORINE

COMPOUNDS. (Zur Phytotoxizitaet staubfoermiger Fluor-Ver-

bindungen). Text in German. Staub, Reinhaltung Luft,

33(10):395-397, Oct. 1973. 8 refs.

The toxicity of particulate fluorides was tested on 3-year old pot-bound pines (*pinus silvestris*), on 4-year old douglas firs (*psuedotsuga menziesii*), and on 1-year old birches (*betula verrucosa*). The first series of experiments was used for determination of the toxicity of more or less water insoluble fluorine compounds at high humidity. The pines were therefore exposed in two different greenhouses. One was normally ventilated, the other had a relative humidity of 75% and more at all times. With the second test series the plants were exposed under outdoor conditions. The effect of the dusts on photosynthesis was statistically not significant in the absence of visible injury. This may be due to the anatomical feature of conifer needles and may be valid for particulate fluoride only.

INHIBITION OF APPARENT PHOTOSYNTHESIS BY AIR

POLLUTANTS. J. Environ. Qual., 2(4):526-S30, Oct.-Dec. 1973.

35 refs.

The reversible effects of hydrogen fluoride, sulfur dioxide, and chlorine exposures on net carbon dioxide absorption rates (apparent photosynthesis) of alfalfa and barley plants were investigated. Carbon dioxide uptake was reversibly suppressed by exposure dosages of these pollutants which did not cause cellular destruction in the leaves. Some necrosis resulted, except for the nitrogen oxides, from treatments which depressed CO₂ uptake rates more than 25-60% by the end of 2-hour fumigation trials. The six air pollutants can be ranked in the following descending order according to the relative amounts that plant CO₂ uptake rates were depressed by the end of 2-hour exposure: HF, ozone, Cl₂, SO₂, nitrogen dioxide, nitric oxide. The phytotoxicants ranked in essentially the reverse order when compared on the basis of the rapidity that CO₂ uptake was suppressed as a function of exposure time. Nitric oxide treatments caused very rapid reductions in the plant CO₂ uptake rates during the first hour of exposure. By this time, plant uptake rates had attained new (depressed) steady state equilibrium levels which were then maintained over the remainder of the exposure periods. Hydrogen fluoride treatment induced more gradual reductions in plant CO₂ uptake rates throughout the test periods. Plant responses to the other

pollutants, SO₂, NO₂, Cl₂, and O₃ were intermediate between those caused by NO and HF. (Author abstract modified)

Miller, G. W., M. H. Yu, and M. Psenak

PRESENCE OF FLUOROORGANIC COMPOUNDS IN HIGHER

PLANTS. Fluoride, 6(3):203-215, Oct. 1973. 20 refs. (Presented at the International Society of Fluorine Research, Annual Conference, 5th, Oxford, England, April 4-8, 1973.)

A number of exotic plants are known to contain fluoroorganic compounds. The toxic component of more than a dozen plant species of fluoroacetate. Indirect evidence using extraction with nonpolar solvents combined with paper chromatography, inhibition of aconitase, and infrared spectrometry indicated the presence of fluoroacetate and fluorocitrate in soybean and crested wheat grass exposed to atmospheric fluoride. Gas chromatographic analysis of organic acids isolated from crested wheat grass collected from areas of high atmospheric fluoride pollution showed the presence of two peaks that corresponded with the methyl esters of authentic fluoroacetate and fluorocitrate. The organic acid pattern in the fluoride-exposed plants was also significantly changed compared to control tissue. (Author summary)

FLUORIDE PHOTOTOXICITY AS AFFECTED BY RELATIVE

HUMIDITY. Proc. Int. Clean Air Congr., 3rd, Duesseldorf, West Germany, 1973, p. A143-A145. 16 refs.

The effects of relative humidities on hydrogen fluoride-induced leaf necrosis and accumulation of fluoride in gladiolus plants are presented. Plants were exposed to 4.5 micrograms F/cu m for 144 hr after acclimation to relative humidities of 50, 65, and 80% relative humidities and were then maintained in the chambers under the same environmental conditions for 24 hr to allow symptoms to develop. Relative humidity did not affect the incidence of injury; the percentage of leaves per plant showing some degree of necrosis was not statistically different at the three relative humidities. The physiological age of the leaves did, however, influence the incidence of necrosis. Relative humidity of the air surrounding the plants during exposure to hydrogen fluoride did affect the severity of HF-induced injury (percentage of leaf length necrotic); necrosis was more severe on plants exposed at 80% relative humidity than that at 65 or 50%. The amount of accumulated F localized in the medial and basal portions of leaves was negligible and was not affected by relative humidity.

EFFECTS OF HYDROGEN FLUORIDE ON PLANT-

PATHOGEN INTERACTIONS. Proc. Int. Clean Air Congr., 3rd, Duesseldorf, West Germany, 1973, p. A146-A149. 32 refs.

Experiments in fumigation chambers with tomato and pinto bean plants were performed to assess the effects of hydrogen fluoride on plant-pathogen (fungal and bacterial) interactions.

Hydrogen fluoride was found to alter the plant-pathogen in-

<xref image="2000WVMC.TIF|V3|2006:09:28:01:41:36.00|117098|0"> image: </xref>

teraction, although the kind and consistency of effect caused by HF depended upon the host, pathogen, and several other factors. A reduction in powdery mildew probably indicates that HF was affecting the infectivity of the pathogen itself because reduction in disease was proportional to the length of the exposure period, infection was continuous during the exposure period, and the pathogen itself was epiphytic. The effect of fluoride on bean rust may have been due to accumulated fluoride in the leaf having a direct or indirect effect on the pathogen because both pre- and post- inoculation exposures to HF were effective and additive. Other evidence for an indirect effect of fluoride was found in halo-blight where stem collapse was affected but foliar symptoms were not, and the site affected was spatially removed from the site of fluoride accumulation. Effects on early blight of tomato also indicated an effect of fluoride in the leaf.

SECTION IV(F): THE DAMAGE TO AGRICULTURE. In: An economic and technical appraisal of air pollution in the United Kingdom. London, H. M. Stationery Office, 1972, p. 140-149. 4 refs.

The effect of air pollution on agricultural plants and animals in Great Britain is described. Sulfur dioxide can affect life in three ways: as a constituent of the air, as rain, or as acidic mist. Depending on its form, SO₂ can affect the soil and the health of the plants, cause delayed blooming, premature senescence, and leaf damage. Smoke reduces the supply of light radiation for photosynthesis and may block the stomatal pores. Fluorine, besides retarding growth in plants as a result of destruction of tissue, can damage animal bone and teeth. Oxides of nitrogen are emitted in relatively small quantities compared to SO₂. The oxidizing action of nitrogen dioxide or nitric acid washed out by rain could produce direct damage to foliage. Other pollutants which adversely affect vegetation include lead, ethylene, ozone, and organic sulfur compounds. A discussion on the cost of damage by air pollution to agriculture in Great Britain is included.

FLUORIDE ACCUMULATION BY FORAGE: CONTINUOUS
VS. INTERMITTENT EXPOSURES TO HYDROGEN
FLUORIDE. J. Environ. Quality, 2(4):501-503, Oct.-Dec. 1973.
9 refs.

The effect of continuous versus intermittent exposures to hydrogen fluoride was investigated with timothy (*Phleum pratense* L.) and red clover (*Trifolium pratense* L.) plants. Fluoride accumulation was greater after continuous fumigations than when the same HF dose was provided in alternate 48 hr exposures. The importance of the intermittent nature of exposures in addition to the pollutant concentration and duration of exposure in governing F accumulation suggests that pollution abatement action to protect livestock from ingested F should be based on the F content of forage rather than the concentration of airborne fluorides. EFFECTS OF HYDROGEN FLUORIDE FUMIGATION OF
BEAN PLANTS ON THE GROWTH, DEVELOPMENT, AND
REPRODUCTION OF THE MEXICAN BEAN BEETLE. Proc.
Int. Clean Air Congr., 3rd, Duesseldorf, West Germany, 1973,
p. A150-A153. 16 refs.

The growth and behavior of Mexican bean beetle populations on control and hydrogen fluoride-fumigated bean plants (*P. vulgaris* L. ev. predominantly) were investigated to assess the effects of such fumigation on beetle growth, development and

reproduction. Beetles that were cultured on HF-fumigated plants were generally lighter than controls, although the occurrence and magnitude of this effect depended upon stage of development, age, and sex of the adult beetle and the number of generations of culture on HF-fumigated plants. A consistently decreased mass of larvae cultured on HF-fumigated plants reflected a delay in development as well as a reduced growth. Larvae from the eggs laid by beetles cultured on HF-fumigated tissue pupated and eclosed three to six days later than controls, and the adults commenced reproductive activity with the same lag in time. Beetles cultured on the fumigated plants also contained greater amounts of fluoride than the controls, and the fluoride content of females was greater than that of males on both HF-fumigated and control plants. Beetles raised on fumigated plants laid fewer egg masses and fewer eggs per mass, although when the first generation was repeated at a later date there was no significant effect. Feeding activity was reduced in both larval and adult stages in beetles cultured on the fumigated plants, and adults showed less flight activity than controls. A difference in color of the elytra was also noted; beetles on HF-fumigated plants were paler than controls.

RELATIONSHIP BETWEEN TREE PESTS AND IMMIS-
SIONS. (Beziehungen zwischen Baumschaedlingen und Inunis-
sionen). Text in German. Anz. Schaedlingskunde, vol. 46:155-
156, 1973. 2 refs.

In a forest in the vicinity of a large sulfur dioxide emission source, lice were discovered on the species *abies concolor* and *abies veitchi* mainly on those needles where injuries from SO₂ and hydrogen fluoride exposure were macroscopically and microscopically visible. All *abies* species whose new shoots were treated with a pesticide until the second half of May showed no injuries on the new 1-year old needles. Non-treated trees showed either injuries or dropped the needles. Contrary to this, mealy bugs on *pinus griffithi*, *pinus silvestris fastigiata* and *pinus silvestris pumily* were mostly found on the non-injured needles and not on those showing macroscopic and microscopic SO₂ injuries. Species of *Ilex aquifolium* uninjured by SO₂ suddenly displayed acute injuries after they had been heavily attacked by the fly *phytomyza ilicis* which coincided with HF concentrations of 6 to 8 micrograms/cu m and half-hourly values of SO₂ of 1.5 to 2.0 mg/cu m. Only those treated with an 0.4% Wuxal-solution (six times in 14-day intervals) showed no injuries. Similar results were obtained with a spider mite (*oligonychus ununguis*) on *picea omorika*. Through treatment with pesticide, the pests and plant injuries could be averted. The *sacchiphantes viridis* louse was found in greater concentrations on parts protected from exposure by walls or other plants. The *blastethia turionella* on *pinus montana* occurred most frequently on heavily injured parts. The extent of pest occurrence among other things was influenced by weather, season, climatic, orographic, and topographic factors. Through efficient pest control, some injuries can be avoided.

HYDROGEN FLUORIDE INJURY IN SUGAR-CANE: SOME
ULTRASTRUCTURAL CHANGES. Proc. Int. Clean Air
Congr., 3rd, Duesseldorf, West Germany, 1973, p. A157-A159.
8 refs.

Mature sugar-cane plants were fumigated with controlled amounts of hydrogen fluoride and subsequently microscopically examined for ultrastructural changes. The first symptoms appeared as a fine stippling followed by irregular chlorotic mottling of the leaf margins and tips. These yellow chlorotic areas became necrotic and changed from yellow to brownish-red to dark brown, followed by a complete collapse of the mesophyll cells in the necrotic areas. First symptoms appeared after exposure to 12.9 micrograms/cu m HF; acute symptoms appeared at 23.0 micrograms/cu m; and severe necrotic symptoms and ultimate collapse occurred at a concentration of 105.0 micrograms/cu m. There was an overall decrease in the size of the chloroplasts and membrane system during the development of the chlorotic fluoride injury symptoms and an increase in the size and number of osmiophilic globules. The middle lamellae were swollen and became densely stained. The tonoplast disappeared during the change from reddish-brown to dark brown, and there was a separation of the primary cell walls at the middle lamellae. The plasma membrane disappeared in the necrotic condition, and the ground plasma was very granular. The chloroplasts were smaller than in the dark brown condition, and the internal membranes as well as the plastid envelope started to disintegrate. Ribosomes were still present in the stroma, and the mitochondria were still intact.

Edmunds, George F., Jr.
ECOLOGY OF BLACK PINELEAF SCALE (HOMOPTERA:
DIASPIDIDAE). Environ Entomol., 2(S):765-777, Oct. 1973. 20
refs.

The ecology of black pineleaf scale which occurs on several species of pine and Douglas fir causing defoliation, discoloration of foliage, and reduced growth is reviewed. All known outbreaks of this scale have been caused by reduction in the population of *Prospaltella* parasitoid that normally keeps the scale populations at very low densities. Abnormal mortality of *Prospaltella* has been found to be caused either by the presence of sorptive dusts or by drift of insecticides. High population densities of scale have been found mainly in areas of high dust fall resulting from industrial sources and roadways. No known causal relationships have been found to exist between atmospheric fluorides and the black pineleaf scale population density. Environmental improvement to conserve the *Prospaltella* parasitoids appears to be the most effective control measure. (Author abstract modified)

Darley, Ellis F.
VEGETATION DAMAGE FROM AIR POLLUTION. In: Combustion-Generated Air Pollution. A Short Course on Combustion-Generated Air Pollution held at the University of California, Berkeley, September 22-26, 1969. Ernest S. Starkman (ed.), New York-London, Plenum Press, 1971, p. 245-255.
24 refs.

Principle air pollutants that adversely affect growth and development of vegetation are discussed. The typical injury symptom from peroxyacyl nitrates is a silvering, glazing, or otherwise metallic sheen on the lower surface of affected leaves. The symptoms from various PANs appear to be the same, but as the carbon number of the molecule increases so does the relative toxicity. Injury from ozone results in stippling, mottling, or a chlorosis that is confined to the upper surface of the leaf. Ozone has a similar effect on growth and cell wall metabolism compared to PAN; but, whereas short periods of darkness before, during, and after exposure prevent

PAN damage, this is not so with ozone. The hydrocarbon ethylene affects flower production of ornamental species; the dry sepal injury to orchids is a prime example. The chief symptom of acute injury from sulfur dioxide is a white to tan bleaching of leaf tissues; the injury goes clear through the leaf and is not confined to one or the other surface. High concentrations of nitrogen dioxide produce similar effects, although recent experiments with a variety of plants exposed to nitrogen dioxide have demonstrated that concentrations of a few tenths ppm for several weeks can reduce growth as much as 35%. The typical symptomology of hydrogen fluoride poisoning is a necrosis of the margin of dicotyledonous or broad-leaved plants and of the tips of monocotyledonous, parallel-veined plants. Certain cement-kiln dusts have been shown to be toxic to plant leaves when deposited in the presence of free moisture. Dry dusts apparently do not have this effect but may interfere with the normal photosynthesis by the fact that they reduce the light reaching the leaf.

56788

Edmunds, George F., Jr. and Richard K. Allen
COMPARISON OF BLACK PINE LEAF SCALE POPULATION-DENSITY ON NORMAL PONDEROSA PINE AND THOSE WEAKENED BY OTHER AGENTS. Proc. Int. Congr. Entomol., 10th, Montreal, Canada, 1956, vol. 4, 1956 (1958).
A study of an infestation of black pine leaf scale, on ponderosa pine revealed a direct correlation between the degree of damage to the tree and the population density of the scale insects. Tests of the hypothesis that the scale insects more readily attacked trees damaged and weakened from other sources revealed the following: significantly lower average scale population density was noted on trees damaged by boron compounds used as weed killers than in trees not so damaged; no significant difference in average population density was noted between trees with moderate needle tip dieback, presumably caused by uptake of atmospheric fluorides, and trees not showing such damage; no significant difference was found in average scale population density between those trees with relatively high fluoride content and those with relatively low fluoride content; and no difference in average population density of black pine leaf scale was noted between trees damaged by infestations of dwarf mistletoe and trees not so damaged. Hence, damaged and presumably weakened trees are concluded to be no more susceptible to attack than trees not so damaged. (Author abstract modified)

INCREMENT STUDIES IN SCOTCH PINE STANDS IN THE VICINITY OF A FERTILIZER FACTORY. (Zuwachsuntersuchungen in Kiefernbeständen in der Umgebung einer Düngere-fabrik). Text in German. Mitt. Forst. Bundesvers., no. 97:173-194, 1972. 8 refs. (Presented at the International Symposium of Forest Fume Damage Experts, 7th, Essen West Germany, Sept. 7-11, 1970.)
Scotch pine stands growing in sandstone in a very dry region of Southern Moravia in the vicinity of a fertilizer factory were studied. Atmospheric pollutants from the plant included sulfur dioxide, sulfuric acid mist, and fluorine compounds. Permanent plots were established in the surrounding pine stands,
<xref image="2000WVME.TIF|V3|2006:09:28:01:41:42.00|122811|0"> image: </xref>

with the plots being positioned so that the effects of decreasing amounts of pollution could be studied. Ring analyses were made on the cores from 100 sample trees in each of the five plots. Disturbances in the annual ring formation and reductions in growth were noted among the sample trees; similar disturbances were found in the smoke-damaged spruce stands of the Erzgebirge. The structural characteristics and health conditions of the trees were evaluated by computer.

POLLUTION AND ITS THREAT TO FORESTS IN THE RUHR. (Immissionsbelastung und Immissionsgefährdung der Walder im Ruhrgebiet). Text in German. Mitt. Forst. Bundesvers., no. 97:53-87, 1972. 30 refs. (Presented at the International Symposium of Forest Fume Damage Experts, 7th, Essen, West Germany, Sept. 7-11, 1970.)

Examples are given of air pollution damage to stands of spruces, pine, and broadleaved species in the forests of the Ruhr region. In the heart of the Ruhr, there are no longer any closed stands of spruce and pine. Although chronic damage occurs to broadleaved and coniferous species in the whole industrial region, the acute damage to the broadleaved species is concentrated in the region containing the chemical factories, aluminum works, galvanizing works, glass factories, and burning tips. The damage is frequently caused by halogen compounds. The causes of chronic fume damage to the forests are sulfur dioxide, fluorine compounds, oxidants, and dusts, the dust affecting the foliage by blocking light and reducing assimilation, and by affecting the roots by accumulating injurious substances in the soil. The danger of pollution to conifer forests in North Rhine/Westphalia is estimated on the basis of an SO₂ measurement program, the SO₂ being regarded both as an injurious substance and as an indicator of the general air pollution index. The basis for predicting the risk of planting conifers is the frequency of occurrence of certain growing-season mean values. In the heart of the region, a growing-season mean value of 0.08 mg SO₂/CU m was exceeded in the last 3 out of 4 years, and, in the marginal areas of the region, it was reached or exceeded in 1 year out of 4.

EFFECT OF FLUORINE COMPOUNDS ON THE DRY MATTER PRODUCTION OF BUCKWHEAT. (Einfluss von Fluorverbindungen auf die Trockensubstanzproduktion von Buchweizen). Text in German. Mitt. Forst. Bundesvers., no. 97:335-351, 1972. 17 refs. (Presented at the International Symposium of Forest Fume Damage Experts, 7th, Essen, West Germany, Sept. 7-11, 1970.)

The effect of fluorine compounds applied to the soil before sowing, at the start of flowering, and during the ripening of the first fruits was evaluated according to the dry-matter production of *Fagopyrum esculentum* M (Doxanska variety). The application of fluorine in the rooting medium of the plants at different stages in their ontogeny produced results which indicated that the reduction in dry matter depended, inter alia, on the form in which the fluorine was applied to the soil. Under greenhouse conditions and on standard soil, the maximum inhibiting effect was found with sodium fluoride; the effect was less when fluorine was applied as potassium fluoride or calcium fluoride. In addition, the reduction in dry-matter production was more marked when the individual fluorides were applied before sowing. Increasing the fluorine level in the soil during flowering and during ripening of the first fruits did not cause significant reductions in dry matter, except in the case of sodium fluoride. The maximum inhibiting effect of sodium fluoride occurred when it was applied to the soil at the start of flowering; the effect was less when it was applied before sowing, and was not very significant when it was applied

during the ripening of the first fruits. An increase in dry matter and leaf area was observed after a single application of fluorine on the 20th day of growth, indicating that calcium fluoride does not significantly affect the physiological processes of buckwheat during the first 6 weeks after application; the effect of sodium fluoride was quite different. The occurrence of necrotic leaves and the death of the most susceptible individuals were associated with a significant decrease in the formation of leaf surface area and with the reduction of dry-matter production. The most resistant individuals, as indicated by the responses to fluorine treatment, equalled or often even surpassed the control plants.

CHANGES OF THE LANDSCAPE CAUSED BY INDUSTRIAL

SMOKE ACIDS. (Ameny v drajine zpusobene emitovanymi kyselinami). TERPLAN-Statni iistav pro uzemni planovani, Ustav krajinne ekologie CSAV, Bioindikatory Deteriorizace Krajiny, Sbornik Z Mezinarodni Konference, Prague, Czechoslovakia, 1971, p. 14-17. (Sept.)

The influence of industrial smoke emissions of sulfur dioxide, fluorine, and chlorine on landscape is examined. Sulfur dioxide emission has been estimated to cause 80% of the plant damage found near industrial surroundings according to the literature, but more recent evidence has pointed to fluorine-containing exhaust as being the main culprit of smoke damage. Two examples are presented in favor of the latter hypothesis. Fluorine-containing exhausts have been found to cause damage in gladiolas, horse-chestnuts, damson plums, apricots, forest plants; leaf burning and permanent damage have been common. Plant damage has also been observed in the vicinity of chlorine-emitting facilities. Growth depression, bleached or lightened leaves, and necroses have been observed. Damage to pear leaves from chlorine appeared as ill defined, brown necroses in contrast to the sharply defined black-brown edges resulting from fluorine damage.

PHYTOINDICATION OF AIR POLLUTION BY FLUORINE

IMMISSIONS. (Phytoindikation der Luftverunreinigung durch fluorimmissionen). Text in German. Biologia, 28(10):827-S36, 1973. 24 refs.

A method of leaf analysis for studying the content of toxic substances in plant leaves is described. It can be used to measure areas polluted with fluorine. Analyses of naturally occurring plant species are suitable in regions with higher fluorine content in the atmosphere. Lower concentrations of fluorine in the air are indicated in a more sensible way by the fluorine content of lichens or of plants that have been cultivated in more or less standardized conditions.

Dept. of Agriculture, Upper Darby, Pa., Northeastern Area, State and Private Forestry

AIR POLLUTION DAMAGES TREES. Washington, D. C., U.

S. Government Printing Office, 1973, 34p. 37 refs.

An examination of air pollution damage to trees indicates that sulfur dioxide and ozone are probably the most important phytotoxic air pollutants in the northeast, though fluorides,

<xref image="2000WVMF.TIF|V3|2006:09:28:01:41:46.00|121304|0"> image: </xref>

chiefly in the form of the gas hydrogen fluoride, also occur. Injury on conifer needles from these pollutants is often manifested as necrosis of the needle tip or the entire needle. Ozone also causes a chlorotic mottle of needles. Most pollutants cause more specific symptoms on broadleaved trees. Sulfur dioxide symptoms generally appear on such trees as an interveinal necrosis, with the injured tissue being a light brown. Ozone causes a reddish-purple stipple or brown to white flecks of the upper leaf surface. Fluoride injury is usually restricted to the margins of the leaf where toxic accumulations of this pollutant cause the tissues to turn brown and die. Minor pollutants cause a variety of symptoms. Air pollution injury to trees is most prevalent during inversions, i.e., meteorological conditions which do not allow pollutant-laden air to rise and disperse. (Author summary modified)

Dost, Frank N., D. J. Reed, and C. H. Wang
 STUDIES ON ENVIRONMENTAL POLLUTION BY MISSILE
 PROPELLANTS. Oregon State Univ., Corvallis Radiation
 Center, Air Force Systems Command/Aerospace Medical
 Research Lab. Contract AF33(615)-1767, Proj. 6302, Task
 630204, Work Unit 630204001, AMRL-TR-68-85, 28p., Feb.
 1969. 3 refs.

Field evaluation of the effects of inorganic fluoride oxidizing agents accidentally released into the environment are discussed. Information is derived primarily from research previously published. The compounds reviewed are nitrogen trifluoride (NF₃), tetrafluorohydrazine (N₂F₄), oxygen difluoride (OF₂), and the interhalogens chlorine trifluoride (ClF₃), chlorine pentafluoride (ClF₅), and bromine pentafluoride (BrF₅). Nitrogen trifluoride has no effect on plants, fish or microorganisms. High concentrations cause reversible toxicity in mammals. Tetrafluorohydrazine has limited effects on plants and its reaction products are fairly harmless to fish. Mammalian toxicity is moderate but reversible. Oxygen difluoride is highly toxic to plants, but does not appreciably harm microbes or fish unless partial pressure remains high. It causes irreversible damage to mammals at very low doses, and as yet no successful decontaminant has been found. The interhalogens are highly toxic to plants. A possibly productive approach to decontamination of the highly toxic OF₂ may be through the immediate reaction of the spilled gas by reagents distributed through the cloud, at a time when concentration is high enough to permit relatively easy reaction in a limited area. The decontamination of spilled interhalogens should be easier to accomplish, since they react with almost any material they encounter. Their reactive aqueous solutions must be dealt with as well, but if the waterborne interhalogen reaction products are eluted or percolated through soil, almost all living elements in the environment will be protected. The problem of quickly and safely destroying each of the inorganic fluoride oxidizing agents in air, leaving products which may be dealt with on a non-emergency basis, is being studied.

Lisicky, Mikulas
 REMARKS ON THE INFLUENCE OF FLUORINE EXHALATIONS UPON THE MOLLUSKS IN THE SURROUNDINGS OF ZLAR NAD HRONOM. (Bermerkungen zur Auswirkung der Fluorexhalationen auf die Malakofauna in der Umgebung von Zlar nad Hronom). Text in German. Biologia, 2S(11):919-924, 1973. 7 refs.
 Seventeen localities in the area contaminated by fluorine and its immediate vicinity were investigated. The malacocenoses in stagnant water and in the forest were most injured. Two hypotheses concerning the possible influence of hydrogen fluoride on the water-mollusks are advanced: direct effect, i.e., corrosion of the conch; and indirect effect—the HF blocks the calcium and the only way out for the snails is to gnaw the conches. In the contaminated area the malacocenoses trend to

show high dominance of one euryoecic species. (Author abstract)

Keller, Th.

TRANSLOCATION OF FLUORIDE IN WOODY PLANTS.

Fluoride, 7(1):31-3S, Jan. 1974. 5 refs.

Foliage of different species of forest trees was analyzed for its fluoride content. The foliage of plants which had been exposed to fluoride exhalates of an aluminum smelter for one to many years was analyzed after it had been allowed to flush and develop in pure air. All samples of the foliage of trees near the factory had increased fluoride content in dry matter as compared to controls. The foliage near the smelter contained 11-136 ppm F in dry matter, whereas controls contained 3-14 ppm. The level of fluoride in first leaves formed in the spring was higher than that in foliage formed later in the year, a fact indicative of depletion of reserves. New foliage of deciduous trees which had been exposed to fluoride fumes in winter exclusively also contained increased amounts of fluoride, a fact which indicates mobilization of fluoride entering the tree via the bark. These data prove that fluoride is being translocated in woody plants. (Author abstract modified)

AN INQUIRY INTO THE DISTRIBUTION OF FLUORIDE IN

THE ENVIRONMENT OF GARRISON, MONTANA. Fluoride,

7(1):7-31, Jan. 1974. 31 refs.

In the fall of 1971 and 1972, the extent and severity of fluoride contamination in the vicinity of Garrison, Montana was determined. Assays of the fluoride content of indigenous flora and fauna were utilized to establish the effectiveness of the air pollution control equipment of a fluoride-emitting industrial facility. Vegetation samples included forage, shrubs, coniferous and deciduous tree species, as well as various species of small mammals in a directional pattern throughout the study area were analyzed for fluoride and compared with control samples collected throughout western Montana. Analysis by individual species allowed comparison of the ratio of fluoride accumulation between species. Fluoride levels in vegetation and small mammals were also correlated. Isopol maps of fluoride concentrations in vegetation were constructed. Wide differences between different species were observed. Fluoride concentrations in different species were compared and presented graphically. (Author abstract)

FLUORIDE POLLUTION ON PLANTS IN AREA NEAR AN

ALUMINUM FACTORY. (Arumi seiren kojo shunhen ni okeru

fukkabutsu ni yoru nosakubutsu osen). Text in Japanese. Taiki

Osen Kenkyu (J. Japan. Soc. Air Pollution), 8(3):543, Oct. 1973.

(Presented at the Japan. Society of Air Pollution, Annual Meet-

ing, 14th, Fukushima, Japan, Nov. 6-8, 1973, Paper 269.)

Fluoride accumulation in produce was examined in area near

an aluminum refining plant to obtain basic data for the health

care of residents in the area. The relationship between F accu-

mulation in produce with the distance and direction from the

<xref image="2000WVMG.TIF|V3|2006:09:28:01:41:50.00|120569|0"> image: </xref>

emission source, the species of produce, and the degree of air pollution were examined. Edible parts of turnip, eggplant, Chinese cabbage, potatoes, spinach, green scallions, cucumbers, and some of their leaves were checked at various distances and directions from the emission source; the area was divided by environmental quality classifications and the F content in the leaves and produce were examined. The measurements were taken by the ion electrode method after burning and distillation of the specimens. Fruit and root vegetables did not have high accumulation at any location, but the leaves had high F content even at a distance of 5 km, compared to the control area. When not taking the wind direction into consideration, the F content varied by the distance but lacked significance statistically. When studied by air quality classifications, the statistics showed a clear and significant relationship between F accumulation and the environment.

FLUORINE ACCUMULATION IN RICE PLANT LEAVES WITH AIR-BORNE FLUORIDE. (Fussokei taiki osen ni yoru suitoyochu no fusso shuseki ni tsuite). Text in Japanese. Chiba-ken Nogyo Shikenjo Kenkyu Hokoku (Bull. Chiba-Ken Agr. Exp. Sta.), no. 12:57-62, March 1972. 21 refs.

Injury of rice plants due to fluorine emitted by aluminum refining and phosphate fertilizer plants in the Keiyo heavy industrial district of Chiba Prefecture in July 1969 and July 1970 was studied. The fluorine determination by AOAC procedure was unsuitable for siliceous vegetation such as rice because of the large amount of silica contained. An improved procedure of fusing calcination with sodium carbonate was more accurate. The new procedure was used to determine F in this investigation. Fluorine caused leaf blade necrosis, but scarcely damaged the leaf sheath before the heading stage. Remarkable injury appeared on the tip of the leaf blade, but was slight on the lower portion of the leaf. The leaf also changed color. Irregularly shaped chlorotic spots appeared in the healthy tissues of severely injured leaves. A large amount of fluorine was contained in the rice leaf, but only a little was found in the stem, leaf sheath, and ear. Concentrations of F in the leaf differs according to the leaf position on the stem. The highest concentration of F was contained in the most severely damaged leaves. Fluorine was scarcely translocated to stem or ear from the leaf. Seven hundred ppm of F on a dry weight basis was contained in the tip of the leaf blade, and 80 ppm F in the base of the leaf. Fifty-six percent of the total F was accumulated in the tip of the leaf. Almost all of the F was accumulated in necrotic tissue of the injured leaf. The remarkable rice injury occurred 1-2 km downwind from the major source of F, and slight injury occurred within 3 to 4 km. From the leaf analysis, F was confirmed to be absorbed in leaves within 4-5 km where visible injury was not recognized.

Gilbert, Oliver L.

NEW TASKS FOR LOWLY PLANTS. New Scientist, vol.

46:288-289, May 1970. 1 ret.

The occurrence and behavior of easily identified lichens and bryophytes can be used as an index of sulfur dioxide pollution, since SO₂ kills them. As these lower plants range from very sensitive to highly resistant, they can be arranged to form a scale from which levels of SO₂ can be estimated. Also, by mapping the distribution of selected species, the size and shape of an area affected by pollution can be determined. Ideally, these indicator species should be widespread, easy to recognize, and among them show a wide range of sensitivity so that the rate of fall off of pollution can be assessed. A table of SO₂ estimates correlated to plant incidence is given, along with some examples of application of the principle. Pollutants other than SO₂ have only barely detectable effects on lower plants, however, observations around aluminum smelters suggest that lichens are also useful indicators of fluorine pollution.

Preuss, Peter W. and Leonard H. Weinstein
STUDIES ON FLUORO-ORGANIC COMPOUNDS IN
PLANTS. H. DEFLUORINATION OF FLUOROACETATE.
Contrib. Boyce Thompson Inst., 24(7): 151-156, April-June,
1969. 13 refs.

Experiments were conducted to confirm that germinating peanut seeds contain enzymes which split the carbon-fluorine bond of fluoracetic acid, an extremely toxic compound to animals, and to determine if fluoracetic acid can be metabolized to fluorofatty acids in *Acacia georginae*. About 15% of the fluorine supplied to germinating peanut seeds as sodium fluoroacetate was found in the inorganic form in the seedlings or in the incubation medium after 48 hr, indicating that defluorination is an important part of the metabolism of fluoroacetate by higher plants. Only 2-5% was detected after incubation of boiled seeds. The gas chromatographic pattern of fatty acids of control and fluoroacetate-treated *Acacia* seeds was the same; and analysis of each peak by mass spectrometry provided no evidence for the presence of a fluorine atom attached to the fatty acids, indicating defluorination is an early step in the metabolism of fluoroacetate in this species. Nakamura, Akira, Shinichi Chiyo, and Makoto Yao
ON SULFUR OXIDES AIR POLLUTION IN TOMAKOMAI,
KOKKAIDO. (Hokkaido Tomakomai chiku ni okeru io san-
kabutsu osen ni tsuite (daiippo)). Text in Japanese. Taiki Osen
Kenkyu (J. Japan. Soc. Air Pollution), 8(3):494, Oct. 1973.
(Presented at the Japan. Society of Air Pollution, Annual Meet-
ing, 14th, Fukushima, Japan, Nov. 6-8, 1973, Paper 224.)
The Tomakomai industrial site at present emits about 6600 N
cu m/hr of sulfur oxides from its paper industries and thermal
power plants. Further development of petroleum refining,
petroleum chemical, and electric power plants in the eastern
development site will increase the emissions. In order to con-
trol the further damages of valuable, rare plants in the eastern
area, the sulfur content in plant leaves were measured. Sam-
ples of oak, Japanese oak, white birch, sage brush and some
others were taken in July, August, and early September; they
were washed, dried, and crushed, and the total sulfur and
soluble sulfur in particles smaller than 40 mesh were quan-
titated by the barium chloride weight method. The patterns of
SO_x concentration in the air and soluble sulfur in leaves had a
<xref image="2000WVMH.TIF|V3|2006:09:28:01:41:54.00|123290|0"> image: </xref>

definite relationship, though the soil sulfur content and the weather must be taken into consideration before using those plants as air pollution indicators. At present, sage brush sampled in East Tomakomai has 0.05-0.08% of soluble sulfur; but in Tomakomai and North Tomakomai, the content ranges 0.25-0.5%. In these areas, visible damages of azalea are noted and in one area, the plant growth is impaired by fluorides. The intake of soluble sulfur in plants is lower in these areas in proportion to the SO_x concentration in the air.

Crocker, Thomas D.

IN POLK AND HILLSBOROUGH COUNTIES, FLORIDA.

Bull. At. Sci., 1965:17-19, June 1965.

Air pollution in the citrus growing area in Polk and Hillsborough counties, Florida, is described. This area has one of the world's largest and richest phosphate deposits, and therefore a large phosphate industry grew in the area. It supplies over 75% of the nation's phosphate rock. Expanded food and fiber production in the area caused removal of most of the phosphorus in the soil used for agriculture. Therefore fertilizers such as triple superphosphate were applied in the area. This resulted in increased fertilizer production at the phosphate plants, and thus, increased air pollution due to fluorides. Cattle in the area were affected by fluorosis, and citrus showed chlorosis due to the gaseous fluorides. Some areas generally had concentrations of 10 ppb fluorides in the air. The air pollution was worse in the winter and early spring; these months also had the greatest occurrence of cattle and citrus damage. Due to combined governmental and industrial efforts, fluoride emissions were reduced from 33,000 pounds/day (winter of 1961-1962) to 13,000 lbs/day (winter of 1963-1964). Since 1959, air pollution control equipment costing \$16 million has been added. A new, pollution-free plant costing \$20 million replaced an old one. A new proposal is being considered to limit fluoride emissions further.

Scholl, Gerhard

A BIOLOGICAL METHOD OF DETERMINING FLUORINE COMPOUNDS IN ATMOSPHERIC POLLUTION. (Bin

Biologisches Verfahren zum Nachweis von Fluorverbindungen in Immissionen). Text in German. Mitt. Forst. Bundesvers., vol. 97:255-269, 1972. 15 refs. (Presented at the International Symposium of Forest Fumes Damage Experts, 7th, Essen, West Germany, Sept. 7-11, 1970.)

A grass culture method for determining the origin and distribution of fluorine compounds in the air has recently been developed. With this method, the accumulation of fluorine in the test plants is used as the measured value. The only plants which are suitable are those which can accumulate the toxic substance in large amounts without showing visible external symptoms of damage or a depression in growth. Certain grasses, such as *Lolium multiflorum* and *L. perenne*, are relatively insensitive to fluorine compounds in the air. These indicator plants are placed for a defined period in a standardized growth substrate with comparable nutrient and water supplies in the vicinity of a pollution source. The plant samples obtained at the end of the exposure period are analyzed for their fluorine content. On the basis of the fluorine values obtained (in mg/100 g dry matter), it is possible to assess the origin and distribution of fluorine compounds in the air and to make a prediction of the fluorine hazard to grazing cattle. Details of the method and the results of some practical field investigations are reported.

STIMULATION OF TOBACCO MOSAIC VIRUS-INDUCED

LESIONS ON BEAN BY FLUORIDE. *Phytopathology*, vol.

56:756-758, 1967. 4 refs.

The possible effect of fluoride on the number of local lesions

developing on Pinto bean leaves following inoculation with tobacco mosaic virus was studied. Plants were grown in fumigation chambers in which atmospheric fluoride concentrations ranged from 0.2 to 2.5 micrograms/cu m; foliar fluoride concentrations ranged from 20 to 637 ppm. The number of lesions increased with foliar fluoride concentrations up to 500 ppm, above which the number decreased. Since the number of lesions that developed varied among fumigations, the lesion numbers were converted to percentages of the control. Lesion numbers on plants in the unfumigated chamber served as a control, and these values represented 100%. The numbers of lesions on the leaves with fluoride concentrations of 100-200, 200-300, and 300-500 ppm were 121, 157, and 179% of the control, respectively. The correlation coefficient of 0.802 between fluoride concentrations up to 300 ppm and lesion numbers was significant at the 1% level. When lesion numbers were grouped according to leaf age, irrespective of fluoride concentration, lesions were most prevalent on the first trifoliolate leaves. The number of lesions diminished on the older leaves and on older plants. When leaves are fully developed and plants reached the four- to five-leaf stage, no lesions could be induced. Woltz, S. S.

FLUORIDE TOXICITY IN GLADIOLUS AND METHODS OF AMELIORATION. Proc. Florida State Hort. Soc., vol. 75.469-471. 1962. 6 refs.

The protection of gladioli from fluoride by spraying is described. Fluorine leaf scorch symptoms were identified using specimens fumigated with 0, 0.48, 0.95, 1.9, 3.8, and 7.6 mg hydrofluoric acid. The leaf-tips and margins turned grayish-green the second day following exposure; by the third day the leaves turned grayish white or tan; by the end of a week the damaged area had a burned appearance with tan to dark brown color. In a field experiment, plants were exposed to fluoride sprays as pesticides under controlled conditions. Calcium, manganese, and magnesium had protective effects through the inhibition of metal-requiring enzymes. The field experiment showed leaf scorch systems were produced on gladioli by sodium fluoride and hydrofluoric spray treatments, the effects of HF were almost as great, even though after drying any unreacted HF was lost to the atmosphere. No reduction in foliar toxicity resulted from soil applications of calcium sulfate, apparently due to a greater native calcium supply. Both sodium fluoride and HF were effective in foliar sprays used to stimulate fluoride leaf scorch.

RAPID ANALYSIS OF FLUORINE DEPOSITS ON VEGETATION GROWING IN POLLUTED AREAS BY RADIOACTIVATION WITH 14MEV NEUTRONS. (Analyse rapide par radioactivation sous neutrons de 14 MeV des depots de fluor sur la vegetation en zone politico). Text in French. 3rd European Fluorine Chemistry Symposium, Aix-en-Provence, France, 8p., July 1970. 11 refs.

A method for the quantitative analysis of fluorine deposits on plants by neutron activation at 14 MeV is described. The plant samples to be analyzed are dried at 70 C, crushed, and in-

<xref image="2000WVMI.TIF|V3|2006:09:28:01:41:58.00|120377|0"> image: </xref>

transduced into a polyethylene container for irradiation for a present duration at 14 MeV for 1 min and subsequent counting for 30 sec, the neutron yield being 30,000,000,000 neutrons/sec/4 pi. The quantity of the irradiated fluorine is determined from the net surface of the total absorption peak at 200 keV against a previously irradiated fluorine samples used as a reference. Comparative chemical and neutron activation analyses of apple-tree leaves from a fluorine-exposed area showed good agreement between the results of the chemical and neutron activation analyses. The neutron activation analysis has the advantage of being rapid, since one complete analytical procedure takes about 5 min. However, it is not suitable for the determination of small quantities of fluorine.

INDICES OF ATMOSPHERIC PURITY AND FLUORIDE

POLLUTION PATTERN IN ARVTOA, QUEBEC. Can. J.

Botany, SO(S):991-998, 1972. 11 refs.

Indices of atmospheric purity (IAP) of 42 sites located in all directions from the aluminum factory at Arvida and spread out in about 250 sq km area, were determined on the basis of phytosociology of epiphytes of *Populus balsamifera*. These index values ranging from 0 to 103 were arranged into six groups and the investigated area was accordingly delineated into six IAP zones to represent areas with different levels of fluoride pollution. A relative picture of the approximate limits of F contamination in different zones is obtained by the F accumulation in *Parmelia sulcata thalli* transplanted at various sites in the area (Author abstract)

Jones, L. H. P. and D. W. Cowling

THE EFFECTS OF SOME AIR POLLUTANTS ON FARM

ANIMALS. Preprint, National Society for Clean Air, Brighton

(England), 18p., 1973. 32 refs. (Presented at the National Society

for Clean Air, Annual Conference, 40th, Torquay, England,

Oct. 15-19, 1973.)

A review is presented on the effects of fluorides and various metal dusts on farm animals. Fluorides reportedly cause more damage to domestic animals than any other air pollutant on a world-wide basis. The fluoride content of forage plants growing in air polluted with the halogen compounds greatly increases either through the absorption of gaseous fluoride (hydrogen fluoride) or by deposition of particulate fluorides; concentrations as high as 292 ppm are reported for grass on a farm in Stoke-on-Trent. The most sensitive sign that an animal is absorbing high amounts of fluoride is mottling of the teeth which occurs with intakes too low to produce the symptoms of more severe fluorosis. Arsenic toxicosis in sheep and cattle grazing in the vicinity of copper smelters is a problem particularly evident during the first 40 years of the present century. Industrial molybdenosis, a more recent problem, results in progressive emaciation, accompanied in all cases by diarrhea; high intakes of molybdenum antagonize the metabolism of copper, especially in the presence of high sulfate intake. Post mortem examinations of cattle and horses grazing in lead-contaminated areas indicate high concentrations of both lead and cadmium in the kidney, suggesting that both elements are involved.

Young, Michael John

THE EFFECTS OF GASEOUS FLUORIDE ON DELICIOUS

AND GOLDEN DELICIOUS APPLES. Washington State Univ.,

Pullman, Dept. of Horticulture, Thesis (Ph.D.), Ann Arbor,

Univ. Microfilms, Inc., order no. 73-29,311, 1973, 82p. 46 refs.

Atmospheric fluorides were monitored in apple and other fruit orchards around two adjacent sources of fluoride emissions in the Wenatchee, Washington fruit growing area, and Delicious

and Golden Delicious trees were fumigated with low (4.6-4.7 micrograms F/cu m) and high (7.8-9.0 micrograms F/cu m) fluoride levels once, twice, or three times a week. The effects of fluorides on fruit trees were then determined. Exposure of limed filter papers was a more sensitive method of detecting ambient fluorides than analysis of apple tree foliage. However, both methods were adequate in the determination of the fluoride distribution pattern in the study area. Considerably higher levels of fluoride were detected at sampling sites downwind of the emission sources. Fluoride-induced tip necrosis on apple leaves was observed in one orchard where a mean seasonal limed filter paper value of 82.4 micrograms F/d sq m/mo and 22.5 F in the washed foliage were recorded. Tip necrosis increased as the F level and frequency of exposure increased. Leaf respiration was inhibited at the lower but not the higher F fumigation level. Fruit respiration was stimulated to equal levels by the two F concentrations used. A trend toward increased inhibition of fruit ethylene production at lower exposure factors (concentration times time) was observed. The loss of green color in the skin of treated fruits was retarded relative to an increase in the F level and the exposure frequency. With the exception of leaf respiration, where an inverse relationship was found, the degree of response with respect to leaf injury, fruit respiration, and color were directly affected by the exposure factor used. Within the scope of this study, fruit shape, firmness, and soluble solids were not affected by the treatments. (Author abstract modified)

WAYS OF DETERMINING DAMAGES TO FOREST STANDS

CAUSED BY INDUSTRIAL AIR POLLUTION. (Možnosti prů-

kazu škod pushobených průmyslovými exhaláty v lesních porostech). Text in Czech. Les. Pr., 43(5):212-216, May 1964.

Solid pollutants affect trees indirectly, mainly by adhering to the leaves and thus depriving them of the benefits of the sunlight. They are, however, less injurious than the gaseous pollutants. The worst offender among these is sulfur dioxide because it is so wide-spread; the effects of chlorides and fluorides are equally as bad, although these elements do not occur as frequently in the atmosphere. Nitrogen oxides are injurious only in the immediate vicinity of the source. Conifers are seriously affected by sulfur dioxide; their needles are discolored, become dry and drop off. Older growth is affected first. Spruce shows serious damage after prolonged exposure to as little as 0.5 mg silicon dioxide/cy rn air. Fir and larch are also very sensitive; pine is less sensitive. Broad-leaved trees are far more resistant to high pollutant concentrations which cause necrosis on the periphery of the leaf and gradually extend to the interior under prolonged attack. Diagnostic methods include determination of the pollutant concentration in the foliage and in the soil. An important factor is the chlorophyll content; SO₂ reduces its overall content, and changes the ratio a:b chlorophyll. The affected foliage contains also pheophytin, which is formed by magnesium abstraction from chlorophyll. In the case of conifers, a quantitative diagnostic tool is the Haertel test (hot water extraction of the needles, measuring of the turbidity of the extract). Another simple test is the sun test in which twigs are cut off and exposed to sunlight. Twigs from trees affected by SO₂ dry much faster than twigs from healthy trees.

Keller, Theodor

AIR POLLUTION EFFECTS ON VEGETATION. (Auswirkungen der Luftverunreinigungen auf die Vegetation). Text in German. *Staedtehygiene (Uelzen/Hamburg)*, 22(6): 130-136, June 1971. 16 refs

The dust filtering effect of vegetation, and the effects of air pollutants, especially gaseous ones, on vegetation in general, and on forests in particular, are reviewed. Vegetation, and especially forests, have enormous dust filtering capacity whereby they are able to considerably reduce the atmosphere dust concentrations without suffering damage themselves, provided the dusts filtered out are inert. While most dusts are harmless for vegetation, gaseous pollutants, especially sulfur dioxide and fluorine, cause serious damages in forests by interfering with cellular metabolism and assimilation, and causing chlorosis, necrosis, or even death. Assimilation and forest production can be seriously damaged even when there are no visible signs of injury. For such reasons, the maximum allowable SO₂ concentration should be substantially lowered from the present level of 0.2 ppm. The resistance of plants to SO₂ greatly varies depending on species, season, period of vegetation, and daytime. Specimens of the same species are usually less sensitive during night and in winter, and so are the youngest and oldest leaves of plants. Automotive emissions, partly responsible for smog formation, represent a potential source of forest damage in Switzerland. Apart from the development of high-efficiency emission control equipment, fuel and flue gas desulfurization, as well as technological improvements in industries with the aim of emission abatement, vegetation damages due to air pollution can be reduced considerably by the selection of resistant species and fertilization.

Keller, Theodor

ON THE PHYTOTOXICITY OF PARTICULATE FLUORINE COMPOUNDS. (Zur Phytotoxizität staubförmiger Fluor-Verbindungen). Text in German. *Staub, Reinhaltung Luft*, 33(10):395-397, Oct. 1973. 8 refs.

The effects of sodium fluoride, calcium fluoride, and cryolite on seedlings of *Pinus silvestris*, *Pseudotsuga menziesii*, and *Betula verrucosa* were studied in laboratory experiments. The fluorine compounds were sprayed on the plants in the form of small particles. Sodium fluoride alone induced visible symptoms of partial or total necrosis of the needles in *Pinus silvestris*. All dusts caused a statistically significant depression of photosynthesis in birch. Calcium fluoride and cryolite may also exert a phytotoxic action classified as invisible injury. In the tested conifera, the depression of photosynthesis was statistically not significant in the absence of visible symptoms of injury. The reduced toxicity of these dusts in conifera is most probably due to the well-developed cuticula and the resin and wax excretions by the needles. The increased susceptibility of conifera growing around aluminum works may be due to gaseous fluorine compounds. All dusts had an increased toxicity and photosynthesis-depressing effect in air with high relative humidity.

FLUORINE CONTENT OF THE MILK FROM COWS IN THE REGION OF ALUMINUM PLANTS. (Zawartość fluoru w mleku krow z okolic huty aluminium). Text in Polish. *Roczniki Panstwowego Zakladu Higieny*, 25(1): 97-103, 1974. 21 refs.

The fluorine content in the milk of cows from farms situated 2-3 km from aluminum plants was determined. The experiments covered the area where fluorine contamination of air, rain water, and green forage was found. Fluorosis occurred in 79.4% of the cows under investigation. Fluorine was isolated from milk by a microdiffusion technique and determined colorimetrically with alizarin complexonate and lanthanum

nitrate. A marked increase (P greater than 0.001) was found in the fluorine content of milk from the cows exposed to fluorine (88.1 micrograms/100 ml) compared with that from the controls (35.5 micrograms/100 ml). In addition, seasonal variation in the fluorine content of milk was connected with the amount of precipitation and with variations of fluorine content in green forage. The highest values were in winter months (117.9 micrograms/100 ml), and the lowest ones were in June (63.8 micrograms/100 ml). The fluorine content in milk, up to 100 micrograms/100 ml (equal to 1 ppm) seemed to have no adverse effect on people and animals, since it did not exceed the permissible limits for fluorinated water, while some hazard may be expected in about 5% of the cows with fluorine content of milk exceeding 200 micrograms/100 ml (equal to 2 ppm).

Taniyama, Tetsuro and Hiroki Arikado

STUDIES ON THE MECHANISM OF INJURIOUS EFFECTS OF TOXIC GASES ON CROP PLANTS. VIH. SYMPTOMS OF INJURY AND STOMATAL APERTURES OF TULIP PLANT EXPOSED TO SULFUR DIOXIDE AND HYDROGEN

FLUORIDE. (Sakumotsu no gasu shogai no kansuru kenkyu:

Dai8ho: Fukkasuiso oyobi aryusan gaku ga churippu ni oyobosu shogai no jiltai narabi ni kiko kaido ni oyobosu eikyo). Text in Japanese. Nippon Sakumotsu Gakkai Kiji (Proc. Crop Sci. Soc. Japan), 39(4): 525-532, Dec. 1970. 13 refs.

The injurious effects of sulfur dioxide and hydrogen fluoride in the atmosphere on stomatal apertures of tulip plants of the flowering stage were investigated. Injuries by 100 ppm SO₂ and HF were observed on leaf, floral axis, and petal of the plant, especially whole leaves, which were severely damaged. Injuries at concentrations of 30 ppm and below were observed only on the leaf. The leaf was changed in color from green to white by SO₂ and from green to greyish brown by HF. There was a significant difference in susceptibility between the injury by SO₂ and HF; the leaf was more sensitive to SO₂. From the result of estimation of stomatal number in the position and the portion of leaf, it is suggested that higher susceptibility of the leaf than that of the floral axis was due to the greater number of stomata per unit area of the leaf. The injury symptom in a leaf developed gradually from the tip to the central and base portions.

POLLUTION AND INJURIES BY HEAVY METALS IN THE VICINITY OF A LEAD AND ZINC PLANT IN LOWER SAX-

ONY. (Belastungen und Schaeden durch Schwermetalle in der Naehة einer Blei- und Zinkhuetۛte in Neidersachsen). Text in German. Staub, Reinhaltung Luft, 34(1):10-11, Jan. 1974. 2 refs.

The dusts emitted at 1 to 3 km distance from the lead and zinc plant in Lower Saxony from 1971 on contained about 15% Zn, 12% Pb, 1.4% fluoride, 0.2% copper, 0.15% arsenic and 0.09% cadmium. During the time of filter break-down in spring 1972 the average Pb concentration at 1.5 km distance was about 12 mg and after repair of the filter 1 mg/sq m/day. Systematic measurements of the lead and zinc concentration in soil and plants to a distance of 12 km revealed that the lead and zinc concentrations in soil were up from thy normal 10 ppm to 34 ppm Pb and 70 ppm Zn. At 12 km distance the grass contained

<xref image="2000WVMK.TIF|V3|2006:09:28:01:42:04.00|122932|0"> image: </xref>

in April about 100 times higher and in May about 10 times higher Pb concentrations than normal. At 1 km distance the Pb concentration in the grass rose to 23,000 ppm in April, dropped to 2000 ppm in May and to 50 ppm in September. The Zn concentration rose to 7000 ppm in April and dropped by September to 1000 ppm. Injuries of cattle observed in the vicinity of the plant were found to be mainly due to the zinc and lead ingested with the food. Feeding experiments with a Zn concentration triple the concentration of lead showed that Zn was more harmful than lead. Concentration limits for Zn are therefore as important as those for lead.

ON THE INFLUENCE OF AIR POLLUTION TO PLANTS AND THE METHOD OF ITS INVESTIGATION. (Taiki osen ga shokubuLsu ni ataeru eikyo to sono chosa hoho). Text in Japanese. Nihon Seitai Gakkai Shi (Jap. J. Ecol.). 23(2):81-89, April 1973. 20 refs.

Sulfur dioxide, oxidants, and fluorine compounds are discussed in relation to plant damage, measurement methods, and synergism of SO₂ and oxidants. Plant damage can be classified as chronic (invisible) and acute (visible). The main symptoms of plant damages are described. Plant indicators must be chosen by their specific susceptibilities to air pollution.

Heagle, Allen S.

INTERACTIONS BETWEEN AIR POLLUTANTS AND PLANT PARASITES. Ann. Rev. Phytopathol., vol. 11:365-388, 1973. 94 refs.

The sources and effects on vegetation of sulfur dioxide, ozone, and fluorides are reviewed. Various fungus diseases differ in reaction to SO₂. Sometimes SO₂ decreases parasitism of fungi, which may at first appear to be a positive effect. However since the SO₂ affects all forms of plant life, it is generally detrimental. While some fungi are resistant to SO₂, SO₂ can decrease fungus growth and spore germination. Field observations of the effects of O₃ on fungi are rare. Laboratory and greenhouse studies show that O₃ can decrease infection, invasion, and sporulation of fungi parasitic on growing plants. Ozone also decreases spore germination. Fluoride effects are minor compared to SO₂, but may add to the effects attributed to SO₂. There is some evidence these pollutants can affect bacteria, but most evidence concerns human pathogens. Both fluoride and O₃ either predispose pinto bean leaves to tobacco mosaic virus infection or somehow increase the ineffectiveness of the virus particles. Trees weakened and injured by SO₂ are more likely to be attacked by insects that normally require weakened trees for successful reproduction. But other studies have shown insects to be injured by SO₂ and other pollutants. Parasitic disease may affect the development of O₃ injury in some cases decreasing O₃ injury.

FLUORIDE EFFECTS ON CHLOROPHYLL BIOSYNTHESIS IN NICOTIANA TABACUM. Fluoride, 7(2):69-77, April 1974. 30 refs.

The effects of chlorine and fluorine on the biosynthesis of chlorophyll were investigated in Nicotiana tabacum. The effect at different concentrations (0.0001 M, .001, and .01 M) was investigated on the incorporation of 14 Carbon-delta- aminoleu- vulinic acid (ALA) into coproporphyrin and protoporphyrin fractions, and ether-extractable pigments (chlorophyll a and pheophytin a) in tobacco leaf discs. Both chloride and fluoride at concentrations of .0001 to .01 M inhibited the incorporation of ALA into chlorophyll a and pheophytin a. At 0.01 M the effect of fluoride on AIA incorporation was greater than that

of chloride. The inhibition on formation of pheophytin a by fluoride was similar to that found in chlorophyll a, indicating an effect on synthesis of chlorophyll rather than degradation. The effect of fluoride on individual enzymes in the chlorophyll biosynthetic pathway is discussed in relation to the action of fluoride on cellular ultrastructure. (Author summary modified)

FLUORIDE-CALCIUM INTERACTION IN POLLUTED FIR

NEEDLES. Fluoride, 7(2):78-84, April 1974. 12 refs.

The fluoride-calcium interaction was investigated in the leaf tissues of fir needles growing in a polluted area. The fluoride and the Ca distribution were established in relation to the effect of fluoride on the chemical forms of Ca. Simultaneous determination of fluoride and Ca by proton microanalysis revealed a simultaneous accumulation in the injured tip, and a large increase in the Ca level throughout the polluted needles. The ratio of the chemical forms of Ca also changes with the accumulation of fluoride; Ca oxalates particularly show an increase. There is a parallel deposition of fluoride and Ca in polluted needles which suggest precipitation of calcium chloride. The largest amounts of Ca and fluoride in equal proportions are localized in the injured area. This localization in the tips suggests a direct relation between the possible precipitation of CaF₂ and apical necrosis. The relationship also suggests that formation of CaF₂ represents either a mode of inactivation of the halogen or a disturbing factor in the cellular equilibrium of Ca. (Author summary modified)

EXACT LOCALIZATION OF FLUORINE ALONG POLLUTED NEEDLES OF ABIES ALBA BY PROTON

MICROANALYSIS. (Localisation exacte du fluor le long d aiguilles polluees d Abies alba par microanalyse au moyen de protons). Text in French. J. Radioanal. Chem., 19(2): 359-365, 1974. 10 refs.

The distribution of fluorine on and near the surface of contaminated needles of Abies alba was studied by proton bombardment, using direct detection of the alpha rays generated during the reaction of F(19) with oxygen. The method is rapid and has a sensitivity of 10 micrograms/g fluorine. Accumulation of fluorine in the necrotic apical zone of the needle in concentrations reaching up to 60,000 micrograms/g, and a slighter degree of accumulation in a narrow zone separation the necrotic from the intact zone of the needle were found. The fluorine concentration in the necrotic apical zone increased rapidly with age, while that in the boundary zone diminished and fell to zero after a certain age. The fluorine concentration was higher in the upper than in the lower surface of the needles.

EXPERIMENTAL STUDY OF FLUORINE DAMAGES IN

PLANTS. (Versuche zur experimentellen Abklaerung der Fluorschaeden auf Pflanzen). Text in German. In: Toxicologie

<xref image="2000WVML.TIF|V3|2006:09:28:01:42:08.00|115467|0"> image: </xref>

des Floors. T. Gordonoff (ed.), Basel/Stuttgart, Verlag Schwabe and Co., 1964, p. 164-178. 4 refs.

The fluorine-inflicted plant damages as occur near aluminum works were studied in pot tests on winter wheat and clover. Plant grown in soil to which sodium and potassium fluorides had been added took up less fluorides, and these fluorides were less soluble than in soils to which the corresponding cryolites had been added. Fluoride doses of up to 180 tng% caused no noticeable loss in yield. Spraying the plants with fluoride solutions resulted in high fluorine contents on the leaves reaching up to 1% without noticeable loss in crops and necrosis. In plants sprayed with fluorides in field tests, damages similar to those occurring in fluorine-polluted areas were observed in rainy weather. Discoloration of the glumes resembling Septoria, and losses in crops occurred in winter wheat sprayed with high concentrations of sodium fluoride solution during the late stages of flowering. Slow increase in the degree of necrosis of the leaf edges in clover smoked with 0.25% hydrofluoric acid by volume for several nights was observed. At the same time, the fluorine content in the leaves increased from a background value of 2.6 mg% to 64 mg% after one treatment, to 104 mg% after two treatments, and to 360 mg% after eight treatments.

Taylor, O. C.

ACUTE RESPONSES OF PLANTS TO AERIAL POLLUTANTS. *Advan. Chem. Ser.*, no. 122:9-20, 1973. 18 refs.

Acute symptoms of injury from various pollutants in different horticultural and agronomic groups are visible on the affected plant. Symptoms include chlorosis, necrosis, abscission of plant parts, and effects on pigment systems. The effects of the following pollutants on plants are described: sulfur dioxide, peroxyacetyl nitrate, fluorides, chlorides, nitrogen dioxide, ozone, and particulates. Minor pollutants causing damage are ethylene, chlorine, ammonia, and hydrogen chloride. Symptoms of acute injury are often used to identify the pollutant source and to estimate agricultural damage. THE SUSCEPTIBILITY OF WOODY PLANTS EXPOSED TO FLUORINE COMPOUNDS AND SO₂. (Zur Widerstandsfähigkeit von Gehölzen gegenüber Fluorverbindungen und Schwefeldioxid). *Text in German. Flora (Jena)*, 161(3):289-302, 1972. 11 refs.

The susceptibility of 80 woody plant species to fluorine compounds was studied in fumigation chambers and in a test area around a major fluorine emission source, and the results are compared with those of previous sulfur dioxide toxicity tests. The hydrofluoric concentrations in the Chambers ranged from 0.3 to 0.5 mg/cu m. *Juglans regia*, *Vitis vinifera*, *Pinus silvestris*, *Berberis vulgaris*, *Rhododendron japonica*, *Picea abies*, and *Larix decidua* were the most susceptible species to HF. *Taxus baccata*, *Tilia cordata*, *Alnus incana*, *Ribes sanguineum*, *Salix elaeagnus*, *Populus regenerata* Harff, *Carpinus betulus*, *Pinus Strobus*, *Pinus nigra austr.*, *Potentilla fruticosa arb.*, *Castanea saliva*, *Lonicera tatarica*, *Larix leptolepsis*, and *Picea pungens* were classed as fluorine-susceptible, while such species as *Pinus montana*, *P. contorta*, *Cornus alba sib.*, *Prunus cerasifera* Piss., *Ulmus campestre*, *Alnus glutinosa*, *Buxus sempervirens*, *Pinus peuce*, *Syringa japonica*, *Acer Negundo*, *Robinia pseudoacacia*, *Ailanthus altissima*, *Fagus silvaticus*, *Populus candicans*, *Fraxinus excelsior*, *Humulus lupulus*, *Crataegus monogyna*, *Salix aquatica*, *Spiraea vonhouttei*, *Platanus acerifolia*, *Quercus borealis*, *Betula pendula*, *Prunus serotina*, *Viburnum carlesii*, and *Hydrangea pan.* were moderately susceptible to HF. *Juniperus squamata m.*, *Laburnum anagyroides*, *Viburnum lantana*, *Tamarix tetr.*, *Spiraea bum.* A. Wat., *Elaeagnus angustifolia*, *Weigelia hybr.* Ruby,

Rosa rugosa, and Synringa vulgaris were relatively resistant. Very high resistance of such species as Acer campestre, Acer platanoides, Evonymus europaea, Philadelphus coronarius, Quercus robur, and Sambucus racemosa was determined. Intercoastal necroses, and necroses on the edges and apices of the leaves and needles were the common symptoms of fluorine damage. The overwhelming majority of the species investigated had identical or comparable susceptibility to both fluorine and SO₂.

Oelschlaeger, W.

HARMFUL EFFECTS OF FLUORIDE. (Fluorschadenswirkungen). Text in German. Ziegeland. (Wiesbaden), no. 4:169-174, 1974.

Studies and observations on the harmful effects of fluoride emissions from various industrial sources on plants and animals are reviewed. Fluorine, hydrofluoric acid, and other gaseous fluorides are most dangerous to plants, and especially to Corufera. Entering through the stomata such fluorides cause necroses and interfere with metabolic processes. The harmful effects are influenced by such factors as solar radiation, water budget of the soil, relative humidity, and fertilization. Fluorosis in cattle, manifesting itself in bone lesions such as periosteal hyperostosis and exostoses, and causing production losses, is due to fluorine present in and on plants ingested. The fluorine tolerance for cattle is proposed to be set at 40 ppm in forage.

EFFECTS OF GASEOUS HYDROGEN FLUORIDE ON OXIDATIVE ENZYMES OF PELARGONIUM ZONALE LEAVES.

Phytopathology, vol. 61:1277-1279, 1971. 7 refs.

Changes in peroxidase and cytochrome oxidase enzymes were established histochemically in hydrogen fluoride fumigated leaves of Pelargonium zonale. Highest peroxidase and cytochrome oxidase activities were localized near the injured areas of fumigated leaves and showed an enhanced benzidine blue coloration in the phloem, with a decreased color or its complete absence in the palisade parenchyma. The enzyme activity was clearly evident in the phloem even after surrounding mesophyll cells had collapsed. Parallel experiments conducted on leaves infiltrated with sodium fluoride solutions showed similar results, though peroxidase activity was inhibited by fluoride levels higher than 0.01 M for 6 hr of bathing. EFFECTS OF FOLIAR SPRAY OF MINERAL SOLUTIONS ON THE LEAF FALL, RECOVERY FROM FOLIAR CHLOROSIS, AND FRUIT SET OF CONTAMINATED SATSUMA MANDARINS GROWN IN THE VICINITY OF AN ALUMINA-REFINING FACTORY. (Arumina seiren kojo kinsetu

onshu mikanen ni okeru kakushu enrui yoeki no yomen sanpu ga higaiju no rakuyoritsu ha no kuroroshi.su kaifuku narabi ni kekkaritsu ni oyobosu eikyo). Text in Japanese. Ehime Daigaku Noagakbu Kiyo (Mem. Coll. Agric., Ehime Univ.), 18(1):143-155, Aug. 1973. 12 refs.

Various chemical foliar sprays were tested for their efficacy in reducing fluorine damage to Satsuma mandarin fruit grown in the vicinity of an alumina refining factory. Foliar spray with lime exerted various desirable effects on the persistency of leaves, setting of fruit, titratable acidity of juice, and chlorophyll content of the leaves. Among the mineral elements in the leaves of the sprayed plants, only magnesium showed consistent changes with the application of various sprays.

EXPLANATION OF A CASE OF FUME DAMAGE IN SCOTCH PINE STANDS IN THE RUHR. (Klarung eines Rauchsadensfalles bei Kiefernbestanden im Ruhrgebiet). Text in German. Mitt. Forst. Bundesvers., no. 97:141-150, 1972.

(Presented at the International Symposium of Forest Fume Damage Experts, 7th, Essen, West Germany, Sept. 7-11, 1970.) Sulfur dioxide emitted from coal-burning factories about 4 km to the south and southwest is responsible for the extremely poor appearance and stagnation in the diameter growth of pine stands in the center of the Ruhr. During the growing season, observations of the vegetation were made repeatedly in a wide circle around the works. These revealed trees and bushes which were completely dead or killed off on one side, asymmetrical growth of many plants, color changes in a wide range of plant species, and a progressive reduction in the frequency of these phenomena with increasing distance from the works in all directions. The symptoms of leaf injury were characteristically more pronounced on the side nearer the works, indicating the emission of fluoride compounds from one of the factories. The results of the chemical leaf analyses for sulfur and fluorine confirmed the visual observations with regard to toxic substances and pollution source. Fluorine contents of 24 mg% in leaves and 10 to 14 mg% in the pine needles were found. Measurements of the annual rings showed that diameter increments ceased completely after 1956, which was the year when pollutants were first emitted from the production of fertilizer. The greatest portion of the damage due to acid fumes was caused by pollutants containing fluorine; by comparison, the damage caused by SO₂ was of lesser importance.

INVESTIGATIONS OF TOXIC EFFECTS IN CATTLE FROM HAY HARVESTED ON SMOKE-DAMAGED FIELDS. (Untersuchungen ueber toxische Wirkungen von Heu aus Rauchsadengebieten beim Rind). Erzmetall, 23(10):498-505, 1972. 21 refs. Translated from German, 24p.

Clinical investigations of cattle stock feeding on hay harvested from a smoke damaged area near a zinc and lead foundry and

a sulfuric acid plant were conducted to investigate whether increased lead, zinc, and fluorine levels in the region produced any toxic effects to the cattle. No signs of poisoning from the above elements were found, with the exception of enamel defects on the incisors of about one-third of the animals examined. Lead and zinc content of the hay was above normal, though still below the toxic limit; while the fluorine content ranged around the upper normal limit. Clinical examinations of blood chemistry, urine, milk, and hair, as well as of the functional capacity of the rumen content at two week intervals showed no signs of poisoning, despite the fact that experimental animals averaged 0.64 l/animal/day less milk yield.

Munshower, Frank F.

BIOTIC MONITORING OF THE EFFECT OF POWER PLANT STACK EMISSIONS ON THE RANGE RESOURCE IN SOUTHEASTERN MONTANA. Preprint, Air Pollution Control Assoc., 14p., 1974. 9 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 67th Denver, Colo., June 9-13, 1974, Paper 74-5.)

Biological monitoring can be used to determine the effects of power plant and other stationary source emissions on the ecosystem. A study was undertaken in southeastern Montana to determine the effect of trace elements (zinc, copper, iron, lead, cadmium), sulfur, and fluoride on the surrounding area. Trace element analyses of soils, plants, and animal were integrated with ecological investigations of the dominant plant communities. Low levels of fluoride occurred in plants and animals. Sulfur levels in plant tissues were 0.1-0.3%. Sulfur concentrations of 0.18% occurred in late summer pasture grasses, decreasing to 0.14% in cured winter grasses. Iron concentrations were normal (50-500 ppm) in all plants examined; concentrations of zinc and copper were below normal; lead and cadmium concentrations were less than 3 ppm and less than 0.3 ppm, respectively, in grasses. Visible sulfur damage occurred only on one pine within 1 mi of the power plant site. This study is the first attempt by a private utility in this area to provide advance warning of environmental degradation in the area surrounding a power plant. (Author abstract modified)

INJURY BY SULFUR DIOXIDE, HYDROGEN FLUORIDE, AND CHLORINE AS OBSERVED AND REFLECTED ON VEGETATION IN THE FIELD. J. Air Pollution Control Assoc., 18(5):307-312, May 1968. 24 refs.

Plants were examined at three different locations in the eastern part of the U. S. to determine whether damage from air pollution had occurred. Sulfur dioxide damage occurred in

<xref image="2000WVMN.TIF|V3|2006:09:28:01:42:16.00|116739|0"> image: </xref>

New York City; hydrogen fluoride occurred near a glass fiber manufacturing plant in the midwest; and hydrochloric acid mist and chlorine damage from a manufacturing operation occurred in an eastern state. The symptoms that developed in the vegetation were often similar. Chemical and microscopical analyses were helpful in diagnosing the toxicants. Pollutant concentrations were measured in the areas studied. Plant damage from SO₂ and/or acid mist results from the conversion of SO₂ to sulfur trioxide and then to sulfuric acid. The effects of SO₂ in the ambient air were more severe than those produced in the laboratory with the same concentration of SO₂ because of an additional chemical reaction attributed to ozone in the ambient air. Sulfur dioxide affected leaves, roots, stems, and plant color. The leaves of gladiolus plants, grown downwind of the fluoride source, were damaged by high concentrations of F in the area. Hydrogen chloride and chlorine levels in the eastern state were higher than concentration thresholds causing plant damage. (Author abstract modified)

McCune, D. C., P. J. Temple, and A. M. Witherspoon
ACCEPTABLE LIMITS FOR AIR POLLUTION DOSAGES
AND VEGETATION EFFECTS: FLUORIDE. Preprint, Air
Pollution Control Assoc., Pittsburgh, Pa., 12p., 1974. 21 refs.
(Presented at the Air Pollution Control Association Annual
Meeting, 67th, Denver, Colo., June 9-13, 1974, Paper 74-226.)
The relationship between the occurrence of atmospheric
fluoride and its effect on vegetation is studied to formulate ac-
ceptable limits for air pollution and suggest changes in the
design and operation of an emission source. Limiting values
for the concentration of hydrogen fluoride range from 10 to 5
ppb for 2- to 4-hour peak concentrations, from 0.6 to 0.3 ppb
for mean concentrations of periods of 30 to 60 days, and 4 to
1 ppb for daily mean concentrations depending upon the mag-
nitude of diurnal fluctuations and the degree to which days of
greater concentration tend to cluster together. These values
are derived from experimental fumigations of plants with HF
and there are several criteria for their selection. The risk of an
unacceptable effect should be low where this risk depends in
part upon the susceptibility, size, and function of the plant
populations to be protected. Periods for which the limiting
concentrations are selected should consider the effects of both
short and long term exposures, temporal variability in at-
mospheric concentrations, and time-dependent changes in the
susceptibility of plants to HF. (Author abstract)

65715

Tsunoda, F., E. Aizawa, and S. Sakurai
STUDIES ON AIR POLLUTION DUE TO FLUORIDES, PART
II: ON THE FLUORINE CONTENT OF RICE SEEN FROM
THE RESPECTIVE SOURCE OF POLLUTION. (Fukkabutsu
ni yoru taiki osen ni kansuru kenkyu -dai 11po- osengen betsu ni
niila sanmai chu no fusso ganyuryo ni tsuite). Text in Japanese.
Nippon Koshu F.isei Zasshi (Japan. J. Public Health), 20(10 Spe-
cial Suppl.): 1p., Oct. 1973. (Presented at the Japan Society of
Public Health, Annual Meeting, 32nd, Hiroshima, Japan, Oct.
1973, Paper 560.)

The fluorine content of rice specimens obtained in the fields at
various distances in various directions from factories which
are regarded as thy major source of fluorine pollution in the
air was determined. The fluorine content per ppm of dried
specimen were as follows: the average was 0.80 + or - 0.18;
the averages of specimens in three areas from four aluminum
refineries A, B, C, and D, respectively, within 1 km, 1-2 km,
and more than 3 km, were 3.96 + or - 1.85, 2.00 + or 1.07 and
0.93 + or - 0.31; the averages of specimens obtained respec-
tively in the field within 1 km, 1-2 km, and more than 3 km of
a pottery manufacturing plant, E, were 7.31 + or - 4.87, 1.55
+ or - 0.97 and 0.82 + or - 0.1; the averages of specimens ob-
tained in the field at the same distances as above from four
phosphate fertilizer factories, F, G, and H were 1.72 + or -

1.13, 1.12 + or - 0.38 and 0.66 + or - 0.03, respectively; and the average contents of fluorine in rice specimens obtained in the field located 1-2 km and more than 3 km from three iron foundries, I, J and K were respectively 0.94 + or - 0.35 and 0.82 + or - 0.18. The fluorine content of rice appeared in decreasing order, at the same distance, from factories E, A, B, C, D, F, G, J, H, I, K. The rice obtained in the fields near the pottery and aluminum refineries was most polluted by fluorine. A case was found in which the rice harvested in a field within 1 km of an aluminum refinery contained more than 10 ppm of fluorine. The ratio of gaseous fluoride to water soluble fluoride particle in the air around potteries and aluminum refineries is given.

Palm, Einar W.

WHAT AIR POLLUTION DOES TO YOUR PLANTS. Crops

Soils Mag., 23(4):14-17, Jan. 1971.

The effects of air pollutants upon plants are summarized. Plants that are sensitive or resistant to sulfur dioxide, fluoride, chloride, nitrogen dioxide, ozone, oxidants, ethylene, and particulates are listed. The damage that smog and other pollutants do to plants often looks like the damage done by diseases, insects, and nutritional imbalances. The various pollutants do not act the same way on each plant. Some pollutants, such as O_3 , will react differently on different species or even varieties of the same plant species.

Gruender, H. D.

DIFFERENTIAL DIAGNOSIS OF FLUORIDE POISONING IN

CATTLE. Fluoride, 7(3): 135-142, July 1974. 29 refs. (Presented

at the Conference of the I. S. F. R., 5th, April 8-11, 1973.)

The effects of fluoride poisoning on cattle are discussed. Chronic fluoride poisoning in cattle is of great economic significance. It prevails in all parts of the world, mainly because of industrial emissions from metallurgic, ceramic, and chemical industries. Damage due to water high in fluoride or to fluoride present in phosphate rocks and other minerals involves only locally limited regions. The maximum threshold for chronic toxicity ranges 1.2 to 1.5 mg F/kg body weight which corresponds to 50-60 ppm in dry substance for readily soluble fluoride or for contaminated forage. Even lesser amounts in the range of 0.7 to 1.2 mg F/kg body weight can induce dental fluorosis without other toxic manifestations. The minimal acute toxic dose for readily soluble fluoride in cattle lies between 6 and 20 mg/kg body weight/day following oral uptake for several days. These values vary according to conditions of absorption.

INFLUENCE OF AIR POLLUTION ON PLANTS. (Invloed van

luchtverontreiniging op planten). Text in Dutch. In: Milieu-

balans van Nederland. J. J. Mulckhuyse (ed.), Amsterdam/

Brussels, Intermediair, 1972, p. 47-55. 8 refs.

The effects of air pollutants, such as hydrofluoric acid, sulfur

dioxide, nitrogen dioxide, peroxyacetyl nitrate, and ozone on

plants are surveyed. While there are substantial species-

specific differences in the resistance of plants to air pollutants,

<xref image="2000WVMO.TIF|V3|2006:09:28:01:42:20.00|121663|0"> image: </xref>

plants are generally more sensitive to them than animals and humans, except for carbon monoxide and hydrogen sulfide. Thus, it is possible to select certain plant species as indicator plants for pollution monitoring. Necrosis of the leaf edges by HF, and interneural necrosis due to SO₂ were observed. Once retained, SO₂ is readily detoxicated in the leaves by metabolism to sulfates. Peroxyacetyl nitrate and ozone cause zonal necrosis of the leaves probably through the inhibition of the enolase enzyme. Changes in the taxonomic composition of the wild flora in polluted areas were observed.

66715

Tesink, J.

AIR POLLUTION AND ITS EFFECTS ON DOMESTIC ANIMALS. (Verontreiniging van de buitenlucht en gevolgen voor landbouwhuisdieren). Text in Dutch. In: Mileubalans van Nederland. J. J. Mulckhuyse (ed.), Amsterdam/Brussels, Intermediair, 1972, p. 56-75. 29 refs.

The effects of various air pollutants on domestic animals are reviewed. Fluorine compounds, inhaled or mostly ingested in contaminated grass, cause osteoid tissue formation, exostoses, mottled tooth enamel, and anorexia in cattle in chronic exposure. Fluorine content of the milk is negligible, and elimination takes place primarily in the urine. Sulfur dioxide irritates the mucosa, intensifies mucus production, and inactivates the cilia. Nitrogen oxides, apart from being irritating, are noxious for domestic animals primarily via the formation of high nitrate and nitrite levels in grass. Chronic exposure to lead, especially in grass growing along highways, leads to anemia, and to the degeneration of brain and nerve cells. Profuse diarrhea and reduced milk production are caused by ingestion of molybdenum-contaminated grass in cattle. The effects of carbon monoxide are due to the reduction of the oxygen supply by hemoglobin.

ELEMENTS OF THE SYMPTOMATOLOGY OF FLUOR

POLLUTED PLANTS. Rev. Roum. Biol. Ser. Bot., 17(2):135-144, 1972. 27 refs.

The toxic effects of fluorine compounds on plants was studied near aluminum and phosphatic fertilizer factories. The general condition of the vegetation in the polluted area, necrosis and foliar and floral discolorations, and sterility in some plant species are discussed. Physiological analyses concerning functional stomata, cellular sap concentration, and biometry were used to explain the fluorine intoxication process. They also constituted an indicative test of the degree of pollution. Symptoms of injury can be used to determine thresholds and tolerance levels for fluoride injuries. (Author abstract modified)

Daessler, Hans-Guenther

THE TOXICITY OF FLUORINE COMPOUNDS. FLUORINE

INJURIES IN AGRICULTURE AND FORESTRY. (Zur Toxizitaet von Fluorverbindungen. Fluorschaeden in der Land- und Forstwirtschaft). Text in German. In: Technik und Umweltschutz Luft - Wasser - Boden - Laerm, Luftverunreinigung bestimmter Gebiete und technologische Verfahren zur Emissionssvermin" :rung. Vol. 5, Leipzig, VEB Deutscher Verlag flier Grundstoffindustrie, 1974, p. 52-57.

Sources for fluorine containing emissions are hydrofluoric acid plants, aluminum plants, the glass industry, producers of phosphate containing fertilizers, brick kilns, and the ceramic industry. Little attention has been paid in the past to fluorine containing coal whose fluorine content ranges from 2 to 3 mg/kg referred to dry coal. The maximum allowable immission concentration for fluorine in the German Democratic Republic is 10 micrograms/cu m air. A review of the effects of fluorine

immissions on agriculture, horticulture, and forestry is given. The fluorine content in plants from immission free areas was determined to range from 0.2 to 2.0 mg/100 g dry substance. Agriculture and forestry strives to reduce fluorine injuries by selecting fluorine resistant species. For this, extensive fumigation experiments in the field and in potted cultures are needed. Exposure to low hydrogen fluoride concentrations and simultaneous measurement of carbon dioxide metabolism supply information on yield reductions and on any possible lowering of the nutrient content. Main emphasis must be placed, however, on reducing the emissions which can be achieved by absorption systems operating with water, diluted caustic soda, and sodium carbonate solution.

SURVEY AND ASSESSMENT OF AIR POLLUTION

DAMAGE TO VEGETATION IN NEW JERSEY 1971. Rutgers

- The State Univ., New Brunswick, N. J., Dept. of Plant Biology, Environmental Protection Agency Contract 68-02-0078, Rept. EPA-R5-72-010, 53p., Oct. 1972. 11 refs. NTIS: PB 214 160

A survey of injury resulting from air pollution episodes and assessment of their resultant effect on crop production in 1971 was conducted in New Jersey. Three hundred fifteen reported air pollution incidences were investigated and documented during the period of the survey which was concentrated in the central and southern counties of the state. Plant injury was observed in 17 counties, but economic loss or crop damage was observed in only 16 of these counties. Over one fourth (\$337,265) of the total crop losses (\$1,185,800) for New Jersey were recorded in Cumberland County. The photochemical pollutants were responsible for 80% of the plant injury recorded, with ozone contributing about 60% and peroxyacetyl nitrate 20% of the total. The other pollutants involved and their percentages of plant injury are hydrogen chloride mist and chlorine gas 6%, ethylene 3%, fluoride 2%, sulfur dioxide 2%, ammonia 2%, particulates 2%, and oil, petroleum, and an unidentified pollutant 3%. Only 29 out of 70 plant species observed exhibited injury. Vegetables accounted for 51% of the total crop loss Damage to lettuce accounted for over one third of the vegetable loss and 12% of the total estimated crops. (Author abstract modified)

Linzon, Samuel N.

EFFECTS OF AIR POLLUTANTS ON VEGETATION. In: In-

roduction to the Scientific Study of Atmospheric Pollution. B. M. McCormac (ed.), Dordrecht, Holland, D. Reidel Publishing, 1971, p. 131-151. 100 refs.

The effects of various air pollutants on vegetation are outlined. Information on symptoms of injury, dosages required to cause injury, sensitivity and tolerance of various plant species, and predisposing environmental and other factors are discussed. Consideration is also given to methods of investigating and preventing the effects of air pollutants on vegetation. The specific pollutants discussed include: sulfur dioxide, oxidants, ozone, O₃ and SO₂ synergism, peroxyacetyl nitrate, nitrogen oxides, fluorides, chlorine, hydrogen chloride, ethylene, ammonia, mercury, and particulate matter.

Jacobson, Jay S.

THE PLANT-MEDIATED CONSEQUENCES OF AIR POLLU-

TION. Colorado Univ., Boulder, Air Water Pollut., Proc. Summer Workshop, Boulder, Colo., 1970, p. 417-424, 1972. 14 refs. (Aug. 3-15.)

The effects of air pollution on plants and vegetation are discussed. The most serious threats to vegetation in North America are from photochemical oxidants (ozone and peroxyacetyl nitrate), fluorides, and sulfur dioxide. Injury to plants by other pollutants as ethylene, nitrogen dioxide, chlorine, hydrochloric acid, and panicle matter play a more limited role. Tobacco plants are widely used as a biological indicator of O₃ because leaves exhibit flecking when exposed to O₃. Parts per billion concentrations of fluoride in air can cause severe damage to sensitive vegetation. Large areas of land are still contaminated by sulfur oxides resulting from pollution from smelters in existence 70 yr ago.

Gilbert, O. L.

THE EFFECT OF AIRBORNE FLUORIDES. In: Air Pollution

and Lichens. B. W. Ferry, M. S. Baddeley, and D. L. Hawksworth (eds.), Toronto, Toronto Univ. Press, 1973, Chapt. 9, p. 176-191. 20 refs.

The effects of airborne fluorides on lichens is discussed. The toxicity of fluorides to lichens was established by field studies showing that the lichen flora in the vicinity of isolated point sources is severely impoverished, field transplant experiments, and fumigation experiments. Exposure to 13 ppb for 36, 72, and 108 hr causes chlorotic spots and curled margins; 65 ppb for 12 hr produces similar symptoms. Accumulation occurred during fumigation whether visible damage was produced or not. Fluoride damage is reported from Britain, Canada, France, Norway, and the United States. These studies all find F₂ toxic to lichens, but there is no agreement on the order of sensitivity. The degree of shelter can have a major effect on the distribution of damage. There is evidence that species can better tolerate the pollution when growing in eutrophicated conditions. Lichens are useful indicators of the spread of F₂ pollution from aluminum smelters.

Nash, T. H., Ill

THE EFFECT OF AIR POLLUTION ON OTHER PLANTS, PARTICULARLY VASCULAR PLANTS. In: Air Pollution and

Lichens. B. W. Ferry, M. S. Baddeley, and D. L. Hawksworth (eds.), Toronto, Toronto Univ. Press, 1973, Chapt. 10, p. 192-223. 201 refs.

The effect of air pollution on vascular plants, mosses, and fungi is reviewed. Specific pollutants include sulfur dioxide, fluorides, ozone, nitrogen oxide, peroxyacetyl nitrate (PAN), and particulates. A mean annual local concentration of SO₂ above 0.01-0.08 ppm causes extensive phytotoxic effects in many species. Symptoms of fluoride poisoning vary tremendously between plant groups. Background variations of F₂ in plants generally range between 0.5 and 25.0 ppm by weight. The range of 25-105 ppm is the critical range for sensitive species. The most sensitive species are injured by O₃ fumigations between 5 and 12 pphm for 2-4 hr, while resistant species tolerate concentrations as high as 100 pphm. Plants respond physiologically to subacute dosages of NO_x although higher concentration of NO_x than SO₂ are required to produce necrotic markings. Damage from PAN can occur at concentrations below 0.1 ppm. The chloroplasts are particularly sensitive. Damage can also occur from ethylene, chlorine, hydrogen chloride, ammonia, and heavy metal particulates as arsenic, copper, lead, zinc, cadmium, iron, nickel, and cobalt. Mosses are approximately as sensitive to air pollution as lichens and are affected by SO₂, O₃, F₂, and some heavy metals. Fungi are also sensitive to SO₂ and O₃.

Phillips, P. H.

THE EFFECTS OF AIR POLLUTANTS ON FARM ANIMALS.

In: Air Pollution Handbook. Magill and Holden (eds.), New York, McGraw Hill, 1956, p. 8-1 to 8-12. 78 refs.

The acute and chronic effects of arsenic, fluorine, and lead on farm animals are reviewed. Symptoms, tolerances, pathological effects, and thresholds are discussed. The use of dusts or sprays of insecticides can cause poisoning of cattle. Fluorine in stack gas can contaminate vegetation; agricultural sprays and dust can also be a source of fluorine compounds. Cattle and sheep are the most susceptible to fluorine toxicosis of all farm animals, with pigs, horses, and poultry next in susceptibility. Lead compounds from industrial sources such as smelters and coal combustion, from dusts and sprays containing lead arsenate, and from automobile exhaust can pollute the environment and cause lead poisoning of animals. Chronic lead poisoning has occurred frequently on horses grazing near smelters, lead mines, and orchards which were sprayed.

BIOLOGICAL METHOD FOR THE DETECTION OF FLUORINE COMPOUNDS IN THE AIR. (Bin biologisches Verfahren zum Nachweis von Fluorverbindungen in Immissionen).

Text in German. Mitt. Forst. Bundesvers., no. 97:255-269, 1972. 15 refs.

A biological method for the determination of airborne fluorine contamination is described. The method involves culturing certain grasses (*Lolium multiflorum* and *L. perenne*) which are relatively insensitive to fluorine compounds for a defined exposure interval in a standardized growth substrate with comparable nutrient and water supplies in the vicinity of a pollution source. The plant samples obtained at the end of the exposure are analyzed for their fluorine content, with the origin and distribution of airborne fluorine compounds being estimated on the basis of the determined fluorine values. The only plants suitable for the method are those which can accumulate the toxic substance in large amounts without the formation of visible external symptoms of damage or growth depression.

DETERMINATION OF FLUORINE INJURIES ON AN ALLEY OF LINDEN TREES IN THE IMMEDIATE PROXIMITY OF A BRICK KILN NEAR ISMANING BY LEAF ANALYSES AND AERIAL INFRARED PHOTOGRAPHY. (Ermittlung von Fluorschäden an einer Lindenalle in unmittelbarer Nähe einer Ziegelei bei Ismaning durch Blattanalysen und Luftaufnahmen in Fälschfarbentechnik). Text in German. *Gesundh.-Ingr.*, 95(9):259-263, 1974. 17 refs. (Presented at the Second Symposium on Branch-specific Emissions, Fluorine Emissions by Brick Kilns, Munich, Germany, Feb. 1, 1974.)

Upon discovery of severe leaf injuries in an alley of linden trees near Ismaning (Munich, West Germany), leaf samples were taken from the lower branches of the trees at three different time periods. The samples were dried, ground, and ashed according to the method by Buck (ashing of 5 g dry substance in a nickel vessel at a temperature of 450 to 500 C in a muffle furnace). The fluorine in the ash was determined by the method of Buck and Stratman. A relationship was determined between the fluorine concentration of the leaves and the location of the tree with regard to a brick kiln close to the alley. The severity of leaf necrosis not only corresponded to the determined fluorine concentration but also to the gray tone of the infrared photographs. The results led to the initiation of measures for reduction of the fluorine emissions by this brick kiln.

SURVEY OF ARSENIC AND FLUORINE LEVELS IN VEGETATION IN THE RODEO-CROCKETT AREAS - 1963 - 1964. Preprint, Bay Area Air Pollution Control District, San Francisco, Calif., *lip.*, April 1965. 2 refs.

Arsenic and fluoride levels in vegetation of the San Francisco Bay area (Rodeo-Crockett areas of Contra Costa County) were determined over the period September 1963 to August 1964 to determine if various industrial sources, particularly a brickworks facility and a lead smelting operation, were contributing to previously observed plant damage. Twelve monthly vegetation samples were taken at six sites in the area; lime-paper strip samples were taken at the same sites plus one additional location. Fluoride in excess of the safe level for beef cattle (50 ppm soluble fluoride) was found in five of 71 pasture grass samples taken during the survey; elevated arsenic levels coincided with the high fluoride levels in the same samples. Grass sample results were generally in agreement with lime paper data for fluoride and arsenic. Seasonal wind data, visual evidence of plant damage and the analytical findings suggested that the major contributing source, both for fluorides and arsenic, was in the Selby area.

Gudenan, Robert

EFFECTS OF AIR POLLUTANTS ON PLANTS. (Wirkungen von Luftverunreinigungen auf Pflanzen). Text in German. *Umwelt*, 1972:206-211, 1972.

The effects of air pollutants on plants are described. Air pollutants, such as sulfur dioxide, hydrofluoric acid, hydrochloric acid, peroxyacetyl nitrate, and ozone may cause acute, chronic, and invisible or physiological damages to plants by deteriorating the growth, yield, and quality. The extent of the damage progresses with increasing pollutant concentration, rather than the length of exposure time. Both SO₂ and HF interfere with photosynthesis, and the former metabolizes chlorophyll to pheophytin, while HF interferes with porphyrine synthesis. Both SO₂ and HF deplete the water reserve of the plant organism. Inert dust is injurious in keeping light away from the leaves and clogging the stomate, while toxic, water-soluble dust components act directly on the ex-

posed parts. Air pollution reduces the resistance of plants to frost and pests. Due to their response to air pollutants, certain plants can be used as bioindicators of air pollution.

Gardner, Wayne S.

OZONE INJURY TO TOBACCO PLANTS IN SOUTH

DAKOTA. Plant Disease Reptr., S7(2):106-110, 1973. 21 refs.

Ozone injury symptoms appeared on Turkish tobacco plants grown in a greenhouse and on Wisconsin 38 tobacco plants grown in field plots at Brookings, South Dakota in 1970. In 1971, ozone injury appeared on greenhouse and field-grown plants of the Bel-W3, Bel-C, and Turkish types. Ozone fleck was most severe in southeast and east-central South Dakota. A decreasing amount of injury was observed in northeast, central, west-central, and southwest South Dakota. The Bel-W3 tobacco showed injury at eight locations, while Turkish, Bel-C, and Bel-B were injured only in the eastern parts of the state. The Bel-W3 was a reliable monitor of air pollution episodes when plants were continuously produced and observed in the greenhouse at Brookings. New injury appeared on newly matured leaves and older leaves as dark gray to black flecks that turned brown to tan to white with age. Periodic ozone occurrences were recorded by new flecks appearing generally on tissue of younger age. Plant indicators for the pollutants peroxyacetyl nitrate, fluoride, and sulfur dioxide showed no injury in South Dakota. (Author abstract modified)

INVESTIGATIONS OF THE TOXIC EFFECTS OF HAY

FROM SMOKE DAMAGED AREAS ON CATTLE. (Untersuchungen ueber toxische Wirkungen von Heu aus Rauchschedengebeiten beim Rind). Text in German. Erzmetall., 2S(10):498-S05, Oct. 1972. 21 refs.

The toxic effect of hay contaminated with lead, zinc, and fluorine, collected from smoke damaged areas around a lead and zinc smelter and another sulfuric acid production plant, on the physiological status of cows was studied by clinical observations and during a 6-month feeding test. The lead and zinc contents in the hay were above normal but below the toxic limit, while the fluorine level approached the upper limit of the normal range. Apart from lesions of the enamel of the incisors, detected in about one third of all exposed animals, no symptoms of poisoning were detected. The recurrent clinical examinations performed every two weeks for hematology, alkaline phosphatase, bilirubin, ornithine carbamoyltransferase, and glutamic-oxaloacetic transaminase-revealed no indications of poisoning. The lead and zinc concentrations in blood, plasma, urine, feces, milk, and hairs were below the toxic range, and the fluorine level in the bones ruled out fluorosis. At the same time, the per-capita milk production was significantly reduced by 0.64 l/day.

SURVEY OF FLUORIDE LEVELS IN THE AREA AROUND

THE BLUFF SMELTER. Proc. Pollut. Res. Conf., Wairakei,

New Zealand, 1973, p. 341-356. 13 refs. (June 20-21.)

<xref image="2000WVMR.TIF|V3|2006:09:28:01:42:30.00|119121|0"> image: </xref>

The environmental control monitoring program at the Bluff Aluminum Smelter is discussed as applied to areas adjacent to the smelter. Fluorine effects on wildlife and vegetation are considered, and the background levels of fluorine in the flora, fauna, air, and water of the area are presented. The effect of smelter emissions on these background levels and the care needed when interpreting these results are also discussed. The results showed that extraneous sources of fluorine may influence the fluoride content of biological tissues and that allowance must be made for this factor in interpreting results against established standards. In particular, the effect of top-dressing with phosphate fertilizers was discovered. There was also a great variation in the fluoride levels in different species of flora and fauna. Emission of fluorides from the smelter had a small influence on the background levels in some areas, but in no instances were the standard limits to prevent damage to vegetation and livestock exceeded. No change was detected in the atmospheric fluoride levels in areas western and northern from the smelter since the smelter began operations. Levels on the eastern side (downwind) of the plant were greater, but standards are not expected to be exceeded. (Author conclusions modified)

LICHENS AND AIR POLLUTION. In: The Lichens. Vernon Ahmadjian and Mason E. Hale (eds.), New York, Academic Press, 1973, Chapt. 13, p. 443-472. 80 refs.

Various aspects of the effects of air pollution on lichens are reviewed including historical aspects, lichen deserts, environmental effects, and use of lichens as biological indicators of air pollution. The area around an industrial area or city may become a lichen desert, since lichens decrease in number in polluted air. Lichen species increase in number and variety with increasing distance away from urban areas. A lack of data makes it impossible to compare lichen deserts on a truly worldwide scale. There are, however, enough studies from Europe and North America to make it clear that in these areas the zoning of epiphytes is outstandingly similar. The most resistant epiphytic foliose lichen in Europe is *Hypogymnia physodes*, closely followed by *Parmelia sulcata* and *Physcia tenella*. On basic substrata, *Lecanora dispersa* is the most resistant lichen. The effect of industrial point sources of sulfur dioxide on lichens is similar to that of cities, despite the different patterns of fumigation involved. The causes of lichen deserts are described. Two phytotoxicants, sulfur dioxide and fluorine, have been identified as the major pollutants affecting lichens. The field, analytical, and experimental evidence supporting SO₂ as the major city influence are reviewed. The effects of SO₂ on growth and metabolism are discussed. The effects of individual habitat factors such as shelter, pH, nutrients, water relations, substratum, serai stage, growth form, and systematic position on the toxic effects of SO₂ to lichens are discussed.

Guderian, R.

DAMAGES CAUSED BY EMISSIONS FROM CONVENTIONAL POWER PLANTS IN VEGETATION AND FOOD.

(Schaeden an Vegetation und Nahrung durch Immissionen aus konventionellen Kraftwerken). Text in German. Strachlenschutz Forsch. Prax., vol. 12:81-97, 1973. 59 refs. (Presented at the Association of German Radiation Protection Physicians and the Association for Radiation and Environmental Research, 12th Conference, Munich and Nueherberg, West Germany, Oct. 8-9, 1971.)

Studies and observations on plant damage caused by gaseous and panaculate emissions of thermal power plants are surveyed. Dust emissions from obsolete power plants with no adequate filters affect plants in the immediate vicinity by reducing exposure to sunlight and increasing the local tempera-

ture on the leaves the dust settles on. While the damaging effect of dust from modern thermal power plants equipped with efficient filters is negligible, such power plants and industries emit considerable amounts of sulfur dioxide and fluorine, the most harmful compounds for plant life. These gases penetrate into the leaves through the stomata. Sulfur dioxide reduces the photosynthesis, temporarily stimulates dissimilation, and, when present in higher concentration, dehydrates the plant by destroying the osmotic potential, and metabolizes chlorophyll to pheophytin. Intercoastal necrosis is caused by SO₂, while apical and edge necrosis is due mostly to fluorine compounds. The plant damage due to SO₂ and fluorine compounds may manifest itself in reduced yield and quality impairment as well as esthetic deterioration. Fluorine, readily accumulating in leaves, is hazardous for animals and humans ingesting fluorine-contaminated plant materials. The extent of SO₂-afflicted damage increases progressively with increasing concentration, and can not be characterized by the product of concentration and exposure time.

EFFECTS OF AIR POLLUTION ON PLANTS. Preprint, National Society for Clean Air, Brighton (England), Part 1, p. 1-13, Part 2, p. 71-79, 1972. 59 refs. (Presented at the National Society for Clean Air, Annual Conference, 39th, Scarborough, England, Oct. 16-20, 1972.)

The effects of air pollution on plants are reviewed. Certain features of plants which affect their susceptibility to pollutants are discussed including stomata, leaves and photosynthesis. Pollutants, environmental factors, and specific pollutants (sulfur dioxide, fluorides, smoke, soot, dust, photochemical smog, and oxidant), and plants as indicators of air pollution are reviewed. The paper is then discussed.

Daessler, H. -G., H. Ranft, and K. -H. Rehn
THE SUSCEPTIBILITY OF WOODY PLANTS EXPOSED TO FLUORINE COMPOUNDS AND SO₂. (Zur Widerstandsfähigkeit von Gehölzen gegenüber Fluorverbindungen und Schwefeldioxid). Text in German. Flora (Jena), vol. 161:289-302, 1972. 11 refs.

The results of fume hardiness tests carried out with several woody plant species in cabin trials and in field tests around a major fluorine emission source with regard to resistance against sulfur dioxide and fluorine compounds are presented. Most of the woody plants were found to respond to both pollutants in a similar way regarding leaf damage and both the time of occurrence of the first injuries and the extent of the damage. Similarly to SO₂-damaged leaves, fluorine-damaged leaves showed apical and edge necroses, while intercostal necroses were prevalent in SO₂-exposed leaves. Needles are more sensitive to fluorine than to SO₂ in the spring. *Juglans regia*, *Vitis vinifera*, *Pinus sylvestris*, *Berberis vulgaris*, *Picea abies*, and *Larix decidua* were found to be most sensitive to fluorine, while *Taxus baccata*, *Tilia cordata*, *Alnus incata*, *Salix elaeagnus*, *Carpinus betulus*, *Pinus strobus*, *Pinus nigra austr.*, *Potentilla fruticosa arb.*, *Castanea saliva*, *Lonicera tatarica*, and *Picea pungens* were less susceptible. *Pinus montana*, *P. contorta*, *Cornus alba sib.*, *Prunus cerasifera Piss.*, *Ulmus campestre*, *Alnus glutinosa*, *Pinus peuce*, *Robinia pseudo-*
<xref image="2000WVMS.TIF|V3|2006:09:28:01:42:32.00|117922|0"> image: </xref>

doacacia, *Fagus sylvaticus*, *Fraxinus excelsior*, *Salix aquatica* and *fragilis*, *Malus eleyi*, *Platanus acerifolia*, *Quercus borealis*, and *Prunus serotina* were characterized by a medium degree of resistance. *Viburnum lantana*, *Rosa* species and cultivars, *Syringa vulgaris*, and especially *Acer platanoides* and *campestre*, *Evonymus europaea*, *Philadelphus coronarius*, *Quercus robur*, and *Sambucus racemosa* were resistant to fluorine. *Castanea saliva*, *Juglans regia*, *Rhododendron japonicum* *Taxus baccata*, *Vitis vinifera*, *Buxus sempervirens*, *Lonicera tatarica*, *Picea pungens*, and *Platanus acerifolia* were more resistant to fluorine than to SO₂, while *Lycium halimifolium*, *Forsythia intermedia*, *Philadelphus coronarius*, and *Pyracantha coccinea* were more susceptible to SO₂ than they were to fluorine.

EXPERIMENTS ON THE EFFECTS OF AIR POLLUTANTS
ON HORTICULTURAL CROPS: PART I. INVESTIGATION
OF LOCAL DAMAGE OF HORTICULTURAL CROPS. SEC.
A. INVESTIGATION OF THE ACTUAL DAMAGE BY AIR
POLLUTION USING INDICATOR PLANTS. (Taiki osen
busshitsu ga engei sakumotsu to ni oyobosu eikyo ni kansuru
shiken (1) - c. shihyo shokubutsu ni yoru higai jittai chosaho).
Text in Japanese. Kanagawa-ken Nogyo Sogo Kenkyujo Gyomu
Nenpo (Ann. Rep. Kanagawa Prefect Agri. Integr. Inst.),
1973:74, June 1974.

To see the actual state of the effects of air pollution, indicator plants such as mulberry trees, Satsuma-orange trees, ginkgos, zelkova trees, and pines were chemically analyzed for sulfur, fluorine, and several heavy metals, along with the air pollution data obtained at the monitoring points. The amounts of air pollutants decreased in the order of Ebina, Sagami-hara, Aikawa, and Shiroyama cities in Kanagawa Prefecture. Fluorine content of the air was on the average 1.0-1.4 micrograms/day/100 sq cm (filter paper method) and higher in the spring than summer. The sulfur content of mulberry leaves was about 1400 ppm without a local difference, and fluorine content was around 11 ppm, a little higher in the middle part of the Prefecture and in Sagami-hara. Sulfur content of Satsuma-orange leaves ranged in 0.1-0.3%, higher in spring than summer; however, no local difference was noticed in sulfur and heavy metal in the leaves. The sulfur content of ginkgo, zelkova, and pine tree leaves was respectively 0.2-0.4, 0.1-0.2, and 0.05-0.15, lower in rural areas than in industrial areas.

Itai, K., F. Tsunoda, and S. Sakurai
ON THE DETERMINATION OF FLUORINE IN BROWN
RICE. (Genmai-chu fusso no teiryō-ho ni tsuite). Text in
Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution),
9(2):373, Nov. 1974.

As the air pollution threat due to fluorine has increased, the content of fluorine in crops for food and feed has become important. Previous methods of determining fluorine in rice gave considerable fluctuation. A newly established method of fluorine determination in rice is therefore described. The route of analysis consists of keeping brown rice in calcium hydroxide for 24 hr, then evaporating it to dryness, and calcinating the rice in a crucible at 550 C. The ashes are added to concentrated sulfuric acid with a small amount of silver sulfate and aqua regia and steam-distilled at 137 + or - 5 C. The 10 ml aliquot of 250 ml of distillate was determined for fluoride ion by the fluoride ion meter. Recovery of fluorine was 92-103.2%.

Gordon, C. C.
MOUNT STORM STUDY. Montana Univ., Environmental Studies Lab., Environmental Protection Agency Contract 68-02-0229, 32p., Nov. 17, 1972.

A 3-year study of coniferous foliage damaged by phytotoxic elements, compounds, and particulate matter in the Ml. Storm

area of West Virginia and Maryland revealed that the major causal agents are waste products from coal-burning utility plants. The primary pollutant causing damage is sulfur dioxide and its by-product sulfuric acid. The SO₂ in the ambient air of the study area causes most of the needle tip necrosis, then progresses to total needle necrosis, and eventually causes premature needle casting. The H₂SO₄ causes the short-long needle syndrome and much of the reduction in terminal shoot elongation of several coniferous species grown for Christmas tree production. This acid is also responsible for premature needle casting of short needles when basal necrosis becomes severe enough to affect the vascular tissues. Fly ash particulates in the Mt. Storm area contain high concentrations of several elements and compounds, some of which are known to be phytotoxic, such as fluorides and sulfates. Iron, aluminum, and other compounds may or may not affect the trees. Gaseous and particulate fluorides in the area are from the burning of coal. Greenhouse and field studies of white, Scotch, and ponderosa pine seedlings demonstrated that fly ash slurries and hydrofluoric acid will cause two growth abnormalities? excessive lateral bud production and excessive terminal stem growth. Inoculation of young emerging conifer needles with HF caused the short-long syndrome. Samples collected in six polluted areas in the northwestern U. S. gave further evidence that HF and H₂SO₄ could cause growth abnormalities. Histological and chemical studies showed the disease syndromes occurring in the Mt. Storm area were identical to those occurring in the northwestern states. It will be impossible to cultivate the three species of conifers under healthy conditions in the Mt. Storm area until adequate abatement equipment is installed at large stationary emission sources of SO₂, fluoride, and particulates in the area. (Author summary modified)

Davison, A. W., A. Marsland, and W. F. Belts
A PROPOSED RAPID TEST FOR SUSCEPTIBILITY TO
GASEOUS FLUORIDES. Environ. Pollut., 7(4):269-282, Dec.
1974. 11 refs.

A rapid test for determining plant susceptibility to gaseous fluorides is proposed based on the use of cut leaves and fluoride solutions. Mature, nonsenescent leaves of *Iris germanica*, *Ligustrum vulgare*, and *Poa annua* were placed in fluoride solutions of 0, 5, 10, 25, 50, and 100 microgram/ml solutions to establish a standard procedure. The percentage of leaf area showing necrosis was directly related to the fluoride solution concentration, with *Poa* developing the greatest degree of necrosis and *Ligustrum* the least. Experiments with barley and maize showed that damage was much greater after 24-hour exposures as compared to 8-hour exposures. Barley, which is relatively resistant to fluoride, required more than 8 hr to show significant damage, suggesting that long exposure may be necessary to cause damage in more resistant species. Experiments with young and mature leaves of *Zea mays* showed that necrosis was greater in the latter after 48 hr of fluoride treatment. Experiments with compound leaves revealed relatively little damage to lucerne leaves exposed to 100 microgram/ml fluoride, whereas soybean exposed to 50 microgram/ml fluoride exhibited typical water-soaked areas and necrosis. Covering the tips of mature barley leaves with

<xref image="2000WVMT.TIF|V3|2006:09:28:01:42:36.00|120222|0"> image: </xref>

petroleum jelly before fluoride treatment resulted in a shift of maximum fluoride accumulation from the tip to areas immediately adjacent it. Overall, the percentage of necrosis was slightly reduced. Significant differences to fluoride susceptibility were noted for maize, barley, and wheat; these differences paralleled the susceptibility of the species to atmospheric fluoride. Significant intraspecies differences in fluoride susceptibility were observed for Zephyr, Sultan, and Julia.

ON THE RELATION BETWEEN AIRBORNE AND
FLUORINE IN PLANTS. (Shokubutsu-chu fusonodo to taiki-chu
fukkabutsu ni tuite). Text in Japanese. Taiki Osen Kenkyu (J.
Japan. Soc. Air Pollution), 9(2):370, Nov. 1974.

A high correlation between atmospheric fluoride and the fluoride content of plants was recognized using several methods. The AP method was used in determining atmospheric content of hydrogen fluoride. The concentrations of hydrogen fluoride; seasonal 1-hour averages highest seasonal values of monthly average values, daily average values, and 1-hour values were examined using the fluoride contents in brown rice and leaves of gladioli. There was a significant correlation between all the atmospheric fluoride values and the fluoride content of brown rice.

A PHOTOCOPY TECHNIQUE TO EVALUATE FLUORIDE
INJURY ON GLADIOLUS IN ONTARIO. Plant Disease Repr.,
58(12):1091-1094, Dec. 1974. 4 refs.

A photocopy method was used for evaluating and reproducing fluoride-induced leaf injury during a gladiolus indicator plant program. Measurements of leaf injury and fluoride content were made on 5000 leaves from potted gladioli plants grown at 31 indicator plot locations in seven surveillance areas located in the Province of Ontario. Harvested plants were transported to a laboratory where a standard office photocopier was used to make reproductions of four middle-aged leaves from each plant. All leaves collected from each plot were divided into terminal and basal portions for chemical analysis of fluoride and other phytotoxic components. Comparisons of fluoride content and leaf injury for three collections of gladioli in a surveillance area near a fertilizer plant showed reductions in leaf injury which paralleled reductions in fluoride content for increasing distances downwind of the source. As the plot distance increased from 3.4 km to 5.5 km from the source, fluoride content decreased from 5.0 ppm to 3.0 ppm and leaf injury decreased from 4.6% to 0.2%.

LOCAL ENVIRONMENTAL CONTROL AND BIOLOGICAL
INDICATOR - AIR POLLUTION AND BIOLOGICAL IN-
DICATOR. (Chiiki no kankyo kanri to seibutsu shihyo - taiki
osen to seibutsu shihyo-). Text in Japanese. Kankyo Gijut.su (En-
viron. Conserv. Eng.), 3(11): 803-812, Nov. 1974.

Two sides of environmental control, the feed forward control and the system of environmental control utilizing feedback, are described with relation to biological indicators. As one of the factors in terrestrial ecological systems, the concentration of air pollutants was related to plant damage, referring to a result of a survey on the frequency of damaged plant (cryptomeria) versus concentration of sulfur dioxide, for several distances from the coast. The merits and the selection standards of a biological indicator are described in detail citing specified plant indicators to respective air pollutants such as SO₂, hydrogen fluoride, nitrogen dioxide, ozone, peroxyacetyl nitrate, ethylene, chlorine, hydrogen chloride, ammonia, and photochemical oxidants. As general biological indicators, some

insects, some amphibians, fishes, birds, mammals including mankind, and plants, can be used. In utilizing plants as an indicator of air pollution, the detailed standard items which represents the active status of the indicator plants were described.

Pell, Eva J. and Eileen Brennan
ECONOMIC IMPACT OF AIR POLLUTION ON VEGETATION IN NEW JERSEY AND AN INTERPRETATION OF ITS ANNUAL VARIABILITY. Environ. Pollut., 8(1):23-33, Jan. 1975. 33 refs.

The economic impact of air pollution on vegetation in New Jersey was surveyed for the years 1971 and 1972. A loss of \$128,019 was sustained in 1972 due to damage of agricultural crops and ornamental plantings exposed to air pollutants. Ozone accounted for 27% of the damage, peroxyacetyl nitrate for 20%, hydrogen fluoride for 18%, ethylene for 15%, sulfur dioxide for 4%, and ammonia for 1%. The loss was only 11% of that estimated for the previous year by a similar method despite the fact that air pollutant concentrations did not decrease from 1971 to 1972 in the agricultural regions during the growing season. An unusual rainfall pattern in 1972 possibly induced a water and/or oxygen stress in the plants such that they were protected from air pollution injury. Other factors such as temperature, humidity, nutrition, the presence of disease, and the use of systemic fungicides may also have enhanced plant resistance to air pollutants. INVESTIGATION OF REAL STATE OF ENVIRONMENTAL POLLUTION BY ANALYSIS OF MULBERRY-LEAVES. (So-
yo bunseki ni yoru nokochi no kankyo osen no jittai). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 9(2):353, Nov. 1974.

Mulberry tree was chosen as an index plant of air pollution, and the leaves were collected from 20 points in Kanagawa Prefecture in August 1972 and 1973, washed, air-dried, powdered, and analyzed. The average content of heavy metals was 126 ppm of iron, 31 ppm of zinc, 41 ppm of manganese, 8 ppm of lead, 5.3 ppm of copper, 2.6 ppm of nickel and 0.72 ppm of cadmium, without large local difference. The average content of sulfur was 1300-1400 ppm on the average, also without large local differences, however, the content of fluorine was only 8.6-8.8 ppm in the leaves of places remote from industrial districts as compared to the average of 13-14 ppm. The analytical values of sulfur and fluorine in leaves collected from four representative places (middle and north) showed a decreasing tendency from the middle- to the north parts of the Prefecture; in the north part of the fluorine content in leaves coincided to that in the air.

H. EFFECTS-PLANTS AND LIVESTOCK

463

sokabutsu no kankyo osen hyoka to sono bunsekiho no kento). Text in Japanese. Preprint, p. 9-10, 1974. (Presented at the Environmental Toxicology Symposium 1st, Osaka, Japan, Nov. 21-22, 1974, Paper 9.)

The atmospheric pollution pattern by fluorine compounds was evaluated by index plants over a period of 8 yr. The growth and appearance of plants were analyzed in reference to F content in plants (on ground and potted), agricultural products, soil, subterranean water, and atmosphere. The sulfuric acid (with addition of sodium silicate)-steam distillation method was most effective for the determination of F in plant samples. The zinc oxide-sodium carbonate fusion method (sample: ZnO:Na₂CO₃ equal 1:2:3, 600-1000 C) was most effective for soil analysis. The F content in plant samples showed a decreasing trend over the years, and the radius of polluted areas decreased with time, reflecting the control measures taken over the past years. On the other hand, the atmospheric F concentration showed no significant decrease. No significant relationship was found between F content in plant and that in soil and subterranean water.

ACUTE INHIBITION OF APPARENT PHOTOSYNTHESIS BY
PHYTOTOXIC AIR POLLUTANTS. Am. Chem. Soc. Syrnop.
Ser., no. 3:115-127, 1974. 23 refs.

Plant fumigation experiments in environmental chamber systems were performed to assess the effect of various air pollutants on photosynthesis. Oat, barley, and alfalfa canopies required treatments with more than 1 ppm hydrogen fluoride, about 5 ppm ozone or chlorine, 20 ppm sulfur dioxide, and 40-60 ppm nitrogen dioxide or nitric oxide before apparent photosynthesis rates were measurably depressed after 2 hr of exposure. Plants previously exposed to NO or SO₂ recovered much more quickly than plants given HF exposures. Plants treated with Cl₂, O₃, or NO₂ recovered at intermediate rates. Sulfur dioxide-NO₂ mixtures induced greater than-additive inhibition of alfalfa apparent photosynthetic rates, with the greatest synergistic effects being observed at low concentrations (15 ppm for each gas). No synergism was evident at 50 ppm of each gas. All other pollutant combinations tested, with the possible exception of SO₂ and HF, caused plant responses which are additive in suppressing apparent photosynthesis rates. Ozone or SO₂ in combination with NO₂ appears capable of measurably suppressing carbon dioxide uptake rates of sensitive plants in concentrations approximating present air quality standards.

INVESTIGATIONS ON THE INFLUENCE OF FLUORO CONTAINING AIR POLLUTANTS UPON THE SUSCEPTIBILITY OF SPRUCE PLANTS TO THE ATTACK OF THE GALL APHID SACCHIPHANTES ABIETIS (L.). (Untersuchungen ueber den Einfluss fluorhaltiger Abgase auf die Disposition der Fichte fuer den Befall durch die Gallenlaus Sacchiphantes abietis (L.). Text in German. Z. Pflanzenkrankh. Pflanzenschutz, 81(12):717-727, 1975. 8 refs.
The influence of atmospheric pollutants (especially fluoro compounds) upon the gall density of Sacchiphantes abietis (L.) in young spruce stands has been demonstrated. A histologically visible defense reaction of the cortex tissue in the basis of the buds against the sting of the Pseudofundatrix stylets is described. Complicated relations were observed between position and distance of the plants to the fluoro pollution focus on the one hand and density and survival rate of the pseudofundatrices and the percentage of defense reactions on the other.

DETOXICULTURE AND URBAN AIR POLLUTION. J. Environ. Plann. Pollut. Control, 1(3):46-49, 1973. 19 refs. The development of plants capable of detoxifying air pollutants is proposed. A scheme is suggested which involves the screening of potential detoxifiers in exposure chambers followed by a breeding program to select the most efficient plants within a species. The establishment of greenbelts around urban areas as well as the utilization of crop plants for pollutant detoxification is also recommended. The use of plants as indicators of dangerous pollution levels is also discussed, with numerous indicator plants being listed for such pollutants as ozone, peroxyacetyl nitrate, sulfur dioxide, and fluorides.

SULFUR DIOXIDE AND HYDROGEN FLUORIDE EMISSIONS IN REGARD TO PHYTOPATHOLOGY. (SO₂- und HF-Inunissionen im Blickpunkt der Phytopathologie). Text in German. Meded. Fac. Landbouwwet., Rijksuniv. Gent, 38(3/2): 1545-1548, 1973. 2 refs.

Observations of the effects of sulfur dioxide and hydrogen fluoride on forest trees and their parasites are presented. *Abies concolor* and *Abies veitchii* in a smoke damaged area were attacked by *Dreyfusia nuesslii* most intensely in areas where 2- and 3-year-old needles had already been damaged by SO₂ and HF. The attack of *Phytomyza ilicis* in *Ilex* was more intense in undamaged specimens than in those exposed acutely to high SO₂ concentrations. The spread of *Oligonychus unguis* in *Picea amara* facilitated the manifestation of SO₂-induced damages in yet undamaged 2- and 3-year-old needles. The invasion of areas sheltered from SO₂ by *Sacchiphantes viridis* indicates the susceptibility of this species to SO₂. This parasite species did not occur in SO₂-damaged areas which were occasionally exposed to sodium fluoride- and arsenic-containing dusts. The considerable damages afflicted by *Blastethia tunonella* to *Pinus montana* in areas with high SO₂ concentrations indicate the high resistance of this species.

Weidensaul, T. Craig

IMPORTANCE OF PLANTS IN OXYGEN PRODUCTION, CARBON DIOXIDE CONSUMPTION, AND AIR PURIFICATION. HortScience, 9(1):8-12, Feb. 1974. 27 refs.

The role of plants in the oxygen-carbon dioxide cycle and their ability to purify the air are discussed. Plants are not necessarily efficient air purifiers, although certain toxic gases can be absorbed by alfalfa. Those most easily absorbed are hydrogen fluoride, sulfur dioxide, and nitrogen dioxide. Carbon monoxide is among the least absorbed of the air pollutants. Ozone, although almost as readily deposited on the surface of plant tissues as HF and SO₂, appears to be somewhat less absorbed. Certain woody plants may also be significant in reducing ambient levels of SO₂ in the microenvironment immediately surrounding individual leaves; however, most plants which readily absorb SO₂ are also the ones most easily injured by it. More research is required for definitive statements to be made about ability of plants to purify the air without suffering significant ill effects.

THE USE OF PEROXIDASE ACTIVITY FOR MONITORING AND MAPPING AIR POLLUTION AREAS. Eur. J. Forest Pathol., 4(1):11-19, 1974. 18 refs. (Presented at the 2nd International Congress of Plant Pathology, Minneapolis, Minn., Sept. 11, 1973.)

The peroxidase activity of various tree species was used to map zones of plant reaction in areas contaminated with air pollution. Initial experiments in a forest exposed to fluoride emissions from an aluminum smelter for over 20 yr failed because the most sensitive plants were eliminated by selection. However, the use of peroxidase activity to map zones of fluoride contamination in an apricot orchard containing small trees of genetic uniformity was successful. Fluoride concentrations as little as 10 ppm in unwashed foliage were related to increased peroxidase activity, and the enzymes activity largely coincided with the area of visible injury. Increased peroxidase activity in the foliage of white ash was related to oxidant exposure resulting from automotive emissions in an urban area, with the increases being significant even in plants showing no visible injury. Thus, the activity of the enzyme appears to offer a sensitive indication of plant exposure to oxidants and fluorides long before the appearance of plant injury.

FLUORINE CONTENT OF ATMOSPHERE AND OF PLANTS AROUND AN ALUMINUM REFINERY. (Alumi-seiren koje shuhen ni okeru kankyo taiki to shokubutsu chu no fussoni tsuite). Text in .Japan.se. Shikoku Koshueisei Gakkai Zasshi (J. Shikoku Soc. Public Health), 20(1):92-94, Feb. 1975. Atmospheric fluorine levels at five points located 1 km, 1.5 km, 3 km, 4 km, and 5 km from an aluminum refinery were 22, 14, 20, 12 and 6 micrograms of F/sq m/ mo, respectively, in 1971; 67, 30, 38, 18 and 12 micrograms of F/sq m/mo, respectively, in 1972; and 46, 21, 28, 16, and 12 micrograms of F/ sq m/mo, respectively in 1973. The background fluorine level was 8-15 micrograms/sq m/mo before the refinery was in operation. Fluorine levels in leaves of pine trees at the five points showed increases from August 1972 to May 1973 of from about 10-15 ppm to 30-55 ppm; however, no increase was observed from Aug 1973 to February 1974. The fluorine content of Artemisia princeps was very large (about 100 ppm) within 1 km of the refinery and became rapidly smaller as the distance from refinery increased, suggesting the usefulness of A.p as an indicator of fluorine, In spite of the fluorine content, no visible symptoms of fluorine damage were observed in plar.ts around the refinery.

Iwanaga, T.

A PROBLEM OF ENVIRONMENTAL POLLUTION IN RURAL AREAS OF GIFU PREFECTURE. (Gifu-ken noson ni okeru kogai mondai). Text in Japanese. Nihon no Kagakusha (Japan. Sci.), 10(7):329-332, July 1975. A problem of untimely defoliation of Japanese pear trees in orchards of Kamo City, Gifu Prefecture which occurred in the summer of 1971 was investigated. The damage to leaves began from both the apex and the periphery as discoloration and then proceeded to the central part. The cause of the untimely defoliation was suspected to be fluoride-containing exhaust from a tile factory. Experiments in which pear leaves were exposed to aqueous hydrogen fluoride solution revealed the accumulation of fluorine in pear leaves, and the major cause of the untimely defoliation was thus attributed to fluoride in the exhaust from the tile factory and also to sulfur dioxide.

BEHAVIOR OF THE NATURAL AND CULTIVATED FLORA
IN THE PRESENCE OF AIR POLLUTANT REPORT. (Etude
du comportement de la flore sauvage ou cultivee a l'egard des
polluants). Text in French. Centre National d'Etudes Techniques
et de Recherches Technologiques pour l'Agriculture, les Forets,
et l'Equipement Rural (France), Groupement de Grenoble, Con-
tract 69.01.884, 22p., 1971.

A complex study of the effects of air pollution by fluorine
compounds on the vegetation in the Vallee de l'Arc, Vallee de
la Romanche, and Vallee de la Durance regions in France is
presented. Iris, Veratrum, album, Picea excelsa, P. sylvestris,
Abies alba, Polygonatum vulgare, Silene inflata, Gentiana lu-
tea, Hypericum species, and Vaccinium myrtillus were the
most sensitive species. Coniferous needles which tend to accu-
mulate fluorine were most susceptible to fluorine which
caused necrosis, premature loss of needles, and reduced
growth. Vast expanses of dead coniferous forests were de-
tected. The fluorine concentrations in the air, determined by
means of exposed, calcium hydroxide-impregnated filter
paper, ranged from 2.77 to 2.82 g/sq cm/day.

74624

Berry, Charles R.
THE DIFFERENTIAL SENSITIVITY OF EASTERN WHITE
PINE TO THREE TYPES OF AIR POLLUTION. Can. J. For.
Res., vol. 3:543-547, 1973. 15 refs.

The possibility of selecting clones of eastern white pine with
specific sensitivities to different air pollution regimes was in-
vestigated. Field screening was carried out by exposing potted
seedlings to field conditions for 1 yr or longer in each of three
areas where a particular phytotoxicant was known to
predominate. The areas were characterized by the following
pollution sources and major phytotoxicants: power plant, sul-
fur dioxide; fertilizer plant, fluorides; and vehicular traffic,
oxidants. Selections were made of trees injured during only
one season in one area; trees injured during both the summer
and winter, but only in one area; trees resistant to air pollution
in all three areas; and trees sensitive to air pollution in all
three areas. These selections are being propagated for use as
specifically sensitive bioindicators of air pollution and as re-
sistant lines for use in seed orchards of white pine. (Author
abstract)

Ionescu, A. and T. Moacalu
PLANT YIELDING POTENTIAL IN AREAS WITH POL-
LUTED ATMOSPHERE. (Potentialul de productie al plantelor
in zonele cu atmosfera impurificata. Text in Romanian. Probl.
Agric., 25(5):27-35, May 1973. 16 refs.

The effect of air pollution on agricultural yields and methods
to prevent crop damage are discussed based on studies con-
ducted in several zones with heavy air pollution. Fluorine pol-
lution leads to necrosis of wheat, rye, and oat leaves. Corn
shows fairly good resistivity. Up to 25% of the plants are af-
fected by air pollution in 41.4% of the cases when they are 500
m from the pollutant source (4.5 ppm fluorine). At 100 m from
the source, 80% of the grains are affected; while 42.8% of the
plants are affected when located at 500 m from pollutant
source. Plants of the Crucifere and Umbelifere species can be
<xref image="2000WVMW.TIF|V3|2006:09:28:01:42:46.00|116302|0"> image: </xref>

cultivated without significant damage. Based on biometric investigation conducted in the Navodari zone, the wheat height in the non-polluted areas was greater than that of wheat in a polluted zone; the yield in unpolluted areas was also greater for both wheat and oats. Sulfur dioxide and oxidants destroy chlorophyll. Losses can reach 34% in the case of *Populus* or up to 32% with *Onopodon achanthium*. The absorption spectrum of chlorophyll is altered by the active substances in pollutant dusts. Plant yields are affected when located at 2000 to 3000 m from the polluting source. Sulfur dioxide from sources located 1 to 3 km away caused a 60% loss in vineyards. Under the same circumstances, corn suffered only a 20% loss in a region where the sulfur dioxide level reached 15 ppm. Organic fertilizers are the most efficient means of blocking the toxic activity of the air pollutants. In air polluted zones, plants such as corn, potato, or castor bean should be cultivated to resist pollutants. Laboratory experiments indicated that Harrach and Triumph more resistant than 301, Bezostala, or Ponca.

Yamamoto, Takeo, Yasunobu Suketa, Eiichi Mikami, and Yoshimi Sato

ENVIRONMENTAL EVALUATION OF AIR POLLUTION BY FLUORIDE UTILIZING PLANT INDICATOR. (Shokubutsu shihyo ni yoru kichu fukkabutsu osen no kankyo hyoka). Text in Japanese. *Nihon Nogeikagaku Kaishi* (J. Agr. Chem. Soc., Japan), 49(7):347-352, July 1975.

Using leaves of *gladiolus gandavensis* and *Citrus unshu* as plant indicators for fluoride in air, the relation between fluoride accumulation in plants and air pollution by fluoride, especially fluoride in the gaseous state, was examined. The relationship between fluoride accumulation and particulate fluoride was also investigated. There was a good correlation between airborne fluoride and fluoride content of the plant leaves. A relationship was also found between the logarithm of fluoride content of leaves and the distance of the plant from the pollutant source. The injury was caused only by particulate fluorides. The average fluoride particle size was about 1.5 micron.

74722

Sukeda, Yasunobu and Takeo Yamamoto
EFFECTS OF ATMOSPHERIC FLUORIDE ON PLANTS.

(Shokubutsu ni oyobosu kichu fukkabutsu no eikyo). Text in Japanese. *Nihon Nogeikagaku Kaishi* (J. Agr. Chem. Soc., Japan), 49(7), 341-346, July 1975. 14 refs.

Gladiolus gandavensis, *Citrus unshu*, *Colacasia antiquorum*, *Cryptomeria japonica*, and *Oryza saliva* were utilized as plant indicators of air pollution by fluoride. There was a correlation between the fluoride content of the leaves of G.g. and C.u., with the correlation coefficient being 0.852 and 0.925, respectively. However, the rate of accumulation of fluoride in G.g. leaves was three times that of C.u. leaves. The content of fluoride in leaves and the visual injury of leaves differed from plant to plant; the fluoride content of C.j. was very high (2180 ppm) with total scorch, while that of C.a. was very low (66 ppm) with severe scorch. The ratio of calcium to silicon in G.g. was 4.38, and that in C.u. was 32.7. The relatively higher tolerance of C.u. to fluoride appeared to be due to the high calcium content and the high ratio of Ca to Si. There was a high correlation between the rice harvest and fluoride content of brown rice, the correlation coefficient being 0.91. When the fluoride content of brown rice exceeded 10 ppm, the harvest was reduced by 2/3 to 1/2 that of controls. Fluoride accumulation in polished rice did not increase by more than 12 ppm.

Suslova, V. V. and V. S. Nikoloyevskiy

EFFECT OF ACID GASES ON THEE PIGMENT COMPOSITION OF THE LEAVES OF TREES AND LAWN PLANTS.

(Vliyaniye kislykh gazov na pigmentnyy sostav yev drevesnykh i

gazonykh rasteniy). Uch. Zap., Perm. Gos. Univ., no. 256:93-132, 1971. 22 refs. Translated from Russian, 44p.

The chlorophyll (I) a and b, carotene (II), lutein (III), violaxanthin (IV), and neoxanthin (V) contents in the leaves of plants which were subjected during various phases of their growth and development to acid gases such as sulfur dioxide, nitrogen dioxide, fluoride, hydrogen fluoride, and phosphoric oxide in various concentrations were studied spectrophotometrically and by paper chromatography. Exposure to the gases caused nonsignificant changes in the pigment content of lawn grasses with different gas resistance. Woody plants revealed an inverse relation between the content of pigments and their gas resistance. The gas-resistant plants contained less pigment and lower la/Ib ratios. Differences in the relative distribution of pigments in all plants were nonsignificant. Lawn grasses decreased their pigment content during phases of growth under the influence of acid gases. Pigment system composition in lawn grasses was dependent on SO₂ concentration, time of exposure, and species properties. Low concentrations of SO₂ during the first day caused pigment decomposition and a decrease of the pigment content on the second day. High concentrations of SO₂ stabilized the plant pigments on the first and strongly decomposed them on the second day. Individual and total pigments in nonresistant and medium-gas-resistant woody plants decreased considerably, and increased with an increase of la/Ib ratio in the gas-resistant plants. Dependence between the gas resistance and individual and total pigment content in the woody plants was observed. The I and II stabilities in the plants in vitro were low. Statistical calculations revealed a dependence of the xanthophylls and II-FV contents on the gas resistance.

Daly, G. T.

DIAGNOSIS AND ANALYSIS OF AIR POLLUTANT DAMAGE TO PLANTS IN NEW ZEALAND. The Clean Air Society of Australia and New Zealand, Clean Air Conf. 1975 Proc., Rotorua, New Zealand, 1975. p. 684-728. 71 refs. (Feb. 17-21.)

The phytotoxic effects of sulfur dioxide, ozone, gaseous fluorides, photochemical oxidants, nitrogen oxides, and various industrial aerosols are reviewed along with studies in New Zealand involving the use of plants as indicators of air pollution. The distribution of lichen and moss cover on trees, buildings, and soil can be correlated effectively with the pattern of air pollutants at ground level, and the accumulation of pollutants by these plants in an industrial area provides a pollution monitor complementary to that of high volume air sampling or precipitation gauging. Sulfur dioxide and gaseous fluorides (hydrogen fluoride), in particular, exert specific effects on several prominent lichen and moss species. Quantitative examples of field surveys and vegetation sampling in areas exposed to SO₂ and fluoride emissions from industrial sources in New Zealand are presented to illustrate how such techniques can be used to help in controlling air pollution. (Author abstract modified)

EFFECT OF AIR POLLUTION ON ANIMALS. (Wirkung von Luftverunreinigung auf das Tier). Text in German. Praxis. Pneumol., vol. 28:818-822, 1974. 6 refs.

<xref image="2000WVMX.TIF|V3|2006:09:28:01:42:50.00|121823|0"> image: </xref>

Animals are exposed to air pollutants, such as fluorine, lead, arsenic, and zinc, primarily through the ingestion of contaminated plants and fodder, while pulmonary uptake is more or less negligible. The pulmonary uptake of fluorine and lead in cattle usually ranges from 1 to 2%. At a daily uptake of 1.2-1.5 g of fluorine in contaminated forage, cows showed yellowish-brown coloration and hypoplasia of the incisors, and slightly disturbed mobility. After 6 years, the fluorine content was 245-890 mg in tail vertebra, and up to 254 mg in teeth, relative to 100 g of ash. The general health status, performance, body weight, and fertility were normal throughout the experiment. Lead emitted by automobiles causes a high degree of contamination of plants near highways, while bushes have an efficient sheltering effect. The concentrations may be normal at distances of 100 to 200 m off the highway. Health damages due to lead in cattle are rated as rather improbable. The determination of the delta-aminolevulinic acid excretion in the urine is suitable for the diagnosis of lead poisoning only conditionally, partly due to the antagonistic effect of zinc.

McCune, D. C.

SUMMARY AND SYNTHESIS OF PLANT TOXICOLOGY.

Advan. Chem. Ser., no. 122:48-62, 1973. 29 refs. (Presented at the American Chemical Society, Division of Agricultural and Food Chemistry Meeting, 161st, IMS Angeles, Calif., March 31-April 1, 1971.)

A general review of plant toxicology is presented. The effects of air pollution on plants are examined in terms of changes that occur within the plant under experimental conditions and the collating of this information with respect to biological organization, changes in the pollutant, and the effects of environmental factors. Topics discussed include: the genetic background of the plant, the effects of specific pollutants on plant enzymes, patterns of chlorosis and necrosis following pollutant exposure, plant adaptation to pollutants, and synergistic effects of various pollutant combinations. Specific pollutants considered include: sulfur dioxide, ozone, fluorides, peroxyacetyl nitrate, nitrogen oxides, chlorine, sulfur trioxide, and sulfuric acid.

76452

Feder, William A.

CUMULATIVE EFFECTS OF CHRONIC EXPOSURE OF PLANTS TO LOW LEVELS OF AIR POLLUTANTS. Advan.

Chem. Ser., no. 122:21-30, 1973. 49 refs. (Presented at the American Chemical Society, Division of Agricultural and Food Chemistry Meeting, 161st, Los Angeles, Calif., March 31-April 1, 1971.)

Studies involving the chronic exposure of green plants to low levels of air pollution are reviewed. The cumulative effects of fluorides, sulfur oxides, ozone, nitrogen oxides, peroxyacetyl nitrate, and photochemical oxidants are considered. Plants exposed to 10 ppm ozone over a long period of time show reduced growth, leaf size, stem length, root weight, and flower production, as well as a delay in the onset of floral initiation. These effects are expressed in terms of the depression of total plant growth or population growth, as distinguished from acute effects which generally cause injury to plants but do not necessarily affect total growth or productivity. Evidence is accumulating which indicates that plants may exhibit depressed growth and yield with or without overt expression of injury symptoms. There appears to be a relationship between the dose-response curves describing acute symptom expression and those which can be used to express suppression of growth and yield. Honing, Frederick W. and Robert C. Loomis

THE IMPACT OF AIR POLLUTION ON THE FOREST

RESOURCE. Preprint, Forest Service, Atlanta, Ga., Environmental Quality Evaluation Group, 13p., 1974 (?). 6 refs.

The effects of air pollutants such as fluorides, sulfur dioxide, and ozone on forest vegetation are reviewed. Fluorides are significant because hydrogen fluoride is toxic to some plants at extremely low concentrations. Fluorides can enter leaves through the stomata and can also be absorbed through the leaf surface. The characteristic symptom of acute fluoride injury on many broad-leaved plant species is necrosis which occurs predominantly at the leaf tips and margins. The characteristic symptom of acute SO₂ injury to broad-leaved plants is an inter-veinal necrosis. These areas of dead leaf tissue first have a water-soaked appearance and take on a bleached ivory color in most plant species upon drying. Ozone probably causes more injury to vegetation than any other air pollutant in the United States. In contrast to SO₂ and fluoride injury, plant injury due to photochemical oxidants is often found many miles from industrial or urban sources. Ozone injuries are of four general types: pigmented lesions, upper-surface or either-surface bleaching, bifacial necrosis, and chlorosis.

THE EFFECTS OF AIR POLLUTANTS ON PLANTS. (Taiki
osen busshitsu no sliokuhut.su ni oyobosu eikyo). Text in
Japanese. In: Survey and Research Report on Medical Examination Method of Pollution-caused Health Damages, Kyushu Environmental Management Assoc., Fukuoka (Japan), p. 107-110, 1974 (?).

The effects of air pollutants, including sulfur oxides, fluorides, chlorine, and chlorides, on plants are reviewed. Leaves of rice plants develop white spots and gradually lose their green color when exposed to SO₂. Leaves of tomato plants develop brown spots although the tomato fruit usually is not injured. The SO₂ threshold concentration for rice and wheat plants is about 200 ppm/hr, whereas that for tomato and strawberry plants is 25 ppm/hr. Other plants which are easily injured by SO₂ include cotton, lettuce, sweet potato, and carrot. Fluorides cause damage to plants at ppb levels. Plants which are easily injured by fluorides include peach, corn, sweet potato, and grape. Chlorides cause plant damage to a greater extent than does SO₂. Radish is injured by chloride concentrations of 1.3 ppm (30 min).

A CASE OF AUTOPSY OF A BULL REARED UNDER AIR
POLLUTION ENVIRONMENT BY FLUORIDE CONDITIONS
FOR 30 MONTHS. (Fukkabutsu ni yoru taikiosen-kankyoka no
30 kagetsu shiiku shita ushi no baiken-rei). Text in Japanese.
Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution, 7(2):200, Nov. 1972.

A bull with body weight of 530 kg which was reared for 30 mo in a place where the fluorine content of the air is about 1 ppb and the fluorine content of daily plant food is 40-60 ppm was autopsied, the examination just before autopsy showing no anemia and no abnormality being shown in WBC (white blood cells), electrolytes, enzymes, or function of liver and kidney. On pa'hohistological examination no abnormal finding was obtained on the heart, lung, trachea, brain, hver, kidney, adrenals, spleen, pancreas or lymphatic glands; there were slight hanges on teeth and bone tissue. The fluorine content of
<xref image="2000WVMY.TIF|V3|2006:09:28:01:42:54.00|121162|0"> image: </xref>

tissues and organs was clearly high only in hard tissues and relatively higher in urine and in serum. The present case was in the stage of chemical fluorosis or the higher stage of bone mottling.

Kumamoto Prefectural Office (Japan)

FLUORINE CONTENT OF PLANTS. (Shokubutsu-chu no fusso ganyuryo chosa). Text in Japanese. In: White Paper on Environmental Pollution in Kumamoto Prefecture in 1974:p. 32-33, 1975.

According to 2-yr survey of the fluorine content of plants done in 1973 and 1974 in Arao City, where air pollution by fluoride from aluminum and phosphate-fertilizer factories exists, the content was larger in 1974 than in 1973, with the exception of rice plants. The values were as follows: 18.8 ppm in 1973 in grapes, 21.6 in Citrus unshu, 16.3 in pears, 18.6 in mulberry trees, and 16.6 in nee plants. In 1974, the figures were, respectively, 20.0, 33.1, 268, 22.5, and 12.1 ppm.

INVESTIGATION OF THE INFLUENCE OF AIR POLLUTANTS ON HORTICULTURAL CROPS AND OTHER

PLANTS. (Taiki osen husshitsu ga engei sakumotsu to ni oyobosu eikyo shiken). Text in Japanese. Kanagawa-ken Sangyo Senta Shiken Kenkyu Hokoku (Ann. Rep. Kanagawa Prefect. Sericult. Cent.), no. 1:124-139, Aug. 1973.

The degree of air pollution was measured at four monitoring points in the prefecture by dust jar (dust-fall) and alkaline filter paper to determine the monthly total amounts of insoluble matter, soluble matter, sulfur oxides, nitrogen dioxide, and chloride ion. The leaves of mulberry trees were collected at the four monitoring points in May, August, and November, and the sulfur and fluorine contents were determined. In August, leaves were collected from locations within the four monitoring areas and the levels of iron, zinc, lead, copper, cadmium, and nickel were also determined. Moreover, an experiment was carried out in a greenhouse where mulberry seedlings were exposed to ozone at 0.2 ppm, and to a mixture of ozone and sulfur dioxide. With some variation, the insoluble matter was larger in August, and generally ranged from 2-5 tons/sq km/30 days. Soluble matter ranged from 1-4 tons/sq km/ 30 days with some variation of area and month. NO₂ and SO₃ trapped on alkaline filter paper was less than 0.08, 0.02-0.13, 0.01-0.015, and less than 0.15 mg/100 sq cm/day (NO₂), and 0.07-0.35, 0.10-0.45, 0.15-0.65, and 0.11-0.35 mg SO₃/100 sq cm/ day. Chloride showed relatively small variations. There was little variation of S, F, Zn, Pb, and Cd in the leaves. The exposure experiment on ozone for 12 days (7 hr/day) showed a negative result on the leaves without any symptoms. However, although no damage was observed just after exposure to a mixture of ozone at 0.2 ppm and SO₂ at 2 ppm for 4 hr, brown spots appeared between the veins with a little larger sulfur content than the control, after 3-4 days exposure.

INVESTIGATION OF THE EFFECTS OF AIR POLLUTANTS

ON CROPS AND PLANTS. (Taiki osen busshitsu ga engei sakumotsu to ni oyobosu eikyo shiken). Text in Japanese. Kanagawa-ken Sangyo Senta Shiken Kenkyu Hokoku (Ann. Rep. Kanagawa Prefect. Sericult. Cent.), no. 2:74-90, July 1974.

An investigation carried out at 19 locations in 4 districts of the Kanagawa Prefecture during 30 days in December 1970 is discussed. Dust concentration, including soluble and insoluble substances, was measured with a dust jar. Other pollutants were trapped by alkaline filter paper and determined by barium chlorimlate (SO_x), Saltzman (NO₂), mercuric chloranilate (Cl ion), and ion electrode (F ion). The sulfur and fluoride

contents, as well as the metal contents of mulberry leaves were analyzed in May, August, and November. The average S and F contents in leaves collected in August were 1435 ppm and 11.57 ppm, respectively. Potted mulberry plants were exposed to ozone and sulfur dioxide and O₃, at low concentrations for 6 hr a day for 2 days. The S content in leaves exposed only to O₃ was the same as that in control leaves, while the leaves exposed to SO₂ + O₃ contained more S, indicating a synergistic effect of the mixture.

Mankovska, Blanka

INFLUENCE OF FLUORINE IMMISSIONS FROM AN ALUMINIUM FACTORY PLANT ON ITS CONTENT IN DIFFERENT DEVELOPMENTAL STAGES OF EUROPEAN PINE SHOOT MOTH RHYACIONIA BUOLIANA DEN. ET SCHIFF.

(LEPIDOPTERA). (Vplyv imisii fluoru z hlinikarne na jeho obsah v roznych vyvojovych stadiach obalovaca mladnikoveno rhyacionia buoliana den. et schiff. (lepidoptera). Text in Czech. Biologia, 30(5):355-360, 1975. 16 refs.

The fluorine content of different developmental stages of the European pine shoot moth Rhyacionia buoliana Den. et Schiff. (Lepidoptera) was examined in relation to fluorine emissions from an aluminum factory in the area. Differences in fluorine content of the moth for control regions versus the region under investigation were statistically significant at the 95% level of significance. The highest fluorine levels were found in dead larvae (465 mg/100 g). Dead pupae showed a level of 152.9-192.5 mg/100 g. Significant fluorine levels were also found in internal parasites, amounting to 68.2-97.6 mg/100 g.

SURVEY OF AIR POLLUTION DUE TO FLUORINE COMPOUNDS, PART II. ON CROP DAMAGE AROUND A TILE FACTORY.

(Fusso kagobut.su ni yoru taikiosen ni kansuru chosa, Sono 2, Kawara kojo shuhen ni okeru nosakubutsu higai ni tsuite). Text in Japanese. Shimane-ken Eisei Kogai Kenkyusno Nenpo (Annu. Rep. Shimane Prefect. Inst. Public Health Control Environ. Pollut. Inst.), no. 15, 1974.

Damage to pine trees, fruit trees, and agricultural crops has been reported since 1972. The areas of damage include forests, paddy field, and upland fields. Plant specimens, soil, clay, and glaze materials were analyzed primarily for fluorine. In rice grown near the factory there was a very high fluorine concentration (130 ppm) in the leaves (13.6 ppm in controls), a high fluorine content carrot tops (27.5 ppm), and in the edible part of Welsh onions (68.0 ppm). Samples of clay and glaze materials for tile contained 161-216 and 51-141 ppm of fluorine respectively. Although the fluorine content of clay and glaze material was not high, the plant damage was due to the exhaust gas from the tunnel-type high temperature furnace of the tile maker, which contained about 20.0 mg fluorine/cu m.

yosan higai ni (suite). Text in Japanese. Shimane-ken Eisei Kogai Kenkyusho Nenpo (Annu. Rep. Shimane Prefect. Public Health Control Environ. Pollut. Inst.), no. 15, 1974.

The death of silkworms attached to mulberry leaves and the unsuccessful production of cocoons near an electric steel works in Yasugi City, Shimane Prefecture were reported. The damage was due to some substance which adhered to the mulberry leaves in 1972. In 1973, dusts and gases in the works and around it were analyzed for fluorine content. Because of the addition of fluorite to electric furnaces in the reduction stage, the dust contained 1-3% fluorine near the furnace, while gases in the smokeway contained an average of 0.6 mg fluorine/cu m. The amount and fluorine content of dust fall in the mulberry orchard fluctuated between 3.28-9.36 mg/sq m/month (water soluble only) and 5.2-17.5 mg/sq m/month (water soluble).

Aizawa, E.

THE FLUORINE CONTENT OF AIR AND RICE GRAINS IN SEVERAL PARTS OF JAPAN. (Honpo kakuchi ni okeru taikichu fussonodo to sanmui chu fussonodo ni tsuite). Text in Japanese. Iwate Igaku Zasshi (J. Iwate Med. Assoc.), 26(6):655-656, 1975.

The concentration of fluorine was more than 1 microgram/cu m in the area around an aluminum refinery and a pottery factory, 0.1-0.5 microgram in larger cities, 0.1-0.3 microgram in local industrial cities, and undetectable (less than 0.05 microgram) in local commercial cities. In rice grains harvested in areas where the fluorine content of the air was more than 1 microgram/cu m, the fluorine content was significantly higher.

McLaughlin, Samuel B., Jr. and Robert L. Barnes
EFFECTS OF FLUORIDE ON PHOTOSYNTHESIS AND
RESPIRATION OF SOME SOUTH-EAST AMERICAN
FOREST TREES. Environ. Pollut., 8(2):91-96, Feb. 1975. 14
refs.

The effects of fluoride on the photosynthesis and respiration of detached pine needles and hardwood leaves were investigated. Apparent photosynthesis was commonly depressed when foliage was allowed to take up sodium fluoride solutions ranging from 0.0001 to 0.01 molar concentration. Dark respiration was commonly stimulated at low levels of NaF (0.001-0.0001 M). Higher concentrations of NaF (0.01 M) either stimulated dark respiration (in most hardwoods) or inhibited it (in pines and some hardwoods). Pines were generally more sensitive than hardwoods, and current-year needles were more sensitive than 1-year-old needles. The concurrent stimulation of dark respiration and the inhibition of apparent photosynthesis suggested that growth reduction can occur in trees accumulating low levels of foliar fluoride. Forest Service

AIR POLLUTION DAMAGES: TREES. (SPECIAL REPORT).
USFS Kept. 1973, 32p., 1973. 37 refs.

Sulfur dioxide and ozone are probably the most important phytotoxic air pollutants in the northeast. Fluorides, chiefly in the form of the gas hydrogen fluoride, also occur. Injury on

conifer needles from all these pollutants is often manifested as necrosis of the needle tip or the entire needle. Ozone also causes a chlorotic mottle of needles. Most pollutants cause more specific symptoms on broadleaved trees. Sulfur dioxide symptoms generally appear on broadleaved trees as an inter-veinal necrosis, the injured tissue being a light brown. Ozone causes a reddish-purple stipple or brown to white fleck of the upper leaf surface. Fluoride injury is usually restricted to the margins of the leaf, where toxic accumulations of this pollutant cause the tissues to turn brown and die. Minor pollutants cause a variety of symptoms. The pollutants discussed include ethylene, oxides of nitrogen, ammonia, chlorine, hydrogen chloride, and particulates. Air pollution injury to trees is most prevalent during inversions. Caution should be exercised in the field when diagnosing air pollution injury as it is often confused with injury caused by many other factors. (Author abstract modified)

ON THE BLACK SPOTS OBSERVED IN THE INTEGUMENT
OF SILKWORMS POISONED BY FLUORINE COMPOUNDS.

(Kaiko no fusso chudoku ni yoru byohan ni tsuite). Text in Japanese. Preprint, Japan. Society of Air Pollution, Tokyo, (9)2:401, 1974. (Presented at the Japan Society of Air Pollution, Annual Meeting, 15th, Fukushima, Japan, 1974.)

The effect of fluorine compounds on mulberry leaves and silkworms were examined experimentally. Artificial foods containing 0, 10, 20, 40, 80, and 100 ppm of potassium fluoride were fed to fourth instar silkworms. While fluorine-free feed produced normal cocoons, the feed containing even 10 ppm of KF produced lighter and thinner cocoons, and feed containing 20 ppm of KF caused silkworms to die. At more than 80 ppm, all worms died at fourth or fifth instar with brownish black discolorations of the internodal integument, a characteristic symptom of fluorine intoxication. The body weight of the worm did not show any increase. The integument became very fragile; the black spots seen on fifth instar fluorine-intoxicated worms were due to the spotlike bleeding caused by broken integuments.

EFFECTS OF HYDROGEN FLUORIDE AND SULPHUR
DIOXIDE ALONE AND IN COMBINATION ON SEVERAL
SPECIES OF PLANTS. Environ. Pollut., 9(2):133-143, Sept.
1975. 26 refs. (Presented at the International Congress of Plant
Pathology, 2nd, Minneapolis, Minn., Sept. 4-12, 1973, Paper 4.)

Bean, barley, and sweet corn were exposed separately to charcoal-filtered air, hydrogen fluoride, sulfur dioxide, and a combination of the two pollutants. Plants in two experiments were exposed to 0.006 to 0.0009 ppm HF, to 0.15 or 0.30 ppm SO₂, and to the combined pollutants for 7 days. Two other experiments used 0.06 to 0.08 ppm SO₂, and exposures were made for 27 days. When high concentrations of SO₂ were used, severe injury occurred on corn and barley leaves, and the combination of SO₂ and HF did not alter foliar symptom

<xref image="2000WVN0.TIF|V3|2006:09:28:01:43:00.00|115400|0"> image: </xref>

production. Beans were not injured by any of the treatments. The foliar response of barley and corn was accentuated by the combination of SO₂ and HF with lower concentrations of SO₂. Symptoms consisted of elliptical lesions on the distal half of older leaves on both of the corn cultivars tested. Foliar accumulation of fluoride was reduced by the combination of SO₂ and HF as compared with HF alone. Fresh and dry weight yields of plant tops were not affected. (Author abstract)

Less, L. N., A. M. Arthur, and A. McGregor
FLUORINE UPTAKE BY GRASS FROM ALUMINUM
SMELTER FUME. Preprint, American Inst. of Mining En-
gineers, 21p., 1974. 8 refs. (Presented at the American Institute
of Mining Engineers, Annual Meeting, Dallas, Tex., Feb. 1974.)
Perennial ryegrass was grown in controlled atmospheres con-
taining either hydrogen fluoride or submicron panicle
fluorides to measure the quantity of fluorine absorbed by the
grass under conditions and exposures similar to those occur-
ring near aluminum smelters. The fluorine levels measured in
the grass were 100 ppm/1 microgram of fluorine as hydrogen
fluoride/cu m of air and 1.2 ppm/1 microgram of fluorine as
fine particulate/cu m of air. These levels were observed for
spring and summer conditions with sub-irrigation in the
absence of rainfall. Traces (1-2%) of HF were also present in
the panicle fluoride atmospheres and perhaps accounted
for part or all of the absorption. The uptake of fluorine from
submicron particulates thus appears to be less than 1% of that
from equal concentrations of fluorine as HF.

Suketa, Yasunobu and Takeo Yamamoto
EFFECT OF ATMOSPHERIC FLUORIDE ON PLANTS
(BIOLOGICAL STUDIES ON ENVIRONMENTAL POLLU-
TION BY FLUORIDE PART I). Text in Japanese. Nippon
Nogeikagaku Kaishi (J. Agr. Chem. Soc. Japan), 49(7):341-346,
1975. 14 refs.
The effects of atmospheric fluoride on gladiolus, mandarin,
taro, Japan-cedar, and rice were investigated. The sensitivity
of these plants against atmospheric fluoride is in decreasing
order: taro, gladiolus, Japan-cedar, mandarin. The pool size of
fluoride accumulation in plant leaves is in decreasing order:
Japan-cedar, mandarin, gladiolus, taro. The calcium contents
in the leaves of mandarin and gladiolus are 4.16% and 1.04%
respectively. The ratio of calcium/silicon in the leaves of man-
darin and gladiolus is 3.27 and 4.38 respectively. The contents
of Ca and Si in the leaves of plants affect the sensitivity of
plants to atmospheric fluoride. Accumulation of fluorine in un-
hulled rice is associated with fluorine content in the rice bran,
but is not associated with that in the polished rice.

A RAPID METHOD FOR THE DETERMINATION OF
FLUORIDE IN VEGETATION. Am. Ind. Hyg. Assoc. J.,
36(10):721-724, Oct. 1975. 7 refs.

An analytical procedure for the determination of fluoride in vegetation was developed. The method involves leaching the vegetation with a hot solution of strong base and then determining the fluoride in an acidified solution directly with M fluoride selective ion electrode. The average value for 14 determinations is 24.4 micrograms F/g sample. The calculated standard deviation of the method based on these analyses is + or - 1.4 micrograms F/g sample, and the relative standard deviation is + or - 5.8%. This corresponds to a limit of error of 13% at the 95% confidence interval. (Author abstract modified)

RELATION BETWEEN THE CONCENTRATION OF
HYDROGEN FLUORIDE IN AIR AND THE ABSORBANCE
OF FLUORINE OF RICE PLANT. (Taikichu fukkasuiso nodo
to suite no fusso kyushuritsu to no kankei). Text in Japanese.
Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):460,
Nov. 1975.

Groups of rice plants (variety koshihikari) grown in pots were exposed at their ear sprouting stage to hydrogen fluoride at average concentrations of 10.1, 22.2, 28.4, 32.8, 37.2, 37.2, 53.1, 71.9, 106.8 and 148.3 ppb for 7 hours (0900-1600) in a growth cabinet under natural light at 30 C and RH of 60%. The content of fluorine was lowest in undeveloped leaves, and highest in the second and third leaves. A linear correlation curve was obtained between the logarithm of the fluorine content of the second leaf (ppm) and the concentration of hydrogen fluoride (ppb) used for exposure, with a correlation coefficient of 0.9185.

ni (suite). Text in Japanese. Nippon Koshu Eisei Zasshi (Japan.

J. Public Health), 22(10):398, Nov. 1975.

Indicator plants such as iris and pine and agricultural crops such as Welsh onion were collected within a radius of 3 km from a superphosphate factory (A) and a fused phosphatic fertilizer factory (B), and their fluorine contents were determined. The fluorine content of iris was 9.9-78.5 ppm of dried plant, corresponding to a gaseous fluorine content in air of 0.04-0.33 ppm, and 0.15 ppm of soluble particulates around the A factory. The fluorine content of air around the B factory was a little higher than that at the A factory, and although the fluorine content in Welsh onion was 11.2 ppm of dried plant there were plants containing more fluorine, such as iris (93.8 ppm), platanas (295 ppm) and acer (117 ppm). Both factories visibly damaged the plants around them.

keitai). Text in Japanese. Nogyo Gijutsu Kenkyu Hokoku B, no.

27:27-37, Sept. 1975.

Rice plants, two species of salting greens, and soybean plants were exposed to sulfur dioxide at low concentrations, (0.25-0.75ppm) for 5-10 hr/day in the daytime for several days (total hours of exposure between 10 and 54), and the sulfur in the plant body was examined. Several plants, including tomato and Pinus densiflora, were exposed to radioactively labelled sulfur dioxide at 0.5 ppm for 5 hours, and the distribution of radioactive sulfur in the plant body was traced. The same experiments and absorption tests were carried out with hydrogen fluoride, radioactive hydrogen fluoride tracer, and sodium fluoride. The findings are summarized as follows: (1) Sulfur dioxide is absorbed from plant stomata, and the absorbed sulfur exists in a water-soluble state in the plant in decreasing concentrations in leaf-blades, petioles, stems and roots, and especially in large amounts in interveinal parts of the leaves. (2) The intake of sulfur into protein (sulfur-containing amino acids) was less via leaf-absorbed sulfur dioxide than via root-absorbed sulfate ion. Visible damage due to sulfur dioxide is described. The leaf-absorbed hydrogen fluoride was accumulated in the leaf apex and leaf-periphery, especially in leaves with vigorous physiological action. The root-absorbed fluorine translocated into aerial parts, especially into active parts; however, local differences of distribution were not so conspicuous as in the case of leaf-absorption.

STUDIES ON THE METHODS OF IDENTIFICATION OF

PLANT DAMAGE DUE TO AIR POLLUTION PART H.

ANALYSES AND IDENTIFICATIONS OF HARMFUL SUB-

STANCES IN POLLUTED PLANTS. SUBPART 4. DETER-

MINATION OF FLUORINE BY ION-ELECTRODE METHOD.

(Taikiosen ni yoru shokubutsu higai no kanteiho ni kansuru ken-

kyu, II. Osenshokobutsu chu no yugaiseibun no bunseki kan-

teiho; 4. Ion-denkyoku ho ni yoru fusso no teiryu). Text in

Japanese. Nogyo Gijutsu Kenkyu Hokoku B, no. 27:20-27, Sept.

1975. 20 refs.

In order to examine in detail the ion-electrode method for the determination of fluorine in plants, which is simpler and more rapid than colorimetry, about 45 species of plants collected in polluted areas were analyzed. The ion selectivity of the ion electrode for cyanamide, silicic acid, and carbonic acid gave a positive error of more than 10%. for calcium, iron II, iron III, aluminum, chromium and magnesium there was a negative error of more than 10%. Fluorine should be distilled as fluorosilicic acid at about 140 C, with the addition of silver nitrate to repress the distillation of chlorine. In cases where plants contain more than 5% silica, the calcined ash should be alkali-melted to prevent the hold-up of fluorine by gel-form-silica. The standard solution is best prepared by neutralizing aqueous sodium fluorosilicate with dilute alkaline solution to a pH of 5 - 6, with a detection range of 0.01 - 1000 ppm of fluorine. It is necessary to carefully read the value of potential difference of the electrode at equilibrium. Fluorine in plants can be determined by the ion-electrode method with an accuracy and precision not less than for volumetric analysis with thorium nitrate or colorimetry with alizarin complex.

79974

Yamazoe, F. and H. Mayumi

STUDIES ON THE METHODS OF IDENTIFICATION OF PLANT DAMAGE DUE TO AIR POLLUTION PART H. ANALYSES AND IDENTIFICATION OF HARMFUL SUBSTANCES IN POLLUTED PLANTS SUBPART 3. DETERMINATION OF FLUORINE BY ABSORBANCY WITH THE ALIZARIN COMPLEX REAGENT. (Taiki osen ni yoru shokubutsu higai no kanteiho ni kansuru kenkyu, II. Osen.shokuhut.su chu no yugaiseibun no bunseki kanteiho; 3. Alizarin complexon shiyaku niyoru fusso no kyukokodo teiryu). Text in Japanese. Nogyo Gijutsu Kenkyu Hokoku B, no. 27:10-20, Sept. 1975. 38 refs.

A method for measuring fluorine in plants, based on absorbancy by alizarin complex reagent is examined. The findings are summarized as follows: (1) In determining fluorine by absorbancy using ALFUSSON, a mixture of alizarin complex-lanthanate-buffer agent, absorption at 620 nm was appropriate. (2) When developing color in a 25 ml measuring flask, the calibration curve showed lineality until 50 microgram (2 ppm) of fluorine during the adding of 3 ml of ALFUSSON solution, making the determination possible. (3) The sensitizing effectiveness of the coexistence of acetone was noticeable; the addition of acetone of 10 ml was appropriate. (4) The absorbancy of the colored solution increases with time; however, it stabilizes after 1.5 hr, and so the determination should be done simultaneously with the standard after 1.5 hours have passed. (5) Because aluminum, iron, and phosphate interfere with the determination, after calcination with milk of lime the plant specimen should be steam distilled in the presence of perchlorate and the distillate should be neutralized with sodium hydroxide. (6) The present method is applicable to low contents, of fluorine. It is more accurate than the volumetric method using thorium nitrate, and especially useful in microdetermination of fluorine in damaged plants.

DIRECTION OF COUNTERMEASURES OF AGRICULTURAL CROPS BY AIR POLLUTION. (Taiki osen ni yoru nosakubutsu higai taisaku no hoko). Text in Japanese. Nogyo oyobi Engei (Agr. Hort.), S0(10):1201-1202, Oct. 1975. The importance of photochemical smog is emphasized in terms of the number of emergency alerts of photochemical smog in Japan in 1974 (288), and the plant damage occurring at 0.05 - 0.07 ppm of oxidant for 2-4 hours. The air pollutants which damage plants are oxidants, sulfur dioxide, nitrogen oxides, hydrocarbons, aromatic compounds, halogen compounds, dusts, smoke, and heavy metals such as cadmium. The economic loss due to plant damage represented by tobacco spot disease (which has a close connection to the concentration of oxidants) was recently estimated as 3 million dollars. The prevention of crop damage due to air pollution is the jurisdiction of the Environment Agency. Environmental standards have already been established for sulfur dioxide, carbon monoxide, floating particulates, nitrogen dioxide, and photochemical oxidant; for hydrocarbons, lead, and fluorine, compounds standards are yet to be established. Methods to protect plants from air pollution, including chemical protectants, have been developed, but no well developed general effort exists.

Sakurai, S.

POLLUTION OF AGRICULTURAL CROPS BY FLUORIDE IN AIR, ESPECIALLY ON BROWN RICE. (Taikichu fuk-kabutsu ni yoru nosakubutsu osen - tokuni gen-mai ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):231-232, Nov. 1975.

Results of a nation wide determination of the fluorine content of brown rice harvested from fields around fluorine sources are reported. The fluorine content of brown rice harvested in fields without specific fluorine sources ranged from 0.5-1.5 ppm of dried specimen. The fluorine content of brown rice harvested from fields within 1 km of an aluminum refinery ranged from 1 to 8 ppm of dried specimen, according to the wind direction. The accumulation of fluorine in brown rice was highest around aluminum refineries and pottery works, followed by phosphate fertilizer factories. These findings indicate that the amount of fluorine intake from the staple food, rice, is far more than that from inhalation. The fact that the accumulation of fluorine in leaf-vegetables such as Chinese cabbage is higher than in brown rice indicates the necessity for further study.

Yamazoe, F.

EFFECTS OF FLUORIDES ON PLANTS. (Fukkabutsu ni yoru shokubutsu eikyo). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):206-209, Nov. 1975. 7 refs. Fluorine compounds known to be air pollutants, such as hydrogen fluoride and silicon tetrachloride, are highly poisonous to plants even at ppm - ppb levels. As solid microparticles, acidic sodium fluoride and cryolite cause problems by adhering to plant leaves and absorbing into plant bodies. Plants are classified by their susceptibility to hydrogen fluoride: gladiolus, apricot, buckwheat, turnip and Vaccinium vitis-idaea are most susceptible showing slight injury at less than 5 ppb for 7-9 days; maize, pepper, and dahlia are fairly susceptible, followed by azalea, rose, lilac, and alfalfa, then by oak and tomato. Gladiolus is used as an indicator plant. The exposure factor for one species was known. The symptoms of plants exposed to gaseous fluorine compounds are described in detail at various concentrations. The causal mechanism of the injuries due to fluorine compounds is described in detail, with the method of determining the

fluorine content of plant parts.

EXPERIMENTAL STUDY ON MULBERRY LEAF POISON-
ING BY AIR POLLUTION DUE TO A FACTORY S EX-
HAUST. (Nihon denshi garasu takatsuki kojo no sansokogai
taisakushiken). Text in Japanese. Shiga Pref. Sericultural Exp.
Stn. Proc., no. 32:93-97, 1975.

The cause of pollution of mulberry leaves used for silkworm
feed was found to be fluorine compounds in the exhaust of the
Takatsuki glass factory. Exhaust cleaning apparatus was in-
stalled. The worms were studied again. In the spring of 1973 a
slight increase of dead worms was seen in some areas around
the factory without changes in growth, or the yield and quality
of cocoons. In autumn of 1973, although there was no change
in worm mortality, the infantile stage was delayed 15 hours
and the adult stage accelerated 20 hours. No difference of
fluorine concentration was found in leaves of several areas
around the factory; in one area of elevated content, the stan-
dard of 30 ppm was not exceeded. Silkworm damage due to
polluted mulberry leaves probably will not be repeated, pro-
vided the cleaning apparatus continues to operate satisfactori-
ly.

FLUORINE-POLLUTION OF PLANTS. (Shokubutsu no fusso
osen ni tsuite). Text in Japanese. Ibaraki-ken Kogai Gijutsu
Center Nenpo (Annu. Rept. Environ. Pollut. Res. Center Ibaraki
Pref.), no. 7:74-77, 1974.

A survey of the fluorine content of plants and of the environ-
ment around a metal processing factory (A) and an aluminum-
slug treating factory (B) is described. In the leaves of an in-
dicator plant, gladiolus, the fluorine content was 59 ppm at (A)
(compared to 31 ppm in a non-polluted area), with visible
damage to the plants. In rice plants planted near factory (B),
the fluorine content was 95 ppm with visible damage at the
apex and periphery of the leaves (compared to 8 - 8 ppm in
rice plants in a non-polluted area). The hydrogen fluoride con-
centration was below the detection limit of the automatic
analyzer; however, the larger fluorine content in plants was
probably due to the environmental accumulation of hydrogen
fluoride. The fluorine content of the plants decreased with
distance from the factory.

ENVIRONMENTAL EVALUATION OF ATR POLLUTION
DUE TO FLUORIDE IN THE AIR BY PLANT INDICATORS.

(Shokubutsu shihyo ni yoru kichu fukkabutsu osen no kankyo
hyoka). Text in Japanese. Preprint, Japan Pharmaceutical As-
soc., Tokyo, p. 3-6, 1975. (Presented at the Environment-Pollut-
ing Substances and their Toxicology Symposium, 2nd, Gifu,
Japan, Oct. 27-28, 1975.)

Hydrogen fluoride is detectable by plant damage even at ppb
levels. Hydrogen fluoride in waste gas invades the plant body
through the plant stomata and is accumulated as fluorides in
concentrations several times those accumulated naturally by
the plant root. A large correlation coefficient between the ac-
<xref image="2000WVN3.TIF|V3|2006:09:28:01:43:12.00|113389|0"> image: </xref>

cumulated fluoride in plant leaves and the distance from the source of fluorides was demonstrated in gladiolus and Citrus unshu. The method of sampling and analyzing fluorides in plant leaves, soil, air, and subterranean water is described.

Gilbert, O. L.

EFFECTS OF AIR POLLUTION ON LANDSCAPE AND
LAND-USE AROUND NORWEGIAN ALUMINUM SMEL-

TERS. Environ. Pollut., 8(2):113-121, Feb. 1975. 10 refs.

Investigations around three aluminum smelters in Norway revealed that air pollution emanating from the works was affecting landscape and land-use for a distance of several km. A zonal pattern of damage to the total flora is described in sufficient detail to act as a field guide for the recognition of this type of fume damage. The main reason for believing that the effects described above are caused by air pollution-particularly fluorides-emanating from the aluminum works is that the damage is concentric around the point source and decreases in severity with distance. Furthermore, a careful examination of the total flora revealed that the degree of injury was closely related to the fluoride sensitivity of the species. Widespread damage to lichen communities over approximately the same area in which the more sensitive conifers are affected is reliable confirmatory evidence as these cryptograms are sensitive to air pollution but hardy to extremes of climate. Analysis of plant material collected near the works showed that fluorides were being accumulated to potentially toxic levels in the leaves of damaged plants.

FLUORIDE DAMAGE TO WOODY VEGETATION IN NEW

JERSEY IN 1974. Plant Disease Rcptr., 59(5):427-429, May 1975. 7 refs.

The impact of air pollution on trees in New Jersey was surveyed. Two incidents of severe damage to woody plants by fluorides emitted from specific industrial sources were observed. Classic fluoride toxicity symptoms were observed on plant species that are generally regarded as sensitive, and also on several species of oak. The symptoms on pine were unusual in that a dark band delimiting the necrotic area on the needle appeared 3-4 wk after the initial injury occurred. Douglas fir and peach trees that were defoliated by the pollutant put out a second flush of growth. Among the species exhibiting extreme resistance to fluoride damage were American holly, white birch, London plane, flowering dogwood, magnolia, mulberry, apple, and Norway maple. INDUSTRIAL FLUOROSIS IN WILD MULE AND

WHITETAIL DEER FROM WESTERN MONTANA. Fluoride, 8(4):182-191, Oct. 1975. 24 refs.

The use of bone tissue of mules and whitetail deer as indicators of environmental fluoride pollution was evaluated from 1970-1972 in western Montana. Fluoride in vegetation was markedly higher than in control areas. Because individual deer do not live in precisely the same location every year, the exact consumption of fluoride could not be determined, but bone fluoroassays from deer inhabiting two contaminated areas showed a 5 to 50 fold greater fluoride concentration than for controls. In any particular deer, the level of fluoride was highest in the mandible, followed by the femur and the ribs, with the lowest concentration in the metacarpals or metatarsals. Cancellous, metabolically active bones accumulated more fluoride than dense compact bones. (Author summary modified)

Diouris, M. and M. Penot

EFFECT OF SODIUM FLUORIDE ON THE PHOSPHATE
ABSORPTION BY POTATO TUBER TISSUE - INFLUENCE
OF CALCIUM. Fluoride, 8(4):208-223, Oct. 1975. 36 refs.

Phosphate uptake by disks of potato tubers aged for 24 hr in 0.5 mM calcium chloride was studied after pretreatment for 15 min in 0.05 M sodium fluoride. The disks aged in the CaCl₂ solution showed an increase in phosphate uptake only when they were pretreated with NaF. This phenomenon was no longer observed when the calcium was eliminated by the action of ethylene diamine tetraacetic acid. Absorption of calcium and fluoride by the potato disks was essentially a non-metabolic process. Disks aged in a calcium solution fixed more fluoride than fresh disks, but the subsequent increase in uptake of phosphate was not directly related to the increased fixation of fluoride. The rise in phosphate absorption by disks treated with NaF was not a metabolic process, because it occurred when all experiments were conducted at 0 C. The increased phosphate uptake was largely localized at the physicochemical level in the membrane.

Manning, William J.

INTERACTIONS BETWEEN AIR POLLUTANTS AND FUNGAL, BACTERIAL AND VIRAL PLANT PATHOGENS. Environ. Pollut., 9(2):87-90, Sept. 1975. 27 refs. (Presented at the International Congress of Plant Pathology, 2nd, Minneapolis, Minn., Sept. 4-12, 1973.)

Interactions between air pollutants and fungal, bacterial, and viral plant pathogens are summarized. Ozone injured plants are more susceptible to invasion by facultative parasitic and facultative saprophytic fungi, whereas obligate parasitism by fungi can be retarded by O₃ and O₃ injury to host tissues. Sulfur dioxide effects are concentrated near point sources. Sulfur dioxide affects microorganisms directly, but indirect effects on roots and root decay are noted. Hydrogen fluoride accumulates in plant tissues and affects plant and microbial pathogen interactions. Fluoride in bean leaves can increase or decrease tobacco mosaic virus lesions, depending on fluoride concentrations. Cement kiln dust deposits increase incidence of Cercospora leaf spot on sugar beets. Limestone dust deposits stimulate leafspot infections on wild grape and sassafras leaves. Increased numbers of bacteria and fungi are found on leaves with light to moderate dust deposits.

Groth, E., Ill

AN EVALUATION OF THE POTENTIAL FOR ECOLOGICAL DAMAGE BY CHRONIC LOW-LEVEL ENVIRONMENTAL POLLUTION BY FLUORIDE. Fluoride, 8(4):224-240, Oct. 1975. 74 refs. (Presented at the International Society for Fluoride Research Conference, 6th, Nov. 7-9, 1974.)

The potential for ecological damage by chronic low-level environmental pollution by fluoride was evaluated. A wide range of organisms can accumulate substantial concentrations of fluoride from the air, water, or soil. Estimates of fluoride air pollution range from 120,000 to 155,000 ton/yr for the United States. Except in the immediate vicinity of a source, fluoride levels in air are generally quite low, below 1 ppb. Concentra-

<xref image="2000WVN4.TIF|V3|2006:09:28:01:43:14.00|114374|0"> image: </xref>

tions below 1 ppb are biologically significant and can occur over widespread areas when pollution is present. These levels of exposure are capable of causing some adverse impact in wildlife species. The effects of fluoride pollution on wildlife organisms are summarized. It is possible that fluoride is transformed by some organisms in the natural environment into far more toxic organic fluorides.

81288

Van Hook, C.

FLUORIDE DISTRIBUTION IN THE SILVERBOW, MON-

TANA, AREA. Fluoride, 7(4):18M99, Oct. 1974. 45 refs.

The distribution of fluoride in soil and plants from a 16,000-acre area contaminated by a phosphorus extraction facility emitting fluoroapatite dust and hydrogen fluoride was investigated. Mean fluoride concentrations in vegetation ranged from 20 ppm to over 100 ppm. Fluoride concentrations as high as 420 ppm, about 40 times greater than control values, were measured in Rocky Mountain junipers, the most commonly sampled tree in the study area. The pattern of fluoride distribution in juniper was similar to that in forage grasses growing in the area. Although localized high concentrations of fluoride were measured in soil samples near the plant, fluoride pollution of the soil appeared to be less widespread than that of vegetation.

Pack, M. R. and C. W. Sulzbach

RESPONSE OF PLANT FRUITING TO HYDROGEN

FLUORIDE FUMIGATION. Atmos. Environ., 10(1):73-81,

1976. 20 refs.

Plants of 10 species representing important crops grown primarily for fruit or seed production were exposed to hydrogen fluoride gas in growth chambers. Soybean produced almost no seeds under continuous exposure to HF at a concentration of 0.64 micrograms fluoride/cu m, whereas cotton showed no apparent effects at 8.0 micrograms fluoride/cu m. Bell pepper, sweet corn, cucumber, pea, grain sorghum, oat, wheat, and barley ranked between soybean and cotton in order of decreasing sensitivity of fruiting to HF exposure. Development of fewer seeds was the most common response of fruiting to HF. Flower development was inhibited on pepper and corn plants. The effects on fruiting were apparently independent of HF injury to plant foliage. (Author abstract modified)

IDENTIFICATION AND JUDGEMENT OF PLANT DAMAGE

DUE TO AIR POLLUTION. (Taikiosen niyoru shokubutusu

higai no kentei). Text in Japanese. Sangyo Kogai (Ind. Public Nuisance), 12(1):27-35, 1976. 7 refs.

Chemical analyses of plants damaged by air pollution, especially by sulfur dioxide and fluorine compounds to which, plants are highly susceptible is described. The sulfur combustion method was preferred over gravimetric techniques involving addition of milk of lime. The water-soluble sulfur fraction was higher in plants acutely damaged by ambient sulfur dioxide, and in experimentally exposed plants. The extinction coefficient at 622 nm by the reaction of alizarin complexon reagent and fluorine in the presence of lanthanum ion was used to measure fluorine; the method of ionic electrode was preferred. An example of the analysis of plant damage due to dusts and smoke is given.

THE EFFECT OF AIR POLLUTION ON THE RADIAL

GROWTH OF SCOTS PINE (PINUS SYLVESTRIS L.). Biol

Conserv., 4(5):361-368, Oct. 1972. 22 refs.

The effect of air pollution on the radial growth of scotch pine trees situated within 1.5 km from a fertilizer plant emitting

fluorine compounds and fertilizer dust was investigated. The radial growth of pines began to increase after the plant started functioning in 1952, and the increase was greatest and most regular in trees under 50 yr old. The radial growth of trees over 70 yr old was not affected significantly by fertilizer dust and other growth-promoting substances discharged by the plant. After the plant started using apatite and began emitting fluorine compounds, a decrease in radial growth was observed. The radial growth decline was greatest in trees 50-100 yr old and occurred before any visible symptoms of damage were manifested.

ENVIRONMENTAL ESTIMATION OF POLLUTION BY ATMOSPHERIC FLUORIDE USING PLANT INDICATOR. (BIOLOGICAL STUDIES ON ENVIRONMENTAL POLLUTION BY FLUORIDE PART H). Text in Japanese. Nippon Nogekagaku Kaishi (J. Agr. Chem. Soc. Japan), 49(7):347-352, 1975. 18 refs.

Leaves of gladiolus and mandarin orange were used as plant indicators for air pollution by fluoride. The fluoride accumulations of these leaves were associated with gaseous fluoride concentrations. An equation is proposed for the relationship between accumulation of fluoride in plant leaves and distance from the fluoride-emitting source. Paniculate fluoride was also collected for 5 yr. Both physicochemical determinations and biological indicators are necessary for monitoring atmospheric fluoride. Paniculate fluoride monitoring must be included. (Author abstract)

Sugai, Ryuichi

PRESENT SITUATION OF FLUORIDE ENVIRONMENTAL POLLUTION. (Fukkabut.su ni yoru kankyo osen no jittai). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4): 199-205, 1975. (Presented at the National Air Pollution Research Conference, 16th, Niigata, Japan, Nov. 5-7, 1975.) The Niigata Prefectural Environmental Pollution Research Institute reports the state of air pollution caused by fluorides. An air pollution investigation was conducted in 1969 in the neighborhood of an aluminum refining plant in the Naoetsu littoral industrial belt. This aluminum refining plant started operation in May 1963 and is the main source of fluorides, and the largest single aluminum refining plant in Japan. A few years before the plant was first operated, no significant agricultural damage was seen. Since autumn of 1967 damage to vegetation has been obvious, and has increased in relation to the multi-stage expansion of the plant. Yearly changes of concentration of airborne fluorides, present concentrations, gaseous fluorides and paniculate fluorides, and the effects of airborne fluorides on vegetation are discussed.

MEASURES FOR PREVENTING PEAR DAMAGE:

ICHIHARA AREA: ANALYSIS OF METEOROLOGICAL

FACTORS AND INVESTIGATION. (Ichi-hara-chiku nashi higai

boshi taisaku jigyo, kisho kaiseki oyobi chosa). Text in Japanese.

Chiba-ken Kogai Kenkyusho Nenpo (Ann. Rep. Chiba Pref. Res.

Inst. Environ. Pollut.), no. 4:20-21, 1972.

The damage to flowers and the leaves of pear trees in the flowering period in the Ichi-hara area on April 11 and 12 was studied. Sulfur oxides, fluorides, and meteorological conditions were investigated by examining the records for April 9-14. Although the weather on the 9th and 12th was bad due to the passing of a trough, the weather on the other days was good. Weather conditions were favorable to air pollution, due to weak winds. Days when the concentration of sulfur oxides was relatively high were the 10th (21 pphm), the 11th (19 pphni), the 13th (17 pphm) the 14th (14 pphm). The concentration of hydrogen fluoride was high on the 12th (0.5 ppb).

CLASSIFICATION AND DIAGNOSIS OF AIR POLLUTION

BY BIOLOGICAL INDICATORS. PART 1. (Seibutsu shihyo ni

yoru taikiosen no bunkyu to shindan (1)). Text in Japanese.

Kankyojo Kagaku (Environ. Inf. Sci.), 5(1):52-63, 1976.

Comparative studies of several biological indicators in an area having the Ube coastal industrial zone as the apex were conducted. Epiphytes on evergreen broad leaf trees, substances on leaves and the sulfur content of leaves were investigated. The vigor of common trees such as *Machilus thunbergii*, *costanopsis* sp, *Myrica rubra*, *Irex rotunda*, *Pinus thunbergii* and *Pinus densiflora* was studied. The destruction of forests in the area was investigated. Soil respiration was determined. The state of inflorescence of *Osmanthus fragrans*, a sensitive indicator, was investigated for 3 years.

STUDIES CONCERNING THE EFFECTS OF AIR POLLU-

TANTS ON HORTICULTURAL CROPS. (Taikiosen busshitsu

ga engei.sakiiniot.su nado ni oyobosu eikyo shiken). Text in

Japanese. Kanagawa-ken Sangyo Senta Shiken Kenkyu Hokoku

(Ann. Rep. Kanagawa Prefect. Sericult. Cent.), no. 3:43-59, July 1975.

Damage to mulberry leaves in fields in May, Aug., and Nov. was studied with respect to the concentration of air pollutants such as dust fall, sulfur oxides, nitrogen dioxide, chloride ion and fluorine. Laboratory experiments exposing mulberry seedlings to ozone at 0.15 - 0.02 ppm for 20 hr, to ozone at 0.15 - 0.20 ppm for 20 hr and to sulfur dioxide at 1.4 - 1.6 ppm for 14.5 hr, with subsequent exposures to sulfur dioxide at 1.4 - 1.6 ppm for 14.5 hr at 30 C (daytime) and 23 C (night) were also conducted. The damage to mulberry leaves, represented by their content of sulfur and fluorine, was not so great as last year, except that the fluorine content was a little higher. The results of exposure experiments were: (1) The visible damage was only observed for exposure for 14.5 hr to sulfur dioxide at 1.4 - 1.6 ppm, in contrast to the presumption that the simultaneous exposure to ozone would show a synergistic effect. (2) In spite of lighter visible damage the leaves, the sulfur content of the damaged leaves was larger than that of the leaves which showed heavier visible damage after exposure to sulfur dioxide at 2 ppm for 11 hr in 1971, suggesting that there is no definite relationship between the visible damage and the sulfur content of the leaves.

ELECTRON PROBE MICROANALYSIS OF FLUORINE IN

POLLUTED NEEDLE SECTIONS OF ABIES ALBA. Fluoride,

9(1):63-70, Jan. 1976. 15 refs.

The effect of hydrogen fluoride fumigation on secretions of needles of *Abies alba* was investigated by electron probe microanalysis. The levels of fluoride varied in different tissues. Most fluoride was found in the spongy mesophyll and the palisade tissues as a function of the distance from the cells of entry and the paths of translocation of fluoride. The differential responses of various tissues of a leaf to fumigation with HF depended on the localization of the tissues rather than on a specific response by a particular tissue to fluoride. (Author abstract modified)

Kuribayashi, S.

ENVIRONMENTAL POLLUTION EFFECTS ON SERICULTURE AND ITS COUNTERMEASURES (2). (Yosan ni okeru kogai to sono taisaku (2)). Text in Japanese. *Sanshi Kagaku to Gijutsu* (Sericultural Sci. Technol.), 10(3):48-49, March 1971. Symptoms on mulberry leaves due to air pollutants such as sulfur dioxide, hydrogen fluoride, chlorine, smokes, heavy metals in floating dust, pesticides applied by airplanes and exhaust gases and dusts (made by friction of tires on pavement) are described in detail. Sulfur dioxide causes oil-soaked type spots to appear on mature leaves (causing silkworms to lose appetite, become inactive, grow nonuniformly, delay coccooning, and suffer softening disease). Hydrogen fluoride causes browning and curling of the leaves only after 14 hr of 30 ppb, causing silkworm inactivity and death. The extent of damage to mulberry fields by air pollution in 1968 was 147 ha by sulfur dioxide, 33 ha by hydrogen fluoride, 172 ha by cement dust, 189 ha by automobile dust and 1388 ha by pesticides (118 ha by airplane).

83182

Mochida, M. and M. Yoshida

SYMPTOMS OF FLUORINE INTOXICATION ON SILKWORMS, ESPECIALLY THE ABNORMAL ARTHROIDAL MEMBRANE. (Kaiko no fussochudokushojo, tokuni setsukanmaku no ijo to sono seppen kansatsu). Text in Japanese. *Japan Soc. Sericulture Annu. Meet.*, 41st, 1971, p. 24. (April.) Fluorine on or in mulberry leaves severely damages silkworms. The symptoms of intoxication of silkworms due to fluorine are usually chronic, consisting of irregular growth, loss of appetite and motion, hardness when touched, tension of the arthroidal membrane, spots and streaks on the arthroidal membranes and on the apex of the abdominal appendages, and fragile epidermis. Histologically, although the shape of the corial cells does not change, the cuticular layers degenerate (solidify) from the outer layer, and lose their dyeability, with a strong silver reaction. The degeneration develops into internal tissues in some cases. These changes seem to be due to abnormality in the cuticle secretion function. After bringing silkworms into contact with monofluoroacetoamide for one day, the belt-like spot in the arthroidal membrane appeared more vividly and typically than other symptoms.

AROUND A METAL FACTORY. (Fussokagobutsu ni yoru taikiosen ni kansuru chosa kenkyu 3. Futatabi kinzoku kojo jshu-ben niokeru yosanhighai ni tsuite). Text in Japanese. Shifhane Ken Eisei Kenkyusho Nenpo (Ann. Rep. Shimane Prefect. Public Health Inst.), no. 16:66-72, 1975. 10 refs.

Results of a survey on the silkworm damage which occurred in March 1973 and reoccurred in Sept. 1974 in the neighborhood of a factory with electric furnaces in Yasugi City, Shimane Prefecture are described. A high content of fluorine (138.4 ppm in dried matter) was found in the mulberry leaves around the factory. A high content of fluorine (3.5-5.8 mg/cu m) in the exhaust of a calcining furnace used in the manufacture of sponge iron was found. The coincidence of the time of the damage, the high content of fluorine in the mulberry leaves, and the high content of fluorine in the exhaust of the furnace indicated that the cause of the silkworm damage was due to the exhaust of the calcining furnace, containing iron sand which contained 30-960 ppm fluorine.

DEGENERATION OF FLOWER PIGMENTS DUE TO AIR

POLLUTANTS. (Taikiosen-busshitsu ni yoru hanairo-shikiso no hensei). Text in Japanese. Kinki Daigaku Kogai Kenkyusho Kenkyu Hokoku (Kinki Univ. Pollut. Res. Inst. Rep.), vol. 3:102-110, Oct. 1975. 4 refs.

Sections of 1 sq cm of flower petals (rose, Chinese bellflower, canna, morning glory, chrysanthemum and sasanqua) were soaked in 0.01 molar aqueous solutions of sodium sulfite, sodium fluoride, and sodium azide for 24 hr at 25 C. The flower pigments were extracted from the intact petals and treated with acidic ethanol and their absorption maxima were determined at 400-600 nm. Paper chromatography was used to separate each pigment, and the components were determined by absorption. Generally, sodium azide caused the most severe damage; the damage showed species specificity. Morning glory was not damaged by sodium azide; canna was not damaged by sodium fluoride; chrysanthemum and sasanqua were not damaged by any of the solutions except sodium azide. Some components of the pigments were damaged by the solutions; some were damaged only by sodium azide. Some pigments in rose petals were very susceptible to the solutions, and some were stable (except for exposure to sodium azide).

EFFECT OF HYDROGEN FLUORIDE GAS ON METABOL-

ISM OF GLADIOLUS, IRIS AND CROCUS. (Gurajiorasu, airisu oyobi kurokkasu no daisha ni oyobosu fukkasuisoga.su no eikyo). Text in Japanese. Nippon Nogeikagaku Kaishi (J. Agr. Chem. Soc. Japan), 49(12):647-652, 1975. 17 refs.

Gladiolus gandavensis, Iris hollandica, and Crocus vernus grown by hydroponics were exposed to hydrogen fluoride at 3.1-3.4 microgram of F(-)/cu m for 24 hr/day or 8 hr/day in light or dark, for total exposure times as long as 20 days. The respiratory quotient of leaves of all the plants declined with exposure. Oxygen absorption by leaves of gladiolus increased conspicuously with exposure in the light, but decreased a little with exposure in the dark. The protein content of Gladiolus leaves decreased conspicuously after exposure in the light, but showed no change after exposure in the dark. The activity of acid phosphatase was inhibited by exposure; the degree of inhibition was largest in Gladiolus, followed by Iris, then Crocus. The relative value of acid phosphatase activity (Y) yielded a regression curve as a function of the respiratory quotient (X): $Y = 0.897X + 0.003$ in the three species of Iridaceae, with a correlation coefficient of 0.983. These facts show the possibility of using acid phosphatase activity as an indicator of fluoride pollution in the air.

Fukuoka Environmental Research Center

RESULTS OF INVESTIGATION ON PLANT DAMAGES DUE

TO FLUORINE. (Fusso ni yoru shokubutsu higai kankei chosa).

Text in Japanese. Fukuoka-ken Eisei Kogai Senta Nenpo (Ann. Rep. Fukuoka Environ. Res. Center), vol. 1973:34, March 1975.

Rice plant withering occurred around a pntt manufacturing factory in July 1973. The fluorine content of the leaves and of the exhaust in the stack of the factory were determined. Although the fluorine content of the exhaust was 0.26 ppm, less than the emission standard, a considerable accumulation of fluorine was found in the rice leaves (34.7 and 352.0 ppm in the upper and lower part of the rice plant grown in a field 200 m distant from the factory, and 56.7 and 228.0 pprn in rice plants grown in a field 350 m from the factory, as compared to 8.9 and 12.4 ppm in a control rice plant). A higher value of fluorine was found in an auto-recorder near an aluminum factory. A determination of fluorine was carried out in leaves of Firmiana platanifolia, chrysanthemum, and salix grown 1000 m from the factory; however, the amount of fluorine (42.3 - 168 ppm) was not much higher than for a control (10 - 46.8 ppm).

Yamazoe, F.

EFFECTS OF FLUORINE COMPOUNDS AS AIR POLLU-

TANTS ON PLANTS. (Taikiosen busshitsu to site no fukkabutsu

no shokubutsu eno eikyo). Text in Japanese. Rodo no Kagaku

(Dig. Sci. Labor), 31(4):22-27, April 1976. 3 k-efs.

Fluorine compounds as air pollutants are mainly hydrogen fluoride and silicon tetrafluoride, and they are known to be highly toxic to plants at concentrations as low as ppb-pphm levels. The order of toxicity to plants runs HF, silicon tetrafluoride, sodium hydrogen fluoride, sodium fluoride, sodium aluminum fluoride, and calcium fluoride. The susceptibility of plants to hydrogen fluoride was classified into categories: those showing injury after exposure for 7 to 9 days at less than 5, at 5-10, and at more than 15 ppb. The most susceptible plant is gladiolus, which is utilized as an indicator plant for hydrogen fluoride. The Adams s exposure factor (average concentration in ppm multiplied by exposure period in hours) is introduced. The symptoms of fluoride injury were peripheral oily immersion, chlorosis, then browning of the leaves. In severer cases, necrosis appeared. A description is given of the mechanism of fluorine injury; it concerns the translocation of fluoride ions in the plant body. Analytical methods of determining fluorine in plants and measures for reducing the damage due to fluorides are described.

83849

DAMAGE DUE TO AIR POLLUTION AND ITS COUNTER-

MEASURE PART 2. DAMAGE OF AGRICULTURAL AND

FORESTRY CROPS. (Taikiosen ni kakawaru higai to taisaku,

2. Noringyo ni taisuru higai). Text in Japanese. In: Chiba Pre-

fectoral Environmental White Paper (1975), p. 335-341, 1975.

Incidents of crop damage due to air pollution in Chiba Prefecture (number due to smog in parentheses) numbered 4(1), 9(7), 12(7), 29(25), 30(17), 13(8) and 7(3), in 1968, 1969, 1970, 1971, 1972, and 1973 and 1974, respectively. The damage has oc-

<xref image="2000WVN7.TIF|V3|2006:09:28:01:43:26.00|125990|0"> image: </xref>

curring around the Keiyo coastal industrial area since 1965. Cases increased until 1972 due mainly to sulfur dioxide and fluorine acutely affecting pears and paddy rice. Acute damage has been prevented by treating exhausts. However, chronic low-concentration pollution and photochemical smog still damage taro, Welsh onion, and maize. One of the causes of damage to red pine and cryptomeria in these industrial areas is thought to be air pollution. Polyvinyl chloride film covering vinyl greenhouses after dust fall resulted in reduced illumination, and thus growth inhibition and poor warming.

83851

RESULTS OF SURVEY OF PLANT DAMAGE DUE TO FLUORINE. (Fusso ni yoru shokubutsu higai kankei chosa). Text in Japanese. In: Annual Report of the Fukuoka Prefectural Center of Hygiene and Environmental Pollution (1973), p. 34, 1974.

An incident of withering of paddy rice plants in the fields around a frit factory in July 1973 was investigated. The content of fluorine in the leaves of the plants and in the off-gas smoke and dust of the factory was determined. Although the stack content was 0.26 ppm, less than the standard, that in the leaves was as high as 34.7 (upper leaves) to 352 ppm (lower leaves) at 200 m from the factory and 56.7 (upper leaves) to 228.0 ppm (lower leaves) at 350 m from the factory, compared to 8.9 to 12.4 ppm 2000 m from the factory. On another occasion of high fluorine in Nov. 1973 around an aluminum refinery, the fluorine content of the leaves of plants nearby (Firmiano platanifolia, chrysanthemum, and willow) was determined. Very small positive values were obtained: 42.3-75.6 ppm in F. p. 1000 m from the factory and 45.5 ppm 4000 m from the factory; 168 ppm in chrysanthemum 1000 m from the factory and 10 ppm 4000 m from the factory; 46.8 ppm in willow 1000 m from the factory and 39.9 ppm 4000 m from the factory.

Div. of Environmental Sanitation, Shimane Prefectural Office
DAMAGE DUE TO THE SMOKE OF A TILE MANUFACTURING FACTORY AND ITS COUNTERMEASURES. (Miyazaki shoten kawara-kojo no baien ni yoru higai to taisaku). Text in Japanese. In: Environmental Pollution in Shimane Prefecture, p. 219-229, 1973.

The withering of leaves of vegetables and rice plants in fields around a tile manufacturing factory was investigated. A survey was carried out revealing that the damage was due to fluorine in the smoke of the factory. The smoke contained 2.67 N cu m/hr of sulfur oxides, 0.06 g of dust/cu m, and 20.0 mg of fluorine/cu m. The harvested brown rice in the field nearby contained fluorine ranging from 1.0 to 9.0 ppm. Vegetables contained 68.0 ppm in leaves and 4.2 ppm in roots. The raw materials of the tile contained from 51.5 to 216 ppm fluorine.

83856

Div. of Environmental Sanitation, Shimane Prefectural Office
DAMAGE OF SILKWORM IN MASUDA CITY AND ITS COUNTERMEASURE. (Masudashi Hanehara chiku ni okeru sanjihigai to sono taisaku). Text in Japanese. In: Environmental Pollution in Shimane Prefecture, p. 316-318, 1974.

The occurrence of silkworm and mulberry damage in July 1974 in the Hanehara area of Masuda City was investigated. Mulberry leaves and the smoke of a ceramic factory nearby were studied. The fluorine content of mulberry leaves near the factory ranged from 11.7 to 33.3 ppm (dry matter); thus, the damage to silkworms was attributed to fluorine in the smoke of the factories. As a countermeasure, fluorine-removing equipment was put into operation in the factories in Jan. 1975.

83885

Mayumi, Y. and F. Yamazoe

ABSORPTION OF FLUORINE FROM LEAF BLADE AND
ROOT, AND DISTRIBUTION OF FLUORINE BY PLANT
BODY, STUDIES UTILIZING RADIO-FLUORINE. (18F riyo
ni yoru fusso no yoinen oyobi keikonteki kyushu to tainaibunpu
ni tsuite). Text in Japanese. Japan Soc. Soil Sci. Manure Meet.,
Osaka, 1972, p. 133. (April.)

Potted tomato and cucumber plants were exposed to hydrogen
fluoride containing air for 1 hr. Other plants were root-soaked
in an aqueous radioactive sodium fluoride solution for 1 hr.
Measurement by autoradiography and scintillation counter
revealed that the fluorine absorbed from the leaf blades accu-
mulated in the leaf periphery or the apex. The absorption was
active in the photosynthetically active leaves of the plant: the
distribution was 9.5% in leaves, 4% in stems, and 0.3% in
roots. The fluorine absorbed from roots moved into the roots
(43.5%), leaves (28.5%), and stems (28.0%) in the case of to-
mato, and into the leaves (39.2%), roots (37.3%), and stems
(23.5%) in another case. The accumulation of fluorine was lar-
gest in the most active leaves.

DIAGNOSTIC TECHNIQUES FOR PLANTS AFFECTED BY
AIR POLLUTANTS. Nogyo Gijutsu Kenkyusho Hokoku (B), no.
27:51-53, Sept. 1975.

Characteristic acute leaf damage following exposure to sulfur
dioxide at concentrations greater than 0.5 ppm and to ozone at
concentrations above 0.1 ppm is described. Water-soluble sul-
fur and total sulfur determination methods were studied. Spec-
trophotometric and ion-specific electrode determination of
fluorine were studied. The mechanism of sulfur dioxide and
fluorine absorption by plants was studied.

Div. of Environmental Sanitation, Shimane Prefectural Office
DAMAGE DUE TO SOOT AND DUST FROM HITACHI
METAL REFINERY AND ITS COUNTERMEASURES.
(Hitachi Kinzoku kara no baijin higai to sono taisaku). Text in
Japanese. In: Environmental Pollution in Shimane Prefecture, p.
217-219, 1973.

Complaints from sericulture farmers about damage to silk-
worms due to mulberry leaves polluted by soot and dust ex-
hausted from the Yasugi factory of the Hitachi Metal Co. in
March 1973 are discussed. Analysis of soot and dust from the
improved facilities showed that in July 1973 sulfur oxides,
dust, and fluorine in the exhaust gas decreased to values
below the standard. However, the dust-fall in the mulberry
field 120 m west of the factory was from 2.47 to 5.29 g/sq
ml month. After the improvements, the fluorine content of the
mulberry leaves in the field was 10-18 ppm, 12-18 ppm and 13-
18 ppm in Aug., Sept. and late Aug., respectively, as com-
pared to 60-71 ppm in July 1973. The percentage of healthy
cocoon, and the weight of cocoons in May (spring season)
were 52.5-72.0% and 1.9-2.0 g; in the autumn these figures
were 90% and 2.0-2.3 g. The improvement of the facilities in-
cluded dust collectors and bag filters.

Kuribayashi, S.

RELATIONSHIP BETWEEN THE CONCENTRATION OF GASEOUS HYDROGEN FLUORIDE AND OF GASEOUS SULFUR DIOXIDE AND ITS EFFECTS ON MULBERRY LEAVES AND SILKWORMS. (Fukkasuiso gas oyobi arysan gas no nodo to Kuwa oyobi kaiko ni oyobosu eikyo tono kankei). Text in Japanese. Japan. Soc. Sericulture Annu. Meet., 41st, 1971, p. 36. (April.)

When mulberry trees were exposed to gaseous hydrogen fluoride at 0.2 ppm for about 2 hr or to 0.03 ppm for about 14 hr, visible signs of damage such as browning of the leaves from the apex or periphery or shrinking appeared, at a leaf fluorine content of 120-160 ppm. The silkworms, after continuously eating leaves containing 35-70 ppm of fluorine, showed chronic damage; after eating leaves containing more than 90 ppm of fluorine they showed acute damage. Mulberry trees exposed to gaseous sulfur dioxide at 2 ppm for about 72 hr showed visible damage, such as scattered oily immersion-type spots and contained as much as 8000 ppm sulfur. Silkworms that ate the leaves had chronic damage.

Prinz, Bernhard and Robert Guderian

EFFECTS OF AIR POLLUTANTS ON PLANTS. (Wirkungen von Luftverunreinigungen auf Pflanzen). Text in German. In: Fundamentals of Air Conservation and Noise Abatement in North Rhine Westphalia, p. 40-46, 1975.

The effect of air pollution on plant life is discussed. Photosynthesis is impaired, acute necrosis of leaves and chronic damage involving sublethal changes due to increasing accumulation of pollutants occurs. Damage to vegetation is often an early indicator of intolerable atmospheric pollution, resulting in measures taken against the sources. Most pollutants produce injury to plant life at concentrations apparently irrelevant for man. Sensitivity of plants to hydrogen fluoride, compared to man's response threshold, is 0.3-1.4 microgram F/cu m: 50 micro g F/cu m. Phytotoxicity of air pollutants over a total area of 3000 sq km with a regional resolution of 5 km was examined. Among them were sulfur dioxide, gaseous fluorine compounds, hydrogen chloride, nitrogen oxides, photooxidants, and dust. A pasture grass was exposed for 2 wk, then examined for its content of sulfur, iron, lead, zinc, and cadmium.

Solinski, Piotr

THE EFFECT OF FLUORINE EMISSION FROM A GLASS FACTORY ON THE SURVIVAL OF SILKWORM CATERPILLARS. (O wplywie Emisji Fluoru Z Hut Szkla Na Przezywalnosc Gasienic Jedwabnika Morwowego). Text in Polish. Pol. Pismo Entomol., 43(2):41S-422, April 30, 1973.

The effect of fluorine emission from a glass-manufacturing plant on breeding silkworms in the vicinity and mulberry leaves on which they fed, was studied in order to demonstrate the toxicity of fluorine compounds. A total of 1000 silkworm caterpillars, strain K-110, were divided into 2 groups of which 1 was prophylactically dabbed with 1% chloramine solution in order to limit external infection while the 2nd one was not treated. On the 2nd and 3rd days after shedding, about 70% of the caterpillars showed symptoms of poisoning, such as sluggishness, skin darkening, cessation of feeding and, finally, death. The remaining caterpillars died at a later development stage. Their bodies hardened within 2 days into a fossil-like consistency. The results obtained from both groups, revealed that the percentage of dead caterpillars in both groups was the same. A number of 41 cocoons collected, showed differences in size, weight and shape. The heaviest female cocoon weighed 2.22 g, the lightest male one 0.975 g. Of the 41 cocoons, 28 were healthy and 13 were sick with 9 dead non-

pupated caterpillars and 4 dead pupae. Out of 4 pairs of copulating butterflies, 1 female laid partly fertilized eggs; the eggs of the rest were not fertilized. The chemical analysis of dead caterpillars and mulberry leaves which they ate showed a content of 0.0506% fluorine, with 0.613% in the ashes of the former and 0.1352% F12 in the ashes of the latter. It was also present in the feces of the caterpillars and their silk. The possibility of fluorine poisoning of other organisms, such as useful insects, breeding animals, and even man, was raised.

Dolhova, L. H. and Z. T. Kosyukina
BIOLOGICAL PURIFICATION OF ATMOSPHERE IN
COKE-CHEMICAL PRODUCTION. (Do pitaniya pro
biologichne ochishchennya atmosferi v umovakh koksok-
himichnogo pidpriemstva). Text in Ukrainian. Ukr. Bot. Zh.,
29(2): 172-176, 1972. 14 refs.

Plants play an important role in biological purification of the atmosphere, accumulating sulfur compounds, chlorine, fluoride, and phenol. Soils also have the capacity to accumulate toxic substances of industrial origin. Phenols are among the most toxic environmental pollutants reaching the atmosphere with other compounds as a result of chemical and coke-chemical production. The ability of certain plants and soil under them to accumulate airborne phenols was studied. Experiments were conducted under conditions of continuous exposure to chemical substances (phenols, sulfur compounds) to determine the action on leaves of ailanthus (*Ailanthus altissima* Sw.), ash (*Ulmus pinnato-ramrose* Dieck), and poplar (*Populus nigra* L.). Determinations of phenol-destroying microorganisms were made in order to study soil phenol-detoxifying ability. Data obtained from experiments warrants the following conclusions: leaves of plants studied which grew for 14-16 yr in a phenol-polluted atmosphere contain visibly higher amounts of phenols compared to a control group from a botanical garden. The phenol content of soil under the plants studied was also higher than in the control group. Raised phenol content in leaves and soil is possibly connected with their ability to accumulate and collect industrial phenols found in polluted atmosphere.

RESULTS OF DAMAGE OF MULBERRY FIELDS BY
SMOKE AND SOOT. (Baiken ni motozuku soen no higai-chosa).
Text in Japanese. Gifu-ken Kogai Kenkyusho Nenpo. (Ann. Rep
Gifu Inst. Environ. Pollut.), no.2:35, 1975.
Damage to mulberry fields in August 1971 in Kani County and
in September 1971 in Ena City due to smoke and soot from
potteries was investigated. Measurement of fluorine in mulberry
leaves of trees grown near the potteries and in raw materials
used in the potteries was carried out. The fluorine content
of the raw materials ranged from 9.2 to 24.7 mg/100 g of sample.
The damage to silkworms and mulberry trees was most
severe around the pottery in which no exhaust treating apparatus
was installed. The content of fluorine in mulberry
leaves around the pottery ranged from 10.0-15.8 mg/100 g dry
weight as compared to 4.4 mg/100 g for the control. When silkworms
were fed with fluorine-containing mulberry leaves, it was found
that leaves containing more than 100 ppm of fluorine gave some
symptoms of intoxication.

Kuribayashi, S.

SILKWORM DAMAGE DUE TO AIR POLLUTANT

FLUORIDES. (Fukkabutsu no taikiosen ni yoru kaiko no higai).

Text in Japanese. Taiki Osen Nyusa (Air Pollution News), no. 74:1, 1973.

In the vicinity of aluminum, phosphate fertilizer, roof tile, and glass factories, silkworms often suffer from intoxication and insufficient growth, resulting in imperfect cocoon formation and death. The cause is fluorides which have been exhausted in minute concentration of S from the factories, and have been deposited on the mulberry leaves which the silkworms ingested. When the fluoride content of mulberry leaves, usually about 15 ppm (dry matter), becomes more than 30 ppm, the silkworms show inactivity, delayed growth, and weight loss, and then die prostrated. Sometime the intoxicated silkworms show a blackening of internodal membranes not seen in intoxication due to other causes.

84545

Kuribayashi, S., K. Yatomi, and M. Kadota

EFFECTS OF HYDROGEN FLUORIDE AND SULFUR DIOX-

IDE ON MULBERRY TREES AND SILKWORMS. (Fukkasuiso

oyobi nisanka io no kuwa oyobi kaiko ni oyobosu eikyo). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), vol. 6:155, 1971.

Potted mulberry trees were exposed to hydrogen fluoride at 30 and 200 ppb for 4-72 hr, and to sulfur dioxide at 2 ppm for 8-72 hr to determine the leaf injury and amount of fluorine in the leaf. The effects of feeding the exposed leaves to silkworms were examined. Visible damage (browning and curling from the apex and periphery of leaves) began after 14 hr exposure to 0.13 ppm and 2 hr exposure to 0.2 ppm. About 120-160 ppm of fluorine accumulated (dry matter) in the damaged leaves. The silkworms continuously ate leaves containing 35-70 ppm of fluorine (dry matter), and showed chronic symptoms such as softening and black spots on the internodular membrane. Those fed with leaves containing more than 90 ppm showed acute intoxication with inactive behavior, then prostration leading to death. In the case of sulfur dioxide exposure, visible injury appeared after about 72 hr of exposure to 2 ppm of sulfur dioxide, in the form of oil-immersion-like spots, with 0.8% sulfur (dry matter). The silkworms which ate these injured leaves continuously showed loss of appetite, inactive behavior and poor growth, with chronic symptoms such as slenderness, growth retardation, or softening leading to death.

CLASSIFICATION AND SURVEY OF AIR POLLUTION BY

BIOLOGICAL INDICATOR PART 2. (Seibutsu shihyo ni yoru

taikiosen no bunkyu to shindun (2)). Text in Japanese. Kankyo Joho Kagaku (Environ. Inf. Sci.), 5(2):61-72, 1976. 20 refs.

In order to establish a monitoring system for air pollution using biological indicators, 41 points were selected in the hinterlands of Ube and Onoda. Pollution sources were in the coastal industrial zone. A case study was carried out in classification of the degree of air pollution using epiphytic bryophytae, measuring soil respiration, the components of matter adhering to leaves, the sulfur content of leaves, the activity of vegetation, and the flowering of *Osmanthus fragrans* in the winter of 1973 and summer of 1974. Pollution sources were found to be sulfur dioxide with relatively less fluorine, dusts, and auto exhaust. Epiphytic bryophytae and the activity of vegetation were sharp indicators of the cumulative effects of low concentrations of air pollution. Soil respiration coincided well with these indicators. Sulfur content was found not to be as appropriate an indicator as the adhered matter on leaves, sulfur dioxide, sulfuric acid, and fluorine. The flowering of *O.f.*, although affected by salty wind, seemed to be a fairly effective indicator of air pollution by sulfur dioxide. The

status of air pollution in the two cities was found to depend on topological abnormality of wind direction. In these situations, biological indicators were found to be effective in indicating air pollution in lower concentrations for long-term exposure.

Nakajima, Y.

RESULTS OF DETERMINING FLUORINE CONTENTS OF

AGRICULTURAL CROPS. (Nosakubutsu no fusso ganyuryo

choya). Text in Japanese. In: Fourth Prefectural Report on the Results of Survey on Air Pollution in the Naoetsu Area. Niigata Prefectural Office (Japan), p. 76-85, Aug. 1975.

Fluorine contents of agricultural crops collected around an aluminum refinery in the Naoetsu area were analyzed by the distance from the refinery, the type of crops, and the season. By comparing the plant contents with the environmental concentration (LTP method) the actual state of pollution was determined with the intention of finding indicator plants and determining the inhabitants intake of fluorine. At first, equiconcentration curves of fluorine content of air with more than 100, more than 50, more than 20, and less than 20 micrograms/sq dm LTP/mo were drawn on the map. The value in the predominant wind direction was about 20 micrograms at a distance from the refinery of 4 km. The fluorine content was higher in leaf-vegetables, fruit-vegetables, and polished rice than in respective controls. Root-vegetables contained lower amounts of fluorine. According to distance from the refinery without regard to wind direction, a trend of reduction of fluorine content was found; however, it was not significant in all vegetables except for polished rice, leaves of Japanese radish and eggplant. By distance, in the predominant wind direction, the content of fluorine showed negative correlation to the distance from the refinery in polished rice, leaves of potato, spinach, Japanese radish and eggplant. There was a significant correlation between environmental air concentration and the content of fluorine. One sample of Chinese cabbage contained fluorine as high as 10 ppm. Spinach was considered to be appropriate as an indicator of fluorine in air, because it gave a correlation between fluorine content and distance, fluorine content and wind direction from the refinery, and fluorine content environmental concentration of fluorine.

Nakajima, Y.

RESULTS OF SURVEY ON PLANT DAMAGE DUE TO

FLUORIDE. (Fukkabutsu ni yoru shokubutsu higai chosa). Text in Japanese. In: Fourth Prefectural Report on the Result of Survey on Air Pollution in the Naoetsu Area. Niigata Prefectural Office (Japan), p. 86-113, Aug. 1975. 9 refs.

In order to elucidate the relationship between environmental fluorine concentration and the fluorine content of agricultural crops and that between visible injuries of crops and crop yield, potted plants of spinach and Welsh onion (both in spring and autumn) and gladiolus were put in locations 200, 500, 1000, 1500 and 2500 in. from an aluminum refinery and their growth and the degree of injury (damaged leaf area of spinach and leaf withering of Welsh onion and gladiolus) was surveyed as well as the fluorine content. Rice plants planted around the refinery were also similarly investigated. The injury to spinach due to fluoride in air appeared in both seasons as shortness, shrunken and whitened leaves, and low yield and growth,

<xref image="2000WVNA.TIF|V3|2006:09:28:01:43:38.00|123258|0"> image: </xref>

H. EFFECTS-PLANTS AND LIVESTOCK

479

especially in places within 1 km of the refinery. Welsh onion was damaged by downy mildew. Gladiolus plants within 1 km of the refinery showed were withered up to the VI leaves. There were high correlations between the fluorine content of crops and fluorine concentration in the air (LTP value), between the degree of injury and fluorine content of crops, and between the degree of injury and fluorine content in air (LTP value).

Sugimoto, E.

STUDIES ON DAMAGE DUE TO AIR POLLUTION-ON THE FLUORINE CONCENTRATION IN NEEDLES OF PINES IN FUKUI AND SAKAI AREAS. (Taikiosen ni yoru jumoku no higai ni kansuru shiken, Fukui, Sakai chiku ni okeru matsu shinyo chu no fusso nodo ni (suite). Text in Japanese. Fukui-ken Ringyo Shikenjo Hokoku (Anmi. Rep. Fukui Prefect. For. Exp. Stn.), no. 13:96-101, 1975. 4 refs.

Samples of needles of *Pinus thunbergii* and *P. densiflora* grown at points in Fukui and Sakai 1, 2, 3, 5, and 7 km remote from a place where factories were to be built were taken yearly for 3 years beginning in 1972, early in August when the growth of new leaves is finished. The fluorine content of the samples was determined. The average for 3 years of new leaves for P.t. was 0.8-2.6 ppm (average of 1.6 ppm); second year leaves of P.t. showed 2.4-3.7 ppm (average of 3.1 ppm); third year new leaves of P.d. had 1.4 ppm, second year leaves 3.1 ppm. When these values were compared to those in air polluted areas and non-polluted areas, it was found that the fluorine content of pine leaves collected in the Fukui and Sakai areas was in the range of natural environmental concentrations. There was a difference of fluorine content between new leaves and second year leaves, the latter containing more fluorine. This was due to more absorption of fluorine via roots.

84579

Sakurai, S., K. Itai, and F. Tsunoda

STUDIES ON AIR POLLUTION DUE TO FLUORIDES. PART

17. ON THE NORMAL CONCENTRATION OF FLUORINE

IN PLANTS. (Jukkabut.su ni yoru taikiosen ni kansuru kenkyu XVII. Shokubutsu chu fusso nodono tsujochi ni (suite). Text in Japanese. Nippon Eiseigaku Zasshi (Japan. J. Hyg.), 31(1):174, April 1976.

The normal concentration of fluorine in 3 indicator plants and crops grown in an area where total fluoride was less than 0.05 microgram F/cu m is reported. In iris, the content of F in upper, middle, and lower leaves was respectively 4.21 (8.88-1.68), 2.81(6.35-0.75), and 1.89 (4.00-0.80) ppm. In pine needles it was 2.95 (5.86-1.10), 3.83(6.25-1.91), and 4.61 (6.46-2.56) respectively in first-year, second-year and third-year needles, showing yearly increases. There are also cases where the content differs from spring to autumn. The leaves of samelh'a a (as tea leaves) contained high amounts of fluorine ranging from 90 to 600 ppm.

Ishikawa, H.

ON THE RELATION BETWEEN THE BROWNING OF
PHYLLOSTACHYS HETEROCYCLA VAR. PUBESCENS
AND AIR POLLUTION PART 1. (Mosochiku no kappen-
gensho to taikiosen tonon kankei ni (suite (1))). Text in Japanese.
Shokubutsu to Shizen (Plan(s) and Na(ure)), 10(5):28-33, May
1976. 9 refs.

In order to select indicator plants for fluorine gas in the air,
several plants grown in southern mountainous areas were sur-
veyed near the Niihama industrial area, and general browning
of the leaves of Phyllostachys heterocycla (variety pubescens)
grown in an area 600-800 m from the fluorine factory was ob-
served (the leaves of the same plants showed a light green
color when they grew 8 km from the factory). A detailed sur-
vey on the same plants grown in 23 places indicated that (1)
The newly developed leaves of P.h.p. in all places were bright
green in color in July. (2) Browning of the leaves of plants
near the factory increased. (3) In April of the next year, al-
most all the leaves of the plants near the factory showed
severe browning, and (4) The degree of browning was more
severe as distance from the factory decreased.

THE AGGRAVATION OF AGRICULTURAL PRODUCTION
AND COUNTERMEASURES. (Nogyo seisan kankyu no akka (o
sono taisaku). Text in Japanese. Nogyo to Keizai (Agriculture
and Economy), vol. 1976: 37-43, 1976.

Japan is the country most deeply impacted by environmental
pollution as it affects food production in the world. Air pollu-
tants which attack agricultural products include ozone, perox-
yacetyl nitrates, nitrogen dioxide, sulfur dioxide, hydrogen
fluoride, chlorine, and ethylene. The specific susceptibility to
each pollutant of taro, lettuce, tomato, alfalfa, gladiolus, rice,
and cattleya is given. The characteristic symptoms are spots
on the leaves (white and brown in color), metallic color on the
lower surface of the leaves, spots (white to brown in color) in
the mesophyll, whitish-yellow from the leaf periphery,
bleached spots between leaf veins, and withering of the sepal
apex, in that order. Metal-containing dust affects agricultural
crops. The importance of invisible damage that occurs before
visible damage appears is emphasized. There is no direct coun-
termeasure against the primary pollutant. The countermeasures
against secondary pollutants such as photochemical oxidant
are now under field study techniques; such as shading, limita-
tion of irrigation, and misting are considered. Damage-reducing
agents are under study for use before the occurrence of
photochemical smog. Air pollutants affect human health as
well as crops.

S. Kleinberg, J.F. Tompkins, Jr., A.H. Singleton, C.J. Sterner
THE PROPERTIES AND HANDLING OF FLUORINE. Air
Products and Chemicals, Inc., Allenton, Pa. (Technical Docu-
mentary Rept. ASD-TDR-62-273.) Oct. 1963. 139 pp. DDC: AD
423751

This report p*resents data on properties of fluorine, methods of analysis, safe-handling procedures, compatibility of materials of construction with fluorine, corrosion rates of metals, and a bibliography of pertinent references. Special attention is given to the compatibility of materials in fluorine. Most metals are not severely corroded by pure fluorine. The presence of hydrogen fluoride (HF) in fluorine increases corrosion of metals markedly. The HF is usually generated in fluorine systems from the reaction of atmospheric moisture or moisture in the system with fluorine. Contaminants in fluorine other than HF do not present corrosion or safety problems. Cleanliness of a fluorine system is emphasized since contaminants may not be removed from the apparatus by passivation procedures. Most corrosion in a liquid fluorine system occurs during the first hour of exposure. When immersed in liquid fluorine for one year, nickel, Monel, 304 stainless steel, Armco steel 15-7 Ph Mo, and copper corroded less than 5 mils; 410 stainless steel less than 70 mils; aluminum 1100, 6061, titanium ALOOAt and C120Av less than 300 mils; magnesium AZ31 less than 350; and magnesium AlC31 less than 700 mils. Data are given for corrosion of metals in gaseous fluorine at various temperatures.

THE EFFECTS OF AIR POLLUTION ON ELECTRICAL
CONTACT MATERIALS: A FIELD STUDY. J. Air Pollution
Control Assoc. 16, (3) 123-7, Mar. 1966. (Presented at the 58th
Annual Meeting, Air Pollution Control Association, Toronto,
Canada, June 20-24, 1965.)

A long-term field and laboratory program designed to determine and understand the effects of air pollutants on electric contact materials and their performance has reached the one-year mark. An extensive variety of precious and nonnoble metals and alloys has been exposed for periods ranging up to one year (August 1963 to August 1964) at 6 field environments. These environments were selected to provide a wide range of air pollutants in typical data processing or process control situations and comprise such diverse locations as an air-conditioned data processing room in New York City, an east coast oil refinery, an east coast chemical plant, a business location in Los Angeles, a paper mill in the south, and a heavy manufacturing plant in Buffalo. The program undertakes to correlate material degradation as a function of time and environment. Humidity, temperature, and sulfur dioxide are measured on a continual basis, and point-in-time measurements of dust, HF, aldehydes, oxidants (ozone), NO₂, SO₂, H₂S, NH₃, and Cl are made on a quarterly basis. Materials are returned periodically and evaluated in the laboratory by contact resistance probing, electrolytic reduction, and standard metallographic techniques. The results of the program to date are presented, and preliminary correlations are drawn. The program is evaluated from the vantage point of the one year mark. Deficiencies and aspects of special utility are described. (Author abstract)

THE DETERIORATION OF MATERIALS IN POLLUTED ATMOSPHERES. J. Air Pollution Control Assoc., 8(3):203-208, Nov. 1958. 34 refs. (Presented at the 14th Annual Conference and 1958 Exhibition, National Assoc. of Corrosion Engineers, San Francisco, Calif., March 20, 1958.)
A group of specific air pollutants known to produce deteriora-

tion of materials, the principal sources of these pollutants, and the most likely mechanisms by which deterioration of a variety of materials can occur are discussed. Specifically, the pollutants are carbon dioxide, sulfur dioxide, sulfur trioxide, hydrogen sulfide, hydrogen fluoride, ozone and solid particulates.

LABORATORY INVESTIGATIONS IN SUPPORT OF FLUID-
BED FLUORIDE VOLATILITY PROCESSES. PART XIV.
THE CORROSION OF NICKEL AND NICKEL ALLOYS BY
FLUORINE, URANIUM HEXAFLUORIDE, AND SELECTED
VOLATILE FISSION PRODUCT FLUORIDES AT 500 C. Ar-
gonne National Lab., 111., Chemical Engineering Div., 40p., Dec.
1966. 26 refs. CFSTI: AML-7241

The corrosion of selected materials of construction by fluorides of interest in the Fluoride Volatility Process has been studied. The metals investigated include: nickel-200, nickel-201, Monel, Inconel, Duranickel-301, HyMu-80, INOR-8, and nickel-200 coupons containing areas of nickel-200 weld, nickel-61 weld, or silver solder. Exposures of these metals for periods up to 30 hr at 500 C were carried out in elemental fluorine, UF₆, SF₆, and some of the following volatile fission product fluorides, both individually and in the presence of fluorine: GeF₄, AsF₅, NbF₅, SbF₅, BrF₅, SeF₆, MoF₆, and TeF₆. Corrosion rates were calculated from both the weight gain of the coupons after exposure and the weight loss of the coupons after descaling in a KNO₃-NaNO₃ bath at 500C. All of the exposed coupons were examined microscopically for intergranular penetration of the base metal. Nickel-200 and Monel exhibited the best overall resistance to corrosion by fluorine, UF₆, and some of the volatile fission product fluorides individually and in the presence of fluorine at 500 C.

I. EFFECTS-MATERIALS

481

Bursting of copper condenser pipes of air conditioners and refrigerators rapidly increased since 1966. Five hundred incidents were recorded in the summer of 1969 in the Osaka area. The primary cause of the incidents was found to be the air pollution from flue gas from factories and automobile exhausts. Construction materials of the cooling system for cooling towers, for example, iron, copper zinc, aluminum, and their alloys, can be corroded or pitted by the following pollutants: NH₃, SO₂, H₂SO₄, HF, HCN, HCHO, H₂S, HCl, NO₂, CH₂ equals CHCHO, Cl₂, CS₂, HSO₃Cl, and Br₂. The water for the condenser is polluted by sulfur dioxide in the atmosphere and by the other pollutants from metal plating, acid rinsing, rubber, and other chemical processes. Ammonia in the exhaust from lavatories or sewage processing plants also becomes the source of corrosion. The cooling water pollution was also found in the vicinity of heavy traffic intersections, polluted rivers, and at the seaside. A cooling tower installed near an ammonia refrigerator had a trouble of this kind. Even in the countryside, insects sucked into a cooling tower caused water pollution. Countermeasures, such as checking the cooling tower, the use of tower water corrosion tester and anti-corrosion agents are described. A sample of Water Quality Check List Card is presented. The paper concludes with a gloomy view of more air pollution and corrosion troubles in the future.

PRINCIPAL EFFECTS OF POLLUTION AND DETERIORATION

PHENOMENA DUE TO AIR POLLUTION. (I principal!

effetti degli inquinamenti e i fenomeni di deterioramento dovuti alle contaminazioni dell'aria). Text in Italian. In: L'inquinamento Atmosferico in Italia. Rept. 27, p. 54-69, 1970. 110 refs.

The effects of pollution on human health, on natural resources and the economy, on building materials, and on plants and animals are reviewed. Reduced visibility and climatic changes resulting from air pollution are also discussed. Among the materials damaged by pollution, the following are mentioned: building stone, textiles, metals, paints, rubber, leather, and paper products. A list is given of types of plants that are highly sensitive, moderately sensitive, and resistant to sulfur dioxide and to the fluorides. A tabulation is also given of the climatic effects of dusts and aerosols, SO₂, carbon dioxide, and carbon monoxide, quoted from an American author.

Yocom, John E.

EFFECTS OF AIR POLLUTION ON MATERIALS. In: Air

Pollution. Arthur C. Stern (ed.), Vol. 1, New York, Academic Press, 1962, Chapt. 7A, p. 199-219. 42 refs.

Air pollution damage to nonliving materials has long been a significant source of economic loss in urban areas. Some of this loss results directly from damage by pollutants such as the corrosion of metal objects, or the weakening and eventual loss of textile or leather articles by direct action of pollutants. The other portion of this loss is indirect and includes, for example, the increased cost of clothing replacement because of excessive cleaning required by a polluted environment, or the loss in property values in highly polluted areas. Mechanisms of deterioration in polluted atmospheres include abrasion, deposition and removal, direct chemical attack, indirect chemical attack, and electrochemical corrosion. Among the most important factors that influence the attack rate of damaging pollutants are moisture, temperature, sunlight, air movement, and position in space. The measurement of materials deterioration is reviewed. Effects of carbon dioxide are noted. Sulfur dioxide has its principal sources in combustion or roasting operations, and its effects are noted on ferrous metals, aluminum, copper, nickel, building materials, leather, paper, and textiles. The effects of hydrogen sulfide on metals and paint are

described. Hydrogen fluoride can attack window glass to the extent that the glass is rendered opaque. Effects of ozone and photochemical smog are discussed for rubber and elastomers, textiles, and dyes. The role of solid air particulates in causing deterioration is normally to produce soiling. Their effect is discussed for metals, building materials, painted surfaces, and textiles. Much of the particulate matter which is responsible for soiling is in the form of minute liquid or semi-liquid droplets.

Steelman, Clarence, Jr.

USE OF PLASTICS TO CONTROL AIR AND WATER POLLUTION. *Materials Protect. Performance*, 11(4):37-40, April 1972.

Areas of application for plastics in equipment and processes designed to control air and water pollution are reviewed. The importance of plastics, e.g., polyvinylchloride, polyethylene, polypropylene, and teflon, lies in their ability to withstand corrosion. Plastics, therefore, are in use as construction materials for control devices and process equipment such as ductwork, fume scrubbers, regeneration systems, pumps, and piping exposed to hydrochloric acid fumes and pickling acid in the hot rolled steel strip pickling process in steel mills; tanks for storing sulfuric, hydrochloric, nitric, and hydrofluoric acid mixtures and exhaust hoods and fume scrubbers in the wire, rod, bar, and tube pickling processes of steel mills; in the chrome plating of steel strips; reaction tanks in the electroplating rinse water treatment; scrubbers and scrubber liquid recirculation systems exposed to ammonia gas in fertilizer plants; water jet fume scrubbers used with corrosive fluoride compounds in the production of super phosphate fertilizer; plate separators for the removal of insoluble oils; within water and sewage treatment plants; and fume scrubbers, exhaust fans, ductwork, and stacks within chemical industries.

HOW MATERIALS STAND UP TO CORROSION AND CHEMICAL ATTACK. *Mater. Eng.*, 73(2):36-59, Feb. 1971.

A detailed report is presented concerning the resistance of metallic and nonmetallic materials to corrosion and chemical attack. The metals studied include: aluminum, beryllium, cadmium, carbon steels, cast irons, chromium, cobalt, copper, lead, low alloy steels, magnesium, molybdenum, nickel, precious metals, stainless steels, tin, titanium, wrought iron, zinc, and zirconium. The nonmetallic materials include rubber, graphite, nylon, and many synthetic materials. The effects of air, sea water, and fresh water on these materials are reported. The effects of many acids were studied, including: acetic, boric, chromic, citric, fatty, formic, hydrochloric, hydrofluoric, nitric, phosphoric, and sulfuric. Other agents studied for their effects on these materials include: bases and salts; solvents and cleaners; oils, fuels, and petrochemical fluids; and other chemicals, such as ammonia, chlorine, bromine, and sulfur dioxide. There are two shortcomings in the data presented. First, there is a wide disparity in the types of tests used by investigators. Also, there are many exceptions to the general rule that the speed of a chemical reaction increases with increasing temperature. Some materials may reverse the usual pattern as temperature increases or decreases.

PROTECTION OF ALUMINUM BUILDING-CONSTRUC-

TIONS. (De bescherming van aluminium bouwconstructies). Text in Dutch. TNO-Nieuws, 26(6):219-227, March 1971. 6 refs. Various techniques for the protection of aluminum construction and parts from corrosion are reviewed. Fluorides, heavy metals, alkali compounds, chlorides, and sulfur compounds are the most dangerous air pollutants for aluminum and its alloys. Humidity, especially 100% humidity and presence of chlorides, sulfur compounds, soot, or smoke are the basic factors to be considered in the choice of an adequate protecting system. Problems of the contact of aluminum and its alloys with other metals and other materials are reviewed. While the rate of contact corrosion is determined by the presence of water, and influenced by both conductivity and polarization, such corrosion can be prevented or considerably reduced by an oxide layer of 20 micron. Zinc coatings provide satisfactory cathodic protection in normal atmospheres, but their effect in an aggressive atmosphere is doubtful. Cadmium, applied in thinner layers than zinc, can replace the latter in corrosive atmosphere. Copper coatings should not be applied to construction exposed to weather, especially in an industrial atmosphere; such coatings, applied in 20 micron-anodic layers, do provide satisfactory protection for indoor parts. Stainless steel coatings may be applied in a mild climate, but not in seashore areas. The same applies to chromium-nickel coatings, while lead coatings protect aluminum and aluminum-magnesium-silicon alloys. The natural oxide layer of 0.01-0.1 micron, formed on the aluminum surface, or additional chromate or phosphate coating, are sufficient in non-corrosive atmosphere conditions, while increased oxide layers with a maximum thickness of 35 micron, or paint are required in aggressive atmospheres. Anodizing and lacquering techniques for aluminum are reviewed.

46606

CORROSION DUE TO AIR POLLUTION. (Corrosie door luchtverontreiniging). Text in Dutch. Polytech. Tijdschr., Ed. Procestechiek, 27(18):582-597, Aug. 1972. 70 refs.

Factors influencing the atmospheric corrosion of materials, the mechanisms of corrosion of different metals, alloys, and non-metallic materials exposed to air pollutants, particularly to sulfur dioxide, and results of corrosion tests are reviewed. The atmospheric corrosion is dependent on such factors as humidity, precipitation, temperature, solar radiation, and particularly the presence of corrosive substances, primarily oxidizing agents and electrolytes (ozone, nitrogen oxides, nitric acid, organic peroxides, sulfur dioxide, sulfurous acid, sulfur trioxide, sulfuric acid, hydrogen sulfide, hydrochloric, hydrofluoric and other acids, carbon dioxide, ammonium sulfate and other ammonium salts, sodium chloride, dust and rust. The processes of the corrosion of iron, steel, zinc, cadmium, nickel, copper, lead, aluminum and its alloys, stone, textiles, paper, leather, rubber, and glass are described. The corrosion of copper, lead, and aluminum takes places at fairly slow rate due to the formation of protective layers. The rate of corrosion of aluminum in urban and industrial atmosphere was 0.015-0.080 mg/sq dm day. Strong attack of copper-alloyed aluminum in marine atmosphere was observed. Gold, silver, and their alloys are attacked by SO₂ and H₂S. Correlations between the rates of corrosion and the average SO₂ level in the atmosphere, the humidity content, and the exposure time were established.

THE CATHEDRAL RACES AGAINST TIME. (Der Dom im Wettlauf mit der Zeit). Text in German. Umwelt (Duesseldorf), 2(6):38-39, 1972.

Pollutants in the air are destroying the figures on the cathedral in Cologne, its glass windows, and its ornaments. Wind and

weather together with sulfur dioxide from combustion processes, hydrofluoric acid from chemical and metallurgical plants, hydrochloric acid, from incinerators, and trace metals such as vanadium and iron which are catalytically active, constantly attack the structure. Measurements at various heights of the acid waste gas components have already revealed that the sulfur dioxide exposure has reached an extent which is comparable to that in Duisburg.

Luckat, Siegbert

THE ROLE OF AIR POLLUTANTS IN STONE DECAY. (Die Wirkung von Luftverunreinigungen beim Steinzerfall). Text in German. Staub, Reinhaltung Luft, 33(7):283-285, July 1973. 13 refs.

Investigations into weathering phenomena on structures built of natural stone, and comparative considerations in the case of increased emissions (in particular, the measurements of absorption rates of noxious substances) clearly show that air pollutants are one of the causes of stone disintegration. Sulfur dioxide and sulfuric acid which forms from it, must be given here as the main components of pollutants. Four different types of prism-shaped sandstone and one trachyte with a base area of 100 by 200 mm and a height of 300 mm were exposed at four different points in North Rhine Westphalia. One was set up on the premises of the Landesanstalt fuer Immissions- und Bodennutzungsschutz in Essen, one at a heavily polluted point in Duisburg, one in Herten, and one near Burgsteinfurt in the Northern Muensterland. Apart from climatological data, the intake rates for SO₂, chloride, and fluoride were determined with the aid of physical-chemical sorption process. The unprotected sample in Duisburg showed the first signs of decay after 6 mo. On the sample in Burgsteinfurt, lichens began to grow. A table lists the emission intake of chloride, fluoride, and SO₂ by the four different samples and by the Cathedral in Cologne. At the point in Essen the average SO₂ emission intake rate for the period May 10, 1972 to Feb. 27, 1973 was 98.58 mg/sq m/day, for chloride 13.63 mg/sq m/day, and for fluoride 0.815 mg/sq m/day. In Duisburg the average values were 129.84 mg/sq m/day for SO₂, 15.77 mg/sq m/day for chloride and 0.789 mg/sq m/day for fluoride. At the Dome in Cologne the average emission intake rate for the period Aug 8, 1972 to Feb. 27, 1973 for SO₂ was 144.27 mg/sq m/day, for chloride 18.00 mg/sq m/day, and for fluoride 1.367 mg/sq m/day.

Detrie, J. P.

POLLUTION AND CORROSION. (Pollution et corrosion). Text in French. Pollution Atmos. (Paris), 15(58): 107-116, April-June, 1973.

The parameters influencing corrosion of materials are too variable to make accurate calculations. Corrosion does not depend only upon the action of pollutants produced by human activity, but also upon temperature, humidity, and ionization. Components of the atmospheric air such as sulfur, nitrogen, chlorine, and fluorine compounds, carbon dioxide, and different oxidants also influence corrosion. In France, the sea lo-

I. EFFECTS-MATERIALS

483

calities of Biarritz and La Rochelle with corrosion level one, the rural locality of Saint Germain en Laye with corrosion level one, and the industrial town Saint Denis with corrosion level 2.5 were examined. Sea shore localities are more exposed to corrosion than areas with a high degree of pollution. In the United States, Pittsburgh had a decrease of SO₂ from 0.15 ppm in 1926 to 0.5 ppm in 1960. In Chicago, an increase from 0.04 ppm to 0.12 ppm was noted over a 12-month period. Los Angeles has a preponderance of oxidant smogs generated by hydrocarbon emissions. Acid rains in Sweden contributed to steel corrosion. In Stockholm, at 3 C and 35 micrograms/cu m of SO₂, the corrosion level was 30/micron/yr. At Flahut, the corresponding values were 3 C, 4 micrograms/cu m SO₂ and a corrosion of 8 micron/yr. At Kiruna, the values were -5 C, no SO₂, and a corrosion of 2 micron/yr

STUDIES ON THE EFFECTS OF AIR POLLUTANTS ON THE BUILDING MATERIALS OF THE DOME IN KOELN.

(Untersuchungen zur Einwirkung von Luftverunreinigungen auf die Baumaterialien des Koelner Domes). Text in German. Proc. Int. Clean Air Congr., 3rd, Duesseldorf, West Germany, 1973, p. A90-A92. 8 refs.

Systematic measurements of the sulfur dioxide, fluorine and chlorine concentrations in the air in and on the dome in Koeln are being conducted to ascertain the causes of the premature stone deterioration. The rate of SO₂, hydrochloric acid, and hydrofluoric acid by the building materials of the dome is measured by means of a Luckat type (IRMA) instrument using a basic liquid. In addition, the actual SO₂ concentrations are measured continuously and corrosion tests are being conducted. The measuring units are placed at different altitudes ranging from 20 m to 100 m. The measurements revealed above-average exposure of the dome building materials to SO₂, HCl, and HF whose concentrations increase with altitude. Rapid increase in the SO₂ concentrations from summer to winter was observed. The SO₂ concentrations measured late December were about three times as high as those measured late August, which indicates the major contribution by domestic heating and power plants to the overall SO₂ emissions.

Nakayama, Masamichi

THE EFFECTS OF AIR POLLUTION ON COATING FILMS.

(Taiki osen ni yoru tomaku e no eikyo). Text in Japanese. Kinzoku Hyomen Gijutsu (J. Metal. Finish.), no. 11:29-36, 1973. 11 refs.

The anti-corrosive surface coatings of oil, phthalic acid resin, vinyl, rubber chloride, or epoxy have been corroded or damaged by various air pollutants. The pollutants causing such damages as discoloring, blistering, peeling, rusting, swelling, and rotting are gaseous pollutants such as sulfur dioxide, sulfur trioxide, hydrogen sulfide, mercaptans, nitric oxide, nitrogen dioxide, nitric anhydride, nitric acid, ammonia, ozone, peroxides, fluoride, chlorine, hydrogen fluoride, hydrogen chloride, acid mists, settling particles, suspended particulates, metal oxide particles, corrosive salts, and marine salts. The degree of damage by these pollutants is heavily affected by their combinations, concentrations, wind direction and velocity, rain quantity, temperature and humidity. The degree of swelling, rusting, and other types of corrosion are much greater in chemical industrial areas with heavy SO₂ concentrations, and in humid areas

LONG TERM IMMISSION EFFECTS ON UNPROTECTED

WOOD. (Langfristige Immissionswirkungen an ungeschuetztem Natzholz). Text in German. Staub, Reinhaltung Luft, 34(6):225-

227, June 1974. 9 refs.

Field experiments to determine air pollution effects on unprotected wood were carried out over a 1-year period in four different locations in North Rhine-Westphalia (the municipal power plant in Duisburg, Essen, Herten, and Burgsteinfurt). Pieces of *Pinus sylvestris* and *Azalia bipidensis* were exposed on a rack with 45 deg inclination facing southwest. Weight and color modifications in the test samples and accumulation of pollutants in the outer layers of the wood served as indicators. Dust fall, sulfur dioxide, and fluorine were measured. Dusts and gaseous pollutants have a significant effect on unprotected wood.

Luckat, Siegbert

RELATIONSHIP BETWEEN THE CORROSION RATE OF STEEL AND THE IMMISSION RATE OF VARIOUS POLLUTANTS. (Beziehungen zwischen der Korrosionsrate von Stahl und den Immissionsraten verschiedener Schadstoffe). Text in German. Staub Reinhaltung Luft, 34(6): 209-213, June 1974. 13 refs.

Steel plates (DIN 1623) of 50 by 100 mm and 1 mm thickness were used for determination of the relationship between the corrosion rate and the emission rate of sulfur-, fluorine-, and chlorine containing pollutants. For exposure of the steel plates Mank's turret (a pivoted disk with arms driven by the air flow) was used. The emission rate analyzer, which has been described elsewhere, uses the surface of an alkaline liquid as a standardized measurement area. The absorption solutions and Soxhlet-cartridges of the analyzers were collected every two weeks and replaced by new ones. The emission rate was likewise determined every two weeks by replacement of the five exposed steel plates by fresh ones. The weight loss of the exposed plates was determined in the laboratory and the corrosion calculated in grams per sq meter per day. The heavily polluted cities Duisburg, Essen and Herten of the Ruhr valley and Haus Alst outside of the industrial area were selected as exposure sites. The seasonal characteristic of the sulfur dioxide emission rate showed for all measuring sites two to 2.5 times higher values in the winter months than in summer. The concentrations of SO₂ in Haus Alst, whose maximum values corresponded to the minimum values measured in Duisburg were surprisingly high. The chloride emission rate showed no marked seasonal characteristic. Several considerable peak values which occurred at the same magnitude at all sites deserve mentioning. Fluoride emission rates, too, show no significant seasonal seasonal fluctuation with the exception of the measuring site at the cathedral in Cologne where the values increase significantly during the summer months. The annual average values here are far above those measured in the Ruhr valley. The seasonal characteristic of the corrosion rates corresponded to that of the SO₂ emission rates which shows that the corrosion rate of steel can be used as a criterion for the effect of air pollutants. Correlation coefficients will be calculated as soon as more data are available.

TITANIUM FOR INCINERATOR GAS SCRUBBING EQUIPMENT. Mater. Performance, 13(4): 17-19, April 1974. 6 refs.

<xref image="2000WVNF.TIF|V3|2006:09:28:01:43:54.00|118387|0"> image: </xref>

The use of titanium in the construction of wet scrubbers for refuse incinerators is described. Flue gases may contain significant quantities of hydrogen chloride, sulfur dioxide, sulfur trioxide, trace hydrogen fluoride, and organic acids. The titanium is resistant to the corrosive environment in gas scrubbing equipment. Good resistance is predicted in the pH range of 1.5 to 11, and resistance to crevice corrosion at temperatures to 74 C and general pitting attack to 110 C. Trace amounts of iron 3 ions in the system or incorporated in the film should extend the range of immunity to attack. Economics of alternate materials and restrictions in performance limit Ti s application to the inlet and induced draft fan rotor assembly. Titanium can be applied where the environment is aggressive with high levels of HCl as in burning of polyvinyl chloride or when the consequences of unexpected scrubber outage can be costly or dangerous. AIR POLLUTION EFFECTS ON CATASTROPHIC FAILURE

OF METALS. Environmental Protection Agency, Research Tri-

angle Park, N. C., Chemistry and Physics Lab., Program Element 1AA008, ROAP 21 AMN, Rept. EPA-650/3-74-009, 38p.,

Nov. 1974. 18 refs. NTIS: PB 238 290/AS

The contribution of air pollution to the catastrophic failure of metal structures through the mechanisms of stress-corrosion cracking, corrosion fatigue, and hydrogen embrittlement is reviewed, with failures being cited for bridges, towers, aircraft, and electrical equipment. An economic analysis of these failures indicates that accompanying injury and loss of life account for an annual economic cost of between \$50 million and \$100 million. No research has been performed to determine the relationships between levels of particular pollutants and the occurrence of catastrophic failure of metals, although agents known to cause metal alloy corrosion problems include nitrates, caustics, hydrogen sulfide, chlorides, sulfur dioxide, ammonia, fluorides, chlorinated hydrocarbons, and cyanides.

Luckat, Siegbert

THE EFFECT OF AIR POLLUTANTS ON THE BUILDING

MATERIAL OF THE DOME OF COLOGNE. PART 2. (Die

Einwirkung von Luftverunreinigungen auf die Bausubstanz des Koelner Domes II). Text in German. Koeln. Domblatt, no. 38/39:95-106, 1974.

Results of air pollutant concentration measurements on the Dome of Cologne are presented, and the effect of air pollutants on the building stones is described in comparison to similar building materials exposed in other sites. The sulfur dioxide concentrations were highest during the November-January period, and were higher than the values measured between June and August by a factor of 2.5 to 3. The chloride concentrations correlated with the SO₂ concentrations at all sites. The SO₂, chloride, and fluoride concentrations were higher on the weather side than on the lee side. Good correlation was established between the pollutant concentrations and the corrosion rates measured at the same sites. Correlation was found between the deterioration of the building stones (sandstone) and the pollutant concentrations by a comparison of similar building stones in the Dome of Cologne, situated in a highly polluted area, and those in buildings in less polluted and rural areas.

Crocker, Thomas Dunstan

SOME ECONOMICS OF AIR POLLUTION CONTROL. Mis-
souri Univ., Columbia, Thesis (PhD), Ann Arbor, Mich., Univ.
Microfilms, Inc., 1967, 274p. 159 refs.

The economic aspects of the atmospheric pollution problem caused by the detrimental effects of airborne fluorides emanating from phosphatic fertilizer manufacturing processes upon the beef cattle and the citrus industries of Polk County, Florida, were studied with an ultimate view to the economic efficacy of alternative air pollution control policies. A review of the effects of airborne fluorides upon plants and animals gave no grounds for attempting to economically construct meaningful receptor damage functions from these materials. There are two distinct advantages of the use of true sale prices of receptor lands to determine differential receptor damages. First, the market rather than the investigator estimates the near infinitude of relevant relations and their interactions; and second, the responses of the owners of the physical and biological entities damaged by air pollution to varying levels of pollutant fumigations are better taken into account. A cross-sectional, multiple regression analysis of agricultural land values resulted in a positive relation between frequency of pollutant fumigations and the market value of pasture sites; and a negative relation between frequency of pollutant fumigations and the market value of citrus sites. Two basic conclusions about air pollution control policy can be drawn from the Polk County case: 1) the imposition of various physical and economic constraints upon the actions of receptors and emitters can generate gains from trade where all such gains had previously been exhausted; and 2) that assumption absolutely necessary for the economically efficient working of the emitter charge stating that negotiations between emitters and receptors are impossible is not fulfilled in reality.

Schreiber, Michael

THE COSTS FOR MAINTENANCE OF CLEAN AIR. THE INFLUENCE OF SOCIAL COSTS ON THE SELECTION OF AN INDUSTRIAL SITE. (Kosten der Luftreinhaltung. Der Einfluss der social costs auf die industrielle Standortwahl). Text in German. Wasser Luft Betrieb, 15(4): 145-148, 1971. 27 refs.

Because of the cost of eliminating brown smoke emissions, Thomas converters were replaced by oxygen lancing converters. An 80-ton Thomas converter emits about twice as much waste gas as an oxygen lancing converter of the same capacity. Similar changeovers to processes with less waste gas production were made in the chemical industry to save waste gas cleaning costs. Sulfur emissions are reduced mainly by switching to low-sulfur fuels, a much less expensive means than desulfurization of the fuel or the flue gases. Such steps are not always possible. In many cases investment in dust collectors, electrostatic precipitators, and scrubbers are unavoidable. The economy of such units depends on the ratio between collection efficiency and maintenance costs. For electrostatic precipitators investment costs rise proportionally to the degree of collection in the efficiency range between 80 and 95%. A collection efficiency of 95 to 98% requires facilities which are 50% larger, increasing costs by 35% and more. The aluminum industry spends an estimated \$50/ton of aluminum of its annual production for facilities to eliminate fluorine emission. The annual operating costs per ton of aluminum are estimated at \$8.40. Metallurgical plants spent similar amounts for reduction of their emissions.

AIR POLLUTION: AN OVERALL VIEW OF THE EFFECTS OF POLLUTANTS AND THE TECHNIQUES USED TO CONTROL THEM. (Inquinamento atmosferico: panoramica sugli ef-

fetti degli inquinanti e sulle tecnologie di abbattimento). Text in Italian. *Inquinamento*, 13(1):27-37, Jan.-Feb. 1971. 29 refs. The damage caused by pollution is discussed in terms of losses not recovered (the fertilizer industry loses 220 tons of fluorine daily to the atmosphere and two-thirds of the fuel oil burned in heating the city of Milan could be saved by more efficient use of fuel), damage to human health, and damage to man's inheritance in the natural world. Devices for the elimination of sulfur dioxide, nitrogen compounds, and particulate pollution are discussed. Mortality in the United States from asthma, bronchitis and emphysema have increased more than 100% in the last 10 years, while mortality from tuberculosis has dropped to 25% of its previous level. It has been estimated that the cost of pollution in the United States is \$50 per person per year. Literature on the recovery of pollutants is reviewed, and schematic drawings are shown of apparatus for the removal of SO₂ and the nitrogen oxides, indicating the availability of a wealth of methods and devices for the removal and recovery of the undesirable emissions, even though some are still in the trial stage.

LeSourd, D. A., M. E. Fogel, A. R. Schleicher, T. E. Bingham, R. W. Gerstle, E. L. Hill, and F. A. Ayer
COMPREHENSIVE STUDY OF SPECIFIED AIR POLLUTION SOURCES TO ASSESS THE ECONOMIC EFFECTS OF AIR QUALITY STANDARDS. VOL. I. (FINAL REPORT).

Research Triangle Inst., Durham, N. C., Operations Research and Economics Div., APCO Contract CPA 70-60, RTI Proj. OU-534, Rept. FR-OU-534, 395p., Dec. 1970. 328 refs. NTIS: PB 197647

Air pollution control costs for mobile sources are presented on a national basis and in terms of unit investment and annual operating and maintenance costs as well as total annual operating and maintenance costs. The analyses cover the estimated emissions and control costs for new cars for Fiscal Year 1967 through Fiscal Year 1976. Control costs for each stationary source, except for residential heating, are shown for 298 metropolitan areas by investment and annual expenditures by Fiscal Year 1976. The impact of control on selected industries and the Nation are also determined. Finally, an extensive bibliography is included. The pollutants from mobile sources selected for analysis are hydrocarbons, carbon monoxide,
<xref image="2000WVNH.TIF|V3|2006:09:28:01:44:00.00|109158|0"> image: </xref>

nitrogen oxides and particulates. The six pollutants for which control cost estimates are made for stationary sources are particulates, sulfur oxides, carbon monoxide, hydrocarbons, fluorides, and lead. Emission standards applied are considered stringent in comparison with many currently in use throughout the Nation. Mobile sources include automobiles and light and heavy-duty trucks. Stationary sources studied include solid waste disposal, commercial and institutional heating plants, industrial boilers, residential heating plants, steam-electric power plants, asphalt batching, brick and tile, coal cleaning, cement, elemental phosphorus, grain handling and milling (animal feed), gray iron, iron and steel, kraft (sulfate) pulp, lime, petroleum products and storage, petroleum refineries, phosphate fertilizer, primary non-ferrous metallurgy (aluminum, copper, lead and zinc), rubber (tires), secondary non-ferrous metallurgy, sulfuric acid, and varnish. Data essential for defining metropolitan areas, emission control standards, and relevant process and air pollution control engineering characteristics required to support the cost analyses for each source and the cost impact on each industrial process are presented and analyzed in separate appendixes to this report. Olson, Robert E.
NATURE OF ECONOMIC LOSSES RESULTING FROM THE EFFECTS OF AIR POLLUTANTS ON PLANTS. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 14p., 1970. 2 reprints. (Presented at the Air Pollution Control Association, Annual Meeting, 63rd, St. Louis, Mo., June 14-18, 1970, Paper 70-105.) A program in progress to estimate the dollar value of air pollution damage to 65 commercially important crops in the U. S. is limited to the effects of ozone, peroxyacetyl nitrate, ethylene, nitrogen dioxide, and fluoride, since these compounds account for at least 90% of such damage. Data on specific air pollution crop damage effects were obtained from plant scientists, while 514 counties with high potential for crop damage from air pollution were identified on the basis of fuel consumption, locations of industrial sources of the compounds under study, and meteorological and topographical conditions. Exposure of plants to pollutants was found greatest near principal urban and industrial centers rather than in major agricultural areas. The level of aggregation was taken as a framework for determining relevant benefits and costs, based on farm production foregone valued at state or county average prices. Thus, for each crop and each county, the three types of data input were production-measured quantity units, producer prices, and estimated yield reduction in percent. A computer program was developed for processing the price, quantity, crop value, and loss data that produces the results for the 514 counties and 65 crops all at once. The computational procedure for estimating economic losses is given, and an example of results presented for Fresno Co., Calif, which includes average price per hundredweight, quantity produced in hundredweights, value of production, and estimated dollar loss for each county crop for the base year 1964.

Lux, H.
FOREST DAMAGES CAUSED BY SMOKE IN SLOVAKIA. (Forstliche Rauchschaadprobleme in der Slowakei). Text in German. Soz. Forstwirtschaft., 21(2):60-62, 1971. Proceedings of the Forest and Industrial Emissions Conference held in Slovakia are reviewed. In Czechoslovakia, the total sulfur dioxide emission amounts to 3.4 million t/yr, causing approximately \$.09 billion damage to forestry. The corresponding damage caused to forestry in Slovakia lies at \$.03 billion. A total forest area of 160,000 ha is affected by air pollution in Czechoslovakia, of which 27,000 ha lie in Slovakia. The damaged agricultural area totals some 600,000 ha. The investments for technical pollution control measures amounted

to \$1.29 million in 1968, and \$5.16 million in 1970. The forestry areas hit hardest by pollution lie in the Erzgebirge (more than 100,000 ha) and in the Ostrava region, with chemical plants and thermal power plants as basic pollution sources. Soil analyses and sensitivity investigations as well as a new method of growth measurement are briefly described. Increasing soil acidification due to sulfur dioxide, chlorine, hydrogen chloride, and hydrogen fluoride gases results in reduced biological activity of the soil, and in nitrogen deficiency. Diagnostic methods and possible connections between emissions and insect proliferation are referred to.

ENGINEERING AND COST EFFECTIVENESS STUDY OF
FLUORINE EMISSIONS CONTROL. (FINAL REPORT).
(VOLUME I). TRW Systems Group, McLean, Va. and
Resources Research Inc., McLean, Va., Office of Air Programs
Contract EHSD 71-14, Rept. APTD-0945, SN 16893.000, 411p.,
Jan 1972. NTIS: PB 207506

Industrial emission sources were inventoried and a study was made of the technical and economic aspects of implementing soluble fluoride emission controls for major industrial sources. Industries included in the study were primary aluminum smelting, iron and steel, electrical power generation, phosphate rock processing, glass manufacture, frit smelting, heavy clay products, expanded clay aggregate, cement manufacture, hydrofluoric acid alkylation processes, HF production, and nonferrous metals smelting and refining. It is technically possible, though not economically profitable, to control soluble fluorides with available devices such as wet scrubbers; the immediate problem lies in implementation of that control, including collection of the evolved fluorides by hoods and similar effluent capture systems for treatment in the abatement devices. Included in the study are discussions of production trends extrapolated to the year 2000, process flow diagrams, estimates of current and projected fluoride emissions analyses of production and control process economics, recommendations for additional research and development programs, environmental and ecological effects of the emitted fluorides on animals, plants, man, glass, and materials, and techniques for sampling and measurement of fluoride pollutants in the various effluent streams.

EXPENDITURES OF THE CHEMICAL INDUSTRY FOR IN-
CREASING ENVIRONMENTAL PROTECTION. (Aufwendun-
gen der Chemie fuer Umweltschutz nehmen zu). Text in Ger-
man. Chem. Ind. (Duesseldorf), 24(5):272-275, May 1972.
From 1960 to 1969, the chemical industry in the Federal
Republic of Germany spent approximately 1.1 billion for en-
vironmental protection measures; 36.8% consisted of invest-
ments for environmental protection; 42.3%, operation costs for
environment protection plants; and 20.6%, for research and
development programs. The emissions of sulfur dioxide, car-
bon monoxide, nitric oxide, fluor and solid particles from the
chemical industry were less than 2% of the total emitted quan-
tity. The nuisance of emissions from the chemical industry is
due more to bad odors than to gases endangering human
health. Investments of the chemical industry for protective
<xref image="2000WVNI.TIF|V3|2006:09:28:01:44:04.00|123768|0"> image: </xref>

measures against air pollution increased from 34.1% in the period 1960/1964 to 35.1% in the period 1965/69 and will amount to only 24% in 1974.

Bertrand, Rene R.

A STUDY OF MARKETS FOR AIR POLLUTION MEASURE-
MENT INSTRUMENTATION 1971-1980. Esso Research andEngineering Co., Linden, N. J., Office of Air Programs Contract
CPA 22-69-154, 93p., June 1971. 20 refs. NTIS: PB 204174

The market for air pollution instrumentation during the decade of the seventies was determined. The market analysis presented is based on the survey of instrumentation requirements conducted at the federal, state, and local level and on an analysis of current legislation and air pollution control codes. The market for three areas of measurement instrumentation is estimated: ambient level monitoring, stationary source emission measurement, and auto exhaust measurement. This market amounts to nearly \$500 million during the coming decade, some 76% of which represents initial purchases of air pollution measuring equipment. Industry will be the major purchaser of instrumentation, accounting for 45% of the market. The market is heavily oriented towards stationary source emission measurement, this area accounting for half the total instrumentation market value. Timing is a critical factor in the market with each of the three areas of measurement reaching maturity at different periods during the decade. In the study of the market for ambient air quality monitoring, only instrumentation required for particulates, sulfur dioxide, oxidants, carbon monoxide, hydrocarbons, nitrogen oxides, fluorides, polynuclear organic matter, and odors is considered. The market estimate for stationary source emission measurement instrumentation includes instrumentation for continuous source monitoring of particulates, SO₂, nitrogen oxides, hydrocarbons, CO, and fluorides. Millecan, Arthur A.

A SURVEY AND ASSESSMENT OF AIR POLLUTION

DAMAGE TO CALIFORNIA VEGETATION IN 1970. Califor-

nia State Dept. of Agriculture, Sacramento, Bureau of Plant
Pathology, Air pollution Control Office Contract CPA 70-91,
Rept. APTD 0694, 51p., June 1971. NTIS: PB 200873

A statewide survey of California was conducted in 1970 to determine areas of occurrence of plant injury due to air pollutants and to assess the damage to agricultural plant crops. Efforts were concentrated in areas with known histories of air pollution problems. On the basis of observations and evaluations by agricultural specialists, 1970 crop losses due to air pollutants were estimated at approximately \$25,690,680. These losses were confined to 15 to 58 counties in the state. Losses (o citrus plantings in the Los Angeles Basin County, with a loss of \$10,723,590, experienced the greatest economic crop loss for any one county. The monetary loss figure does not include losses attributed to reduction in crop yield as a result of invisible damage, with the exception of citrus and grapes. Monetary losses to native vegetation including forests or to landscape plantings also were not included. On-the-spot observations made by trained agricultural specialists provided 450 reports, 359 of which recorded plant injury caused by air pollution. Plant injury was observed in 22 counties. Photochemical smog accounted for most of the economic losses. Analysis of the reports showed six pollutants to be involved and accounted for the following percentages of plant injury: ozone 50%, peroxyacetyl nitrates 18%, fluorides 15%, ethylene 14%, sulfur dioxide 2%, and particulates 1%. Benedict, H. M. and R. E. Olson

ECONOMIC IMPACT OF AIR POLLUTANTS ON PLANTS.

VOLUME I. Stanford Research Inst., Irvine, Calif., Coordinating Research Council Contract APRAC-CAPA-2-68, Report CRC-CAPA-2-68-1, 68p., Jan. 1971. 13 refs. NTIS: PB 200235

The loss in dollars that occurs annually as a result of the effects of air pollutants on plants has been estimated. The program has involved individuals trained in agricultural economics and in physiologic and pathologic reactions of plants to air pollutants. The study was limited to the effects of ozone, peroxyacetyl nitrates, nitrogen dioxide, sulfur dioxide, and fluorides, as these compounds appear to account for at least 90% of the damage to vegetation by air pollutants. In the initial phases of the study, estimates of loss are limited to the direct effects of these pollutants on yield, quality, and marketability of important commercial crops, with losses for ornamental plants based on losses to vendors. Dollar loss estimates were made for each crop reported for each county where air pollution sources apparently existed. These estimates included losses due to ozone, nitrogen oxides, PAN, sulfur dioxide, and fluorides. (Author abstract modified)

Benedict, H. M., C. J. Miller, and R. E. Olson
ECONOMIC IMPACT OF AIR POLLUTANTS ON PLANTS
IN THE UNITED STATES. (FINAL REPORT). Stanford
Research Inst., Menlo Park, Calif., Coordinating Research
Council Contract CRC-APRAC CAPA-2-68(1-70), SRI Proj.
LSD-1056, 77p., Nov. 1971. 37 refs. NTIS: PB 210667

An investigation was made to develop gross estimates of economic losses resulting from the effects of air pollutants on plants. In a previous report, estimates of severity of pollution in various counties were based on emission data only, and the effects of meteorological and other factors in concentrating or diluting these emissions were not given proper consideration. In estimating the loss of individual crops, it was assumed that crops considered sensitive to a given pollutant were equally sensitive and those resistant were equally resistant. The present report is aimed primarily at revising the estimates to correct the deficiencies just mentioned and to include estimates of loss to ornamental plants. Revised estimates of dollar losses due to oxidants (ozone, peroxyacetyl nitrate, and nitrogen oxides), sulfur dioxide, and fluoride are presented.

Fredriksen, Heige
POLLUTION PROBLEMS IN THE NORWEGIAN INDUSTRY.
(Forurensningsproblemer in norsk industri). Text in Norwegian.
Tidsskr. Kjemi, Bergvesen, Met., 32(2):9-14, Feb. 1972.

The state of pollution control and planned investments in various branches of industry in Norway are reviewed. In addition to \$70,000,000 already invested in industrial emission control, about \$14,000,000 more will be necessary over the next few years. The aluminum industry, with a yearly output of 500,000 tons, has completed a comprehensive emission control program. Some 8000 tons of fluorides, out of a total of 10,000 tons, are collected. The operating cost of cleaning equipment adds \$5.60 to the cost of 1 ton of aluminum. Red smoke emissions from iron and steel plants have been considerably abated, from 1000 to 20 kg/hr in one case. The additional costs are 70-118 cents. The chemical industry has invested \$9.52 million for emission control equipment, whose operating costs are \$9.3 million/yr. Oil refineries, emitting considerable amounts of sulfur dioxide, soot, and hydrocarbons, will invest \$1.4 million over the next 2 years in addition to a \$2.1 million invest-

<xref image="2000WVNJ.TIF|V3|2006:09:28:01:44:06.00|129876|0"> image: </xref>

ment already realized. One refinery recovers 6000 tons of sulfur from high-sulfur raw products yearly. Cement works have invested \$5.60 million for electrostatic dust precipitators. Some 70-90% of the total SO₂ emission is bound to the clinker. The fish processing industry has invested \$.84 million for odor control; while combined scrubbing and incineration would require another \$11.9 million. The melting industry has invested \$7.28 million for the control of dust emissions. The investments by the wood processing and pulp and paper industries run to \$14 million.

Pell, Eva J.

NINETEEN SEVENTY-TWO SURVEY AND ASSESSMENT OF AIR POLLUTION DAMAGE TO VEGETATION IN NEW JERSEY. Rutgers-The State Univ. New Brunswick, N. J., Dept. of Plant Biology, Environmental Protection Agency Contract 68-02-0078, EPA-R5-73-022, Program Element 1A1004, 45p., June 1973. 27 refs. NTIS: PB 223089

The economic impact of air pollution on New Jersey vegetation was studied from May 1972 through May 1973. Direct losses to agronomic crops and ornamental plantings were evaluated; crop substitution and indirect yield reduction were not accounted for. The total losses to these crops during the study period amounted to \$128,019. Forty-seven percent of the plant damage was caused by oxidants, 18% by hydrogen fluoride, 16% by ethylene, 4% by sulfur dioxide, and 1% by anhydrous ammonia. Cumberland, Warren, Atlantic, and Salem Counties sustained the greatest damage. The damage reported in this survey was only 11% of that reported for New Jersey during the 1971-72 period. Reduced losses did not result from decreased air pollution concentrations but from altered environmental conditions. The unusual rainfall patterns in 1972 placed the plants under water stress and probably protected them from air pollution injury. In addition to evaluating crop losses, unknown problems were documented and research needs assessed. (Author abstract)

Gillette, Donald G.

AGRICULTURAL LOSSES AND ASSESSMENT OF AIR POLLUTION DAMAGE. Preprint, Virginia Polytechnic Inst., Blacksburg and Univ. of Puerto Rico, Rio Piedras (Puerto Rico), 14p., 1974. 11 refs. (Presented at the Air Pollution Workshops, Blacksburg, Va., March 4-6, 1974 and Rio Piedras, Puerto Rico, March 13-15, 1974.)

Estimated losses from air pollution damage to vegetation in the United States range from less than \$100 million to more than \$500 million per year, and approximately 80% of the estimated damage is attributed to oxidants. Damage from sulfur oxides and fluorides accounts for about 10%, and about 10% of the total loss can be charged to other miscellaneous pollutants. Over one-third of the total loss is associated with damages to ornamentals and shrubs in heavily polluted urban areas, while the remaining losses of approximately \$100 million are incurred by commercial crops grown in urban fringe areas or around major rural point sources. Over half of the estimated vegetative losses from air pollution in the United States occur in the state of California. The opportunity costs incurred by farmers as a result of pollution infringement on their productive capabilities are extremely difficult to quantify because of the intangible nature of the value or cost of the opportunities lost.

Benedict, Harris M., Clarence J. Miller, and Jean S. Smith

ASSESSMENT OF ECONOMIC IMPACT OF AIR POLLUTANTS ON VEGETATION IN THE UNITED STATES: 1969 AND 1971 (FINAL REPORT). Stanford Research Inst., Menlo Park, Calif., Coordinating Research Council Contract CAPA 2-68(1-71) CPA 70-16 and Environmental Protection Agency Contract 68-02-0312, SRI Proj. LSU-1503, Rept. EPA-650/5-73-002,

100p., July 1973. 46 refs. NTIS: PB 224818/AS

The economic impact of air pollutants on vegetation in the United States was assessed by selecting counties where major air pollutants such as oxidants, nitrogen oxides, sulfur dioxide, and fluorides were likely to reach plant damaging concentrations. Calculations for 1969 estimates indicated that 40% of the dollar value of agricultural crops, 36% of the value of forests, and over 50% of the ornamental value lie in polluted areas of the United States. Total annual dollar loss to crops in the United States was calculated to be about \$87.5 million, with oxidants accounting for \$77 million, SO₂ accounting for \$4.97 million, and fluorides accounting for \$5.25 million. Applying loss factors to the 1969 crop data and adding the increase in crop values between 1969 and 1971 resulted in an estimated \$123.3 million loss due to oxidants and an \$8.2 million loss due to SO₂ for the year 1971. The greatest percentage of crop losses on a regional basis occurred in the heavily populated and industrialized areas of the southwestern, middle Atlantic, and midwestern states.

LONG-TERM PLANNING OF ENVIRONMENTAL PROTECTION IN ALUMINUM WORKS. (Planification a long terme pour la protection de l'environnement dans les alumineries). Text in French. Preprint, Assoc. for Clean Air Maintenance, Quebec, 8p., 1975. (Presented at the Strategy of Air Management Conference, St-Jovite, Canada, May 25-27, 1975.)

Different alternatives for the long-term abatement of particulate and gaseous fluorine emissions in aluminum factories in Quebec are discussed. The complete reconstruction, i.e., the shutdown of obsolete plants, and the introduction of the most advanced technology, including dry filtration or electrostatic precipitation of particulate emissions, would require an investment of about \$1,000,000,000. In the long run, this solution would reduce the energy use by 15%, and also the operating costs in general. Acceptable air quality could be achieved by the use of wet filtration techniques at an investment of \$100,000,000 at a rate of \$25,000,000 annually. Extended modernization, involving the introduction of dry filtration or electrostatic dust precipitation, would cost \$300,000,000. These latter alternative solutions would bring about a 3% increase in the energy use, and another increase in the operating costs.

K. STANDARDS AND CRITERIA

03032

METHODS OF MEASUREMENT OF AIR POLLUTION.

Metodi di Misura Dell'Inquinamento Atmosferico. Fumi Polveri (Milan) 6, (7-8) 217-21, 1966. It.

The Organ of Cooperation and Economic Development (O.C.D.E.) with its headquarters in Paris, decided in January 1957, to create a 'work group' to study the methods of measurement of atmospheric pollution. In 1963 a document was drafted by highly qualified specialists and technicians from all the member countries of (O.C.D.E.) and it dealt with the measurement of smoke, anhydrides of sulfur, sulfuric acid, hydrocarbons and fluorine. It is suggested that standard units of measurement be used, in the cgs system Smoke and anhydrides of sulfur are measured in micrograms per cubic meter (O C, 760 mm Hg). A method of measuring smoke in the atmosphere consists of passing a volume of air through a filter and measuring a color change in the machine. A correlation is obtained between the material collected in the machine and the color change based on a 'standard smoke' measurement. Sedimentable materials are measured in milligrams per square meter per day. (Author summary)

03582

CALIFORNIA STANDARDS FOR AMBIENT AIR QUALITY AND MOTOR VEHICLE EXHAUST (TECHNICAL REPT.)

(SUPPLEMENT NO. 2 ADDITIONAL AMBIENT AIR QUALITY STANDARDS). California State Dept. of Public Health, Berkeley. 28 pp., 1962.

Amended ambient air quality standards are tabulated. The basis for ethylene, hydrogen sulfide, and fluorides standards are received in terms of their effects on man, on vegetation, and on livestock. The 'adverse' level for ethylene was 0.5 ppm for 1 hr or 0.1 ppm for 8 hr (damage to vegetation) and for hydrogen sulfide, 0.1 ppm for 1 hr (sensory irritation). When forage crops containing 30 to 50 ppm of fluoride, measured on a dry weight basis, are consumed over a long period, teeth and bones of cattle may show changes, depending upon age, nutritional factors, and the form of fluoride ingested

07605

Middleton, John T

AIR QUALITY CRITERIA ASSOCIATED WITH VISIBILITY REDUCTION, SOILAGE AND DAMAGE TO VEGETATION.

Preprint, California Univ., Riverside, Air Pollution Research Center, 14p., 1963. (Presented and Methods of Measurement, Geneva, Switzerland, Aug. 6-12, 1963. Paper No. WHO/AP/15.) Panicle loading of the atmosphere is primarily responsible for reduction in visibility. The amount of visibility reduction, in turn, is due to the nature of the particle. The criterion for visibility is perhaps best given in terms of visible distance at a specific relative humidity. Air quality criteria for soilage may be developed where specific contaminants have direct effects upon particular materials. Since in general the soilage of goods is a function of multiple actions, air quality criteria for soilage are difficult of description and perhaps of lessened general utility. Air quality criteria for visible effects of vegetation damage can be developed for those toxicants which have direct effects, such as sulfur dioxide, ethylene, nitrogen dioxide, peroxyacyl nitrates, and ozone. Air quality criteria for fluorides cannot now be determined because of the multiplicity of factors which control the rate of accumulation and the subsequent effect of fluoride upon plant tissues. Levels of fluoride responsible for damage to livestock can be established and a criterion based on this is feasible.

Brodovicz, Bey A.

AIR QUALITY CRITERIA FOR PENNSYLVANIA. J. Air Pollution Control Assoc., 18(1):21-23, Jan. 1968. 4 refs.

In late 1965 the Pennsylvania Air Pollution Commission ap-

pointed a Council of Technical Advisors to develop air quality criteria. Recently this Council set forth its recommendations for ten pollutants. The philosophy of the Council is expressed. The major difficulties and rationale are mentioned. The recommendations are given and the potential use of the criteria is also explained. The establishment of firm guidelines of air quality is based solely on consideration of effects both on health and aesthetics. The criteria are broken into two distinct groups; air basin average and single point measurement. The pollutants included: 1. Suspended particulates (total), 2. Settled particulates (total), 3. Lead (tentative), 4. Beryllium, 5. Sulfates (as H₂SO₄), 6. Sulfuric acid mist, 7. Fluorides (total soluble, as HF), 8. Sulfur dioxide, 10. Oxidants, 11. Hydrogen sulfide, and 12 Carbon monoxide.

10168

SANITARY STANDARDS FOR PLANNING INDUSTRIAL ENTERPRISES. In: A Collection of Most Important Official Items Related to Sanitary and Anti-Epidemiological (Prophylactic) Problems. An Aid to the State Sanitary Inspector-Physician and Physician-Epidemiologist. T. E. Boldyrev and V. M. Zhdanov (eds.), Vol. 2, 3rd ed., Moscow, State Publishers of Medical Literature, Medgiz, 1953, Chapt. 1, p. 113-148. Translated from Russian.

Standards are presented which apply to the improvement of existing industrial enterprises or the planning of new buildings with respect to the site of the enterprise, the nearby residential environment, the water supply source, and the manner of sewage disposal. Conditions prevailing in the territory of the planned enterprise must accord with the sanitary requirements with regard to precipitation, drainage, direct sunshine, natural ventilation, and level of ground water. Plans for the construction of plants must include provision for the health of the workers, as well as the execution and maintenance of a sanitary clearance zone and the adequate planting of appropriate trees, shrubs, and other green plants. Requirements are indicated for various chemical processing plants, metal processing and machine construction industries, ore and mineral production, building industries, wood processing in-

<xref image="2000WVNL.TIF|V3|2006:09:28:01:44:12.00|99757|0"> image: </xref>

dustries, textile industry, plants processing animal products, and food industries. Periodic physical examinations are recommended for workers exposed to lead and its organic compounds, ethylated gasoline, mercury and its compounds, manganese, chromic acid and its salts, arsenic compounds, phosphorus, cobalt, fluorine, sulfuric acid, chlorine, bromine, carbon bisulfide, hydrogen sulfide, crude oil and petroleum products, chlorinated and brominated hydrocarbons, and radioactive substances.

K. Biersteker

FRESH AIR QUALITY STANDARDS. (Kwaliteitsnormen Buitenlucht.) Translated from Dutch. T. Soc. Geneesk., No. 46:166-176, 1968. 58 refs.

Fresh air quality standards in different nations are reviewed. Considerable differences exist because the hazards of air pollution are assessed differently. However, the differences in clean air specifications appear to disappear as the maximum permissible impurity concentrations become gradually lower. The Committee for Soil, Water and Air in Rotterdam developed standards which have no legal significance but help government and industry to establish clean air policies. These standards are tabulated for chlorine, hydrogen fluoride, carbon monoxide, ozone, nitrogen dioxide, sulfur dioxide, hydrogen sulfide and sulfuric acid-with comparable standards shown for West Germany, Russia, and the United States. The permissible SO₂ concentration in California is higher than in Europe. This is due to the fact that SO₂ plays a minor role in summer fog formation. In Europe, however, fog occurs in the winter and is accompanied by high SO₂ and smoke concentrations. Another notable difference in air quality standards is that the Russians have unrealistically high standards for clean air while in Western Europe air is considered as a raw material which should be left in a reasonably good condition for the next consumer. Air quality directives, being used for the city of Rotterdam, and air pollution alarm systems used for Los Angeles and proposed for New York, are discussed.

McCune, D. C.

THE TECHNICAL SIGNIFICANCE OF AIR: FLUORIDE CRITERIA FOR VEGETATION REFLECT THE DIVERSITY OF PLANT KINGDOM. Environ. Sci. Technol. 3(8):720-73S, Aug. 1969.

Problem areas in the development of air quality criteria and the application of standards are (1) the nature and occurrence of the pollutant, (2) the effects of the pollutant on a receptor and the factors that determine the dose-response relationship, and (3) the characteristics of present air monitoring techniques. Atmospheric fluorides present specific problems in each area and illustrate problems of general significance with respect to the effects of air pollution on vegetation. Criteria, for example, can be established only for gaseous fluoride pollutants. However, if air quantity standards are to be meaningfully evaluated and enforced, monitoring techniques must be developed that can discriminate between particulate and gaseous forms. Soundly-based criteria and standards must also consider the temporal distribution of atmospheric fluorides. Unfortunately, not enough is known about the effects of fluorides on plants to allow the formulation of concentration, duration, and frequency parameters. It is doubtful that continuous function can describe the effects of fluorine under given biological and environmental conditions. A better method for presenting criteria is a dose-response surface for an effect of a certain degree and type in terms of the probability of its occurrence. If standards are to be useful, the art of determining fluoride levels must be refined. Acceptable standard monitoring methods may result from the work of the Halogen Subcommittee of the Intersociety Committee on Manual of Methods for Air Sampling and Analysis. Included is

a discussion by R. H. Daines of the implication of standards for industrial plant design. Variations in plant sensitivity to fluorides are discussed by H. R. Hickey.

Weaver, Neill K.

ATMOSPHERIC CONTAMINANTS AND STANDARDS.

STATUS REPORT. J. Occupational Med., 11(9):45S-461, Sept.

1969. 23 refs.

The Federal Air Quality Act of 1967 furnishes the methodology for the abatement of air pollution. Its provisions include the designation of air quality control regions and the issuance of air quality criteria and control technology documents, which will be followed by the promulgation of ambient air standards and emission standards at regional, state, and local levels. The atmospheric pollutants of current major concern are sulfur oxides, particulates, nitrogen oxides, hydrocarbons, oxidants, carbon monoxide, fluorine, and lead. Their toxic and other deleterious effects, exhibited at various concentration-time exposures, can be related to levels reached by the individual contaminants in the air of cities. While such an evaluation does not allow for possible interactions between pollutants, it appears that sulfur dioxide, oxidants, and carbon monoxide may be harmful to human health when the agents are concentrated, as in focal areas of emission or during sustained meteorologic inversions. Gains to be achieved by controlling these and other contaminants during non-peak conditions are probably derived from aesthetic, economic, and welfare benefits rather than health. Abatement procedures should eliminate rises in pollutant levels beyond the average ranges generally present in urban ambient air. (Author summary modified)

Hodge, Harold C. and Frank A. Smith

AIR QUALITY CRITERIA FOR THE EFFECTS OF

FLUORIDES ON MAN. J. Air Pollution Control., 20(4):226-

232, April 1970. 42 refs.

Atmospheric and industrial concentrations of fluoride are considered, together with the effects of fluoride on man. Urban concentrations of fluoride range from less than 0.2 micrograms/cu m to 1.9 micrograms/cu m. Depending on the processes involved, factories using fluorides release to the atmosphere elemental fluorine (F₂), soluble gaseous fluorides (HF), and soluble or insoluble fluoride dusts. Industrial air concentrations of fluorides range from a fraction of a milligram of fluoride per cu m to values mostly less than 10 mg/cu m. Average urinary F concentrations not exceeding 5 mg/l, which corresponds approximate! to a daily intake of 5 mg, are not associated with osteosclerosis in workmen. The amount of fluoride retained by an individual inhaling air containing 2.5 mg of fluoride dust per cu m (the current threshold limit value) is approximately 5-6 mg. The available evidence indicates that, with a few exceptions, the health of persons in the vicinity of factories emitting fluoride fumes or dust is not adversely influenced. However, some types of vegetation are highly susceptible to the effects of fluorides and an air quality standard to protect vegetation will be far lower than that encountered in the factory. If the standard is set at 10 ppb, the probable daily human intake would be 0.16 mg, which is far below the level required for the production of clear-cut effect in the human.

Pennsylvania State Dept. of Health, Harrisburg, Air Pollution Commission

PENNSYLVANIA AMBIENT AIR QUALITY STANDARDS.

6p., Oct. 20, 1969. 10 refs.

Annual, 30-day, 24-hr and/or 1-hr air quality standards are given for 12 pollutants (suspended and settled particulates, lead beryllium, sulfates as H₂SO₄, sulfuric acid mist, fluorides as HF, sulfur dioxide, nitrogen dioxide, oxidants, hydrogen sulfide, and carbon monoxide) in accordance with the requirements of the Pennsylvania Air Pollution Control Act of 1960. These standards, which will be reviewed at least once a year, are for single-point measurements; they represent minimum, and not necessarily desirable quality. The 24-hr standard for SO₂ is 0.10 ppm; for suspended particulates, 195 micrograms/cu m. An antidegradation policy is stated to the effect that where present air quality is significantly higher than the established standards, the difference will be conserved, based on a long range forecast of probable land and air uses in areas of high air quality. Sampling and analytical procedures to be employed for measuring ambient levels are specified for each of the 12 pollutants.

19818

LIST OF JAPANESE INDUSTRIAL STANDARDS ON AD*
PURIFICATION AS OF MARCH 1970. (Kuki seiyo ni kansuru JIS ichiranhyo. 1970 nen sangastsu genzai). Text in Japanese. Kuki Seiyo (Clean Air - J. Japan Air Cleaning Assoc., Tokyo), 8(2):62-64, June 1970.

Japanese industrial standards listed under special alphabetical, four-digit codes include the following: methods for continuous measurement of carbon monoxide, carbon dioxide, and hydrocarbons in automotive exhausts; analysis of ammonia, nitrogen oxide, fluorides, chlorine, hydrogen chloride, hydrogen sulfide, and hydrogen cyanide in flue gas; polarography; conductivity; potential difference titration methods; gas chromatography; light absorption; infrared spectroscopy; granular activated charcoal; powdered activated charcoal; cokes; industrial gasoline; automotive gasoline; kerosine; light oils; heavy oils; airplane gasoline, jet fuels; liquefied petroleum gas; air filter oil metal corrosion experiment, quantitative analysis of lead anti-knock agent in gasoline; analysis of sulfur in petroleum products; kerosene stove; tests by Geiger-Muller counter; radiation survey meter; air filter for radioactive particulates, measurement of smoke and dust in flue gas; tests for airborne particulates (weight method by electrostatic dust-sample); and measurement of sterilizing ultraviolet light.

25933

INORGANIC FLUORIDES. Am. Ind. Hyg. Assoc. J., 30(1):98-101, 1969. 21 refs.

Inorganic fluorides are ubiquitous; they are found naturally in most soils, water, vegetation, and animal tissue. In the small amounts present, they produce no harmful effects and are considered by many nutritionists as essential minor elements. They are important as air pollution since excessive amounts can produce damage both in vegetation and in animals that consume contaminated forage. The fluoride content of forage should not exceed 40 ppm F as a yearly average, be in excess of 60 ppm F for more than two consecutive months, or in excess of 80 ppm F for more than one month. Values of gaseous fluorides suitable as an air quality guide for residential and agriculture areas are as follows: 4.5 ppb average for 12 hrs; 3.5 ppb average for 25 hrs, 2.0 ppb average for 1 wk; and 1.0 ppb average for 1 month.

McCune, Delbert C.

ON THE ESTABLISHMENT OF AIR QUALITY CRITERIA,

WITH REFERENCE TO THE EFFECTS OF ATMOSPHERIC FLUORINE ON VEGETATION. American Petroleum Inst., New York, Div. of Environmental Affairs, No. 69-3, 33p., Feb. 1969. 66 refs.

The significance of the form of airborne fluorides to air quality criteria is that the type of fluoride compound will determine its toxicity to plants, and available data upon which criteria can be established have as their basis the effects of gaseous fluorides. Air quality standards or air monitoring techniques that consider only the total fluoride cannot be justified by present air quality criteria. The identification or classification of an effect does not by itself solve the problem of what constitutes damage. Some of the problems in the interpretation of effects with respect to what could be called injury or damage are discussed for tomato, alfalfa, sorghum, corn, gladiolus, tree fruits, citrus, and conifers. It is apparent that there can be no single criterion for the effects of atmospheric fluorine on vegetation. The temporal distribution of atmospheric fluorine is another important factor in the evaluation of data or the selection of criteria. Precision, sensitivity, response time, and accuracy of air monitoring and analytical methods are also mentioned. The relevance of criteria to standards is discussed.

Blokker, P. C.

COMMENTS ON AIR QUALITY STANDARDS IN DIFFERENT COUNTRIES. Stichting CONCAWE, The Hague (Netherlands), Document 2126, 12p., Sept. 1969. 17 refs.

A comparative survey is given (in tabular form) of maximum allowable concentration values for oxidants, nitrogen dioxide, chlorine, hydrogen fluoride, sulfur dioxide, sulfuric acid, carbon monoxide, hydrogen sulfide, smoke, soot and dust in different countries in Europe and the U.S.A. In addition to the table for nitrogen oxides, the biological, phytotoxic, coloration, and photochemical smog effects of contaminant are discussed. The standards show important differences from country to country because their bases differ appreciably. For this reason the bases of the best known standards are summarized. These are the standards of California, New York, Colorado, Rotterdam, West Germany, East Germany, and the U.S.S.R.

Yamamoto, Norimasa

ON EMISSION STANDARD OF SMOKE (HARMFUL SUBSTANCES) BASED ON AIR POLLUTION CONTROL LAW.

(Taiki osen boshiho ni motozuku baien - yugai busshitsu - no haishutsu kijin ni (suite). Text in Japanese. Preprint, Smaller Enterprises Promotion Corp. (Japan) 72p., 1971. (Presented at the Public Nuisance Prevent. Tech. Seminar, Japan, 1971.) Characteristics of smoke, dust collection equipment, average paniculate diameter, and other factors are tabulated. The number of boilers in Tokyo, Osaka, and Kanagawa are compared. The emission standard for dust is 0.06 g/N cu m-0.20 g/N cu m for boilers and furnaces, in newly constructed installations, which utilize heavy oil as fuel. The average cadmium concentration at nine monitoring stations in 1969 was 0.020 micrograms/cu m. Environmental pollution due to heavy metals is also considered. At 0.1 ppm, the odor of chlorine can be detected with slight irritation; at three to six ppm, there is irritation of the eyes, nose, throat, and headache, while life is threatened at 14-21 ppm. Chlorine also damages plants after about 0.5 ppm. Chlorine, up to 0.5 ppm, is contained in tap water. The environmental standard should be less than 0.02 ppm. Even small amounts of fluorine in the atmosphere can damage plants, and the standard should be two to five micrograms/cu m. Above two to eight ppm of F, teeth have motley patterns, and eight to 15 mg/day for 10 years would bring about softening of the bone. Standards are also given for sulfur dioxide, carbon monoxide, oxidants, hydrocarbons, and nitrogen dioxide. Air pollution control agencies, districts, plans and alerts are mentioned.

33107

EXPLANATION OF DUST ETC. DISCHARGE STANDARD

AS IN AIR POLLUTION CONTROL LAW ENFORCEMENT

REGULATIONS. (Taiki osen boshiho seko kisoku ni mini baijinto no haishutsu kijunchi no kaisetsu). Text in Japanese. Kogai To Taisaku (J. Pollution Control), 7(7):588-590, July 1971.

In Japan, the emission standard for sulfur dioxide is based on diffusion formulas, according to a system of area allocations. The country is divided into eight ranks which represent from between 0.020 and 0.045 ppm maximum ground concentration of SO₂, depending upon the degree to which the area has been industrialized. Old facilities must be equipped with electrostatic precipitators, bag filter, multicyclones, or other dust collection equipment, while even stricter standards exist for newly constructed buildings. Even in areas where fuel consumption will double, air pollution levels are to be reduced one-third their present amount in five years. If necessary, more rigid standards may be applied by prefectural governments. Emission standards exist for cadmium, chlorine, hydrogen chloride, fluorine, hydrogen fluoride, lead, and other harmful substances. Standards for fuels also exist, so that they cannot have a sulfur content higher than 1.0-1.5%.

34063

Ministry of International Trade and Industry (Japan) Dept. of Thermal Power

THE CONTENT OF AIR POLLUTION CONTROL LAW REVISIONS AND THEIR APPLICATIONS FOR ELECTRIC

WORKS. (Taikiosen boshiho kaisei no naiyo to denki kosakubutsu ni okeru unyo). Text in Japanese. Karyoku Hatsuden (Thermoelectric Power Generation), 22(10): 1107-1113, Oct. 1971. The 1970 revisions of public nuisance related laws are discussed with regard to purpose, content, application, and enforcement. The, range of toxic pollutants was expanded to include cadmium and its compounds, chlorine and hydrogen chloride, fluorine and hydrogen fluoride, bromine fluoride, lead and lead compounds, and nitrogen oxides. Boilers using

gases containing more than 0.1% sulfur content, coke furnaces, mineral depositories, mineral conveyors, crushers, graters, and sifters were added to the list of soot and dust creating facilities. Hydrocarbons, lead compounds, and nitrogen compounds were added to the list of toxic automotive emission gases. Emission standards are determined as before by the K figures obtained by the stack gas dispersion formula; but the entire country was divided into classifications according to various K values ranging from 11.7 to 26.3 (maximum allowable concentration of sulfur oxides 0.020 - 0.045 ppm). Soot and other dust particulate emission standards were revised on a large scale. Among electric power generator boilers, heavy oil and gas boilers were classified into three groups: Maximum allowable emission is 0.1 g/N cu m for boilers with more than 200,000 N cu m/h capacity; 0.2 g/N cu m for boilers between 40,000 and 200,000 N cu m; and 0.3 g/N cu m for boilers with less than 40,000 N cu m/h capacity. These compare with the former 1.0 g/N cu m uniform standard. For low grade coal boilers, the maximum allowable concentration is 0.8 g/N cu m, and for high grade coal boilers, 0.4 g/N cu. Sulfur oxides standards and toxic pollutant emission standards are reviewed by tables.

EMISSION STANDARDS OF STACK GASES (TOXIC MATERIALS) BASED ON THE AIR POLLUTION CONTROL

LAW. (Taiki osen boshiho ni motozuku baien (yugai busshitsu) no haishutsu kijun ni (suite). Text in Japanese. Taiki Osen Nyusu (Air Pollution News), no. 67:3-39, Nov. 1971.

Emission standards for various toxic materials in stack gases, based on the Air Pollution Control Law, are presented in tables. Items reviewed are the dust emission standard; average emissions and dust collection rates according to various types of furnaces and various types of dust creating installations; standards and average emissions for settling particles, suspended particulates, chlorine, and fluorides; and the epidemiological study of the influences of fluorides. The Japanese Air Control Law, WHO indexes, Forecast and Warning systems of New York City, the United States National Primary Secondary Ambient Air Quality Standards Federal Register, Air Pollution Emergencies Episode Criteria, and the E.P.A Federal Register are included. Also included in table forms are the records of Tokyo air pollution monitoring stations on suspended particulates; total emission quantity by pollutants and by sources; carbon monoxide saturation of hemoglobin and symptoms; influences on the human body of various toxic matter such as sulfur dioxide, sulfuric acid mist, nitrogen dioxide, ozone, and suspended particulates; nitric oxide and NO₂ concentration in Tokyo; emission standards for lead and lead compounds; a review of lead emitting industries; total dust particles and the lead content in the main cities of Japan; lead emission standards in various countries, and the 1969 SO₂ measurements in various controlled areas in Japan.

K. STANDARDS AND CRITERIA

493

Dozens of heavy industries, including steel mills, paper plants, and cement factories, have joined petrochemicals and food processing to bring a new image of diversification to the economy of the South Central states. To minimize pollution problems attending industrial development, Arkansas, Louisiana, Oklahoma, and Texas have each enacted programs to guard their air and water. The air and water quality standards in these states are given along with a summary of the tax incentives and low-interest financing programs for pollution control equipment and facilities. Air quality standards are included for smoke shade, incinerator emissions, particulates, sulfur dioxide, dust fall, sulfuric acid mist and/or sulfur trioxide, carbon monoxide, oxidants, hydrocarbons, odor, hydrogen sulfide, hydrogen fluoride, sulfuric acid plants, steam generators, boilers, effective stack height, and nitric acid manufacturing.

STANDARD OF SOOT AND DUST EMISSION (INJURIOUS SUBSTANCES) BASED ON AIR POLLUTION CONTROL

LAW. (Taikiosen boshiho ni motozuku baien (ugai bussitsu) no haishut.su kijun ni tsuite). Text in Japanese. 69p., May 1971. Standards of emission of soot and dust, cadmium and its compounds, chlorine and hydrogen chloride, fluorine and its compounds, and lead and its compounds are discussed. The emergency contamination level is mentioned. A summary of the report of the experts conference on the criterion of soot and dust emission includes standards of emission for newly established or existing facilities, the characteristics and collection rate of soot and dust at different emission sources, the consumption of fuel, the amount of soot and dust at six prefectures in 1969, and the standard of emission from the special facilities provided by ordinance. Concentrations in the air, effects on man, the standard value of concentrations in the ambient air or standards of emission were discussed for Ca, Cl, HCl, F, and Pb. Emergency measures and alarm systems during an emergency in Los Angeles and New York discussed with relation to the Air Pollution Control Law.

Kato, Keiji
THE PRESENT POLLUTION CONTROL STANDARDS IN-
DEXES (AIR POLLUTION). (Genjo ni okeru kogai kisei suchi
(taiki kankei). Text in Japanese. Kagaku Kogyo (Tokyo),
23(9);1194-1202, Sept. 1972.

A general review is given on the air pollution control standards in Japan. Three categories of pollutants, sulfur oxides, particulates, and harmful substances, such as carbon monoxide, have been subjected to control, and the standards are established. The sulfur oxides emission standards are determined by an equation which consists of two factors, the effective stack height and a district dependent parameter K. The present K values of different districts vary from 7.01 to 18.7. The national environmental standard of particulates is stated by the following two conditions, the hourly average concentration for 24 consecutive hours must be under 0.10 mg/cu m, and the hourly concentration must be under 0.2 mg/cu m. The conditions for CO are: an hourly average for 8 consecutive hours under 10 ppm. The emission standards of other harmful substances, such as cadmium compounds, lead compounds, chlorine and hydrogen chloride, fluorine and fluoro compounds, are also listed.

46081

Kakunan, Taira
THE RECENT SITUATION OF REGULATIONS ON AIR
POLLUTION. (Kogai kisei no doko, Taiki kankei). Text in
Japanese. Sekiyu Gakkai-Shi (J. Japan Petroleum Ins!., Tokyo),
15(7):601-605, July 1972.

The environmental criteria for sulfur oxides, carbon monoxide, and suspended particles 10 micron in grain size are discussed. One-hour averages for successive 24 hours should be 0.10 mg or lower per 1 cu m of the atmosphere; 1-hour values should be 0.20 mg per 1 cu m of the atmosphere. Lead, nitrogen oxide, hydrocarbon, and fluoride criteria are being set up. Sulfur oxides emission criteria were set up on Jan. 5, 1972. The new SO_x criteria, are different by district such as 9.34 (K value) for Sapporo and Hokkaido, while they are 7.01 and 6.42 for Tokyo. Except for five over-congested areas, the criteria will have been met by some time in 1973. A nationwide survey of environmental and emission concentrations of SO_x is planned for some time in 1973 to re-appraise effectiveness of the criteria and revise them if necessary. Regulations on fuel are presently enforced only in big cities, but the enforcement will cover more areas in the coming year. Not only the automotive emissions, but also other general sources of NO_x emission should be considered in establishing the criteria. Studies are already underway. Dust emission criteria have been drastically strengthened effective June 1972.

Stern, Arthur C.
AIR AND WATER POLLUTION QUALITY STANDARDS.
PART 1: AIR POLLUTION STANDARDS. In: Industrial Pollution Control Handbook. Herbert F. Lund (ed.), New York, McGraw-Hill, 1971, Chapt. 4, p. 4-1 to 4-22.
In general an air quality standard is developed by formally or informally considering air quality criteria, which are compilations of effects associated with various concentrations and du-

rations of exposure of pollutants, plus other factors, such as cost and technological feasibility of emission control, and social questions. The Clean Air Act and the process involved in the adoption of air quality standards in the United States are outlined. Development and features of the air quality standards in the Soviet Union, Poland, West Germany, and other countries are indicated. State air quality standards are given for carbon monoxide, ethylene, fluorides, hydrogen sulfide, nitrogen dioxide, oxides of nitrogen, oxidants, sulfur dioxide, beryllium, calcium oxide, lead, sulfates, sulfuric acid, and suspended particulate matter. Standards which attribute to a source, and limit the emission from the source on this basis, are emission standards. The promulgation and features of the emission standards in the United States, Great Britain, the Federal Republic of Germany, Japan, and other countries are presented. Tables of both emission and air quality standards are included. Stack height and fuel standards are mentioned.

Subcommittee on Permissible Concentrations (Japan)

DOCUMENTATION OF PERMISSIBLE CONCENTRATIONS

OF HAZARDOUS SUBSTANCES IN WORKING ENVIRON-

MENT. (BASIS OF PROPOSAL). (Kyoyonodo to no kaisetsu

(Teian riyu)). Sangyo Igaku (Jap. J. Ind. Health), 14(1):45-90,

1972. 429 refs. Translated from Japanese by Seizaburo Aoki,

Japanese Language Translation Service, Fujisawa, 199p.

Permissible concentrations of hazardous substances in the at-

mosphere are documented for the years 1963-1970. The bases

for the proposals are given for each substance. For 1963 sub-

stances included: sulfuric acid, hydrochloric acid, nitric acid,

hydrogen sulfide, ozone, acetic esters, methanol, gasoline, ar-

senious acid, beryllium, cadmium oxide, selenium, pen-

tachlorophenol, and trichloroethylene. Substances for 1964 in-

clude: hydrogen fluoride, bromine, methyl ethyl ketone, car-

bon tetrachloride, acetone, inorganic phosphorus; for 1965: or-

ganic lead, xylene, hydrogen arsenide, tolylene diisocyanate,

methyl chloride, vinyl chloride, chloroform, tetrachloroethane,

monoethanolamine, and industrial powder and dust causing

pneumoconiosis. For 1966 the list includes: nitroglycol, ethyl

ether, methyl isobutyl ketone, isopropyl alcohol, isoamyl al-

cohol, manganese, nickel carbonyl, ethylene oxide,

dichloroethanes, methylene dichloride, chlorobenzene,

orthodichlorobenzene, paradichlorobenzene, ethyleneimine,

ethylenediamine, methylamine, normal hexane, cellosolve, cel-

losolve acetate, acrylonitrile, and vanadium; for 1967: nickel,

ethyl chloride, dichloroethyl ether, butylamine,

propyleneimine, zinc, and methylene-bis-phenyl isocyanate.

the list for 1968 includes: iodine, phosgene, styrene, chlorop-

icrin, and ammonia; for 1969: phosgene, toluene, butanol,

zinc, and powder and dusts. The list for 1970 includes: amyl

acetate, cyclohexane, cyclohexanol, cyclohexanone, and

propyl acetate.

ment plants, kraft pulp mills, primary aluminum reduction plants, aluminum smelters, ponds, and aluminum manufacturing plants. Ambient air standards are given for smoke, sulfur dioxide, reactive sulfur, suspended sulfate, sulfuric acid mist, hydrogen sulfide, total suspended particulates, settled particulates, lead, beryllium, and fluorides. Emission rates based on process weight rates are given for particulate emissions. Ground-level sulfur oxide emission limits are also given.

51229

WYOMING Am QUALITY STANDARDS. Ind. Develop., 142(1):31-32, Jan./Feb. 1973.

Emission standards in Wyoming are presented for visible emissions, particulate emissions from new and existing sources, wood waste burners, sulfuric acid mists, and fuel burning equipment. Maximum allowable concentrations are given for total suspended particulates, suspended particulates, sulfur oxides, sulfation, hydrogen sulfide, photochemical oxidants, hydrocarbons, nitrogen oxides, hydrogen fluoride, gaseous fluoride, and carbon monoxide. Emission rates based on process weight rates for particulates are given along with a formula to calculate emissions.

Stokinger, H. E.

TOXICITY OF AIRBORNE CHEMICALS: AIR QUALITY STANDARDS--A NATIONAL AND INTERNATIONAL VIEW.

Ann. Rev. Pharmacol., vol. 12:407-422, 1972. 22 refs.

Official air quality standards (AQS) for industry and community in the United States are discussed and compared to those in the USSR. The basis for AQS in the USSR is unknown. They have no limits for ethylene, iron oxide, hydrocarbons, particulates or photochemical oxidants. Their standards tend to be lower than in the U. S. In the U. S. there are considerable differences between the limiting concentrations of the threshold limit values (TLV) for industrial air with the AQS for community air. Depending upon the type of air pollutant, not only is the protection of human health and well-being considered, but foliage and crop damage, soiling, visibility reduction, and corrosion may ultimately be the prime determinants of AQS. Depending upon the specific basis on which the AQS ultimately rests, differential factors between AWS and TLVs may range from one half (ozone) to one hundredth (nitrogen dioxide, sulfur dioxide, iron oxide) to one thousandth (lead) or more (hydrogen fluoride). The scientific basis for the differences in the limited concentrations of the standards for community and industrial are discussed for carbon monoxide, SO₂, NO₂, hydrocarbons, O₃, particulates, and lead.

Fujiwara, M.

REGULATIONS AND CRITERIA FOR ATMOSPHERIC POLLUTION, WITH SPECIAL REFERENCE TO NOX AND LEAD.

(Taiki osen no kisei to kijun, tokuni NOx to namari ni (suite). Text in Japanese. Kankyo Kenkyu (Environ. Studies), no. 4:45-52, Oct. 1973.

Emission standards for sulfur dioxide, carbon monoxide, suspended particulates, nitrogen dioxide, oxidants, hydrocarbons, lead, and hydrogen fluoride are discussed. Emission standards for SO₂ are 3 times as strict as those published the previous year. Automobile emissions constitute 93% of the CO, 40% of HC, and 39% of NOx total concentrations. Emission standards for 1975 cars limit CO to 2.1 g/km, HC to 0.25 g/km, and NOx to 1.2 g/km. A 5-year intermediate value for NO₂ limits the daily 1-hour average concentration to 0.02 ppm for 60% of the days. Criteria for establishing standards for HC and Pb emissions are under consideration. Nitrogen oxides are regulated for boilers, furnaces in the petroleum and metallurgical industries, and sulfuric acid plants.

MAXIMUM ALLOWABLE EMISSION CONCENTRATIONS
FOR 20 SUBSTANCES. TARGET CONCENTRATIONS FOR
THE AIR. (Maximale Immissions- Konzentrationen fuer 20
Stoffe erarbeitet. Zielwerte fuer die Luft). Text in German. Um-
welt (Duesseldorf), 3(6):37-38, 1973.

The term maximum allowable emission concentration is
defined, and the new maximum allowable emission concentra-
tions worked out for 20 substances are listed in a table. For
carbon monoxide the maximum allowable average emission
concentration over 24 hours is 10 mg/cu m; for lead 0.002; for
sulfur dioxide 0.3; for sulfuric acid 0.1; for nitrogen dioxide
0.1; for nitric oxide 0.5; for nitric acid 0.1; for ammonia 1 0;
for hydrogen fluoride 0.1; for sodium fluoride 0.2; aluminum
fluoride 0.3; for cryohthe 0.3; for calcium fluoride 0.5; for
ozone 0.05; for airborne dust of less than 10 micron 0.1; for
zinc 0.1; for tetrahydrofuran 60; for trichloroethylene 5 mg/cu
m; and for methylene chloride 50 mg/cu m. For cadmium only
an annual average standard has been set which is less than
0.00005 mg/cu m.

GUIDES FOR SHORT-TERM EXPOSURES OF THE PUBLIC
TO AIR POLLUTANTS. National Academy of Sciences-National
Research Council, Washington, D. C., Advisory Center on Tox-
icology, Aerospace Medical Research Laboratory Contract
F33615-70-C-1046 and Air Pollution Control Office Contract
CPA 70-57, Proj. 6302, AMRL-TR-71-120, Paper 16, 6p., Dec.
1971, 1 ref. (Presented at the Systemed Conference on Environ-
mental Toxicology, Annual Meeting, 2nd, Kail-born, Ohio,
1971.) NTIS, DDC: AD-751 438

Short Term Public Limits (STPL) and Public Emergency
Limits (PEL) were defined for nitrogen dioxide, hydrogen
chloride, and hydrogen fluoride. Nitrogen dioxide as a freely
diffusible gas has the capacity to cause adverse health effects
as a deep lung irritant at high concentrations (several hundred
ppm for a few minutes) that might lead to pulmonary ederna.
Many variations in toxicity patterns occur with NO₂: toxicity
is enhanced in the presence of ozone, sulfur dioxide, al-
dehydes, and a high density of respirable particles. The am-
bient temperature and the age of the exposed person also mar-
kedly influence individual response. The following short-term
limits are recommended: STPL--10 min, 1 ppm, 30 min, 1
ppm, and 60 min, 1 ppm; PEL?10 min, 5 ppm, 30 min, 3 ppm,
and 60 min, 2 ppm. Depending on the severity of exposure,
the physiological responses to the inhalation of irritating levels
of HCl are coughing, pain, inflammation, edema, and desqua-
mation in the upper respiratory tract. If concentrations are
high enough, acute irritation may bring about constriction of
the larynx and bronchi, closure of the glottis, and breath hold-
ing. Fatal inhalation of HO would be expected only when the
victim is unable to escape from the contaminated atmosphere.
The following limits are recommended: STPL-10 min, 4 ppm,
30 and 60 min, 2 ppm, and 5 hr/day, 3^(days/mo, 0.67 ppm;
PEL?10 min, 6.7 ppm, and 30 and 60 min, 3.4 ppm. The pri-
mary effect of acute exposure to gaseous HF in concentra-
tions above a few ppm is irritation to the skin, eyes, and
<xref image="2000WVNR.TIF|V3|2006:09:28:01:44:30.00|117884|0"> image: </xref>

respiratory passages. Localized tissue damage may result on exposure to concentrations above recommended limits. At 12 ppm the mucosa are irritated, at 30 ppm for about 3 min the gas is detectable by taste, at 60 ppm the severity of irritation is noticeably increased, and at 120 ppm a stinging sensation of the skin is added, and the other irritations become so intense that man is unable to withstand the exposure for more than one min. The following limits are recommended: STPL-10, 30, and 60 min, 4 ppm, 5 hr/day, 3-4 days/ mo, 1 ppm; PEL--10 min, 10 ppm, 30 and 60 min, 5 ppm.

Quarles, John

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES. PROPOSED RULE FOR PRIMARY ALUMINUM PLANTS. Federal Register, 39(206): 37730-37741, Oct. 23, 1974.

Standards of performance for new and modified primary aluminum plants are proposed. The proposed standards do not differentiate between primary and secondary emissions and encourage owners of new plants to obtain maximum containment of the gaseous emissions at the cell. Two types of control devices will be used: wet gas scrubbers in series with an electrostatic precipitator or dry fabric filters which use alumina as an adsorbent. Gases discharged into the atmosphere from the potroom cannot exhibit 10% opacity or greater and those from the anode bake plant cannot exceed 20% opacity. Gases cannot be discharged which contain total fluorides in excess of 1 kg/metric ton of aluminum produced. Procedures and methods for testing and monitoring are specified.

66916

Quarles, John

STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES. FIVE CATEGORIES OF SOURCES IN THE PHOSPHATE FERTILIZER INDUSTRY. Federal Register, 39(205):37602-37607, Oct. 22, 1974.

Standards of performance for five categories of sources within the phosphate fertilizer industry are proposed. The sources are wet process phosphoric acid plants, super-phosphoric acid plants, diammonium phosphate plants, triple superphosphate plants, and granular triple superphosphate storage facilities. The standards require installation of high efficiency gas scrubbers. Construction of both of the more common processes for manufacture of superphosphoric acid is permitted even though one also emits pollutants other than fluorides (sulfur dioxide and hydrocarbons). Visible emission standards are proposed for diammonium phosphate plants, triple superphosphate plants, and granular triple superphosphate storage facilities. The effluent gas streams from these processes include particulate matter (both fluoride and non-fluoride), as well as gaseous fluorides. The possible odor environmental impact was determined to be negligible.

McCune, Delbert C.

ON THE ESTABLISHMENT OF AIR QUALITY CRITERIA, WITH REFERENCE TO THE EFFECTS OF ATMOSPHERIC FLUORINE ON VEGETATION. Boyce Thompson Inst. for Plant Research, Yonkers, N. Y., American Petroleum Inst., Air Quality Monograph 69-3, 36p., 1969. 66 refs. The establishment of air quality criteria for atmospheric fluorine is considered, with particular reference to the pollutants effect on vegetation. The problem of formulating criteria for ambient airborne fluorine is complex since the sequence of fluoride exposure may outweigh the influence of the actual fluoride level within a fumigation concentration range of 0.5-10 micrograms F/cu m. There can also be no single criterion for the effects of atmospheric fluorine on vegetation owing to the differences among plants in their susceptibility to fluorine and consequence of fluorine-induced effects. The form of at-

atmospheric fluoride is also a factor that determines its phytotoxicity, and air quality standards or air monitoring techniques that consider only the total fluoride cannot be justified by present air quality criteria. The temporal distribution of atmospheric fluorine is another important factor in the evaluation of data or the selection of criteria; models for airborne fluorine are not yet derived or tested, and the relationships of peak values, sampling or averaging periods, and mean values are not known.

Wilcox, Sandra L., Edwin L. Keitz, and Linda J. Duncan
ESTABLISHING SAFE AMBIENT AIR QUALITY LEVELS
FOR EIGHTEEN HAZARDOUS POLLUTANTS. Preprint,
World Health Organization, New York, 6p., 1974. (Presented at
the World Health Organization International Symposium, Paris,
France, June 1974.)

Average safe 24-hour levels for 18 hazardous air pollutants are reported based on investigations conducted by personal contact with 23 recognized experts in the epidemiology of air pollution from the medical and public health professions. The average experts 24-hour levels in micrograms/cu m are as follows: arsenic, 5.9; barium, 77.5; beryllium, .005; boron, 50; cadmium, 1.2; chromium, 4.6; copper, 10; fluorides, 47; lead, 4.7; manganese, 11.4; mercury, 0.8; nickel, 3.7; selenium, 5.4; tin, 13.7; vanadium, 6.8; and zinc, 34. The average safe level for asbestos is .05 fibers/ml. Comparisons are made among the tonnage of pollutant emitted, the population in areas adjacent to the major emitter, and the safe ambient air quality level in order to indicate priorities which should be established for research and development of control technology for these pollutants. Safe ambient air quality levels are also compared with typical air quality levels to indicate relative priorities.

68582

Brun, M.-J. and P. Jarrault
MAXIMUM ALLOWABLE CONCENTRATIONS AND EMISSIONS LIMITED FOR INDIVIDUAL POLLUTANTS, INDUSTRIES, AND COUNTRIES ACCORDING TO STANDARDS AND RECOMMENDATIONS. (Teneurs limites dans l'air ambiant et a l'emission. Valeurs par polluant, par Industrie, par pays d'apres les normes et recommandations). Text in French. C.I.T.E.P.A. Technical Interprofessional Study Center for Air Pollution, Etudes Documentaires 42, CI 805, CI 809, 53p., Feb. 1, 1974.

Maximum allowable concentrations and emissions from different sources of dust, sulfur dioxide, carbon monoxide, hydrogen sulfide, nitrogen oxides, chlorine, hydrochloric acid, fluorine, hydrocarbons, and heavy metals, as recommended or imposed by acts or standards in various countries, such as Bulgaria, Belgium, Canada, U.S.A., Finland, France, the Netherlands, Israel, Italy, Japan, West Germany, East Germany, Rumania, Sweden, Czechoslovakia, Turkey, and the USSR are listed. Percentages of the times during which the maximum allowable concentrations may be exceeded are given. Detailed listings are presented of the maximum allowable emissions from various sources, such as the metallurgical, chemical, and pulp and paper industries, waste incineration, domestic heating, cement works, petroleum refining, power generation, and surface treatment.

Bisselle, C. A., S. H. Lubore, and R. P. Pikul
NATIONAL ENVIRONMENTAL INDICES: AIR QUALITY
AND OUTDOOR RECREATION. Mitre Corp., Washington, D.
C., Council on Environmental Quality Proj. 1910, MTR-5169,
262p., April 1972. 60 refs.

Separate indices of air pollution and outdoor air quality were formulated and computed for selected cities in the United States. Guidelines for implementation of an operational data collection and reporting system to allow routine computation of these indices are described. There was a general decline in the percent of cities exceeding standards on a national basis for sulfur dioxide and nitrogen dioxide. The percentage of cities with a total suspended particulates problem increased from 1968 to 1969 and declined only slightly in 1970. The nitrogen dioxide and total suspended particulates problem is far more severe and extensive than the sulfur dioxide problem, based upon present National Ambient Air Quality Secondary Standard values. The northeast region contributes the largest percent to the total value of the National index. The inclusion of photochemical oxidants for western cities or carbon monoxide for major cities would alter this depiction. The effects of contaminants such as fluorides, lead, cadmium, pesticides, and other toxic airborne substances require further studies and monitoring.

Subcommittee on Air and Water Pollution
AUTOMOBILE EMISSIONS STUDY. In: Decision of the Administrator of the Environmental Protection Agency Regarding Suspension of the 1975 Auto Emission Standards, Part 2. 93rd Congress (Senate), First Session, Serial 93-H9, p. 465-470, May 14, 17, 18, and 21, 1973. 5 refs. (Hearings before the Committee on Public Works.)

An elaboration of the Environmental Protection Agency's reply to the automotive industry concerning criticism of the automotive emissions standards is presented. Topics covered include: criteria for establishing air quality standards and emission standards, the effects of automobile emissions on humans and vegetation, commercial engines that meet federal standards, an analysis of the American auto manufacturers' approach to emission control, the balance of costs versus gains to the public resulting from automotive emission standards, and the systems analysis approach for determining appropriate trade-offs in emission control. Human health effects are tabulated for ozone, nitrogen oxides, sulfur dioxide, carbon monoxide, hydrocarbons, and particulates. Vegetation effects are summarized for SO₂, O₃, fluorides, ethylene, and nitrogen dioxide.

72145

Japan Environmental Agency
DEVELOPING BASIC MEASURES FOR ENVIRONMENTAL
PROTECTION. In: Quality of the Environment in Japan, p.
210-212, 1974.

The establishing and tightening of environmental air quality standards in Japan are described. Environmental standards exist for sulfur dioxide, carbon monoxide, suspended particulate matter, nitrogen dioxide, and photochemical oxidants. Standards for hydrocarbons are scheduled for 1974. Consideration will be given to environmental standards for lead and fluorine compounds, and consideration of environmental standards for aldehydes and vanadium will be initiated. Future environmental standards will consider protection of the entire living environment, including preventing damage to plant life. Environmental impact assessment techniques will be developed and include urban air pollution.

72151

Japan Environmental Agency
EMISSION STANDARDS (APPENDIX 2). In: Quality of the

Environment in Japan, p. 245-251, 1974.

The emission standards in Japan are presented for sulfur oxides, soot and dust, harmful substances, nitrogen oxides, odors, and motor vehicles. Sulfur oxide emission standards vary according to the region, and are tabulated for seven areas. There are special standards for newly constructed facilities. The soot and dust standards are listed for boilers, incinerators, and furnaces. At all facilities the standards for cadmium and its compounds is 1.0 mg/cu m N, 30 mg/cu m N for chlorine, and 80 mg/cu m N for hydrogen chloride. The standards for fluorine, hydrogen fluoride, silicon fluoride, lead, and nitrogen oxides vary by type of facility. Regulatory standards are listed for these odors: ammonia, methyl mercaptan, hydrogen sulfide, dimethyl sulfide, and trimethylamine. Exhaust emission standards are tabulated for carbon monoxide, hydrocarbons, and nitrogen oxides from trucks and automobiles.

74109

Osaka Prefecture, Div. of Life Environment (Japan)

DATA PERTAINING TO ESTABLISHMENT OF REGULATIONS ON EMISSION STANDARDS ACCORDING TO PROVISIONS OF ATMOSPHERIC POLLUTION CONTROL LAW, ARTICLE 4, ITEM 1, AND ON WASTE WATER STANDARDS ACCORDING TO PROVISIONS OF WATER QUALITY DETERIORATION CONTROL LAW, ARTICLE 3, ITEM 3. (Taiki osen boshiho Dai 4-jo, Dai 1-ko no kitei ni yoru haishutsu kijun oyobi suishit.su odaku boshiho Dai 3-jo, Dai 3-ko no kitei ni yoru haisui kijun o sadameru jorei no kansuru shiryō). Text in Japanese. 25p., Feb. 1974.

The atmospheric emission (smoke) standards and waste water quality standards established by Osaka Prefecture, Japan, in accordance with key provisions of the Atmospheric Pollution Control Law (Law 97, 1968) and the Water Quality Deterioration Control Law (Law 138, 1970), are listed in tabular form. These standards are more stringent than those established by Law 97 and Law 138, and go into effect in 1974, with some extensions granted to 1976, for attaining waste water standards. Smoke emission standards are determined by maximum volume of exhaust gas emission per hour from the source (under 10,000 cu m; under 40,000 cu m; over 40,000 cu m corrected to 0 C and one atmosphere pressure) and by type of fuel (coal; heavy oil or other liquid fuel; and gas). Temporary excesses (not over 6 min/hr) in emission during ignition and cleaning procedures are not included in the effective emission levels. Allowable weights of smoke particulates per 1 cu m of exhaust gas range from 0.05 g to 0.40 g. Industrial waste water standards apply to five water basins and one coastal construction area. Waste water standards are also established from human waste and residential sewage treatment plants in Osaka Prefecture. For all types of waste water the range of pH is 5.8-8.6. Other water pollutant standards vary with data of plant construction (for industry), and type of treatment installation and population density (for residential sewage and human waste). The average daily BOD (biological oxygen demand) and SS vary from 20-120 mg/l, with allowable maximum of 150 mg/l for some industries. Average daily coliform count should be 3000 colonies/cu cm in industrial waste water. Cyanides and organic phosphorus compounds are not to be present in industrial waste water in analyzable amounts. Other controlled substances are cadmium, lead, chromium, arsenic, zinc, soluble iron and manganese, fluorine, phenol, and n-hexane extracts.

Giese, H. J.

INCINERATORS FOR MEDICAL WASTES. (Verbrennungsanlagen fuer Medizinabfaelle). Text in German. *YVasser Luft Betrieb*, 19(4):171-174, 1975.

General hygienic and environmental requirements imposed on incinerators for medical wastes in West Germany are outlined. Medical wastes must be incinerated without any infection hazards for the incinerator personnel and for the environment. Wastes from hospital wards of infectious diseases have to be sterilized before incineration. The temperature of the after-burning chamber of the waste incinerator must be at least 800 C. Cyclones and wet type dust separators are best for incinerator flue gas cleaning. At a flue gas oxygen content of 17%, the dust concentration is limited to 100 mg/N cu m. The hydrochloric acid and hydrofluoric acid emissions are limited to 6 kg/hr and 0.2 kg/hr, respectively, which values are generally not exceeded in incinerators with throughput capacities of up to 750 kg/hr.

McCutchen, Gary D.

NEW SOURCE PERFORMANCE STANDARDS, PRESENT AND FUTURE. In: *Air Pollution Control and Industrial Energy Production*. Kenneth E. Noll, Wayne T. Davis, and Joseph R. Duncan (eds.), Ann Arbor, Mich., Ann Arbor Science, 1974 (?), Chapt. 2, p. 5-40. 60 refs.

The legislative history of new source performance standards (NSPS) is reviewed. These standards are expected to play an important role in maintaining air quality, preventing significant deterioration, controlling noncriteria pollutants, and hastening the development and application of control technology. The Environmental Protection Agency has promulgated NSPS for twelve source categories, and standards for a total of approximately 40 categories are expected to be promulgated or proposed by the end of 1975. Standard-setting priorities will be based on the expanded role envisioned for NSPS. Nitrogen oxides and hydrocarbon sources, emerging industries, and large sources are considered important. New Source Performance Standards encourage the improvement of existing control technology and radically new approaches to air pollution problems. Control of stationary sources may consume less energy than would be used to counter the effects of that pollutant in the atmosphere. The EPA proposes to further strengthen NSPS by seeking authority to set equipment standards when emission standards prove impractical, and to provide for exceptions to the NSPS for facilities attempting pioneering research in control techniques. New Source Performance Standards can significantly reduce air pollution emissions by requiring the best control of new facilities. They appear to constitute the preferred approach to control of fluorides, and may also be utilized for lead and other pollutants.

Ishida, Hitoshi

PRESENT STATE OF AIR POLLUTION AND ITS REGULATION IN JAPAN. Environment Agency (Japan), Air Pollution Control Div., World Energy Conf., 9th, Detroit, Mich. 1974, p. 1-23. (Sept. 22-27.)

A review of the present state of air pollution and its regulation in Japan is presented. Sulfur dioxide pollution which reached a peak around 1967 and 1968 appears to have levelled off and may be decreasing. Dust fall in major cities has significantly decreased since around 1960 as a result of a nationwide energy switchover from coal to oil and the installation of industrial dust control devices. Suspended particulate concentrations are still relatively high, though they do not appear to be increasing. Nitrogen oxide levels are steadily increasing in the absence of effective controls. Decreases in carbon monoxide levels in urban areas appear to be associated with automobile

exhaust emission controls. Hydrogen fluoride, hydrogen chloride, chlorine, and photochemical oxidants are among pollutants which are showing increasing levels in certain urban areas. Ambient air quality standards are established for sulfur dioxide, carbon monoxide, suspended particulates, nitrogen dioxide, and oxidants. Emission standards are set for sulfur oxides, soot and dust, cadmium compounds, chlorine, hydrogen chloride, fluorides, lead compounds, and nitrogen dioxide. A total of 15 national air sampling networks are established throughout the country. (Author summary modified)

Office of Air and Waste Management, Research Triangle Park, N. C., Emission Standards and Engineering Div.

BACKGROUND INFORMATION FOR STANDARDS OF PERFORMANCE: PRIMARY ALUMINUM INDUSTRY. VOLUME 3: SUPPLEMENTAL INFORMATION. Rept. EPA-450/2-74-020c, SOP., Jan. 1976. 4 refs. NTIS: PB 250667/AS

Background information dealing with performance standards for primary aluminum plants is presented. The information includes comments to proposed regulations and Environmental Protection Agency responses to these comments, updated economic impact data, and problems encountered with source sampling procedures. Growth in total domestic primary aluminum capacity and supplies is not expected to be adversely affected by the promulgated standards. The standards are estimated to require an investment cost increase at new primary aluminum plants amounting to about \$95/ton of capacity (first quarter of 1975) or approximately 8% of the cost of a new uncontrolled plant. Fluoride emission reductions resulting from the standards are expected to be about 48 lb of fluoride/ton of aluminum produced (96%) for uncontrolled plants and 11 lb/ton (85%) for plants employing the industry's current average level of control.

84395

Beck, David A.

PROPOSED STANDARDS OF PERFORMANCE FOR THE PRIMARY ALUMINUM INDUSTRY. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 6p., 1975. 3 refs. (Presented at the Air Pollution Control Association, Southern Section, Annual Meeting, 6th, Nashville, Tenn., Sept. 17-19, 1975.)

Proposed standards of performance for the primary aluminum industry are reviewed. As a result of testing the best controlled existing primary aluminum plants, the Environmental Protection Agency is proposing an emissions standard of 2.0 lb of total fluoride/ton of aluminum produced. This means that the sum of the primary and secondary emissions (and the anode bake plant emissions for prebake facilities) must not be greater than 2.0 lb of total fluoride/ton of aluminum produced. Opacity standards of 20% for anode bake plant emissions and 10% for potroom emissions are also proposed. The standards are designed to force the best demonstrated control technology without adversely affecting the economy of the industry

AMBIENT AIR QUALITY OBJECTIVES - PART 500 (STATUTORY AUTHORITY: PUBLIC HEALTH LAW. 1271, 1276). New York State Air Pollution Control Board, Albany, Dec. 11, 1964, 11 pp.

Ambient air quality objectives are tabulated for various pollutants. The objectives vary according to subregions which are determined by land use. Included is a list of references for the sampling and analytical methods employed in the measurement of particulates, sulfur dioxide, hydrogen disulfide, fluorides, beryllium, oxidants, carbon monoxide, and sulfuric acid mist.

06734

COMMONWEALTH OF PENNSYLVANIA, DEPARTMENT OF HEALTH, AIR POLLUTION COMMISSION, AMBIENT AIR QUALITY CRITERIA. 90th Congress 'Air Pollution-1967, Part IV (Air Quality Act)' Senate Committee on Public Works, Washington, D.C., Subcommittee on Air and Water Pollution, May 15-18, 1967.) p. 2396-7.

Ambient air quality criteria are tabulated as set forth in section 5 (f) (8) of the Pennsylvania Air Pollution Control Act of January 8, 1960, P.L. 2119. These criteria were adopted on April 25, 1967 by the Air Pollution Commission. Included in the tabulation are: particulates, lead, beryllium, fluorides, sulfur dioxide, carbon monoxide, and others. References are provided for the sampling and analytical methods employed for each pollutant.

(EXCERPTS FROM THE ANNUAL REPORT FOR 1964 OF THE STATE INSTITUTE FOR THE PRESERVATION OF CLEAN AIR AND AGRICULTURAL LAND.) Aus dem Jahresbericht 1964 der Landesanstalt für Immissions- und Bodennutzungsschutz. Reinhaltung der Luft im Land Nordrhein-Westfalen (3) 39-48, 1965. Ger.

A survey was made of the activities of an agency of the State of North Rhine-Westphalia concerned with air pollution problems. Air pollution control programs are described, in particular the first, second, and third program for measuring SO₂ and dust concentrations. Instrumentation for measuring SO₂, F, H₂S, NO₂, and NH₃ is mentioned. Some practical results of reducing the emission in various industrial plants are presented, mostly of the metal and coal-using industries. Extensive experiments have been made to determine harmful effects of air pollutants on plants. A list of plants ordered according to their susceptibility is given.

Public Health Service, Washington, D. C., National Center for Air Pollution Control

A COMPILATION OF SELECTED AIR POLLUTION EMISSION CONTROL REGULATIONS AND ORDINANCES.

(REVISED EDITION.) 142p., 1968.

This compilation contains selected sections of many emission control regulations and ordinances. It has been prepared to provide state and local air pollution control agencies, industries, and other interested people with selected examples of the many types of regulations and ordinances in use today. All sections of regulations and ordinances included have been copied directly from the original text of individual state and local laws. The regulations and ordinances have been arranged in such a manner that each section of this report is a compilation of laws pertaining to a specific type of pollutant or pollutant source. These sections include Smoke Emissions and Equivalent Opacity Regulations, Particulate Emissions from Fuel Burning Plants, Particulate Emissions from Refuse-burning equipment, Particulate Emissions from Manufacturing Processes, Particulate Emissions from Asphalt Batching Plants, Sulfur Compound Emissions, Organic Solvent Emissions, Hydrocarbon Emissions, Fluoride Emissions, Motor Vehicle Emissions, Odor Emissions, and Zoning Ordinances. The regulations and ordinances compiled were selected to represent the different methods of controlling emissions by law and to represent varying degrees of control.

STATUS OF AIR POLLUTION BY NOXIOUS AND OFFENSIVE GASES AND THEIR CONTROL PROGRAMMES. (Yugai gasu to niyuru osen no genjo to sono taisaku ni tsuite). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 2(7):441-444, Aug. 15, 1966.

A procedure for the adequate control of noxious gases, some of which are not yet covered by legislation, is discussed. Though dust fall is decreasing as a consequence of regulatory control, noxious and offensive gases are increasing in many in-

<xref image="2000WVNV.TIF|V3|2006:09:28:01:44:42.00|88097|0"> image: </xref>

dustrial areas. The Labor Standard Law of 1947 provides for the control of working environments in the interest of worker health, but is no longer consistent with the present state of industrial pollution which poses a hazard for persons living in the vicinity of plants. The 1948 law regulating agricultural chemicals is concerned only with preventing injuries to people and livestock caused by the unrestricted use of chemicals; it does not consider the contribution of the chemicals to air pollution. High pressure gas control, fire prevention, mining, and other laws are subject to the same criticism. What is characteristic of these control laws is that they do not specify total noxious gas emission nor the relationship between a gas and its effect. The Smoke Dust Control Law is intended to compensate for these shortcomings; it now deals with sulfurous gas, anhydrous sulfuric gas with hydrogen fluoride, hydrogen sulfide, selenium oxide, hydrogen chloride, nitrogen dioxide, sulfur dioxide, hydrogen cyanide, carbon disulfide, ammonia, phosgene, and silicon tetrafluoride. More offensive gases are to be covered by the law.

17472

Duemmler, Friedrich
THE ANTI-AIR POLLUTION ACTIVITIES OF THE
TECHNISCHE UEBERWACHUNGS-VEREIN. (Die
Technischen Ueberwachungs-Vereine im Dienste des Immissionsschutzes). Text in German. Tech. Ueberwach (Duesseldorf), 10<10>:339-345, Oct. 1970.

One of the most important tasks of the Technische Ueberwachungs-Verein (TUV) is to measure dust emissions by steam plants. By checking the performance of new measuring units and determining whether they fulfill the manufacturer's specifications. Measurements by the TUV taken in 1967 on steam boilers with capacities of up to 25 t/h showed that plants without dust collectors emitted on the average 560 mg dust/cu m; those with dust collectors, 170 mg/cu m. For plants with more than 100 Gcal/h, the authorities require the installation of automatic measuring devices for dust and sulfur dioxide. In this connection, TUV checks the available units for suitability and calibrates each individual unit. For dust measurements, photometric units were suitable; for SO₂ measurements, infrared absorbers and electroconductivity analyzers were selected. In addition to these activities, TUV is presently engaged with fluorine, hydrocarbon, hydrogen sulfide, sulfur trioxide, carbon monoxide, hydrogen chloride, lead, and zinc oxide measurements. In the years 1965-1966, TUV conducted extensive studies of CO and CH content of automobile exhausts in the idling stage. Infrared absorbers were used for the measurements. Ten percent of the vehicles with four-stroke engines emitted more than 8% CO in the idle; but 45% of the vehicles emitted less than 4.5%. Beginning with October 1, 1970, newly registered automobiles with Otto engines may not emit more than 25 g CO and 1,5 g CH per 100 g fuel consumption. TUV will check the new automobiles for compliance with this law. Finally, odor and noise measurements also belong to the activities of the TUV.

Katz, Morris
CITY PLANNING, INDUSTRIAL-PLANT LOCATION, AND
AIR POLLUTION. In: Air Pollution Handbook. P. L. Magil, F. R. Hokten, and C. Ackley (eds.), New York, McGraw Hill, 1956, Sect. 2, 53p. 68 refs.
Detroit, Philadelphia, Pittsburgh, Los Angeles, and Houston are cited as examples of cities that have made extensive improvements through city planning. In 1953 there were 75 people in New York City employed by Air Pollution Control, and the budget was about \$375,000. The history of pollution control efforts is described for Great Britain, St. Louis, Pittsburgh, Los Angeles, and Detroit-Windsor. The role of meteorological factors is considered, with an enumeration of 6 basic principles of control in the designing of smokestacks.

Topographical influence is discussed for Trail, B. C. and Los Angeles. Figures are given on fallout of dust and gas concentrations for various urban areas. Gases discussed include sulfur dioxide, hydrogen sulfide, hydrogen fluoride, hydrogen chloride, organic sulfides, aldehydes, and smog.

Yocom, John E.

AIR POLLUTION REGULATIONS-THEIR GROWING IMPACT ON ENGINEERING DECISIONS. Chem. Eng., 69(15):103-114, July 23, 1962. 9 refs.

Choice of raw materials, equipment, process variables, plant site, and plant size are all affected by air pollution control requirements. How the regulations work, how they are enforced, and the direction in which they are moving are reported. Local control agencies and state and federal agencies are becoming increasingly interested and active in the area of air pollution control. Various geographical areas are discussed with California getting the major emphasis as the state which has pioneered most of the air pollution control activities. The three broad categories into which control agencies divide emissions into the atmosphere are identified as visible, particulate, and gaseous. One significant and universally accepted policy is that where regulations overlap, all applicable regulations must be complied with. The most widely used type of control regulation for visible emissions is based on the use of the Ringelmann chart. Originally conceived to evaluate shades of grey in smoke plumes from coal fired boilers, its extension to non-grey plumes through the principle of equivalent opacity has created serious problems in interpretation and enforcement. Wet or detached plumes also are the subject of controversy. Regulations covering the control of particulates are generally based on stack concentrations or percent of process weight. The latter concept was conceived by the Los Angeles County Air Pollution Control Department to prevent circumvention of the intent of regulations by diluting stack air. A variation of the stack concentration concept is permitted by the Bay Area Air Pollution Control District which accepts readings based on ground level concentrations. Only a few control agencies have specific limits on SO₂ emissions. Most of these are in California and base their regulations on the LACAPCD limit of 0.2 by volume calculated as SO₂. Fluorides are controlled 'to the extent technically feasible' in San Bernardino and to a limit of 40 ppm in forage grass by the Florida Air Pollution Control Commission. Carbon monoxide remains an automotive problem and will probably not concern the processing industries until the auto makers have finished with it. The trend is to have enforcement remain with local and district agencies with policy and research being handled at the state and federal levels.

19434

Ministry of Labour and Social Welfare, North Rhine-Westphalia, Germany

KEEPING THE AIR PURE IN NORTH RHINE-

WESTPHALIA. (Reinhaltung der Luft in Nordrhein Westfalen).

Congr. Reinhaltung der Luft, Duesseldorf, West Germany, 1969. (Oct. 13-17.) Translated from German. Belov and Associates, Denver, Colo., 133p., Feb. 11, 1970.

The centers of industrial concentration in North Rhine-Westphalia are also those of population concentration. The close juxtaposition of these concentrations of emittants of air

<xref image="2000WVNW.TIF|V3|2006:09:28:01:44:46.00|121996|0"> image: </xref>

pollutant material and the densely situated population causes extreme problems. The directed measures of the last ten years against the unbearable dust load and the harmful sulfur dioxide emissions have led to considerable improvements. Measurements show an extraordinary reduction of dust and SO₂ in the air since 1963. While infringements on the dust limit values were found on 22% of the measurement surface at the beginning of the measurement period with 5% of the measuring surface violating the SO₂ limit value, in the year 1968 violations were 5% for dust and 1% for SO₂. These successes were predominantly due to severe licensing practices for new industrial plants and improvement programs for existing industries that do the most to determine emission concentrations: steel converters, ore sintering plants, coking furnaces, foundries, and steam power plants. The experiences of the last few years have shown that the problems of air pollution are subject to change and have a continuous connection with the developments in technology and production in industry. An increase of around 25% to 5 million tons SO₂ emissions per year is projected from 1967 to 1975. From 1975 on, the production of electric power, which will then account for 40% of the SO₂ emissions, will be considerably influenced by atomic energy; SO₂ emissions will first stop their increase and then start to decline. Fluorine, hydrocarbons, chlorine, and numerous odor substances will become the focus of attention. The dust problem will no longer be a question of loads due to coarse dust, but dangers to health due to fine dusts. Precipitation measurements will be extended to include concentration measurements. In the coming 10 years, the State will also take an increasingly critical look at emissions from automobiles and domestic heating units. The goal of the State Government is the development of a control system on a regional basis. Data banks will be set up to provide regional data on individual industrial emission sources, as a tool to the development of control programs. This program has already begun in the area of metropolitan Cologne and will soon be extended to the Duisburg/Oberhausen/Mulheim a.d. Ruhr, Essen/Bottrop, Gelsenkirchen/Wanne/Eickel/Bochum, Castrop/Rauxel, and Dortmund regions.

Fletcher, R. H.

KITIMAT POLLUTION CONTROL BY-LAW. Pulp Paper

Mag. Can. (Quebec), 71(7):78-90, April 3, 1970. (Presented at the 5th Paper Industry Air and Stream Improvement Conference, Toronto, Ontario, Oct. 21-23, 1969.)

Land use in the 16-yr-old town of Kitimat, B. C., was planned to minimize the conflicts that can exist between residential areas and industry. Prior to the advent of a pulp and paper complex with a 930 tpd Kraft mill and a 150 million fbm per year saw mill, the town's principle industry was an aluminum smelter. To preserve the quality of its environment, the town passed a waste emission by-law that requires the monitoring of selected emissions from the pulp mill and smelter. The law, to become effective in December 1970, identifies a tolerable level of pollution which is expected to be met, but not exceeded, by the two industries. The level of emission from an industry is related both to the type of equipment used and to the way in which it is operated. The levels, determined from experience recorded elsewhere and those found tolerable by local authorities in an assimilation study, are as follows: cinders from power boilers, 150 gr per 1000 cu ft; sodium compounds, 200 gr per 1000 cu ft. all particulate matter; volatile organic sulfur compounds, 0.2 lbs/ton; calcium compounds, 250 gr per 1000 cu ft all particulate matter; and volatile fluorine compounds, 2.5 lbs/ton.

24010

TEST CASE ON INJURY CLAIMS. Chem. Week, vol. 77:34, 36, Dec. 3, 1955.

Reynolds Metals Company has decided to petition the U. S. Court of Appeals in San Francisco to reverse the Sept. 16 verdict in a district court at Portland, Ore., which awarded \$38,293 to the Martin family. Up to 1950, the Martins were operating a 1500-acre cattle ranch on a ridge a mile or so east of the Reynolds plant. Their first successful move against Reynolds was a civil suit in which they were awarded \$47,000 for damages to cattle and ranch property. In the personal injury suit, Martin contended that fluorine fumes from the plant contaminated not only the air that he and his family breathed but also the vegetables they grew and ate on the ranch. Since 1946 when Reynolds had acquired the plant on the Columbia River, it has installed \$2.5 million worth of waste gas treatment equipment. Principal witnesses in the trial are listed, as well as the basis for Reynolds' appeal.

Ludwig, John W.

THE U. S. GOVERNMENT AIR POLLUTION CONTROL PROGRAM. Preprint, Department of Health, Republic of South Africa, 66p., 1970. (Presented at the Conference on Air Pollution, Republic of South Africa, Oct. 14-15, 1970.)

A description of the air pollution control program of the United States Government is presented. The Clean Air Act is the basic document outlining the approach to air pollution control in the U. S. The Air Quality Act of 1967 calls for a systematic, regional effort to combat air pollution. The operating responsibilities for the Federal air pollution program are carried out by the National Air Pollution Control Administration. In its present form, there are 11 organizational units to carry out the operations of the Administration. The Bureau of Criteria and Standards has sub-divisions of Health Effects, Economic Effects, and Air Quality and Emissions Data. The Bureau of Engineering and Physical Sciences has sub-divisions of Process Control Engineering, Chemistry and physics, and Meteorology. The Mobile Source Program involves motor vehicles as sources, and also does research and development work. The Bureau of Abatement and Control is the interface between the Federal program and State and local Agencies. An indication of funding distribution is presented to give a feel for the major program emphasis. The control programs utilize a priority system of pollutants. The order is: sulfur oxides, particulates, nitrogen oxides, carbon monoxide, fluorides, and odors. Many of the control methods now being studied are described. The measurements methods and instrumentation used by NAPCA are described. Programs initiated to forecast air pollution potential and models used in predicting air pollution concentrations are described. The thrust of NAPCA's efforts to control automobile exhausts lies in three areas: induction system alterations, such as fuel injection; alternative fuels, such as natural gas; and exhaust treatment, such as thermal reactors. The functions of the various Offices within NAPCA are described.

Belknap, Herbert J.

AIR POLLUTION CONTROL ON A COMPLEX INDUSTRIAL SITE. Preprint, American Society of Mechanical Engineers, New York, 5p., 1970. 5 refs. (Presented at the American Society of Mechanical Engineers the Plant Engineering and Maintenance Conference, Fort Worth, Tex., March 16-18, 1970, Paper 70-PEM-11.)

<xref image="2000WVNX.TIF|V3|2006:09:28:01:44:48.00|131569|0"> image: </xref>

The key feature of the centralized air pollution control program at a complex industrial site is the appointment of a staff specialist who is chairman of the plant's Atmospheric Control Committee, composed of chemists and plant, process, and maintenance engineers from each division and building on the site. The specialist has various advisory and coordinating duties for the whole plant, in addition to responsibilities including stack sampling and atmospheric testing. The testing program includes monthly sampling at six locations ringing the plant and colorimetric analysis for sulfur dioxide, nitrogen dioxide, ammonia, and sulfuric, hydrochloric, and hydrofluoric acids; suspended particulates are measured by high volume samples. Metal corrosion tests are also made. The packed bed fume scrubber, extended surface scrubber, and fan-spray scrubber used at the plant are described. Company standards include stack emission limits lower than those permitted by the Texas Air Control Board and concentrations of pollutants in air effluents at (or below) the Threshold Limit Values set by the American Conference of Governmental Industrial Hygienists. Texas Air Control Board regulations are briefly summarized.

Scaiola, Gianni

ESTIMATION OF THE INVESTMENTS AND EXPENDITURES NECESSARY FOR THE ELIMINATION OF POLLUTION. (Stima degli investment! e dei costi necessari per l'eliminazione dell'inquinamento). Text in Italian. In: L'Intervento Pubblico Contro l'Inquinamento: Rapporto di Sintesi, p. 107-136, June 1970. 9 refs.

The investment, maintenance, and operating costs involved in the elimination of the more important forms of air and water pollution are estimated with reference to automotive emissions (hydrocarbons, carbon monoxide, and nitrogen oxides), industrial emissions (particulate pollution, sulfur dioxide, nitrogen oxides, hydrocarbons, and fluorine compounds), electric power plants, domestic heating (with a table of central heating plants and corresponding population figures for eleven Italian cities), liquid effluents from industrial and private sources, and the marine transport of petroleum and petroleum products. For each category, the procedure is described by which the estimates are made.

Haar, Ulrich de

THE MONITORING STATION PROJECT 'KEEPING THE AIR CLEAN'. (Das Messtellen Projekt 'Reinhaltung der Luft'). Text in German. Umschau (Berlin), 70(23):746-774, Nov. 5, 1970. 3 refs.

The carbon dioxide content in the atmosphere has increased by 16% since the beginning of the century and is expected to double in the first half of the next century. While CO₂ does not absorb sunlight, it does absorb night-time long-wave radiation with a resulting increase in atmospheric energy. Increased emission of sulfur dioxide reduced the pH of natural precipitation in the Schwarzwald in Germany from 4.9 in 1965 to 4.5 in 1970 with a resulting decrease of pH in surface waters possessing only a limited buffering capacity and a shift in the hydrobiological equilibrium. It is not enough to measure pollution in highly industrialized areas; pollution spreading to so-called clean air is more dangerous in the long run. For this reason, a network of measuring stations has been established over the Federal German Republic whose objectives are the recording of slow atmospheric changes, the gathering of comparative data for epidemiological studies of population groups from highly polluted areas, and the study of long-term chronic effects of low levels of pollution on humans, plant life, animals, and materials. The data sought include pH, conductivity, dust concentration, soluble and insoluble dust precipitation, chlorine, ammonia, sulfates, CO₂, SO_x, NO₂, F, radioactivity, pollen and spore count, lead level, residual levels of

cancerogenic substances and pesticides, N2O, ozone, particle count, SO2 and aerosol spectra, iodine level, heavy metals and terpenes, and the usual meteorological parameters. It is hoped that a similar network will be established all over Europe.

Mein, William Wallace, Jr.

THE CALAVERAS CEMENT CO. DUST SUIT. Mining Engineering, 3(6): 534-536, June 1951. (Presented at the American Institute of Mining, Metallurgical and Petroleum Engineers Meeting, Los Angeles, Calif., Oct. 1949 and New York, Feb. 1950, Paper TP 3047H.

An account is given of the background, testimony, and outcome of a 1949 trial resulting from a suit by five landowners, all cattle ranchers, whose properties are located in the vicinity of a cement plant. The plaintiffs sued for dust damages of \$120,338 and for an injunction preventing the company from casting dust on their properties in injurious quantities. Testimony for the plaintiffs was designed to establish that the flue dust had damaged the hind and forage and had caused fluorine poisoning to the cattle, both results causing substantial loss of profits. Defense testimony sought to establish that the damage had been enormously exaggerated and should be limited to the much lower loss of rental values, and that the claim of fluorine poisoning was spurious. A jury verdict awarded the ranchers \$7508 in damages and the court issued an injunction following the lines of a company proposal requiring a minimum stack dust recovery of 87%. The plaintiffs subsequently filed an appeal, contending that their proposed version of the injunction should be the one adopted by the court; this appeal was still pending at time of writing.

Osaka Prefectural Government (Japan)

OSAKA PREFECTURE PUBLIC NUISANCE CONTROL CODE (PROPOSED). (Osakafu kogi boshi joreian). Text in Japanese. 29p., Feb. 1971.

The proposed code for Osaka Prefecture consists of general regulations, measures to control public nuisances, such as environmental standards, public nuisance control plans, and regulations for factories, including regulating smoke and dust, and reporting nuisance-creating facilities. Public nuisances from factories consist of smoke and dust, polluted water, bad odors, noise, and vibrations. There are special provisions concerning extraction of ground water, special construction activities, automobile traffic, use of loud speakers, and monitoring of air pollution. Air pollutants under consideration are sulfur oxides, dusts, cadmium, chlorine, hydrogen fluoride, lead and other substances potentially harmful to human health.

28014

LEGAL NOTE ... LIABILITY FOR AIR POLLUTION. Public Health Rept. (U. S.), 74(2):104, Feb. 1959. 1 ref.

In a suit for damages resulting from fluoride poisoning allegedly caused by the defendant's aluminum reduction plant, the plaintiff was unable to specify any particular acts of negligence by the defendant and was compelled to rely on the legal doctrine of 'res ipsa loquitur' (the thing speaks for itself).

This doctrine, according to which the facts of the occurrence

<xref image="2000WVNY.TIF|V3|2006:09:28:01:44:52.00|124697|0"> image: </xref>

warrant the inference of negligence, was held applicable by a court of appeals. The defendant's evidence of reasonable care was considered insufficient to require finding as a matter of law that inference of negligence had been overcome.

28349

Industrial Engineering Center (Japan)
 DATA FOR THE SEMINAR ON INDUSTRIAL POLLUTIONS
 PREVENTION COUNTERMEASURES, NO. 1: PROBLEMS
 AND FUTURE TRENDS IN LEGISLATION RELATED TO IN-
 DUSTRIAL POLLUTION PREVENTION. (Sangyo kogai boshi
 taisaku semina shirjo, No. 1, sangyo kogai boshi kanren horei
 no mondaiten to kongo no doko). Text in Japanese. 12p., 1970
 (??)?

At the 64th Extraordinary Diet session, held from November to December, 1970, 14 laws including the partial amendment of Pollution Countermeasures Fundamental Law, the Air Pollution Prevention Law, and the Water Pollution Prevention Law were passed. With the exception of the law partially amending the Agricultural Chemicals Control Law, all laws were promulgated as of December 25, 1970. Although the Fundamental Law came into force immediately, most of the other laws will become effective six months later due to the time required to prepare ordinances, ministerial regulations, and public notices. A comparison between the old, the new legislation concerning water pollution is given in tabular form, and the scope of each new law is explained. In sections on 'objectives' of the Fundamental Law, Air Pollution Prevention Law, the Water Pollution Prevention Law, and the Noise Control Law, the phrase 'in harmony between living environment and sound level development of economy' is deleted. The system designating special areas for the control of air and water pollution is lifted; control is to be extended to all the areas and public waters in Japan. National minimum discharge standards are established. In the Fundamental Law, soil pollution was stipulated as the seventh typical pollution and a law on 'the prevention of soil pollution for agricultural use' was established. A drastic amendment of the old Cleaning Law was made and the new law on 'treatment and cleaning of wastes' was established. Besides sulfur oxides, soot and dust, chlorine, hydrofluoride, cadmium and lead are controlled under the Air Pollution Prevention Law, while heated and colored water discharge are controlled by the Water Pollution Prevention Law. The range of industry is extended from primary to tertiary. Responsibility of entrepreneurs is clarified in the Fundamental Law to mean that they are to take 'necessary measures to prevent pollution such as treatment of sooty smoke, filthy water, and wastes'. The law on the sharing of pollution-control expenses was established, in keeping with Article 22 of the Fundamental Law, which stipulates the responsibility of entrepreneurs to bear the burden of expenses. Some responsibilities and authority are entrusted by the national government to local autonomous bodies. The future problems are: steps to make adequate use of land, further improvement in enterprises to prevent pollution, establishment of Environmental Agency, financial assistance to local area, enterprises, legislation on odor, and promotion of technology.

29421

OUTLINE OF LEGISLATIONS CONCERNING POLLUTIONS
 PASSED BY THE EXTRAORDINARY DIET SESSION. (Rinji
 kokkai seiritsu kogai kankei horitsu yoko). Text in Japanese.
 16p., Dec. 21, 1970.
 Legislation is outlined including, the Water Pollution Prevention Law, the law which partially amends the Pollution Countermeasure Fundamental Law, the law which partially amends the Air Pollution Law, the Water Pollution Prevention Law, the law which partially amends the Noise Control Law, the

Marine Pollution Prevention Law, the law on the sharing of the financial burden for pollution prevention, the law on the punishment of crimes involving pollution harmful to human health, the law concerning waste treatment and cleaning, the law concerning the prevention of soil pollution, the law which partially amends the Sewer law, the law which partially amends the Road Traffic Law, the law which partially amends the Agricultural Chemicals Control Law, and the law which partially amends the Poison and Poisonous Matters Control Law. The definition of pollution is changed to include soil pollution, heated water from thermal generating stations, and paper mill sludge. The phrase, harmony with sound development of economy was deleted, and it is now the responsibility of entrepreneurs to dispose of industrial wastes. The system of designating special areas for air and water pollution was abolished, and the emission standard is applicable all over Japan. Besides sulfur dioxide in factory smoke, cadmium, hydrogen fluoride, and lead are specifically mentioned. Governors can limit the use of facilities which emit sooty smoke and advise them to comply with standards on the use of fuel, improve water pollution, and prevent soil pollution. Also, the discharge of oil from vessels is restricted. A person in charge of controlling oil pollution must be designated to each vessel. Of willfull damages to health and life, are punishable by prison terms of detention of less than 2 years or of fines less than 716 dollars. Heavier penalties occur in the case of death or injuries. Individuals and corporations are punishable. Companies must manufacture easily disposable goods. Areas are designated which are feared to be heavily contaminated. Sewers must have a terminal disposal plant, or be connected with the sewer system. The Public Safety Commission can install and control traffic signals, and prohibit traffic, if necessary.

Secretariat

COLLECTION OF LEGISLATIONS RELATED WITH MITI
CONCERNING POLLUTIONS. (Tsusho sangyo kankei
horeishu). Text in Japanese. Tokyo, Japan, Tokyo Hoki Publish-
ing Co., May 1971, 270p.

As of April 1, 1971, the ordinance on the enforcement of the Air Pollution Control Law and the law on the consolidation of the Kinki region (regarding the designation of special areas for the maintenance of the environment) were revised. The ordinance referred to in paragraph 5, Article 2 of the Law designates these substances: ammonia, hydrofluoric acid, hydrogen cyanide, carbon monoxide, formaldehyde, methanol, hydrogen sulfide, phosphoric acid, hydrochloric acid, nitrogen dioxide, acrolein, sulfur dioxide, chlorine, carbon disulfide, benzene, pyridine, phenol, sulfuric acid (including sulfur trioxide), silicon fluoride, phosgene, selenium, dioxide, chlorosulfonic acid, yellow phosphorous, phosphorous trichloride, bromine, nickel carbonyl, phosphorous pentachloride, and mercaptan. The allowable limit for SO₂ in the atmosphere is 2/10 mil, an annual hourly maximum, or 0.6/10 ml annual hourly average. When hours exceeding 2/10 mil do not exceed 75 hours a year, only the annual hourly average can be taken. The measurement of the hourly figure is determined by the ordinances of the Ministry of Health and Welfare and the Ministry of International Trade and Welfare. The measurement of sooty smoke and particulates are also in accordance with the law. In the Construction Standards Law Enforcement Regulations, revised December 2, 1970, as Ordinance No. 333, Arti-

cle 126 stipulates smoke elimination facilities and chimney stacks for buildings. Law No. 144 limits factories in already established urban areas in the Kinki Region.

29598

Toyama Prefecture (Japan), Dept. of Environmental Pollution
PRESENT SITUATION OF ADMINISTRATION CONCERN-
ING POLLUTIONS. (Kogai gyosei no genkyo). Text in
Japanese. 74p., Oct. 1970.

Aluminum smelters and thermal generation stations in the hinterland of Toyama prefecture, have signed an agreement with Toyama Prefecture concerning the prevention of air pollution, but the problem of air pollution is becoming complicated and diversified. Although no concentration is as high as the environmental standard, control was strengthened by amending K 29.2 to 20.4 and adding five observation stations, and a central telemeter monitoring system. Dust collector facilities for electric furnaces lowered the concentration of exhaust smoke from electric furnaces to within the range of standard. With the increase of ferro-alloy, iron, and steel production, on-site checks will be made and guidance will be given on high efficiency dust collecting equipment. With the revision in the sulfur dioxide standard, 56 production facilities, 17% of the factories under control, no longer qualified. At the moment, the chimney height is being raised, a switch to LS heavy oil is being made, and as of the end of March, 1970, about 40% had completed the improvement. Carbon monoxide checks were made in 196 at major locations on traffic congestion in two cities, and they will be continued this year. Since the start of aluminum production by Sumitomo Chemical Industry, an agreement was signed with the company concerning fluorine. Indicator plants were placed, and on-site checks have been made. Of the 13 staffs on environmental pollution at the prefectural government, four are in charge of air pollution. Of 192 complaints concerning pollution received in 1969 42 were on air pollution. Between September 19, 1969 and October 30, 1969, \$583.60 was spent on a survey of air pollution by the prefectural government. As of end of March, 1970, 430 facilities which emit smoke reported in accordance with Air Pollution Prevention Law. Between 1967 and 1969, nine smaller enterprises were given financial aid to improve facilities to prevent air pollution.

29818

Tokyo Metropolitan Government (Japan), Bureau of Sanitation

MATERIALS FOR REFERENCE ABOUT ENVIRONMENTAL
POLLUTION CONTROL. (Kogai hoken sanko shiryo). Text in
Japanese. 39p., March 1971.

The present state of and the future problems of the administration of environmental pollution control in Tokyo, the injuries to health by these pollutants, and their prevention are discussed. Materials for reference are as follows: the definition of environmental pollution in the basic law of environmental pollution (Kogai); Japanese Air pollution regulations; the history of air pollution in Japan; kinds, physical and chemical characteristics amounts, actions and sources of air pollutants; standards for warnings, and alarms pollutions; influence on the human body; and items in the Tokyo medical examination of community inhabitants for environmental pollution (physical examination of the respiratory organ system). The division of duties in the Pollution Disease Section and the organization of the Bureau of Environmental Protection are also mentioned. Major pollutants discussed include nitric oxide, chlorine, fluorine, carbon dioxide, methane, nitrogen dioxide, ozone, sulfur dioxide, ammonia, sodium chloride, carbon monoxide, iodine, dusts, fumes, mists, hydrogen sulfide, and sulfuric, nitric, hydrofluoric, and hydrochloric acid.

30620

Kawamoto, Hirotaka

EXPLANATION OF AIR POLLUTION CONTROL ACT.

(Taiki osen boshiho no kaisetsu). Text in Japanese. Ryusan (J. Sulphuric Acid Assoc., Japan), 24(3):21-31, March 1971. The Air Pollution Control law passed by the 64th Extraordinary Diet session, aims at control of smoke, dust, exhaust gas, and special matter. Smoke is divided into sooty dust, sulfur oxides, harmful matter, and special harmful matter. Facilities which generate smoke are defined. Sooty dust generated by the incineration of fuel or by the use of electricity is the same as the traditional soot and other dusts; it includes soot, ash, metal, and other oxides generated by combustion. Use of electricity as a heat source implies the electric furnace process, for instance Harmful matter is defined as that generated by combustion, synthesis, decomposition, or other waste disposal methods (except mechanical process). Examples are cadmium, chlorine, fluoride, and lead. Special harmful matter is that generated, for example by combustion of nitrogen oxides. Facilities which generate harmful substances include electrolytic furnaces, reactors, crucibles and converters. Those who want to establish smoke-generating facilities must provide regional authorities with necessary information. Those who do not conform to the smoke standard are punished, ordered to alter their plan, or to abandon it. Mines are excluded from the definition of the facilities which generate smoke, as they come under the more strict Mine Safety Law. The smoke discharge standard is universal throughout Japan. The following smoke environmental standards apply: hourly values must be less than 0.2 ppm for 99% of the total hrs/yr; daily averages must be less than 0.05 ppm for over 70% of the total days/yr; hourly values must be less than 0.1 ppm for over 88% of the total hrs/yr; the average annual hourly value cannot exceed 0.05 ppm. In any area, the number of days calling for emergency measures is not to exceed three percent of the total days/yr or to continue beyond three days. The standards are to be realized within 10 year in congested areas and within five years in already polluted areas.

Boer, Wolfgang

BASIC PROBLEMS OF AIR POLLUTION IN THE GERMAN DEMOCRATIC REPUBLIC AND POSSIBILITIES FOR THEIR SOLUTION. (Grundprobleme der Reinhaltung der Luft in der Deutschen Demokratischen Republik und Moeglichkeiten ihrer Loesung). Text in German. Energie Tech., 21(6):274-277, June 1971.

In the German Democratic Republic, it is expected that the sulfur dioxide pollution, caused by the combustion of fossil fuels, will continue to rise until 1975 and the following years. In industrial centers, SO₂ will thus continue to be the major pollutant. The exhaust gases from automobiles pose problems. Tests of two-stroke engines revealed that they do not emit more pollutants than four-stroke engines. A solution of the exhaust gas emission is seen only in the construction of an entirely new type of engine. As long as there are combustion engines there will be emissions. Numerous injuries to crops and forests were found to stem from fluorine emissions, rather than from SO₂ emissions. The present air pollution situation was used as basis for the air Pollution Regulations, which call for maximum allowable emission concentrations, which are set by the Health Ministry and which will be established by the individual organs in the economic sector. The emissions will be

controlled by the district hygiene inspectors and the companies themselves. Any negligence in meeting the standards will be punished by the collection of a certain fee.

32173

Orange County Air Pollution Control District, Anaheim, Calif. RULES AND REGULATIONS. 34p., Dec. 23, 1969. Rules and regulations governing air pollution emissions and control are reviewed for Orange County. General terms and standard conditions are defined. Permits, fees, and fee schedules are examined. Emission standards are presented for panaculate matter, visible contaminants, sulfur compounds (sulfur dioxide), combustion contaminants (carbon dioxide), fluorine compounds, scavenger plants, dust, fumes, storage of petroleum products, open fires, incineration, gasoline loading, oil-effluent water separator, sulfur content of fuels, gasoline specifications, organic solvents, fuel burning equipment, architectural coatings, and orchard or citrus grove heaters. Legal procedures before the Hearing Board are delineated.

32245

San Bernardino County Air Pollution Control District, Calif. RULES AND REGULATIONS. 62p., Aug. 18, 1970. (Includes Amendments to San Bernardino County Air Pollution Control District Rules and Regulations). Rules and regulations concerning air pollution emissions and control in San Bernardino County are reviewed. General pollution terms are defined. Permits and fees for schedules of electric motor horsepower equipment, fuel burning equipment, electrical energy use, incinerators, stationary containers, and orchard heaters are discussed. Pollution emission standards are examined for panaculate matter, specific contaminants (sulfur dioxide, carbon dioxide, and fluorine compounds), scavenger plants, dust, fumes, storage of petroleum products, open fires, incineration, oil effluent water separators, gasoline loading, sulfur content of fuels, gasoline specifications, organic solvents, architectural coatings, and fuel burning equipment. Procedures of the board are reviewed. Emergency regulations are determined for air sampling and sampling stations, alerts, communication systems, and toxic air pollutant levels of carbon monoxide, nitrogen oxides, sulfur oxides, and ozone.

32272

San Diego County Air Pollution Control District, Calif. RULES AND REGULATIONS. 34p., Aug. 1970. Rules and regulations governing air pollution emissions and control in San Diego County are reviewed. General terms and standard conditions are defined. Permits and fees are explained. Standards on emissions are examined with respect to the Ringelmann chart, panaculate mattei, specific contaminants (sulfur dioxide, carbon dioxide, and fluorine compounds), scavenger plants, dust, fumes, open fires, incineration, and sulfur content of fuels. Rules concerning orchard or citrus grove heaters and legal board procedures are determined.

32354

Nordrhein-Westfalen Arbeits-und Sozialminister (West Germany) PLANS AND GOALS OF THE STATE GOVERNMENT TILL 1975. (Plaene und Ziele der Landesregierung bis 1975). Text in German. In: Reinhaltung der Luft in Nordrhein Westfalen. Essen, West Germany, Brinck and Co. KG, 1969, p. 84-93. The state government has adopted a new regional approach to all pollution control planning. Abatement programs instituted for Thomas steel converters, ore sintering plants, cokerries, foundries, and steam power plants will terminate in 1973. In selected industrial centers with high pollution emissions, all industrial, domestic, and automotive polluters will berechecked and results of the survey will be used as a basis for pollution

control improvement and for planning and legislative purposes. An emission register (map) of Cologne, Duisburg-Oberhausen-Muelheim an der Ruhr, Essen-Bottrop, Gelsenkirchen-Wanne/Eickel-Bochum, Gastrop-Rauxel, and Dortmund will be compiled and used for purposes of pollution forecasting. Measurement data show that chemical and petrochemical plants contribute an inordinately large share to overall pollution; these plants will have to install new equipment to reduce emissions of concentrated reaction gases, odorous gases, and gases with high particulate content. New monitoring programs will be instituted for fluorine, hydrocarbons, odorous sulfur and nitrogen compounds, hydrogen chloride, and oxidants and particulates in an area extending from Cologne to Dortmund. New regulations will be issued governing maximum permissible emissions from all domestic heating plants fired by oil, coke, or coal. The incineration of solid waste in heating plants will be prohibited.

32789

Public Nuisance Control Assoc., Tokyo (Japan)

LAWS AND ORDINANCES RELEVANT TO MR POLLUTION. (Taiki osen boshiho seko rei). Text in Japanese. Sangyo Kogai (Ind. Public Nuisance), 7(7):322-331, July 1971.

On the basis of the Air Pollution Prevention Act, regulations have been issued designating pollutants, the maximum permissible emission, emission sources, and pollution areas. Among the materials produced by combustion, synthesis, and decomposition, elements that have been designated as toxic are cadmium and its compounds, chloride and its compounds, fluoride, hydrogen fluoride, and silicon fluoride, lead and its compounds, and nitrogen oxides. Toxic materials emitted by automobiles are carbon monoxide, hydrocarbons, lead compounds, and nitrogen oxides. Toxic material that should be guarded against at the time of accidents at manufacturing plants consist of 28 items including NH₃ and HF. The maximum permissible amount of toxic matter concentration per hour at the highest point during the year should be less than 0.1 ppm. Twenty-six kinds of soot producing apparatus and systems are subject to regulations, and five kinds of particulate producing furnaces and apparatus are subject to regulations. Also included are areas subject to sulfur oxides concentration control and areas subject to advice for the use of low-sulfur content fuels.

32884

Smaller Enterprises Promotion Corp. (Japan)

AMENDMENT DRAFT AND EXPLANATION OF AIR POLLUTION CONTROL LAW ENFORCEMENT REGULATIONS.

(Taiki osen boshiho sekorei no kaiseian oyobi kaisetsu). Text in Japanese. Preprint, 20p., 1971. (Presented at the Public Nuisance Prevent. Tech. Seminar, Japan, 1971.)

Air pollution control laws and amendments in Japan are examined. Regions are divided into eight classes based on the discharge standard of sulfur dioxide, for which the maximum allowable concentration is 0.020-0.045 ppm at ground level. Industries discharging smoke, cadmium, or lead and boilers burning heavy oils must be equipped with electric dust collectors, bag filters, or multi-cyclones. In certain areas, buildings with central heating must install multi-cyclones or more effi-

<xref image="2000WVO1.TIF|V3|2006:09:28:01:45:02.00|119340|0"> image: </xref>

cient dust collectors or change to gas or electric heating. The prefectural governments may adopt emission standards stricter than those enforced by the national government. Industries discharging chlorine or fluorine must be equipped with alkali washing devices. Sulfur content in fuels is limited to 1.0-1.5%.

33495

Morgan, George B. and Guntis Ozolins
AIR QUALITY SURVEILLANCE. Preprint, Air Pollution Control Office, Cincinnati, Ohio, Div. of Atmospheric Surveillance, 23p., May 21, 1971.

The specific needs for air quality data, the scope and requirements of monitoring activities, and the chief components of ambient air quality surveillance such as sampling-measurement networks, laboratory support, and data handling and analysis were presented. The monitoring conducted by state and local air pollution control agencies is directed toward enforcement activities. The Federal monitoring system provides a uniform data base throughout the country against which all other air quality data can be verified. States must provide adequate monitoring of total suspended particulates, sulfur dioxide, carbon monoxide, nitrogen oxides, oxidants, and total hydrocarbons. The number of sampling stations required depends primarily on existing pollution levels, their geographical and temporal variability, and the size of the region. The number of sampling stations must be adequate to allow definition of the area or areas where ambient concentrations may be expected to exceed those designated in air quality standards. Station locations and sampling site characteristics were discussed. The sampling frequencies for mechanical samplers and the averaging times for automatic samplers are dictated by ambient air quality standards. The frequencies (continuous, daily, or weekly) are given for suspended particulates, lead, polycyclic organic matter, fluorides, SO₂, CO, HC, nitrogen dioxide, NO_x, and ozone for urban and rural areas. With automatic instrumentation the need for routine laboratory support is greatly reduced but a problem of data transmission, validation, and reduction is introduced. Trends in urban air quality were also reviewed.

33722

Tokyo Metropolitan Equipment and Supplies Bureau (Japan),
Air Pollution Regulation Project
STANDARD REGULATION FOR THE TREATMENT OF
POISONOUS GASES (1). (Yugai gasu shorishisetsu shido
hyojun (1)). Text in Japanese. 186p., March 1970.

A standard regulation was established for treating generated poisonous gases in Tokyo. A packed tower or the combination of packed and spray towers should be used for the treatment of ammonia gas. Gas-liquid contact equipment may be used to wash gas provided it is equal to or higher than the towers in control efficiency. Maximum ammonia concentration in waste gas was determined at 500 ppm; average concentration during manufacturing was 250 ppm. For reference purposes, gas cleaning apparatus, absorption of waste gas, analysis of waste gas and drained water, standards for regulation of waste gas from a factory, and the standard of the treatment of drained water from a factory were described. Fluorine and fluorine compounds should be treated by washing with a jet scrubber or spray tower. Maximum fluorine concentration was set at 15 ppm and average concentration during manufacturing was 10 ppm. General properties of fluorine compounds, sources of fluorine compounds emissions and examples of equipment for treating gases containing fluorine are examined. Hydrogen sulfide should be treated with the aspiration system of a tower using alkali. Maximum H₂S concentration in waste gas, was set at 50 ppm, 30 ppm was the standard average during manufacturing.

Shirmura, Gakushi

PARTIAL REVISION OF ORDINANCES RELATED TO AIR POLLUTION CONTROL LAWS. (Taiki osen boshi ho kankei horei no ichibu kaisei nado ni tsuite). Text in Japanese. Nihon Gasu Kyokai-shi (J. Japan Gas Assoc.), 24(9):26-29, Nov. 1971. Commentaries are made on the main points of revisions in the Air Pollution Control Act passed by the 64th Diet session in the fall of 1970 and ministerial ordinances issued on June 26, 1971 on related matters. The main revisions in the Air Pollution Control Act include: the abolishment of specific control area systems and the application of emission and maximum concentration standards to the entire nation; prerogatives of local governments in issuing more strict emission standards than the national standards when deemed necessary; regulations controlling the use of fuels for especially polluted urban areas; and designation of emission standards for toxic materials and dust particles. Revisions made on the enforcement ordinances give specified toxic materials as cadmium, chlorine, hydrogen chloride, fluorine, hydrogen fluoride, silicon fluoride, lead, and nitrogen oxides. Comments and explanations are given on various dust and soot creating facilities and emission standards, areas with special sulfur oxide emission standards, fuel use control areas, emergency countermeasures, administrative responsibilities, and various technical standards and applications in gas work operations.

37747

Kobayashi, Gen

THE CHARACTERISTICS OF POLLUTION CONTROL LAWS OF IBARAGI PREFECTURE AND THE ROLE OF THE POLLUTION CONTROL AGREEMENT. (Ibaragiken ni okeru kogai boshi jorei no tokucho to kogai boshi jorei no tolcucho to kogai boshi kyotei no yakuwari). Text in Japanese. Kagaku Koho (Chem. Factory), 15(I3):94-98, Dec. 1971. The background, content, characteristics, and the role of the pollution control laws of Ibaragi prefecture are discussed, particularly with regard to the liquid waste discharge standard. As to air pollution, special permission must be obtained for the construction or operation of new factories engaged in metal refining, electroplating, dye adjusting, paper or pulp mills, or manufacturing of cement, asphalt, alcohol, fertilizer, or starch; for those factories which use mercury, cadmium, lead, fluorine, cyanogen, organic phosphorus compounds, arsenic, or chromium; and for those factories which emit a maximum of more than 5000 cu m or consume the maximum of more than 50 kl heavy oil. The maximum permissible hydrogen chloride emission in the air is 70 mg, and for fluorine, hydrogen fluoride, and silicon fluoride it is 4 mg, in the Kashima area. Permission to operate certain kinds of plants depends on strict adherence to the standards, and violation will lead to cancellation of permission. Unauthorized companies and those which have lost permission must stop operating immediately; violation of the ordinance will lead to the most severe penalty. Such regulations are applicable to dust creating installations such as ash manufacturers, power cotton gins, agricultural chemical plant, pottery factories, soil and stone packers, and bad odor producing installations such as livestock yards, chicken feces, drying plants, and pulp mills.

Toyama Prefecture (Japan)

TOYAMA PREFECTURAL WHITE PAPER ON ENVIRONMENTAL POLLUTIONS REPORT FOR 1970, ADMINISTRATIVE ACTIONS FOR 1971. (Toyama-ken kogai hakusho, showa 45 nendo nenji hokoku, showa 46 nendo no shisaku). Text in Japanese. 186p., Aug. 1971.

The situation of environmental pollution consists of air, water, noise pollutions, and odor pollution. Complaints due to environmental pollution are mentioned. Air pollution tends to be high in the Toyama-Takaoka area and Uozu or Kurobe. Falling soot and dust occurs locally in Toyama, Takaoka, and Shin Minato cities where smelting and iron factories are located, but it tends to decrease annually. In the first two cities, sulfur oxides concentrations which exceed the environmental standard is observed. The floating dust is generally low. Pollution due to fluoride compounds or carbon monoxide is considered to be important as a future problem. The poultry industry and hog raising are sources of bad odors, and the marine products industry is also a problem. Actions for the prevention of environmental pollution, countermeasures taken for each kind of pollution, and fundamental measures are explained. Items on the environmental atmosphere, a plant survey, environmental health measures, polluted soil, and countermeasures for farming crops, are explained. Fundamental preventive measures that are scheduled to be taken for 1970 and concrete actions for each kind of pollution are also discussed. The Itai-Itai disease and the Toyama Prefectural Ordinance for preventing environmental pollutions are mentioned.

Collin, Fredrik C.

CHOICE OF SITE FOR AIR POLLUTION CAUSING INDUSTRIAL PLANTS AND COSTS OF GAS CLEANING. (Litt om plasering industri med luftforurensningsproblemer og om utgiftene med gassrensning). Text in Norwegian. Tek. Ukeblad (Oslo), 119(S):15-17, 19, Feb. 1972.

Air pollution-related conflicts between industrial plants and their surroundings can be minimized or eliminated by preliminary studies and proper choice of sites. The requirement for the possibility of eliminating wastes without direct damages to the environment should be considered in addition to the economic aspects of the choice of the site. In the metallurgic industry, ferroalloy and aluminum plants pollute the air in a radius of about 10 km. A minimum distance of 5-10 km should be kept between new plants and residential areas, taking future expansions into account. Any home building should be prohibited near existing or planned industrial plants. Costs involved in air pollution control in the aluminum industry are discussed. The actual costs are reduced by the fluorine recovery at the Lista Aluminiumverk. Electrostatic filters proved to be unsatisfactory for the cleaning of gases from open-hearth furnaces in a ferrosilicon manufacturing plant. The glass-fiber bag filters applied now cause 10% increase in the price of the products. Changes are needed in the raw material treatment to reduce both smoke emissions and power requirements. To produce marketable products, international cooperation in air pollution problems is needed. Contributions by the state towards investments are a necessity.

38669

Osaka Prefectural Government (Japan), Div. of Atmosphere

AIR POLLUTION CONTROL LAW INSTRUCTIONAL DATA.

(Taiki osen boshiho setsumei shiryō). Text in Japanese. 14p., 1971.

Instructions and explanations are given concerning the air pollution control law and the main points of revisions. The organization and system of the law are explained by a flowchart. Regulations are applicable to stack gases including sulfur oxides, soot, general and special toxic gases, special toxic

materials, and dust particles. With regard to emission standards, sulfur oxide emission standards are categorized in eight groups and are determined locally. Stack gas, soot, and toxic gas emission standards are determined nationally, and special emission standards are applicable to soot and special toxic gases. Violations in all categories of stack gases are subject to penalties. Standards for special toxic materials are determined case by case at the time of accident. Dust emission standards are determined depending on the structure, use, and maintenance of facilities. These last two items are not subject to penalty. The method of enforcement of improvement orders and the period of improvements are reviewed by a table. Items and facilities that require registration and reporting are reviewed by a table. Facilities designated as soot and stack gas emission sources are reviewed by a table. Emission standards with regard to categories and usage, the old and new standards, and control areas are reviewed by tables and maps. Emission standards of special toxic materials such as cadmium and compounds, chlorine, hydrogen chloride, fluorine, hydrogen and silicon fluorides, and lead and compounds, are reviewed by a table. Dust creating facilities and their management standards are given.

Mahler, E. A. J.

THE FIGHT AGAINST AIR POLLUTION IN THE VICINITY OF INDUSTRIAL WORKS IN GREAT BRITAIN. (Die Bekaempfung der Luftverunreinigung in der Umgebung industrieller Betriebe in Grossbritannien). Text in German. Eidgenoessische Kommission fuer Lufthygiene, Zurich (Switzerland), Probleme der Luftverunreinigung durch die Industrie, p. 15-22, 1968. (Sept. 9-10) (Presented at the Schweizerisches Treffen fuer Chemie, 2nd, Basel, Switzerland.)

British regulations for combatting emissions from emissions from industrial plants include the Public Health Act of 1936, the Clean Air Act of 1956, the Alkali Works Regulation Act of 1906, and the Alkali Works Order of 1966. The Clean Air Act contains regulations about minimum height of chimneys and limitations in soot emissions. The Alkali Acts specify recommended means for determining standards of maximum permissible concentrations of air pollutants. The manufacture of Fletton bricks from clay containing 10% carbon and 500 to 700 ppm fluorine which generates emissions of sulfur dioxide, fluorine compounds, and an offensive smell. Various methods for removal of SO₂ and F, such as the Monsanto method, have been tried but have proved impractical in view of the very large volume of waste gases to be handled. For the time being, dispersion of waste gases by means of high chimneys has been the only effective practical remedy. In thermal power stations, removal of sulfur dioxide by forcing the waste gases through ammonia scrubber installations has been very satisfactory, provided that inexpensive ammonia is available and a market for ammonium sulfate assured. Other power plants use water with additions of chalk or calcium carbonate as scrubbing liquids. The drawback of this method is the cooling of the waste gases which then lose their buoyancy and descend to the ground, causing formation of haze and offensive smells. Dispersion of waste gases by 600 to 800 foot chimneys is so far considered the most practical remedy.

Damon, W. A.

THE ALKALI ACT AND THE WORK OF THE ALKALI IN-

SPECTORS. Roy. Soc. Health J. (London), 76(9):566-575, 1956.

16 refs. (Presented at the Conference of Sanitary Inspectors, Health Congress, Blackpool, England, April 26, 1956.)

About the middle of the last century, great indignation was caused by the discharge of hydrogen chloride from the new process for manufacture of alkali or sodium carbonate. So great was the outcry and so frequent were the actions for damages that a Royal Commission was appointed, and following its report the first alkali Act of 1863 was passed. It stipulated that not less than 95% of the HCl produced in the process of making alkali should be condensed or absorbed. The residual 5% might be discharged into the air provided it was diluted to contain not more than 1/5 grain of HCl per cu ft. The Act also provided for the setting up of a central staff of inspectors under the control of the Local Government Board. The original Act was extended by subsequent legislation at intervals until 1906 when the current Alkali Act- Works Regulation Act was passed. General provisions, statutory limits, and the Alkali Inspectorate are described. Chemical and physical methods for treating waste gases and chimney dispersal are mentioned. The owners of process schedules under the Alkali Act are required to adopt the best practicable means whereby this discharge of noxious or offensive gases may be reduced and the residue discharged harmlessly and inoffensively. Sulfuric acid processes, viscose processes, cement manufacture, and petroleum refining are mentioned. Non-scheduled processes include electricity generating stations, coal carbonization works, ironworks, steelworks, ceramic works, and fluorine emissions. The clean Air Bill is cited.

40461

ENVIRONMENT PROTECTION. (Umweltschutz). Text in Ger-

man. Tech. Ueberwach. (Duesseldorf), 13(5):181-187, May 1972.

The German Federal Government is actually reading the bill concerning the protection against harmful environment influences due to air pollution. The bill states that plants emitting air polluting gases or substances require a special authorization. The supervision of emissions will be intensified. Analyses have been made in various enterprises like melting plants, incineration plants, and cement works concerning the emission of dust, sulfur dioxide, sulfuric acid, gaseous fluoride and chloride compounds, hydrogen chloride, hydrogen sulfide, and carbon monoxide. With regard to the emission of CO, nitric oxide, and hydrocarbons by automobile engines, a test station has been established at Essen which undertakes all exhaust gas examinations. However, these examinations concern only relatively new vehicles so that a sensible reduction of the CO contents in the exhaust gases will be reached only if the new exhaust gas prescriptions are generally valid for all vehicles.

Crone, J., R. Schumacher, and E. Luescher

DEMANDS ON A MEASURING SYSTEM FOR MONITOR-

ING AIR POLLUTION DEMONSTRATED BY THE EXAM-

PLE OF THE CITY OF MUNICH. (Anforderungen an ein Mes-

system zur Ueberwachung der Luftverunreinigung am Beispiel

der Stadt Muenchen). Text in German. Gesundh. Ingr., 93(3):71-76, March 1972. 6 refs.

The plans for the development of an air pollution monitoring grid for Munich are reviewed. The measurement grid must be capable of determining the momentary air pollution situation over the entire city and its suburbs; simultaneously provide an air pollution alert service; determine the type of air pollutant and locate its source; and draw conclusions from short-term data on the long-term changes of atmospheric pollution. The

parameters to be measured will include sulfur dioxide, carbon monoxide, carbon dioxide, nitric oxide, nitrogen dioxide, hydrocarbons, ozone, hydrogen sulfide, hydrogen fluoride, hydrogen chloride, aerosols, temperature relative humidity, and wind direction and velocity. For the first phase, 30 stations will suffice. The main stations will monitor all parameters with the exception of halogens and hydrogen sulfide. Secondary stations which measure the SO₂, CO, NO, and NO₂ concentrations; 2 stations will monitor single emission sources such as incinerators with additional measurement of halogens and H₂S. One mobile station will be used at an arbitrary place for all measurements and even for long-term measurements. All data will be transmitted to a data computer center. The minimum sensitivity of the units will have to correspond to the background concentration in the atmosphere of non-polluted areas. Proposals by various companies will be evaluated according to certain criteria giving priority to scientific and technological perfection rather than costs.

Swieboda, M.

AIR CONSERVATION IN THE CRACOW VOIVODSHIP. Air

Conserv. (English translation from Polish of: Ochrona Powietrza), 3(1): 1-9, 1969, 19 refs. NTIS: TT 70-55123/1

The Cracow province is second only to Silesia in the magnitude of the threat posed by air pollution and is classified as an area where the threat of air pollution is of medium intensity. A number of industrial concentrations, however, present serious problems. The dense network of industrial plants in the Cracow industrial region has allowed an overlapping of emissions resulting in an extremely complex condition. The principle noxious substances emitted are sulfur compounds, i.e., sulfur dioxide, sulfuric acid, hydrogen sulfide, and carbon bisulfide, carbon monoxides, nitrogen oxides, fluorine compounds, chlorine, hydrocarbons, and lead and zinc dusts. Lead dust concentrations around the Boreslaw Mining and Foundry Plants were estimated at one ton/sq km/yr; zinc was estimated at 0.3-0.5 ton/sq km/yr. An increase in the degree of air pollution was noticed in Cracow city itself. Dust precipitation varies between 200 and 600 ton/sq km/yr. A sharp increase in ambient dust concentration is noted in the fall and winter the admissible standard is 0.21 mg/cu m. The industrial regions of the Cracow area have suffered great vegetation damage. In the Olkucz forest and in the Chrzanow district, over 21,000 hectares of wooded land were destroyed. Industry alone holds the key to preventing or controlling air pollution and forest injuries in industrial districts. Existing abatement regulations place the responsibility on offending factories with respect to building, installing, and operating dust removal equipment. Numerous attempts were made between 1918 and 1938 to control air pollution in the city of Cracow. The principle legal document upon which control operations and cooperation can develop is the Resolution of the Cracow City Government and the Act on Air Pollution Control.

Japan Environmental Agency

WHITE PAPER ON ENVIRONMENT - A NEW GOAL FOR

ENVIRONMENTAL POLICY. (Showa 47 nenban kankyo

hakusho, kankyo seisaku no atarashii zahyo). Text in Japanese.

486p., June 1972.

<xref image="2000WVO4.TIF|V3|2006:09:28:01:45:14.00|123366|0"> image: </xref>

The present status of air pollution in Japan and the control policy of public nuisance is discussed. Forty major cities have higher sulfur oxide concentrations than standard values, as high as 40% of the cities subjected to investigation. In addition to SO_x, other pollutants such as hydrogen fluoride, chlorine, and hydrogen chloride have complicated the pollution problem. The injuries to human health, such as chronic bronchitis, and damages to agricultural products and forests have become more and more significant. According to the new regulations passed on Jan. 11, 1972, the hourly average particulate concentration for 24 continuous hours must be less than 0.10 mg/cu m, and hourly concentration must not exceed 0.20 mg/cu m. New SO_x standards are revised for different districts, and emergency threshold values of all pollutants are also listed. In the nation, 85,487 facilities have been registered as smoke and soot polluters. Restrictions on automobile exhausts have been tightened, and wide district observation systems were established.

42188

Japan Environmental Agency

AIR POLLUTION CONTROL IN JAPAN. 67p., May 1972.

Pollution caused by such substances as sulfur oxides, suspended particulates, and carbon monoxide, for which various countermeasures have been taken have recently shown a tendency to decrease, or at least not to increase. However, with regard to nitrogen oxides and oxidants, for which no regulatory measures have been implemented, the situation has been aggravated resulting in the appearance of new air pollution problems such as the photochemical smog. Damages to property, agriculture, and human health traced to these pollutants as well as to lead, chlorine gas, and hydrogen fluoride are reviewed. The history of regulations on air pollution is described and countermeasures against air pollution are outlined, including the establishment of environmental quality standards and emission control of smoke, soot, and other pollutants. Other measures include pollution control organization at specified factories, relief systems for victims of environmental pollution diseases, countermeasures for photochemical smog including emergency traffic and industrial production curtailments, promotion of fuels with low sulfur content, pollution control measures by local governments, regional industrialization planning and environmental pollution control programs, and limitations on emission from mining, smelting, and refining operations. The monitoring systems for air pollution at the local and national levels are described. Research and development projects currently in progress are listed.

Hashimoto, H.

APPROACHES TO AIR POLLUTION AS INTEGRAL PARTS OF ENVIRONMENT PROBLEMS AND POLICY BY OECD.

International Union of Air Pollution Prevention Associations, Proc. Int. Clean Air Congr., 2nd, Washington, D. C., 1970, p. 1341-1342. (Dec. 6-11, Paper P2 D.)

The Organization for Economic Cooperation and Development (OECD), an intergovernmental organization with 22 member states, has been instrumental in the formulation of economic policy and the quality of life, in terms of a livable environment as well as social welfare. With a view to incorporating environmental considerations into economic policy, the Environment Committee within the OECD consists of senior governmental officials with central responsibilities for environmental questions. Prior to the formation of this committee, an air management research group (AMRG) was organized to deal with abatement technology, measurement of air pollution, and effects of air pollution. Results of the abatement technology research indicated priorities in industrialized countries in relation to the automobile, fuel combustion, fluorides, and odors. The measurement panel studied the emerging administrative

requirements, examined the present measurement capabilities in member countries, and showed principal areas of deficiency in technical capability in regards to air pollution modelling. Examining research in relation to the technical information needed for administrative decisions in abatement of air pollution, the effects panel defined the categories of health effects, economic consequences, and amenity and long term biological and physical effects. Recommendations of the AMRG include: cost-effectiveness studies of available technology transmission and transformation of air pollutants, research on effects of air pollution, and the implementation of a plan for a project on mass transport of air pollution.

42873

AIR POLLUTION PROBLEMS. (Problem der Luftverschmutzung). Text in German. In: Bericht der Bundesrepublik Deutschland ueber die Umwelt des Menschen. p. 53-61, May 1972.

Problems of and measures planned in West Germany to control air pollution are outlined. Air pollution, particularly due to carbon monoxide, sulfur and nitrogen oxides, fluorine, heavy metals, dust, and odors, represent health and corrosion hazards. Model experiments to elaborate adequate pollution abatement measures have been carried out. Clean air maintenance plans, including regional programs, the set-up and extension of monitoring networks, the use of low-emission raw materials, fuels, technologies, equipment, dust separators, gas cleaning equipment, and high stacks will be the basic means of abating air pollution. Further pollution standards, implying limitations on fuel sulfur content, will be introduced. Partial desulfurization of fuel and Diesel oil has been applied. The emissions from Otto engine vehicles will be successively reduced to 1/10 of the 1969 level by 1980. Carbon monoxide and hydrocarbon emissions have been limited as a first step, followed by a lead emission standard in 1971, requiring a maximum concentration of 0.4 g/l which will be further reduced to 0.15 g/l in 1976. As the possibilities to control emissions from conventional engines are limited, studies on new power sources are promoted. Radioactivity as created by human activity is negligible in comparison with the background level.

42874

AIR POLLUTION CONTROL POLITICS. (Immissionsschutzpolitik). Text in German. In: Bericht der Bundesrepublik Deutschland ueber die Umwelt des Menschen. p. 67-92, May 1972.

Tasks of the different lands in connection with the Clean Air Act, emitted Aug. 1971, as well as short and long-term programs are outlined. The basic activity of the land will lie in enforcement, set-up of expert teams, authorities, and institutions, as well as in the elaboration of regional standards. In Baden-Wuerttemberg, where dust, sulfur and nitrogen oxides, fluorine, and odors are the chief pollutants, the suppression of any further increase in the emissions is a long-term objective. Domestic heating and traffic are the main problems in West Berlin. Continuous air quality monitoring regarding fluorine, hydrocarbons, odorous substances, dust, sulfur and nitrogen oxides, hydrochloric acid, and oxidants is carried out in highly industrialized Northrhine Westphalia where increases in nuclear energy output and intensive growth of the chemical industry are observed.

<xref image="2000WV05.TIF|V3|2006:09:28:01:45:18.00|125096|0"> image: </xref>

dustry are the basic trends. Abating emissions levels, particularly in the Ruhr area, is the long-term goal to be reached, and emissions from 100 large industrial plants will have to be eliminated or reduced by 1975. Comprehensive air pollution measuring programs are run in Saarland. Measures planned in air pollution, noise and radioactivity control areas in other lands are reviewed.

43007

Douce, W. C.

THE AMERICAN PETROLEUM INSTITUTE S ACTIVITIES IN THE FIELD OF AIR AND WATER POLLUTION ABATEMENT. Oklahoma Eng. Exp. Sta. Publ., no. 97, 23(1):55-61, Dec. 1955.

The American Petroleum Institute has conducted work on pollution problems since 1921. With the formation of the Committee on Disposal of Refinery Wastes within the Division of Refining in 1930, action on waste control in the industry was vigorously promoted. The committee has published a five-volume manual on sources, types, and recommended methods of disposal of refinery wastes and has sponsored fundamental research work on the design of gravity oil-water separators, the effects of refinery wastes on aquatic life, air pollution, and the design of disposal equipment. Revisions of the manual are continually undertaken with many new topics discussed. Current research projects sponsored by the committee concern the applicability of a bio-assay method to natural bodies of water typical of those into which the petroleum refineries discharge wastes, the determination of the effects of long-time exposure to extremely low concentrations of fluorides in the atmosphere, the organization of available information on dust collecting devices, and the critical evaluation of available data on the acute and chronic toxicity for man and animals of selected chemical pollutants found in waste streams from petroleum refineries. In addition, much work has been done by the committee on air pollution, especially in California. With the growth of the petroleum industry, stronger abatement measures appear inevitable; however, final solutions to some of the more complex problems will take time and will be expensive.

Chung, Kyou Chull

AIR POLLUTION AND ITS CONTROL MEASURES IN EUROPEAN COUNTRIES AND THE U.S.A. (Gumi Gakguk eu daegi oyum gwa geu gwanri silate). Text in Korean. Taehan Uihak Hyophoe Chapchi. (J. Korean Med. Assoc.), 14(10):735-739, Oct. 1971.

Control measures in England started as smoke controls in 1819. Since then many measures have been adopted, such as the Alkali Works Regulation Act (1906), and the Clean Air Act (1956). In the U. S., an air pollution control district was organized in 1947. A U. S. technical conference was held in 1950. The National Air Sampling Network began work in 1953. The Clean Air Act was revised in 1963 and in 1967. Regulations for restricting smoke, other air pollutants, noise, and automotive exhaust have been set up since the Clean Air Committee was organized in 1955 in West Germany. Measures for protecting the public were enacted in France in 1917. In 1963, regulations were enforced to limit smoke, the sulfur content of oil, and auto exhaust. Emission standards in Japan for smoke, dust, and sulfur oxides according to various sources are given. Emission standards for smoke, dust, and sulfur dioxide in New York, Chicago, Los Angeles, England, Germany, and France are listed. Air quality standards in Japan for smoke, sulfur dioxide, and aldehydes and in California for sulfur dioxide, ethylene, hydrogen sulfide, hydrogen fluoride, carbon monoxide, oxides, and particulates are given. West German standards are given for nitrogen dioxide, SO₂, H₂S, and chlorine. The dust level in West Germany for residential and industrial districts is discussed. Russian air quality standards

for SO₂, mercury, hydrogen chloride, CO, Cl₂, NO₂, manganese dioxide, carbon disulfide, fluorine, bromine, and H₂S are listed. The air pollution warning level in Los Angeles for CO, oxides of nitrogen and sulfur, and ozone is mentioned.

Largent, Edward J.

FLUORIDES AND CLAIMS OF DAMAGE. In: Fluorosis. The Health Aspects of Fluorine Compounds. Columbus, Ohio State Univ. Press, 1961, Chapt. 13, p. 124-127. Deleterious biological effects attributed to air-borne fluorides have been reported in Italy, Switzerland, France, Germany, Australia, Norway, England, and the United States. However, there are few readily available records of the claims filed for recovery of alleged damages, of court trials, or settlements made out of court. Claims of damage to plants and animals appeared in almost epidemic numbers along the Delaware River in the Philadelphia area in 1944 and 1945. According to the information available, damage suits growing out of these allegations did not go to trial, and compensation for damage, if any, was made by out-of-court settlements. Since the beginning of this same period of time, a series of claims of fluoride-induced damage have appeared in Tennessee. One of the results of the allegations of damage or injury caused by fluoride contaminants in the atmosphere has been to stimulate extensive investigations of the biologic effects of fluorides. During the period 1944-1956, important research programs of this type were initiated in New Jersey, New York, Ohio, Oregon, Tennessee, Utah, Washington, and Wisconsin. Court trials have dealt with permissible tolerance levels for fluorides on apples and pears and the use of hydrofluosilicic acid as a preservative in beer. Hearings have been held relative to the use of chemicals in food and cosmetics, and attempts have been made in certain cities to prevent fluoridation of water by the use of injunction.

45783

LEGAL NOTE-LIABILITY FOR AIR POLLUTION. Public Health Rept. (U. S.), 74(2):104, Feb. 1959. 1 ref. In the case between the Reynolds Metals Company and Ytur-bide, the plaintiffs claimed they were poisoned by fluorides originating from the plant of the defendant. Their injuries were found by a jury to have been caused by excessive emission of fluorides by the defendant's plant. On appeal by the defendant the court of appeals, sustaining the verdict for the plaintiffs, held that the defendant's evidence of reasonable care in operation of the aluminum reduction plant was not sufficient to rebut the presumption that the excessive emission of fluorides was attributable to the defendant's negligence. A finding that excessive amounts of fluorides were deposited on the plaintiff's property from the plant whose construction, operation, and maintenance was under the exclusive control of the defendant could reasonably be accepted as circumstantial evidence of negligence.

MOSTLY PROTEST AGAINST CITY PLANNING. (Meist Proteste gegen die Stadtplanung). Text in German. Umwelt (Duesseldorf), 2(5):38[^]2, 1972.

<xref image="2000WVO6.TIF|V3|2006:09:28:01:45:20.00|120118|0"> image: </xref>

Hamburg is trying to get the help of each resident to combat environmental pollution. In order to create a green belt in the city, newlyweds were asked to plant a tree at a point of their own choice. Unfortunately the trees are threatened by automobile exhaust gases. The erection of an automatic air monitoring station at a cost of 1 million dollars is planned, as is the use of electrically driven garbage collection trucks. The planned erection of an aluminum plant in Stade met heavy opposition from public authorities. The emitted gases from such a plant which contain fluorine compounds which would be carried with the main wind direction East to Pinneberg, which has the largest tree nursery of the world. Another aluminum plant in Hamburg itself is scheduled to begin operation in 1973. Because of the regulations concerning fluorine emissions and red sludge, this plant will begin operation at a later date. Eight agencies deal with the protection of the environment. One environmental protection center coordinates information between the agencies. Since Mid-May of this year, an advisory panel of seven representatives of industry, research, and the public has been created, headed by the mayor of Hamburg. A first report by this panel concerning environmental protection will come out in November.

Frankenfeldt, R. E.

COMPARATIVE CONSIDERATION OF THE ENVIRONMENTAL PROTECTION REGULATIONS CONCERNING THE ALUMINUM INDUSTRY IN VARIOUS COUNTRIES. (Vergleichende Betrachtungen der Vorschriften zum Umweltschutz fuer die Aluminiumindustrie in verschiedenen Laendern). Text in German. Preprint, Gesellschaft Deutscher Metallhuetten und Bergleute, Clausthal-Zellerfeld (West Germany), 13p., 1972. (Presented at the Gessellschaft Deutscher Metallhuetten Bergleute-, Hauptversanunlung, Stuttgart, West Germany, April 26-30, 1972.)

The countries of West Germany, France, Great Britain, Italy, the Netherlands, Norway, Austria, Sweden, Switzerland, and Spain have laws concerning environmental protection which are of special interest to the aluminum industry. The laws in West Germany are listed as example. West Germany, Italy, Norway, Sweden, and Spain have laws specifically regulating the fluorine emissions. The regulations differ among the various countries. In Germany and in the Netherlands the regulations pertain solely to the emission of gaseous fluorides, this is, hydrogen fluoride. In Norway and Sweden the regulations pertain to both gaseous and particulate fluorine. The maximum allowable emission in the Netherlands is 0.4 kg gaseous F/t aluminum. In Norway the maximum allowable emissions are 1.0 and 2.6 kg gaseous and particulate F/t Al. Gaseous F is damaging to plants and ruminants. The laws and regulations affect only new industrial plants, with the exception of Germany and the Netherlands where already existing aluminum plants may have to comply with the law if its emissions affect the environment in any way. A short-term (0.002 mg gas F/cu m air) and a long-term (0.005 mg F/cu m) maximum allowable value will be issued for West Germany. In Italy the value of 0.020 mg gaseous and particulate F/cu m may not be exceeded during 24-hour measurements and 0.060 mg gas and particulate F/cu m during 30-minute measurements.

Humphreys, Vic

INDUSTRY GUIDE FOR CONTENDING WITH POLLUTION

CONTROL STANDARDS. Oilweek (Calgary, Can.), 23(29):16-17, 19, 22, Sept. 4, 1972.

Various Federal and provincial governments in Canada have established environmental departments, regulations, and legislation. Air quality standards have been established for fluorides, hydrogen fluoride, oxidants (as ozone), nitrogen oxides (as nitrogen dioxide), carbon monoxide, ammonia, lead,

hydrogen sulfide, sulfur dioxide, dust fall, suspended particulates, and soiling. Emission standards have been formulated for the pulp and paper industry, petroleum refineries, oil and gas production, and many other industries. Water quality standards and noise regulations have also been established.

Gaessler, Willi

EUROPEAN ENVIRONMENTAL PROBLEMS AND SOLUTIONS-AIR POLLUTION. Preprint, Sp., 1972. (Presented at the International Pollution Engineering Congress, Cleveland, Ohio, Dec. 4-6, 1972, Paper 8b.)

Air pollution regulations adopted and proposed for West Germany and for the European Economic Community as a whole are reviewed. Under existing West German laws, licenses are required for the construction and operation of plants and installations that generate large amounts of pollutants. Sulfur oxides emissions will be limited as soon as flue gas desulfurization processes are developed. Maximum emission values will be set or reduced for dusts, SO₂, nitrogen oxides, carbon monoxide, hydrocarbons, hydrogen sulfide, and fluorine and chlorine compounds. Limits have been established for CO and HC in automotive exhausts, and gasoline can contain no more than 0.4 g lead/l. Present (1969) and projected (1980) annual emission rates of the major air pollution sources in West Germany are summarized. The European Commission recognizes the need for a common policy in the field of air pollution control and has proposed a number of joint research and development projects. Activities to be carried out in 1973 are described.

Conway Research, Inc., Atlanta, Ga.

GEORGIA: BRIDGING THE GAP BETWEEN ECONOMIC IMPERATIVES AND ENVIRONMENTAL INTEGRITY. Site Sel. Handb., vol. 2:1-16, 1972.

Although the Georgia Department of Industry and Trade administers one of the biggest budgets in the country to attract new industry, the department will work only with firms whose prospective plants in Georgia will meet State and Federal water, air, and noise pollution regulations. In the matter of industrial pollution, the department works closely with the Air and Water Quality Control Sections in the Department of Natural Resources. The 1972 air and water quality standards developed by the two Sections are shown. Enforcement of the standards and regulations governing solid waste disposal is the responsibility of the Environmental Protection Division of the Department of Natural Resources. The 1972 standards tightened the original 1968 regulations, particularly with respect to ambient air standards and particulate matter from fuel-burning installations. New air quality and emission standards were set for sulfur dioxide, smoke, fluoride, and particulate emissions, asphaltic mix plants, Portland cement plants, nitric acid and sulfuric acid manufacturing plants, conical burners, incinerators, and cupola furnaces. Additional standards for fertilizer plants and cotton gins and source monitoring became effective in Sept. 1972. The new water quality standards tightened controls over thermal pollution, dissolved oxygen, and bacteria. State progress in water pollution control, surface mine reclamation programs, pesticide control, and solid waste management is described. Research programs of the Institute of Ecology and the Institute of Natural Resources, University of Georgia, are discussed.

Japan Environmental Agency, Tokyo, Bureau of Atmospheric Safety

INSTRUCTIONAL DATA ON MATERIAL CONCERNING THE ATMOSPHERIC SAFETY BUREAU, FROM THE ALL-JAPAN POLLUTION CONTROL ADMINISTRATORS CONFERENCE. (Zenkoku kogai kankei shukanka(bu)cho kaigi taiki hozenkyoku kankei setsumei shiryo). Text in Japanese. 104p., Feb. 1973.

Countermeasures on photochemical smog, offensive odors, urban air pollution, noise, and vibration are discussed. In 1972, 14 Prefectures issued warnings on photochemical smog, and the numbers of warnings increased in 13 Prefectures except in the Tokyo Metropolitan Area. The total warnings increased from 103 in 1971 to 176 in 1972. Air pollution monitoring networks for automatic measurements of sulfur oxides, nitrogen oxides, hydrocarbons, hydrogen fluoride, hydrogen sulfide, oxidants, ozone, and of metallic particulates were planned. In Dec. 1972, a new limitation for the allowable automotive exhaust gas was issued, and a remarkable decrease of exhaust gas pollution was expected. The environmental standards of some air pollutants in this country as well as in America, Russia, Sweden, Canada, and Czechoslovakia are also given.

52026

Toyama Prefecture (Japan) Public Nuisance Center ANNUAL REPORT ON POLLUTION CONTROL ACTIVITIES. NO. 1. 1971 AND 1972. (Gyomu nenpo, daiichigo. Showa 45, 46 nendo). Text in Japanese. 267p., Dec. 1972. The Toyama Prefecture Public Nuisance Control Center was constructed in June 1970, and further expanded and moved into a newly constructed Prefectural Government Office building in Aug. 1972. The Center comes under the jurisdiction of the Department of Environmental Protection of the Prefectural government. The physical structure of the center consists of an automatic and continuous air pollution monitoring room on the top floor, the pollutant chemical analysis room, the air pollution experimental lab, the standard gas experimental lab, an air analysis room, an odor experimental lab, and various other analysis rooms. There are similar but smaller labs for water pollution and solid waste. The center is staffed by 31 persons. This annual report presents a comprehensive study and statistics compiled by the center including special investigations in various areas with air pollution problems, investigation of fluoride gases, investigation of complaints by questionnaires, measurements of soot, dust, and suspended particulates in various electric furnace areas, inspections of designated factories, measurements of fuel sulfur content, inspections of toxic gas emission facilities, the records of continuous monitoring on settling particles and sulfur oxides, studies on heavy metal pollutants in the air, studies on particulate sizes and crystalizations, and investigations on automotive emissions. The average suspended particulates range from 0.100 mg/cu m in the busiest center city and factory areas to 0.06 mg/cu m of suburban agricultural areas.

ENVIRONMENTAL SURVEILLANCE FOR FUEL FABRICATION PLANTS. Battelle Memorial Inst., Richland, Wash., Pacific Northwest Labs., Atomic Energy Commission Contract AT(45-1):1830, 71p., April 1973. 70 refs. NTIS: BNWL-1723 An environmental surveillance program for air, water, and other media is presented for fuel fabrication plants; the program is sufficiently general to cover plants fabricating uranium oxide or mixed uranium and plutonium fuels and is not specific to a particular plant. It provides for surveillance of media believed either to be significant in terms of dose to man or to be potential centers for long-term accumulation of contaminants. Surveillance of the air is treated in terms of equip-

ment and techniques for sampling, quality controls, and the potential for pollution from radionuclides, fluorine compounds, and nitrogen compounds. Regulations and standards for nuclear plants are discussed.

Engineering-Science, Inc., McLean, Va.
FIELD SURVEILLANCE AND ENFORCEMENT GUIDE FOR
PRIMARY METALLURGICAL INDUSTRIES. (FINAL REPORT). Office of Air Quality Planning and Standards Contract 68-02-0627, Program Element 2A5137, Rept. EPA-450/3-73-002, 379p., Dec. 1973. 49 refs.

A step-wise enforcement procedure intended for use by state and local air pollution control agencies is presented in manual form. Included are process descriptions, a discussion of emission sources, typical control devices, stack gas and process monitoring instrumentation, and inspectors worksheets for such primary metallurgical operations as the iron and steel, aluminum, copper, lead, and zinc industries. All major operations in each of these are analyzed, including an enforcement procedure for the storage and handling of raw materials. Upset conditions and abnormal operating circumstances are examined in relation to their role in air pollution. Examination of the major pollutants from these five industrial categories provides the most concern for particulates. Sulfur oxides and fluorides are also of concern in specific metals operations. Sections on the inspection of pertinent air pollution control devices are also provided. (Author abstract modified)

Durand, G.
ADR POLLUTION. LAWS - DECREES AND REGULATIONS. SUMMARY AND COMMENTARIES. (Pollution atmosphérique. Lois - Decrets et reglements. Resume et commentaires). Text in French. Commission Eau et Pollution Atmosphérique, CT/MTP Service 526 67-456, 13p, April 1967.
Clean air maintenance-related laws, decrees, and regulations enacted in France during the last years are reviewed. The Law of Aug. 1961, blaming domestic heating, industries, and automobile traffic for causing air pollution by such substances as carbon monoxide, sulfur dioxide, and fluorine, which are regarded as the most dangerous air pollutants are discussed. The Sept. 1963 Interdepartmental Decree, along with the Aug. 1964 Decree, call for the limitation of combustion-generated air pollutant emissions in special protection zones in urban areas such as Paris. Bans on the use of solid fuels with high volatile contents, and of fuel oils with high sulfur contents hope to achieve this goal in protection zones. Regular inspection of combustion equipment and the employment of qualified personnel are required.

Air Management Research Group
REPORT OF THE POLICY PANEL ON ABATEMENT
TECHNOLOGY. In: Air Management Problems and Related
Technical Studies, p. 163-172, 1972.
The results of a panel on abatement technology are reviewed. The general situation and abatement problems are reviewed in the area of fuel combustion, the emission of fluorides from
<xref image="2000WVO8.TIF|V3|2006:09:28:01:45:28.00|124795|0"> image: </xref>

primary aluminum smelting and production of phosphate fertilizer, abatement techniques for particulates and odors, and emissions from motor vehicles. Results are presented of a questionnaire listing specific abatement problems, interest in these problems, work in progress, and further research in the countries of the Organisation for Economic Co-operation and Development.

64940

A GUIDELINE FOR THE EVALUATION OF ENVIRONMENTAL EFFECTS (A PROGRESS REPORT). (Kankyo eikyo hyoka no unyojo no shishin ni tsuite (chukan hokoku). Text in Japanese. Kenkocho Kogai Senmon Shiryo (Public Nuisance Gaz.), 9(4):24-35, July 1974. Standards for environmental protection are based on human health, purity of living environment, and conservation of the natural environment. New environmental standards are required for newly recognized pollutants while existing standards must be reviewed constantly and revised when necessary. Pollutant standards which have been studied include those for hydrocarbons, lead, and fluorides. The most basic condition for evaluating the environmental effect is complete information on pollution sources, population, traffic, and meteorological data. In air pollution evaluation, in addition to sulfur oxides, nitrogen oxides, carbon monoxide, and airborne particulates, predictions of other industrial pollutants must be carried out by diffusion models. Meteorological conditions required for the prediction include average temperature, amount of precipitation, and wind velocity. Air pollution from fixed sources are evaluated by the type of fuel used and their total consumption, and those from moving sources are evaluated by total numbers of vehicles and traffic and road conditions.

Smith, Clifford V., Jr.
OREGON. PROPOSED REVISION TO IMPLEMENTATION PLANS. Federal Register, 39(199):36602-36603, Oct. 11, 1974. Proposed revisions to the Oregon implementation plans are announced. The revisions establish specific emission standards for fluorides and particulate matter for new and existing primary aluminum plants. For new plants total fluoride emissions cannot exceed 1.3 Ib/mo/ton Al or 1.0 Ib/yr/ton Al. Any one plant cannot exceed 12.5 ton/mo. Total particulate matter emissions cannot exceed 7.0 Ib/ton of Al and an annual average of 5.0 Ib/ton Al. Visual emissions from any source cannot exceed 10% opacity or 0.5 on the Ringelmann Smoke Chart. For existing plants, total fluoride emissions cannot exceed 3.5 Ib/mo/ton Al or 2.5 Ib/yr/ton Al. Any one plant cannot produce 22.0 tons F/mo. Total particulate emissions cannot exceed 13.0 Ib/mo/ton Al or 10.0 Ib/yr/ton Al. Visible emissions from any source cannot exceed 20% or 1.0 on the Ringelmann Smoke Chart. Regular monitoring and reporting of progress by the sources are required.

67888

Hager, J.
THE LICENSING PRACTICE FOR BRICK KILNS IN BAVARIA. (Aus der Genehmigungspraxis bei Ziegeleien im bayerischen Raum). Text in German. Gesundheits-Ingr., 95(9):253-257, 1974. 10 refs. (Presented at the Second Symposium on Branch-specific Emissions, Fluorine Emissions by Brick Kilns, Munich, Germany, Feb. 1, 1974.)
Brick kilns emit hydrogen fluoride and other fluorine compounds. Injuries to vegetation in the vicinity of such plants have become increasingly known and are due to stacks being too low. Therefore brick kilns have been included in the list of industrial plants which require an operating license. Difficulties arose, however, because fluorine emissions from brick

kilns are subject to considerable fluctuations which cannot be foreseen. Therefore a new licensing method was adopted in which a limit concentration of 30 mg F/cu m in the waste gas referred to 3 vol% CO₂ is used. The procedure differs depending on whether a stack exists or not. In the case of the existence of a stack, a limit value of the pollutant concentration is determined with the aid VDI (Verein Deutsche Ingenieur)-guideline 2289. In the case of the absence of a stack, a stack height calculation is performed using the mentioned limit value.

Shizuoka Prefecture! Government (Japan)

ENVIRONMENTAL POLLUTION CONTROL PROJECT.

(Kogai boshi keikaku). Text in Japanese. In: 49 nenban Kogai Hakusho (Environmental White Paper, 1974), p. 335-340, 1975. The procedure for formulating pollution control plans is discussed. The 5-year pollution control plan for Fuji district (including two cities and four townships) which was put into effect in Dec. 1973 is described. The air pollutant concentration standards are as follows: sulfur oxides, 1-hour value 0.1 ppm and daily average 0.04 ppm; suspended particulates, 1-hour value 0.20 mg/cu m and daily average 0.10 mg/cu m; nitrogen oxides, daily average 0.02 ppm; and hydrogen fluoride, yearly average 0.02 ppm. The present value and target value of water pollution load (biological oxygen demand) for eight rivers and one bay are given. The air pollution control measures to be taken by industries are desulfurization and low sulfur content fuel for SO_x, fuel conversion and electrostatic precipitator for suspended particulates, improvement in combustion methods and denitrification for NO_x and alkali washing for HF. The pollution control measures to be taken by industries and municipalities for water, noise, and malodor pollution are also described. The total budget for the 5-year plan is \$90,000,000 for industries and \$70,000,000 for municipalities.

Ehime Prefectural Government (Japan), Div. of Life and Environment

ENVIRONMENTAL POLLUTION IN EHIME PREFECTURE

IN 1974: AIR POLLUTION CONTROL MEASURE. (Ehime no kogai: taiki osen boshi taisaku). Text in Japanese, p. 41-78, 1975.

The environmental pollution monitoring, measurement, and control measures based on the Ehime Prefectural environmental control regulations issued in Oct. 1969 and revised in March and July 1971 are reviewed. The environmental standards for sulfur oxides, carbon monoxide, nitrogen oxides, suspended particulate, and oxidant are given. The administrative system for emission control regulations, emission control methods, and emission standards for emission sources and pollutants are described. The total emission quantity control method introduced in March 1974 for sulfur dioxide is described with characteristics of simulation calculation and simulation method. The emission source control for boilers and furnaces is discussed with statistical data. The data on fluorine, hydrogen fluoride, chlorine, hydrogen chloride, and hydrogen sulfide concentrations measured at emission sources are given. The environmental monitoring system, emergency

<xref image="2000WV09.TIF|V3|2006:09:28:01:45:32.00|118003|0"> image: </xref>

communication system, and emergency procedures are also discussed. As for photochemical smog, the NO_x concentration is constantly monitored at emission sources and oxidant concentration is measured.

Varkonyi, Tibor and Magdolna Kerteszne-Saringer
AIR POLLUTION MONITORING SYSTEM IN HUNGARY. (A legkori levegőszennyezés ellenőrzésének rendszere Magyarországon). Text in Hungarian. Energiagazdalkodás, 16(10):464-466, Oct. 1975.

The national air pollution monitoring system being set up in Hungary under the guidance of the Ministry of Public Health is described. The network will be operated by the Sanitary Epidemiological Stations in cooperation of the National Institute of Public Health. A total of 438 sampling stations will be installed in 28 communities in the first step of the project. The sulfur dioxide, carbon monoxide, nitrogen oxides, fluorides, dust, and dust lead concentrations will be measured. The use of Philips SO₂ monitors and URAS CO recorders is envisaged.

76847

Fukuoka Prefectural Government (Japan), Bureau of Public Health

AIR POLLUTION COUNTERMEASURES. (Taiki osen taisaku). Text in Japanese. In: 1974 Environmental White Paper, p. 95-123, Jan. 1975.

Air pollution countermeasures taken in Fukuoka Prefecture, Japan, in accordance with various 1973 air pollution control regulations for sulfur dioxide, carbon monoxide, airborne particulates, nitrogen dioxide, and photochemical oxidants, are reviewed. A telemetry network, covering the entire prefecture, has been in operation since September 1974. Pollutant values in compliance with the new standards were observed at only a few of the monitoring locations. In Fukuoka Prefecture, K values for sulfur oxides range from 4.67 to 17.5, under the standards established on April 1, 1974. Maximum ground concentrations (ppm) are proportional to K values: A K value of 17.5 corresponds to SO_x concentration of 0.03 ppm. In Fukuoka Prefecture, at the end of 1973, there were 4612 soot-emitting facilities in 1897 enterprises, registered according to law. Forty percent of the facilities were located in Kitakyushu City. A system of alerts for sulfur oxides and photochemical smog has been established, in cooperation with Kumamoto Prefecture. On-site factory inspections have been conducted for sulfur oxides, soot, and toxic substances. Environmental protection agreements have been made by various Fukuoka cities and industries located in them. Emissions of cadmium (zinc refinery, Omuta City; emission standard, 1 mg/N cu m) hydrogen fluoride (aluminum refinery, Omuta City; total amount standard, monthly average value of emission, based on hourly values, 4.64 kg/H). Wind tunnel experiments and diffusion calculations were conducted in Kitakyushu City and Omuta City. Fuel standards are being established.

76965

GOVERNMENT ORDINANCES TO DECIDE DATE OF ENFORCEMENT OF PARTIAL AMENDMENTS TO AIR POLLUTION CONTROL LAW. GOVERNMENT ORDINANCES FOR THE PARTIAL AMENDMENT OF AIR POLLUTION CONTROL LAW ENFORCEMENT ORDINANCES. ORDER FROM PRIME MINISTER'S OFFICE ON THE PARTIAL AMENDMENT OF ENFORCEMENT PROVISIONS TO AIR POLLUTION CONTROL REGULATIONS. (Taiki osen boshi no ichibu o kaisei suru horitsu no shiko kijitsu o sadameru seirei. Taiki osen boshiho shikorei no ichibu o kaisei suru seirei. Taiki osen boshiho shiko kisoku no ichibu a kaisei suru sorifurei). Text in Japanese. Taiki Osen Nyusu (Air Pollution News), no. 87:7-16, March 1975. The text of the order from the Japan

Prime Minister's Office (Order No. 71, November 30, 1974) is reproduced. Summaries of two government ordinances and a set of partial amendments to air pollution control regulations to which these ordinances apply are also included. Government Ordinance No. 374 sets the date of enforcement of regulations (Law No. 65, 1974), partially amending the air pollution control regulations, to be November 30, 1974. The partial amendments (Law No. 65, 1974) include the following points: Prefectural governors can establish more stringent schedules for reduction of total amounts of smoke (sulfur oxides) emission, subject to approval by the Prime Minister's Office, in designated pollution regions where maintenance of environmental standards is difficult by present procedures. Prefectural governors can order improvement in smoke treatment installations and order other necessary changes (such as fuel conversion). Fines will be levied for non-compliance. Government Ordinance No. 375 amends Air Pollution Control Regulations Enforcement Order (Ordinance No. 329, 1968) as follows. Types of smoke are defined by their content of sulfur oxides. Part of metropolitan Tokyo is to be included as one of the designated pollution regions. Desired Atmospheric environmental standards for smoke emission should be attained in March 1978, with due regard given to practical aspects of equipment installation and factory operation. Jurisdiction of the Department of Atmospheric Control is enumerated. Misprints in Ordinance No. 329 are corrected. Explanatory excerpts from the Air Pollution Control Regulations (Law No. 97, 1968) and the Basic Pollution Control Regulations (Law No. 132, 1965) are included. According to Law No. 97, smoke, as defined by law, in addition to sulfur oxides and products of combustion synthesis, and decomposition, also includes cadmium, chlorine, hydrogen fluoride, and lead.

77234

Central Council for Environmental Pollution Control (Japan),
Planning Committee

LONG-TERM PROSPECTUS FOR PRESERVATION OF THE
ENVIRONMENT: AN INTERIM REPORT, p. 1-71, 1974.

Air pollution as well as water pollution and refuse are included in the long-range environmental considerations. Pollution forecasts are made for 1985 for Japan as a whole, with sulfur considered as a typical air pollutant. Pollution forecasts are made for 1980 for various regions of Japan, considering soot and particulates as well as sulfur. The increased public desire for environmental improvement is discussed. A model is used to predict the economic effects of environmental protection. Advances in environmental technology are predicted, including development of an effective carbon monoxide elimination device for automobiles and an economical device for eliminating hydrogen fluorides in 1977, and development of an economical catalyst for eliminating the emission of nitrogen oxides from stationary sources in 1978. Maintaining an environment which protects human health is stressed as the primary objective of environmental planning.

CURRENT CRITERIA FOR THE CONDITIONS FOR THE
EMISSION OF GASEOUS FLUORIDE COMPOUNDS FROM

BRICKWORKS. (Aktuelle Bewertungsmaassstaebe fuer die Bedingungen der Emission gasfoermiger Fluorverbindungen aus

<xref image="2000WVOA.TIF|V3|2006:09:28:01:45:36.00|113313|0"> image: </xref>

Ziegeleien). Text in German. Ziegelind. (Weisbaden), no. 4:139-141, April 1975. 3 refs.

Emissions criteria for gaseous fluoride compounds generated by brickworks are reviewed as set forth in the Federal German Emission Control Law. A general emission limit of 30 mg fluoride/cu m flue gas is specified at 3% carbon dioxide, a temperature of 273 K, and a pressure of 1013 millibar. Gaseous fluoride emissions of up to 200 mg/cu m exist at various brickworks in North Rhine Westphalia where special control measures are not being used. Over 50% of these uncontrolled operations are emitting fluorides at levels of over 30 mg/cu m. Emission values for hydrogen fluoride are also specified by the clean air regulations.

ENVIRONMENTAL POLLUTION BY INDUSTRIAL GASES CONTAINING FLUORINE. (Zagadenje okoline industrijskim gasovima sa fluorom). Text in Serbo-Croatian. Tehnika, 28(7):1251-1256, 1973.

The origin of the fluorine content of gases, their effect on the environment, and the levels at which they may be tolerated in the atmosphere are described. The Yugoslavian aluminum industry has been expanding rapidly and better information and legislation in this area are necessary. Available data on safe pollution levels are all from other countries and there is disagreement as to the proper limits. The USSR and Czechoslovakia allow 8 mg fluorine per cu mg of air as a permissible 24-hr average. Some Western European industries are allowed up to 7 mg, while the limit in the U. S. is 5 mg. Standards for maximum concentrations at plant sites, methods of measuring emissions and environmental levels, the influence of alum hydration on hydrogen fluoride formation, and effect of pollution on plant life in industrial areas are discussed.

McManus, T.

AIR POLLUTION IN IRELAND. Inst. for Industrial Research and Standards, Dublin (Ireland), Air Pollution Symp. Proc., Dublin, Ireland, 1972, p. 77-97. (March 22.)

There is a dearth of firm information on levels of air pollution in Ireland. The Department of Local Government operates volumetric sulfur dioxide and smoke apparatus in Dublin, Cork, and Galway. The smoke concentration peaks at about 230 microgram/cu m in winter in Dublin, while in summer levels drop dramatically. The E.S.B. has had 28 volumetric SO₂ and smoke monitors located around Dublin since 1970. Air pollution levels in central Dublin are significantly lower than the average of British urban areas. Air pollution control legislation in Ireland is discussed. An interdepartmental working party has been set up to produce a draft policy on the control of both air and water pollution. Domestic sources contribute major amounts of pollution in Ireland. The Institute for Industrial Research and Standards has operated an industrial air pollution control service since the middle of 1970. The specific pollutants investigated during the first 18 mo include dust, sulfur dioxide, odors, metals, solvents, smoke, fluoride, cyanide, wet plumes, and carbon monoxide. High stack policies in Ireland will probably be affected by new European standards to control international atmospheric transport of pollutants. A mobile monitor for SO₂ concentration was recently introduced.

AIR QUALITY MONITORING IN NORTH RHINE WESTPHALIA. (Luftqualitaetsueberwachung in Nordrhein-Westfalen). Text in German. In: Grundlagen Lultreinhalting Laermbeakaempfung Nordrhein-Westfalen, vol. 2:52-61, 1975. 16 refs.

The principles, status and prospects of air quality monitoring

in Northrhine-Westphalia are described. Air quality monitoring serves the acquisition of information on background concentrations as a basis of licensing procedures for planned emission sources, air pollutant concentration monitoring for smog alarm, and for compliance control and for the substantiation of additional emission control measures. At present, there are three hierarchic monitoring networks, including a mobile network for random sampling of sulfur dioxide, dustfall, fluorine compounds, nitrogen dioxide, total organic carbon, and suspended matter at about 4000 sampling sites. This network furnishes data for licensing decisions. Another partly automated network of 71 stations is used to measure suspended matter and heavy metals, e.g., arsenic, and other carcinogenic metals. The mobile stations will be increasingly used for the monitoring of organic substances, e.g., benzene and its homologs, formaldehyde and related compounds. A fully automated real-time telemetric network, comprising presently 15 SO₂-monitoring stations, is used partly for the measurement of carbon monoxide, NO₂, and nitric oxide. This network furnishes data for smog alarms.

ADMINISTRATIVE STEPS. (Gyosei taio). Text in Japanese. Preprint, Japan Society of Air Pollution, Tokyo, p. 222-230, 1975. 11 refs. (Presented at Japan Society of Air Pollution Annual Meeting, 16th Niigata, Japan, Nov. 5-7, 1975, Paper 9513.)

The Niigata Prefectural Administration's policy for environmental pollution, primarily fluoride emissions from the aluminum refineries in the Joetsu area, is discussed. The Joetsu area comprises the Noetsu littoral industrial belt, chiefly heavy chemical industries. The major gaseous fluoride emission, 67 kg F/day, is traceable to the electrolytic furnaces of the aluminum refining process. Legal regulations for fluoride emissions control include the Niigata Prefectural Environmental Pollution Act of January 1970, the Air Pollution Prevention Act of the Ministry of Health and Welfare and the Ministry of International Trade and Industry, promulgated in June 1971, and the Niigata Prefectural Ordinance 52 of December 1971. Agricultural damage has been significantly and rapidly increasing since the aluminum refineries started their operation in the Joetsu area in May 1963, and the cause of the damage has been determined to be fluoride contamination of the air. After several revisions of the regulations for fluoride emissions control, the mean value of the fluoride emission is now restricted to below 1.3 microgram F/cu m/10 day, and the agricultural conditions are gradually improving.

began in 1964; pollution control regulations were promulgated in 1970. Fukushima Prefecture and Iwaki City established a joint pollution control center in January 1972. Telemetric monitoring and warning systems are in effect. Photochemical smog and inversion layer monitoring have been undertaken. Standards have been established for toxic substances unique to Fukushima Prefecture (zinc and copper and their compounds; hydrogen cyanide; hydrogen phosphide). Standards stricter than national standards have been established for cadmium and its compounds, chlorine, hydrogen chloride, fluorine, hydrogen fluoride, silicon fluoride, and lead and its compounds. In 1975, Fukushima Prefecture concluded an agreement with 9 enterprises in the Iwaki region, for reduction of emissions of sulfur oxides, from the present hourly level of 2318 cu m to 989 cu m by the end of 1978.

RELATIONSHIPS BETWEEN ENVIRONMENTAL PROTECTION AND PUBLIC HYGIENE IN KOMAROM COUNTY

(HUNGARY). (A környezetvédelem és közegészségügy összefüggései Komárom megyében). Text in Hungarian. Budapest! Közegészségügy, no. 1:16-19, 1975. 11 refs.

General environmental and hygienic problems of Komárom county, Hungary, are reviewed. This county has the highest population density and highest level of urbanization and industrialization in the entire country. Accordingly, the air pollution levels measured in this county are among the highest country-wide. In Tatabánya, a highly industrialized town, the settling dust, total sulfur, and sulfur dioxide concentrations are substantially higher than the hygienic standards. The total sulfur and SO₂ concentrations are further increased by domestic heating during the winter months. The fluorine concentrations measured in a 2000 m radius around an aluminum smelting plant exceed the maximum allowable concentrations. The measures taken so far (construction of high stacks, dust separation in industrial plants, neutralization of fluorine-containing waste gases, and liquidation of residential districts near polluting industrial plants) have not been sufficient for a substantial improvement of the environmental quality. The incidence of respiratory tract diseases is above the national average, which may be due to air pollution.

84415

STATUS REPORT. National Research Council Canada, Ottawa, Associate Committee on Scientific Criteria for Environmental Quality, 90p., Jan. 1976.

The status report of the Associate Committee on Scientific Criteria for Environmental Quality is presented. The following priorities are identified for study by the Subcommittee on Air: mixed system involving sulfur dioxide such as SO₂ in presence of particulates associated with power plants, SO₂ with hydrogen fluoride associated with fertilizer plants, and other special situations; automobile exhaust including hydrocarbons, carbon monoxide, lead, and benzopyrene; and miscellaneous systems not found in the other classes.

FARMERS AWARENESS OF HEALTH IN POLLUTED ENVIRONMENT. (Kankyo osen chiku nomin no kenko ishiki ni tsuite). Text in Japanese. Preprint, Japan Assoc. for Rural Medical Care, 23(3):284-285, 1974. (Presented at the Japan Association for Rural Medical Care, General Conference, 23rd, Shizuoka, Japan, Oct. 1974.)

In recent years, trees around a ceramic tile factory in a small village in Toyama Prefecture began to die; since the tree damage was concentrated around the factory, the local residents began to question and blame the factory management, and this became a political issue. First, sulfur oxides were suspected, but the measurements were low enough so that the trees would not have been affected. After further search, it was found that fluorine in the glaze had polluted the air of an area of 250 m radius around the factory, and the concentration was as high as 100 ppm in the entire area. This developed into a law suit against the factory management. But when health examinations were given to the village residents, of the total 439 residents of the polluted area, 115 did not receive an examination. This was 26.2% of the total population; to compare their health consciousness with others, 420 residents of control area were invited for examination and 38.6% did not comply. The reasons given were: 24.5% of men and 32.5% of women answered they felt perfectly healthy, 21.8% of men and 9.1% of women answered that they received examinations elsewhere. This data shows the level of awareness of the resident concerning their health and air pollution. Although there were no symptoms of damage among the people who received a health examination, physicians wished that more people would show more concern about their own health.

THE PRESENT STATUS OF AIR POLLUTION. Clean Air Heat Management (Tokyo) 15, (7-8) 7-18, Aug. 1966. Jap. The present status of air pollution in Japan is given naming the kinds of contaminants and their origin, factors affecting contamination density, and various types of smog. The types of contaminants are: 1) minute particles (less than 1 micron in size) such as found in soot, carbon, ashes, dust; 2) coarse particles (greater than 1 micron in size), as found in dust, ashes, and minerals; 3) reactive substances found in mist, fog, and vapor such as SO₂, SO₃, H₂S, CO₂, CO, NO₂, N₂O₃, O₃, aldehydes, HCl, NH₃, HF, Pb, Hg, Cd, As, Be and 3, 4-benzopyrene. The contaminants originate from factories, chemical plants, power stations, domestic heating, public baths, hotels, laundries, dry cleaning establishments, hospitals, schools, and public buildings. Also discussed are the human factors affecting air pollution such as public awareness and interest, seasonal, weekly, and daily changes in heating and cooking. Meteorological aspects are covered such as wind direction and velocity, turbulence, temperature, rain and snow. The types of smog found in New York, London, Los Angeles, Pittsburgh, and Yokkaichi are described. Graphs and tables list symptoms and diseases affecting plants and humans and give the density of dust particles and SO₂ in the main cities of Japan. Data on the sulfur content of various oils produced by Japanese refineries and on the number of Japanese automobiles produced is included for information on emission sources of pollutants.

Harris, Robert L., Jr.

AIR POLLUTION. Preprint, Ohio Cooperative Extension Service, Columbus, Ohio Dept. of Agriculture, Columbus, and Ohio Agricultural Council, 16p., 1969. (Presented at the Conference on Pollution Control - Air, Soil, Water, Columbus, Ohio, Feb. 13, 1969.)

After a brief general discussion of air pollution, the interrelationships between air pollution and agriculture are enumerated. Serious effects on agricultural crops and livestock are caused in particular by atmospheric sulfur dioxide, photochemical oxidants, and fluorides. At the same time, many agricultural operations add to air pollution. Prescribed forest burning, burning of logging debris or for range improvement or seed bed preparation, and burning of crop residues for disease and pest control add millions of tons of particulate matter to the air. Windblown soil, much of which results from agricultural tillage, is distributed through the atmosphere for great distances. Use of pesticides has created an entire range of pollution problems, and agricultural industries such as alfalfa dehydrating, cotton ginning, grain milling, and animal products processing cause serious emissions, often of odorous pollutants. The major elements of the Federal air pollution control program are outlined, including a brief description of the Air Quality Act of 1967, of the designation of air quality control regions, and of some of the problems involved in determining air quality standards and criteria.

NEW CONTROL METHODS FOR THE GATHERING AND TREATMENT OF GASES WITH FLUORINE CONTENT FROM ALUMINA ELECTROLYSIS. (Methode noi de control la captarea si tratarea gazelor cu continut de fluor de la electroliza aluminei). Text in Romanian. Rev. Chim. (Bucharest), vol. 20:445-447, July 1969. 2 refs. By developing new methods of determining the content of NaF, NaAlO₂, and Na₂SO₄ in the wash water used for recovering HF, it is possible to reduce by half the time required for checking the recovery process in the aluminum plant laboratory. Detection of NaF is by titration of a solution

adjusted to a pH of 2.7 with $\text{Th}(\text{NO}_3)_4$ in the presence of Alizarine S. The NaAlO_2 is titrated with a 1N solution of HCl until permanent turbidity is reached, then titrated with bromothymol blue until greenish-yellow. The sulfate is determined by titration with BaCl_2 dissolved in acetone or alcohol, in an acetic acid milieu, with Alizarine S as an indicator.

SECOND REPORT OF THE (SWISS) FEDERAL COMMISSION FOR AIR HYGIENE TO THE FEDERAL INTERIOR DEPARTMENT (1962-1967). (Zweiter Bericht der Eidgenössischen Kommission für Lufthygiene zuhanden des Eidgenössischen Departements des Innern) (1962-1967). Text in German. Bull. Eidgenöss. Gesundheitsdienst, Beilage B, No. 3, 1968. 25 rels.

A survey of the activities of the Swiss Federal Commission for Hygiene, and a list of publications by its members, is followed by a discussion of the sources and the extent of air pollution in Switzerland. Also examined are the dispersion and dilution of pollutants, their effects on plants, animals, and humans, and control technology. In conclusion, existing regulations are reviewed. Domestic heating systems, motor vehicles, and industries are found to be main sources of pollution. In summer, air pollution is negligible in rural areas and in many urban residential areas. In winter, emissions caused by domestic heaters become apparent. On some winter days the SO_2 content exceeds 0.3 ccm/cu m. In the vicinity of some industries, considerable amounts of dust, soot and smoke are accompanied by disagreeable odors. However, no health impairment in humans has yet been reported. Emissions of fluorine compounds have injured plants and animals. Because of demographic and economic developments, it is assumed that the extent of air pollution will increase. Recommended preventive measures include obligatory inspections of heating aggregates, adequate chimneys on each home, regular sweeping of the chimneys, limitation of the sulfur content of fuels for domestic heaters to 0.5%, and centralization of home heating systems. As far as motor vehicles are concerned, highways, when possible, should bypass villages and cities. The flow of traffic in inner city areas should move quickly. Limits must be established for industrial emissions, suitable sites selected for new industrial complexes, and regulations governing domestic heaters standardized.

CHEMICAL ASPECTS OF ATMOSPHERIC POLLUTION.

(Les aspects chimiques de la pollution atmospherique). Text in French. Ind. Chim. Beige, 34(9):739-744, 1969. 21 refs. (Presented at a Symposium Sponsored by the International Union of Pure and Applied Chemistry, Cortina d'Ampezzo, Italy, July 9-10, 1969.)

The symposium papers to be published in the journal 'Pure and Applied Chemistry' covered the following topics: the toxic aspects of atmospheric pollution and recommended limits on concentrations of 24 pollutants; a method of determining the surface area of very small particles; simple methods of separating aerosols by particle size; the influence of certain substances on the transport of hydrolysable ions; the deleterious effect of fluorides on the flora and, indirectly, on the fauna as well; techniques for sampling, isolation, and quantitative analysis of F compounds; different varieties of 'smog'; a method for correcting benzo(a)pyrene determination for the concomitant benzo(k)fluoranthene; polycyclic aromatic hydrocarbons in the exhaust gas of internal-combustion engines; applications of analytic methods for determining polycyclic compounds; several methods of determination of Pb compounds in air; and a survey of the distribution of traces of pollutants in the atmosphere. Oxygen obtained by distillation of liquefied air is polluted by automobile-exhaust and industrial waste gases. The application of the interface electrode of extremely high sensitivity in air pollution studies and the use of mathematical models in air pollution investigations which would reduce the cost and expenditure of time required for an extensive test program were also covered.

APPLICATIONS OF AEROSPACE TECHNOLOGY IN AIR

POLLUTION CONTROL. (FINAL REPORT). NASA Contract

NSR-34-004-056, RTI UE-411-3, 65p., June 1969. CFSTI: N69-36186

The Technology Application Team of the Research Triangle Institute, Research Triangle Park, N. C. acts as an information and technology interface between the National Aeronautics and Space Administration and National Air Pollution Control Administration and as a catalyst among the various sources of information involved in the technology. It identifies very specific technology-related problems and prepares air pollution problem abstracts on each specific requirement which describes the problems in a concise manner using functional nondisciplinary terminology. The specifically described problems include automobile drivers performance tests; remote temperature and wind vector sensing techniques for the lower 2 km of the atmosphere; long-term geophysical effects of carbon dioxide and of particles in the 0.2 to 0.5 micron size range; development of advanced pollutant sensors for methane, sulfur dioxide, fluorine, carbon dioxide, total hydrocarbons, carbon monoxide, nitric oxide, nitrogen dioxide, and total oxides of N₂; improvement of adsorption and absorption techniques for removing pollutants from carrier gas streams; instrumentation for the investigation of flame chemis-

try; effect of trace quantities of metals and impurities on pollutant identity and output in combustion; analytical techniques for the trace metals in combustion effluent and waste gases from metal processing, both in collected particles and in situ; fluidized bed combustion processes; working fluids for Rankine cycle engines; heat transfer to small gas-borne particles; physical consideration in optimizing fuel-air mixture; measuring techniques for air-borne particulates; and gas exchange capacity of lungs. Other problems mentioned, but not specifically described are odor classification and identification; development of advanced pollutant sensors for As, Be, Hg, Ni, NH₃, carcinogens, Cl and HCl, H₂S, V, ozone, Br, Ce, F, I, Pb, reactive hydrocarbons, and Cd; holographic techniques for measuring particulate flux, and combustion chamber aerodynamics.

21287

MAINTENANCE OF CLEAN AIR. (Reinhaltung der Luft).

Text in German. Oel Gasfeuerung, 14(10): 1020-1024, 1969.

The major sources of air pollutants are industries, vehicles, and domestic heating. In the industrial sector, power plants, cement kilns, steel plants, and the chemical industry are the primary sources for pollution. Air pollutants may affect humans, animals, and plants. The harmfulness of dusts is determined by their composition, grain size, and shape. Fine dust particles which penetrate into the lungs are particularly dangerous. Soot requires special attention because it may be a carrier of toxic and carcinogenic substances. The most dangerous gaseous pollutants are carbon monoxide, sulfur dioxide, fluorine, chlorine, and unburned hydrocarbons. The federal government is sponsoring a program of air monitoring and research and development; it took legal measures to avoid or reduce air pollution. Large industrial plants must fulfill stringent regulations laid down in the 'Technical Directives for the Maintenance of Clean Air'. The federal law on preventive measures for the maintenance of clean air requires the installation of automatic measuring stations in industrial centers. Automobile exhausts, too, will soon be subject to regulations.

Stern, Arthur C. and Leonard Greenburg

AIR POLLUTION-THE STATUS TODAY. Am. J. Public

Health, 41(1): 27-37, Jan. 1951. 21 refs. (Presented at the American Public Health Association, 78th Annual Meeting, St. Louis, Mo., Nov. 2, 1950.)

An increase of attention to air pollution as a nationwide problem was initiated by the emergence in 1945 of Los Angeles smog as a local problem of the first magnitude. By the fall of 1948, Southern California was the center of university, private, and public research in air pollution and the California public had become air pollution conscious. The Donora smog episode aroused the hitherto complacent East at about the same time. Defense research projects and the significance of recent symposia are mentioned. Damage to vegetation by sulfur dioxide, fluoride damage to livestock, other effects on vegetation, and eye irritation in Los Angeles are discussed. The results of the Public Health Service investigation following the Donora episode are summarized. Air pollution standards are cited, as well as meteorological investigations, jet dilution of stack effluents, dilution by turbulent mixing, dust dispersion and prediction of smog, air sampling and analysis,

<xref image="2000WVOF.TIF|V3|2006:09:28:01:45:50.00|121547|0"> image: </xref>

520

new tools for sampling, scrubbers, adsorbers, and dust collectors, governmental regulations, Los Angeles control district rules, and smoke abatement.

Nordrhein-Westfalen Arbeits-und Sozialminister (West Germany)

THE SITUATION IN NORDRHEIN-WESTFALEN IN 1970 AND DEVELOPMENTAL TRENDS. (Situation in Nordrhein-Westfalen 1970 and die Entwicklungstendenzen). Text in German. In: Reinhaltung der Luft in Nordrhein Westfalen, Essen, West Germany, Brinck and Co. KG, 1969, p. 75-83.

The population density of the industrial regions of the state is 1300 to 3000 inhabitants per sq km. These regions are the home of 90% of all coal mines, 70% of the steel industry, 50% of the heavy chemical industry, and 35% of the refineries in all of West Germany. To the emissions from these industries must be added those from 5.5 million households and from 3.5 million automobiles. Since the introduction of mandatory certification of polluters, air pollution in the entire area has decreased markedly. The projection for SO₂ emission in West Germany is that it will increase by about 25% until 1975 and from then on will decrease because of the construction of nuclear power plants. In the U. S., in contrast, SO₂ pollution will double until 1980 because of widespread use of coal. Pollution trends will be further affected by the growth rate of the chemical industry, which will expand from an index of 100 in 1962 to an index of 320 in 1975. The importance of SO₂ as a pollutant will diminish to be replaced by fluorine, hydrocarbons, chlorine, and odorous emissions. The emission of fine dust as a health hazard will increase and dust fall measurements will have to be supplemented by dust concentration measurements. The problem in the steel industry will be fine dust control; in the aluminum industry, fluorine emission control; in steam power plants, fine dust control; and in domestic heating, nitrogen oxide control. Pollution from automobiles is expected to increase until 1975, especially from nitrogen oxides.

THE WORKING PARTY ON AIR POLLUTION - EUROPEAN FEDERATION OF CHEMICAL ENGINEERING. International Union of Air Pollution Prevention Associations and National Society for Clean Air, London (England), Intern. Clean Air Congr. Proc., London, England, 1966, p. 267-268. (Oct. 4-7, Paper VHI/S.)

The organization, composition, aims, and activities of the Working Party on Air Pollution of the European Federation of Chemical Engineering are described. The field of activity lies in problems of air pollution arising from carrying out chemical processes and in the removal of noxious or offensive constituents produced in such processes. The current status of progress in controlling emissions, including grit, dust, sulfur dioxide, nitrogen oxides, and fluorine compounds, is noted.

44066

Turk, A., D. Turk, and D. T. Wittes

AIR POLLUTION. In: Ecology; Pollution; Environment. Philadelphia, W. B. Saunders Co., 1972, p. 79-108. 8 refs. Various aspects of air pollution are reviewed. Expressions of concentration for gases and particles are explained. The components of pure air are described and a definition of polluted air is presented. The sources and effects of the following pollutants are discussed: carbon monoxide, carbon dioxide, hydrocarbons, sulfur dioxide, sulfur trioxide, sulfuric acid, nitric oxide, nitrogen dioxide, ozone, oxidants, hydrofluoric acid, and viable and nonviable particulate matter. The effects of air pollution include reduction of visibility and other atmospheric effects, damage to vegetation, direct effects on man, injury to animals, and deterioration of materials. Pollu-

tion control measures include filters, cyclones, electrostatic precipitators, scrubbers, adsorption on activated carbon, and incineration. Methods for reducing sulfur dioxide emissions include change of energy sources, fuel desulfurization, emission control devices, more efficient methods of fuel combustion, encouragement of less fuel use, and decreasing the rate of population growth. Problems involved in the switch-over from gasoline-driven to battery-operated automobiles are discussed.

46820

Wende, E. and F. Bister

AIR POLLUTION ASSOCIATED WITH CIVILIZATION.

(Zivilisationsbedingte Luftverunreinigungen). Text in German.

Z. Allgemeinmed., 48(14):665-673, May 1972.

In the Federal Republic of Germany, the principal sources of emissions are households, industry, and automotive traffic. The volume of these emissions rises every year at approximate average rates of 7, 5, and 3%, respectively. The most significant gaseous emissions are sulfur dioxide, hydrofluoric acid, nitrogen oxides, carbon dioxide, carbon monoxide and hydrogen sulfide. The finer dusts are more noxious, since upon inhalation they can penetrate into the lungs. The effects of benzopyrene and lead as dust or in aerosol form, the history of the several past smog catastrophes due to weather inversions in polluted areas, and mortality in relation to air pollution are discussed. Regular sampling and analysis of air is needed. Control methods include modifying technology, eliminating pollution in stack gases, or dissipating emissions by the use of chimneys. Control equipment includes filters, washers, and collectors. West German regulations and recommendations for the preservation of clean air are mentioned.

Ortega Torres, J.

CONTAMINATION OF THE ATMOSPHERE. (Contaminacion

Atmosferica). Text in Spanish. Am. Med. Acad. Ciencias Med.

Cataluna, 58(2): 147-165, April 1972. (Presented at the Asociacion de Microbiologia, Higiene y Medicina Preventiva, Dec. 17, 1971.)

The air pollution phenomenon is discussed in terms of definitions, causes, effects on human health and economy, control, and reevaluation of certain attitudes of modern man. The main air pollutants such as sulfur dioxide, hydrogen sulfide, hydrogen fluoride, nitrogen oxides, aldehydes, carbon monoxide, and polynuclear hydrocarbons, resulting from combustion of sulfur-containing fuels, petroleum refineries, aluminum producing plants, fertilizer manufacturing, and traffic are reviewed. The photochemical mechanism of smog formation is discussed along with the meteorological and orographic factors involved in enhancing the process. The air pollution-induced pathology is reviewed and illustrated by the classical episodes recorded in the Meuse-Valley at Donora, at the Baltic Sea, and in Mexico. Los Angeles is referred to as the city with 262 days/yr of thermal inversion incidence. Air pollution monitoring in terms of sampling and analytical methods is discussed along with control possibilities. The latter are reviewed in terms of fuel improvement, combustion process improvement, technological process modifications, and emission control treatment. All the aspects involved in the air pollution control process should be supervised by appropriate administrative

<xref image="2000WVOG.TIF|V3|2006:09:28:01:45:54.00|119497|0"> image: </xref>

authorities. Maximum local autonomy should be given in terms of correlating the source with the orography and the climatology and the possibilities of controlling pollution. Special associations should campaign in educating and in trying to explain the real hazards caused by pollution. Because of the wide range of unknowns involved, national and worldwide cooperation between science, technology, industry, economy, and law should be established. The modern man should become aware of the threat to the environment caused by affluent living and try to save the environment before its deterioration becomes irreversible.

50748

Japan Environmental Agency

PRESENT STATE OF AIR POLLUTION COUNTERMEASURES

SIJRES. In: Quality of the Environment in Japan. 1972, Chapt. 1, p. 54-80.

Although air pollution in Japan, with the exception of nitrogen oxides, has generally abated, it is still a severe problem. There are 40 cities which do not meet the environmental standard for sulfur oxides; they comprise a little less than 40% of the 110 cities with monitoring stations. The air pollution problem in local districts has recently become aggravated by the increases in such hazardous pollutants as hydrogen fluoride, chlorine, hydrogen chloride, and oxidants. The primary cause is a sharp increase in energy consumption. Air quality with respect to SO_x suspended particulates, NO_x, carbon monoxide, oxidants, and hydrocarbons are discussed. Environmental and emission standards and air pollution control measures are reviewed.

50867

Hishida, Kazuo

INTRODUCTION TO AIR POLLUTION. (Kogai gairon). Text

in Japanese. PPM (Japan), 4(4):2-20, April 1973.

Air pollution is discussed in general. Data on sulfur oxides, suspended particulates, dust fall, and nitrogen oxides in Japan are discussed. The automatic monitoring system for Japan, automobile exhaust pollution in terms of carbon monoxide pollution in Tokyo and photochemical smog, pollutant sources, toxic effects of pollution, and air pollution episodes are also mentioned. The effects of sulfur dioxide and fluorides on vegetation are outlined. Local and national programs and legislation for controlling air pollution are reviewed. Desulfurization of fuels oils and other control methods are briefly mentioned. Enforcement of legislation and monitoring systems are discussed.

51942

Olschowy, Gerhard

ENVIRONMENTAL PROTECTION A TASK OF SCIENCE,

PLANNING AND PROTECTION. (Umweltschutz als Aufgabe

von Wissenschaft, Planung und Verwaltung). Text in German.

Btr. Abwassertech. Ver., vol. 25:17-31, 465-466, 1973.

(Presented at the Abwassertechnischen Vereinigung e.V., Main Meeting, Kassel, West Germany, Sept. 8, 1971.)

The present day pollution of the water and air in the Federal Republic of Germany is discussed. Solid waste disposal problems are mentioned. More than 300 chemical compounds and physical substances are known to be air pollutants. Of the gaseous pollutants, sulfur dioxide assumes the largest portion. Fluorine compounds are rarer in the atmosphere than SO₂, but they are far more toxic. While the threshold concentration for SO₂ is 0.5 mg/cu m air (0.2 ppm), it is 0.01 mg/cu m air for fluorine. The combination of several pollutants, primarily of waste gases with dusts is particularly dangerous, which is further compounded by temperature inversions. In the Ruhr area the haze caused by air pollution reduces solar radiation by about 30%. This haze absorbs particularly the important ultraviolet radiation. A considerable amount of air pollution stems from traffic. The Federal Republic of Germany

presently has 16 million cars which produce 25 billion cu m of waste gas. The numerous combustion processes with fossil fuels such as coal and oil lead to changes of the composition of the atmosphere. Global carbon dioxide emission rose between 1950 and 1963 from 700 billion tons to 1100 billion tons, of which about 50% remain in the atmosphere.

Marier, J. R.

THE ECOLOGICAL ASPECTS OF FLUORIDE. Fluoride, 5(2):92-97, April 1972. 21 refs. (Presented at the International Society of Fluoride Research, Annual Conference, 4th, Hague, N. L., Oct. 24-27, 1971.)

The ecological aspects of fluoride are reviewed. Sources of fluorides, fluoride distribution, and final deposition in air, soil, and water are mentioned. Vegetation can be an environment for fluoride, but it can also serve as one of the modes of transport for fluoride uptake by other forms of life. In this way, biological transfer occurs, and food chains are built, increasing the air pollution problem. It is further complicated by recourse to fluoride-containing fertilizers, insecticides, and mineral supplements for livestock. Fluoride burden is also increased from sources such as food and beverage processing, and fluoride-containing aerosols and Pharmaceuticals.

INTERMEDIA ASPECTS OF AIR AND WATER POLLUTION

CONTROL. Environmental Protection Agency, Washington, D.

C., Office of Research and Development, Contract 68-01-0729, Program Element 1H1093, EPA-600/5-73-003, 357p., Aug. 1973.

411 refs. GPO

On the basis of emission quantity, toxicity, and current conditions, the air pollutants sulfur oxides, sulfur compounds, nitrogen oxides, nitrogen compounds, heavy metals, particulates, carbon monoxide, hydrocarbons, fluorides, hydrogen chloride, arsenic, hydrogen cyanide, ammonia, and ethylene are discussed and classified according to the Standard Industrial Classification Code. The interaction and transport between air and water, sources, treatment, and fate of these pollutants are discussed. The environmental impacts, main sources, and control methods are discussed in detail for each pollutant. Mathematical models are given for various control strategies, cost information, and choice of control program. Intermedia pollution management in the city of Los Angeles is discussed in detail.

Gilbert, T.

SIMPLIFIED METHOD FOR THE CALCULATION OF
MINIMUM CHIMNEY HEIGHTS IN CASES OF EMISSION
OF GASEOUS FLUORIDE COMPOUNDS FROM

BRICKWORKS. (Vereinfachtes Verfahren zur Berechnung der Schornsteinmindesthoehen bei der Emission von gasfoermigen Fluorverbindungen aus Ziegeleien). Text in German. Ziegelind. (Weisbaden), no. 4:152-154, 1974. 7 refs.

A simplified pragmatic method for the determination of the minimum stack heights in brickworks emitting gaseous fluorides is presented with respect to the problems involved in the application of the diagram given the Clean Air Manual to

<xref image="2000WVOH.TIF|V3|2006:09:28:01:45:56.00|114567|0"> image: </xref>

522

the calculation of the minimum stack height in such cases. The ground-level fluoride concentrations were evaluated for the immediate vicinity of the emission source under most unfavorable meteorological conditions. The wind speed and the evaluation period were 3 m/sec and 30 min, respectively. In view of the mainly rural location of brickworks, it is not expedient to use the dispersion parameters determined for urban conditions.

Detrie, J.-P.

STUDIES AND RESEARCH ON THE MEASUREMENT OF NUISANCES, THEIR EFFECTS AND THEIR PREVENTION.

PROBLEMS OF SPACE PLANNING. (Les études et recherches sur la mesure des nuisances leurs effets et la prevention. Problemes d'aménagement territoire). Text in French. Apave, 52(175):57-62, 1971.

Studies on the generation, effects, measurement, dispersion, and prevention of air pollutants in France are surveyed. The effects of particulate, unburned matter, and asbestos on lung tissues; effects of carbon monoxide, sulfur dioxide, and exhaust gases on animals; and the effects of SO₂ and fluorine compounds on plants are being studied. Shell-Bacharach opacimeters and automatic recording instruments adopting the beta-ray attenuation principle for dust captured on filter are available for the measurement of smoke emissions. The ground level concentrations of combustion process-generated air pollutants are measured by means of S.F. (Smoke-Sulfur) measuring instruments. The dispersion of air pollutants is studied by hydraulic models. Fuel and flue gas desulfurization processes are being studied, partly on a semi-industrial scale. The implementation of emission standards and the introduction of improved firing techniques have resulted in a considerable abatement of the SO₂ and smoke concentrations both in Paris and London for the last 10 years.

64937

Hishida, K.

THE OUTLINE ON ENVIRONMENTAL POLLUTION. (Kogai gairon). Text in Japanese. PPM (Japan), 5(S):2-22, May 1974. Wide area pollution generally refers to environmental pollutions such as smog and other air pollutants caused emissions from mobile sources. Pollutants such as stack gases emitted from specific factories are called local pollution. Primary pollutants can react together to form pollutants, also affect humans and plants. There are four techniques to reduce air pollution. Low-sulfur fuels can reduce the amount of sulfur oxides emitted by combustion. Generation of noxious materials can be controlled by efficient combustion of fuel. Dust collectors and other control equipment reduce noxious materials. The pollution concentration above the ground can be controlled through a diffusion by high chimneys. The diseases caused by environmental pollution include respiratory diseases such as chronic bronchitis, bronchial asthma, asthmatic bronchitis, and emphysema. Poisonous gases affecting plants are sulfur dioxide, sulfur trioxide, hydrogen fluoride, chlorine, hydrogen chloride, ammonia, hydrogen sulfide, and nitrogen dioxide, among which SO₂ causes most plant damage.

Berge, Helmut

AIR POLLUTANTS IN THE KOELN AREA. (Luftverunreinigungen im Raume Koeln). Text in German. Allg. Forstz., 20(5):51/52):834, 836-838, Dec. 1965. 5 refs.

An evaluation is presented of systematic air pollution monitorings conducted in the Koeln area in West Germany. The strong influence of industrial emission sources outside the city on air pollution levels measured in Koeln was noted. Except for streets with heavy, slow traffic and frequent traffic jams, other parts of the Koeln area were characterized by very low concentrations of polycyclic aromatic hydrocarbons. Phenols

caused reversible acute and chronic damages to the environment, while mercaptans were detected in concentrations high enough to cause irreversible chronic and acute changes in the living environment. Sulfur dioxide, hydrofluoric acid, hydrogen sulfide, nitrogen oxides, and particulate matter in general, and soot in particular, inflicted serious damages on plants and woods. The separation of industrial and residential areas, especially by green belts, is an essential principle of modern space planning.

66718

Hermans, K. H.

DETERMINATION OF ENVIRONMENTAL POLLUTION-GENERATED DAMAGES. (Het vaststellen van schade door milieuverontreiniging). Text in Dutch. In: Milieubalans van Nederland. J. J. Mulckhuyse (ed.), Amsterdam/Brussels, Intermediar, 1972, p. 117-128. 18 refs.

General problems of damages afflicted by pollution and contamination to the natural environment, and methods for their determination are described. The detection of damages caused by pollution is complicated by the fact that pollutant levels below a certain limit generate invisible damages. The potentiality of damage is characterized by the tolerance of the living organism or the absolute or relative maximum allowable concentration. Plant damages caused by air pollutants can be determined by systematic pollution monitoring and by aerial photographs. Extensive damages in coniferous forests from sulfur dioxide, fluorine compounds, peroxyacetyl nitrate, and peroxybutyryl nitrate were observed in Europe.

Flower, Franklin B.

EFFECTS OF AIR POLLUTION ON THE ENVIRONMENT.

In: Air Pollution and Industry, R. D. Ross (ed.), New York, Van Nostrand Reinhold Co., 1972, Chapt. 2, p. 18-78. 194 refs.

The effects of air pollution on the environment are reviewed with particular emphasis on mechanism of cause-and-effect relationships and socioeconomic implications. Topics discussed include: air pollution effects on materials deterioration; acute and chronic effects on human health, with particular reference to specific industrial emissions; pollution effects on animals and vegetation; and meteorological implications involving global air temperature and urban effects on fog, precipitation, solar radiation, and visibility, with a relationship being given for the effect of atmospheric particulate loadings on visibility. Types of pollutants examined include: metallic and nonmetallic particulates, sulfur oxides, photochemical oxidants, pollens, aldehydes, ammonia, nitrogen oxides, aliphatic and aromatic hydrocarbons, asbestos, carcinogens, pesticides, odorous compounds, inorganic acids, chlorine gas, radioactive substances, carbon monoxide and carbon dioxide, hydrogen sulfide, fluorides, ozone, and peroxyacetyl nitrate.

Gilbert, T.

A SIMPLIFIED METHOD FOR CALCULATION OF THE MINIMUM STACK HEIGHT AT EMISSIONS OF GASEOUS FLUORINE COMPOUNDS FROM BRICK KILNS. (Ein

<xref image="2000WVOI.TIF|V3|2006:09:28:01:46:00.00|115493|0"> image: </xref>

verenfachtes Verfahren zur Berechnung der Schornsteinmindesthoehen bei der Emission von gasfoermigen Fluovoverbindungen aus Ziegeleien). Text in German. *Gesundh.-Ing.*, 95(9):257-258, 1974. 7 refs. (Presented at the Second Symposium on Branch-specific Emissions, Fluorine Emissions by Brick Kilns, Munich, Germany, Feb. 1, 1974.)

A new pragmatic procedure for the calculation of stack height for brick kilns uses, aside from the guideline VDI (Jerein Deutsche Ingenieur) 2289 and No. 2.6 of the Technical Directives for Clean Air Conservation (TALuft), the following conditions. The emission conditions are evaluated in the vicinity of the source only under the unfavorable condition of the rarely occurring labile stability class V by Klug. In a first coarse approximation it is then assumed that the emission conditions under other stability conditions are better. For the wind velocity, the average velocity in the waste gas plume of 3 m/sec is used. For the emitted concentration of fluorine compounds, the 60% value of the recommended maximum allowable short-term emission concentration of 5 micrograms F/cu m, i.e. 3 micrograms F/cu m, is inserted into gas plume incrementation the method of Briggs was used. The point of the theoretically anticipated emission was used for the calculation. A numerical example is presented.

15. SUPPLEMENTARY NOTES

16. ABSTRACT

The Air Pollution Technical Information Center (APTIC) of EPA's Office of Air Quality Planning and Standards prepared, selected and compiled the approximately 2600 abstracts in this bibliography. The abstracts are arranged within 14 general subject categories. The abstracted documents are thought to be representative of available literature. Subject and author indexes are included. The indexes refer to the abstracts by a category code and abstract number. The author index lists all authors individually; primary authorship is indicated by an asterisk. Generally, higher abstract numbers have been assigned to more recent documents. The aim of this bibliography is to bring together these abstracts which were previously scattered throughout "Air Pollution Abstracts" (1970-1976).
