Air pollution effects(Materials) Air--Pollution--Bibliography ; Fluorine--Bibliography ;
Air--Pollution--Abstracts ; Fluorine--Abstracts</subject>

The Air Pollution Technical Information Center (APTIC) of EPA's Office of Air Quality Planning and Standards prepared, selected and compiled the approximately 2600 abstracts in this. The abstracts are arranged within 14 general subject categories. The abstracted documents are to be representative of available literature. Subject and author indexes are included. The indexes of the abstracts by a category code and abstract number. The author index lists all authors and individual primary authorship is indicated by an asterisk. Generally, higher abstract numbers have been assigned to more recent documents. The aim of this bibliography is to bring together these abstracts which were previously scattered throughout 'Air Pollution Abstracts' (1970-1976).

FLUORINE, ITS COMPOUNDS, AND AIR POLLUTION:
A BIBLIOGRAPHY WITH ABSTRACTS

INTRODUCTION

The Air Pollution Technical Information Center (APTIC)* of the Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, has prepared, selected, and compiled the approximately 2600 abstracts in this bibliography. The abstracts are arranged within the categories listed in the Contents. The abstracted documents are thought to be representative of available literature, and no claim is made to all-inclusiveness.

The subject and author indexes refer to the abstracts by category letter and abstract number. Generally, higher numbers have been assigned to more recent documents. The author index lists all authors individually; primary authorship is indicated by an asterisk.

This bibliography brings together relevant abstracts that were previously scattered throughout "Air Pollution Abstracts" (1970-1976).

All of the documents abstracted by APTIC are on file at the library of EPA, Research Triangle Park, North Carolina 27711. Readers outside EPA may seek the documents directly from publishers, authors, or libraries.

*Now re-organized into the Manpower and Technical Information Branch.

J. P. Sheehy, J. J. Henderson, C. I. Harding, and A. L. Danis
AIR POLLUTION IN JACKSONVILLE, FLORIDA (A PILOT
STUDY - AUG.-SEPT. 1961). Public Health Service, Cincinnati,
Ohio, Div. of Air Pollution (AP-3). Apr. 1963. 65 pp. GPO: 802-
899-6

The objectives of this pilot study were: (1) To develop a preliminary opinion as to whether the city of Jacksonville has a generalized air pollution problem. (2) To determine whether certain pollutants - fluorides and SO₂, were present in the atmosphere in concentrations capable of producing the damage to vegetation that had been experienced in the Jacksonville-Duval County area. To accomplish the first objective, a one-week intensive investigation was carried on in downtown Jacksonville, at (emming Park, from August 3 to 10, 1961. To accomplish to second objective, additional studies were conducted during the periods August 4 to 12, and September 5 to 13, 1961, in the area in which damage to vegetation had occurred. The two fertilizer plants, located in the industrial area of Jacksonville, were not in production during the first phase of this study. Pollutants sampled in this study included fluorides, SO₂, H₂S, NO₂, nitrogen dioxide, and particulates. As a result of the investigations it was concluded that: (1) Photochemical smog was being produced in the air over Jacksonville. (2) Concentrations of fluorides occurred in certain parts of Jacksonville during the period of the study that could cause damage to sensitive plants. (3) Pollutants from the city of Jacksonville can be transported across the St. John's River. H₂S concentrations measured during this study were not of the magnitude known to cause discoloration of paints containing lead pigments and/or mercury base fungicides. Subsequent to the study, an incident of darkening of paints occurred in the arlington area. Therefore, it is evident that an H₂S problem exists in this area. SO₂ concentrations observed during this study did not reach levels known to cause damage to vegetation. However, it appears possible for SO₂ concentrations to reach levels during the heating season capable of causing damage to sensitive plants, particularly in localized areas downwind of major sources of SO₂.

SOURCES & QUANTITIES OF FLUORIDES EVOLVED
FROM THE MANUFACTURE OF FERTILIZER & RELATED
PRODUCTS. Preprint. J. Air Pollution Control Assoc. 11, (12)
682-4, Dec. 1966. (Presented at the 59th Annual Meeting, Air
Pollution Control Association, San Francisco, Calif., June 20-
24, 1966, Paper No. 66-8.)
Fluoride emission levels from the manufacture of phosphoric
acid, run-of-pile triple superphosphate, diammonium

phosphate and granular triple super-phosphate are presented in tabular form. The information is discussed together with variations and unusual layouts or operating conditions. In addition, fluoride emissions from the manufacturing of such products as defluorinated and calcined phosphate rock, normal super-phosphate, superphosphoric acid and elemental phosphorus are discussed. The information applies to the fertilizer and related phosphate products manufactured in Polk and Hillsborough Counties in Florida. This area produces 75% of the marketable phosphate rock in the United States. Some 40% of the rock remains in these two counties for chemical or thermal processing. The phosphate industry is required to report annually on fluoride emission levels found by their sampling and monitoring programs. These values are compared with those found by spot checking various sources by the Florida State Board of Health. (Author)

AIR POLLUTION AND COMMUNITY HEALTH (CHAPTER EIGHTEEN). Medical Climatology 505-18, 1964.

In this chapter author reviews major pollution episodes which have occurred since 1930 in various parts of the world. These episodes have demonstrated the danger and the lethality that may result when certain meteorologic phenomena occur in geographical areas where potentially high concentrations of air pollutants may form. Certain pollutants that might be tolerated in low concentrations in some inhabited areas might become dangerous when mixed with pollutants from other sources that could exert an accentuating or synergistic action. SO₂, particulates, CO, beryllium, lead, fluoride, photochemical, and allergenic pollutants and their effect on man and animals are discussed. The most important animal experiments as well as other research are reviewed.

EXPOSURE CRITERIA FOR FLUORINE ROCKET PROPELLANTS.

Arch. Environ. Health VoJ 12:399-407, Mar. 1966.

(Presented at the Fourth Inter-American Conference on Toxicology and Occupational Medicine at Miami Univ., Fla., Aug. 24-27, 1964.)

A subject of considerable interest is the use of liquid fluorine for propulsion because it is the most powerful of all the chemical oxidizers. Space vehicles currently in the developmental stage utilize elemental liquid fluorine (LF₂) as well as liquid fluorine and liquid oxygen (FLOX) mixtures. Rocket testing with, and handling of, fluorine oxidizers call for the utmost care and consideration for the health and safety of personnel. Although closed and zero-loss handling systems are used, total and complete containment of all fluorides is generally infeasible. Environmental releases can come from engine exhaust gases, burned purge gases, and accidental discharges from pipe burnouts and spills. Because releases to the atmosphere, either normally or accidentally, usually involve F₂/HF mixtures, industrial hygiene controls and site planning are based on toxicity criteria for HF and F₂. PRACTICAL SOLUTIONS OF AIR POLLUTION PROBLEMS FROM CHEMICAL PROCESSES . (Realizzazioni nel Campo della Prevenzione dell' inquinamento Atmosferico di Origine Industriale.) Translated from Italian, ("chim. Ind. (Milan), 48(2):251-261, March 1966.

A strict control of pollutant to be dispersed in the atmosphere offers technical and economic problems, both in the design and the operation of chemical processing units. Three examples of processes for which pollution control has been established are described: SO₂ derived from contact sulfuric acid and from hydroxylamine sulfate plants, nitrous gas from low and high-pressure nitric acid plants, and fluorine-containing effluents from hydrogen fluoride production. The general approach, kind of abatement process adopted, materials and construction costs are discussed.

CONTROL OF AIR POLLUTION FROM PHOSPHATE PROCESSING. Proc. (Part I) Intern. Clean Air Cong., London, 1966. (Paper IV/7). PP. 97-9.
Phosphorus is one of the elements essential for the growth of human, plant and animal life. Most phosphate ores must be treated in some manner to make the phosphorus soluble and thus available for life, usually by addition of acid or by heating. One-third of the world's phosphate is processed in Florida, where practically all the products normally made from phosphorus rock are produced. This results in a variety of air pollution problems involving particulates, fluorides and

sulphur oxides. The manufacturing processes and sources of pollutants are described briefly. Further described are the general effects of the emissions. Based on the experience of a number of years of investigation and application, procedures for alleviating the air pollution are discussed. The sequential application of these procedures has resulted in a substantial reduction in contaminant emissions. (Author abstract)

AIR RESOURCES OF UTAH. Utah Legislative Council, Salt Lake City, Air Pollution Advisory Committee. June 1962. 32 pp.

A survey was made of the available information concerning air pollution problems in Utah. No evidence was found to indicate that Utah has a major air pollution problem at this time; however, a few persistent problems exist in restricted areas. Over the years three air pollution situations in Utah have produced injury to plant and animal life or have constituted a public nuisance. These are: (a) sulfur dioxide in Salt Lake Valley (non-ferrous smelters, burning of coal, gasoline combustion, and petroleum refining are the principal sources); (b) smoke and smog along the Wasatch Front and in other localized areas (burning of coal, open burning on municipal dump grounds and in junk yards, and waste disposal around private homes constitute the major sources); and (c) fluorides (processing of Utah ores by steel mills in Utah County, brick and ceramic plants, phosphate fertilizer plants, and general combustion processes are the principal sources. Industry has made substantial progress in alleviating sulfur dioxide, fluorides, smoke, and hydrocarbons by installing expensive control equipment and by supplementing this equipment with extensive research, survey, and monitoring programs. Legislation authorizing the state, or cities and towns, to deal with public nuisances if found in the Utah Code. There is no definition of air pollution, however, and its treatment as a nuisance is questionable. Enabling legislation should define the problem, permit study of its effects, and permit actions to control injurious practices. (Author summary modified)

FLUORINE-CONTAINING IMMISSIONS IN THE VICINITY OF BRICKWORKS. STAUB (ENGLISH TRANSLATION) 25, (3) 45-50, MAR. 1965. CFSTI TT 66-51040/3

Damage to vegetation by brickworks is widespread all over Germany. It is characterized by spontaneous occurrence and particularly aggressive character, dying off very rapidly in the interior of woods and greatly varying degrees of damage. Harmful substances are HF and SiF₄. Areas up to about 100 ha in extent occur. The destruction and reduction in growth there and the damages arising therefrom reach amounts at times running into five figures of German marks. Three causes of damage exhaustively investigated in recent years are reported. In two cases on the plain it was possible, by means of 50 m-high chimneys erected later, to prevent the damage over a long period. At a third, in the mountains, on the other hand, this measure increased the scale of the initial damage considerably. (Author summary)

BORDEN CHEMICALS, INC. GRANULAR TRIPLE SUPERPHOSPHATE, PINEY POINT, FLORIDA. (FINAL REPORT). Office of Air Programs Contract 68-02-0232, Rept. 73-FRT-9, 45p., Sept. 11-12, 1972. 1 ref.

Emission tests were conducted on the granular triple superphosphate process at the Borden Chemical phosphate works in Piney Point, Fla. in order to obtain data for use by both the Industrial Studies Branch and the Performance Standards Branch of the Environmental Protection Agency. Measurements were made at the outlet stack for soluble and insoluble fluorides; and grab samples of scrubbing liquids, process reactants, and process product were analyzed for fluoride and phosphorus pentoxide content. Values for water soluble fluorides in lb/ton P2O5 fed ranged from 0.04-0.10, while those for total fluorides (lb/ton P2O5 fed) had an identical range. Total fluorides in lb/hr varied from 0.5-1.2. Cyclones and scrubbers serve as control apparatus.

W. Oelschlager
THE CONTAMINATION OF THE ATMOSPHERE BY FLUORINE. Staub (English Transl.) 25, (12) 5-10, Dec. 1965. CFSTI TT66-51040/12

Fluorine plays an important role among toxic air pollutants, because even a relatively small amount of it can be harmful for plants and animals. The main emitting sources of fluorine are plants producing hydrofluoric acid, aluminum, superphosphate and enamel; further, brickworks, metallurgical works and industrial plants consuming very high amounts of low quality coal. Fluorine contents of raw materials, fluorine emissions in different processes and harmful effects on plants and animals are reported. Finally, the measures to be taken to reduce fluorine emission are briefly discussed. (Author summary)

03129

Avy., A. P.
METHODS OF REDUCING POLLUTION CAUSED BY SPECIFIC INDUSTRIES. (CHAPTER VI. CHEMICAL INDUSTRY). European Conf. of Air Pollution, Strasbourg, 1964. p. 337-356.

The pollutants discharged by the chemical industry may be subdivided into several classes. The first and most important class is that of harmful products emitted in large quantities by the 'heavy' chemical industry and, in particular, organic chemical works: Sulphur dioxide, sulphuric acid, chlorine, whether manufactured or in the form of impurities in the basic material' fluorine in the case of fertilizers and fluorine again in aluminum electro-chemistry. The chemical industry has a wide range of special problems which is in a constant state of flux owing to the wide and ever-increasing variety of new synthetic products (intermediate and finished) in the organic chemical industry. From the technical point of view, the prevention of pollution by such products depends on their presentation and manner of application. A problem directly connected with chemical manufacture is that of smell: mercaptans, hydrogen phosphide, methylamines, etc., although, of course, it does not arise in the chemical industry alone. Technical methods used to reduce pollution are highly developed for dusts and smoke and there is a wide choice of apparatus. The chemical industry, like all others, is subject to laws and regulations governing industrial air pollution. A fairly sharp distinction, however, should be drawn between laws, which lay down in general terms the objects to be attained and the obligations to be fulfilled, and the regulations which embody details of the limits imposed and the degree of reduction demanded. In this last report, caution is necessary and impossible or unnecessary standards should not be set. It is clear that international liaison or even international collaboration is not only desirable, but

necessary.

C. I. Harding, S. B. McKee, and J. J. Schueneman
FLORIDA'S AIR RESOURCES. Florida State Board of Health,
Jacksonville. Feb. 1961. 66 pp.

The purpose of this survey is to describe the State's characteristics as they relate to air resources, review present control activities, assess the present and potential status of air pollution. The survey accumulated reports of air pollution problems due to 265 particular sources of pollution. The most serious problem is due to 18 phosphate rock processing plants which are responsible for emission of gaseous and particulate fluorides and other dusts. Nine pulp mills which emit odorous materials and particulate matter are another major problem. Other problems including automobile exhausts have also been reported. The State of Florida first took official notice of its air pollution problems in 1955 when Chapter 381 Florida Statutes was amended giving the State Board of Health authority to promulgate rules and regulations for the control of air pollution. On the basis of information developed in this survey recommendations have been made in the interest of protecting and restoring the air resources of the State of Florida.

BORDEN CHEMICALS, INC. DIAMMONIUM PHOSPHATE,
PINEY POINT, FLORIDA. (FINAL REPORT). Office of Air
Programs Contract 68-02-0232, Rept. 73-FRT-13, 62p., Sept.
26/27, 1972. 3 refs.

An Office of Air Programs source emission test conducted by Environmental Engineering, Inc. is reported for the Borden Chemical phosphate works in Piney Point, Florida. Measurements were made for soluble and insoluble fluorides at the scrubber outlet to the atmosphere; and grab samples of the scrubbing liquids, the process reactants, and the process product were analyzed for fluoride and phosphorus pentoxide content. Total fluoride in mg ranged from 3.6-5.2, while total fluoride in gr/SCF was 0.0008. Water soluble fluoride in lb/hr ranged from 0.54-0.66, and total fluoride in lb/ton P205 Fed was 0.03. Total fluoride in gr/CF stk. cond. was 0.0007. This data will be used to establish performance standards.

M. B. Belaga and P. N. Maistruk
EXPERIMENTAL SANITARY IMPROVEMENT OF WORK-
ING CONDITION IN THE YA. M. SERDLOV SU-
PERPHOSPHATE PLANT. Gigiena i Sanit. 28 (1), 80-2 (Jan.
1963). Russ. (Tr.) (Translated by B. S. Levine in U.S.S.R.
Literature on Air Pollution and Related Occupational Diseases,
Vol. 12.)

The most significant sanitary measures instituted in the phosphate plant's basic production departments to improve sanitary working conditions are the following: The apatite unloading from the railroad gondolas and loading onto small delivery cars was changed from manual to electric crane shovels or buckets, which lowered the stockyard air dust density by 80 - 90%. Manual cleaning of the bunker grates, from which the apatite was picked up by the elevator, was replaced
<xref image="2000WVA3.TIF|V3|2006:09:28:01:16:44.00|115095|0"> image: </xref>

by automatically operated electric scrapers, which also lowered the air dust density by 80 - 90%. The acid diluting, dosing, and temperature regulating in the operating section had been automated, the conduits made leakproof, and the exhaust ventilation was operated at 30 mm of mercury or below; all this lowered the department's air dust density to 17 - 12% of the original. At the silico-fluoride department, the use of coal for drying-oven heating was replaced by natural gas, and the oven had been heat insulated, which eliminated the presence of coal dust in the air and lowered the intensity of heat radiation by the drying ovens from 0.5 to 0.2 cal/sq cm.min. At the department of granulated superphosphate, the following improvements have been instituted: natural gas instead of coal is burned in heating the drying drums, a two-step air purification from fluorine and superphosphate dust has been installed, all ventilation conduits have been examined and made absolutely leak-proof, etc. The tail gases discharged into the atmosphere now contain only 0.18 g/cu m of dust and 0.002 g/cu m of fluorine. In conclusion, study of the plant's personnel medical and work records indicated that due to the above described system of sanitary, therapeutic, general medical and prophylactic services the rate of morbidity and loss in work days have been steadily declining in this plant.

Environmental Engineering, Inc., Gainesville, Fla.
BORDEN CHEMICAL, INC. DIAMMONIUM PHOSPHATE,
PINEY POINT, FLORIDA. (FINAL REPORT). Office of Air
Programs Contract CPA-70-82, Rept. 72-CI-3, 126p., Jan. 19-
20, 1972. 1 ref.

Emission tests were conducted at the Borden Chemical diammonium phosphate plant located in Piney Point, Fla. in order to obtain data for the use of both the Industrial Studies Branch and the Performance Standards Branch of the Environmental Protection Agency. Measurements were made for both total fluorides and ammonia in the inlet and outlet ducts of the reactor and dryer scrubbers, the inlet duct of the cooler scrubber, and the common outlet stack to the atmosphere. Grab samples of the scrubbing liquids, the process reactants, and the process product were taken and analyzed for fluoride and phosphorus pentoxide content. Total fluorides at the Station U outlet ranged from 0.0006-0.0012 gr/SCF, while those at the reactor tail gas scrubber outlet (Station J) varied between 0.0018-0.0043 gr/SCF. The dryer tail gas scrubber outlet for Station L showed a total fluoride concentration of 0.0014-0.0083 gr/SCF. Ammonia concentrations at the Station U common outlet varied between 0.0001 and 0.0002 gr/SCF, and the reactor tail gas scrubber outlet (Station J) had an ammonia output of 0.002-0.005 gr/SCF. The Station L dryer tail gas scrubber outlet registered 0.001-0.002 gr/SCF NH₃.

Pfaff, Roger O.

KAISER AGRICULTURAL CHEMICALS, INC., REIGEL-

WOOD, NORTH CAROLINA. Office of Air Quality Planning

and Standards, Research Triangle Park, N. C., Emission Measurement Branch and Weston (Roy F-), Inc., Office of Air Quality Planning and Standards Contract, Rept. 73-F'RT-16, 19p., 1973. 1 ref.

Emission measurements for phosphorous pentoxide, particu-

lates, fluoride, and ammonia were performed at the inlet and outlet of a granulator scrubber situated in the granulated NPK fertilizer plant at Kaiser Agricultural Chemicals in Reigelwood, North Carolina. All inlet tests were run simultaneously with the corresponding outlet tests, and P2O5 analyses were obtained from the fluoride test runs. Ammonia tests were run within the same time period as the fluoride tests. Total particulate concentrations at the outlet ranged from 0.03735-0.1309 gr/DSCF and from 0.09494-0.31164 gr/DSCF at the inlet. Particulates for the probe, cyclone, and filter catch ranged from 0.00874- 0.1119 gr/DSCF at the outlet and from 0.04255-0.23106 gr/DSCF at the inlet. Ammonia concentrations were 0.00202 gr/DSCF at the inlet and 0.00116 gr/DSCF at the outlet Total fluorides measured 0.00076 and 0.00055 gr/DSCF at the inlet and outlet, respectively. Total P2O5 for the inlet was 0.00153 gr/DSCF, while the outlet concentration measured 0.00023 gr/DSCF. This data will be used to establish performance standards.

Pfaff, Roger O.

SWIFT AGRICULTURAL CHEMICALS, INC., BIRMINGHAM, ALABAMA. Environmental Engineering, Inc., Gainesville, Fla., Office of Air Quality Planning and Standards Contract, Rept. 73-FRT-6, 22p., 1973. 1 ref.

Emission measurements of phosphorus pentoxide, fluorides, particulates, and ammonia were performed at the outlet of the control system for the granulated NPK fertilizer plant at Swift Agricultural Chemicals in Birmingham, Alabama. Total particulates ranged from 0.04943-0.10764 gr/DSCF; while those for the probe, cyclone, and filter catch were between 0.02105 and 0.08459. Ammonia concentration at the outlet ranged from 0.00034-0.00050 gr/DSCF, and total fluorides varied from 0.00056- 0.00101 gr/DSCF. Values for total P2O5 fell between 0.00053 and 0.01065 gr/DSCF. Data will be used for establishing performance standards. Control equipment includes cyclones and scrubbers.

R. R. Ott and R. E. Hatchard
CONTROL OF FLUORIDE EMISSIONS AT HARVEY ALUMINUM, INC. - SODERBERG PROCESS ALUMINUM REDUCTION MILL. J. Air Pollution Control Assoc 13 (9) 437-43, Sept. 1963. (Presented at the 29th Annual Meeting, Northwest Pollution Control Association, Salem, Ore., Oct. 24-27, 1962.)

A 300 Soderberg, vertical-stud type aluminum mill, located just north of the municipal boundaries of The Dalles, Ore., began production in July 1958. Multiclone type dust collectors and scrubber towers were provided as part of the initial mill installation. Tests have shown that the fluoride removal efficiencies of the scrubbers are 95% or higher if satisfactory maintenance and operation are provided. In response to complaints filed by a private party in 1959 and by agricultural interests in The Dalles area in the spring of 1960, the Sanitary Authority intensified the area, mill, complaint, and air sample surveys and evaluations. Horticultural damage from fluorides has been shown to occur in certain foliage and fruit grown in The Dalles area. Research investigations by the Oregon State University's Agricultural Experiment Station are continuing and include a proposed project for the evaluation of any effect of fluorides upon sweet cherry crop production. The emissions from individual reduction cells, which by-pass the vacuum collection ducts to the control system, have been a suspected source of fluoride discharges that were contributing to the horticultural damage. These emissions originate at the cells during several operational steps including inadequate maintenance of the cell. Roof monitor fluoride sample data obtained in 1961 led to a pilot project including an evaluation of fluoride removal efficiencies. The Authority has granted conditional approval for the roof monitor control system subject to its operation at a maximum fluoride removal efficiency. The five cell building roof monitor systems were completed in September 1962. These controls include an arrangement of spray nozzles for wetting fluoride particulates, aerosols, and gases prior to impingement or absorption on poly-vinyl plastic screens - built into the cell building roof monitors. The final evaluation of the effectiveness of this fluoride removal system will depend upon its over-all reduction in the occurrence of horticultural damage in The Dalles area. (Authors' summary)

Semrau, Konrad T.
EMISSION OF FLUORIDES FROM INDUSTRIAL PROCESSES--A REVIEW. J. Air Pollution Control Assoc., 7(2):92-108, Aug. 1957. 131 refs. (Presented at the American Chemical Society Annual Meeting, 130th, Atlantic City, N. J., Sept. 1956.)

The principal mechanisms of the liberation of fluorides, in high temperature processes is pyrohydrolysis, resulting in the formation of hydrogen fluoride, as indicated by thermodynamic studies and a review of the literature. The principal variables in pyrohydrolysis in most industrial processes were the equilibrium of the reaction, the water vapor concentration in the process atmosphere, and the factors determining mass transfer. Reaction rates were generally high, although little information is available. Significant formation of silicon tetrafluoride was limited to cases involving thermal decomposition of fluosilicates or the reaction of fluorides and silica with acids at relatively low temperatures. Formation of volatile metal fluorides may be a significant liberation mechanism in some cases, although it is generally of less importance than pyrohydrolysis.

Semrau, Konrad T.

EMISSION OF FLUORIDES FROM INDUSTRIAL PROCESSES - A REVIEW. Preprint, American Chemical Society, Washington, D. C., 17p., 1956. 134 refs. (Presented at the American Chemical Society, Meeting, 130th, Atlantic City, N. J., Sept. 1956.)

A review of industrial sources of gaseous and particulate fluorine emissions is presented along with the mechanisms involved in fluorine liberation. The principal mechanism of fluorine liberation in high temperature processes is pyrohydrolysis, which results in the formation of hydrogen fluoride. Variables affecting the formation of hydrogen fluoride include the equilibrium of the reaction, the water vapor concentration in the process atmosphere, and the factors determining mass transfer. Significant formation of silicon tetrafluoride appears to be limited to cases involving thermal decomposition of fluosilicates or the reaction of fluorides and silica with acids at relatively low temperatures. The formation of volatile metal fluorides may be a significant mechanism of liberation in some cases but is generally of less importance than pyrohydrolysis. Fluorine emissions in terms of the percent of fluorine input are tabulated for the following industrial processes: calcining ironstone, steelmaking, brick making, glass making, roasting zinc oxide fume, calcining topaz, calcium metaphosphate manufacture, and the defluorination or manufacture of superphosphate. The table can be used to make order of magnitude estimates of the probable fluorine emissions from a given process. (Author summary modified)

HYGDZNIC ANALYSIS OF THE INFLUENCE OF NOXIOUS

FACTORS ON THE ENVIRONMENT AND STATE OF

HEALTH OF THE POPULATION IN THE VICINITY OF AN

ALUMINIUM PLANT. J. Hyg. Epidemiol. Microbiol. Immunol.

(Prague) 7, 389-403 (1963).

The state of health of all children aged 6-14 years living for at least six years in the fall-out area of the aluminum works was studied. Special attention was paid in their history and in objective examination to the signs described in the literature as the manifestations of the action of fluorine compounds on the human organism, i.e. the haemoglobin percentage, the erythrocyte and leucocyte count and the differential white cell count. Fluoride excretion was controlled in a single urine sample collected over a period of four hours. Bone radiograms were made of the lumbar spine, together with the hip joint, and of the shoulder and arm, together with the elbow. In all the children the teeth were also examined. The average haemoglobin values among children in the given age group (6-14 years) in the fall-out area of the aluminium plant were significantly lower than in the controls. Average erythrocyte values were significantly higher. Average leucocyte values in children aged 6-8 in the fall-out area were higher than in the controls. In the higher age groups the situation was reversed. In the differential white cell count no significant differences were found between average granulocyte values. The significant difference between the amount of haemoglobin in children in the fall-out area of the aluminium plant and in the control group shows

<xref image="2000WVA5.TIF|V3|2006:09:28:01:16:50.00|124846|0"> image: </xref>

that the lower haemoglobin findings in the affected community could be attributed to the less favourable environmental conditions resulting from its proximity to the aluminium plant. The experiences and the individual results obtained from these analyses are used as a basis for suggestions for essential health measures in concrete situations and for the formulation of principles of preventive hygienic protection when projecting and selecting the site of large industrial plants.

ATMOSPHERIC FLUORIDE CONTAMINATION IN THE POTTERY INDUSTRY. Ann. Occupational Hyg. (London), 6 (3), 127-30 (July 1963) (Presented at a Scientific Meeting, British Occupational Hygiene Society, Jan. 4, 1963.)

Investigations were carried out during a health survey in the pottery industry with the object of determining the nature and amount of the fluorine compounds liberated during the firing of ware in muffle type kilns at temperatures in the region of 1150 deg C. Gas samples were taken using sintered plate gas scrubbers which were known to be almost 100% efficient against acid gases. The amount of fluoride trapped in the second scrubber was of the order of 50% of that trapped in the first, and repeatable results could not be obtained. Thus, effective absorption was not being achieved. These results, together with the incongruous etching pointed towards the presence of some agent other than hydrofluoric acid. Thermal precipitator samples showed that the air of the kiln room contained particles having a median size of 0.1 micron, almost all particles being less than 0.4 micron. Samples taken from the dust collecting on ledges of doors of the kilns and on beams in the workrooms were examined by X-ray analysis and were found to contain substantial quantities of ammonium fluosilicate. Having established the nature of the atmospheric contaminant, efforts were next directed toward a method of trapping the sub-micron particles while retaining a sufficient air-flow to enable large samples to be taken so ensuring reliable estimations down to less than one part per million. The method used showed that over 99% of the fluoride present was trapped by this method. Samples were taken at numerous positions in the kiln workrooms and in every case the highest figures were associated with the higher kiln through-puts. Various ventilation control methods are discussed. A better method of dealing with the problem would be to use materials in the body containing little or no F. The hazard from fluorides is not considered to be serious if relatively simple precautions are taken. The etching of the glass in the kiln room, surrounding rooms and buildings cannot necessarily be taken as indicative of the concentration present in the air. External effects due to the emission of fluosilicates will follow the general pattern associated with panicle clouds.

TAKE A DEEP DEADLY BREATH. Middlesex County Dept. of Public Welfare, New Brunswick, N. J., Board of Chosen Freeholders, 35p., ((1967)). (110 rets.)

A proposal was made to construct an aluminum reduction plant in the Raritan Bay area in New Jersey. In an effort to prevent the location of the plant in this area, a report is presented describing the air and water pollution deriving from this industry. The aluminum reduction process is described and sulfur dioxide and fluorides are cited as being major effluents from the process. The health hazards associated with these two pollutants are discussed, and several law suits are mentioned which were brought against various aluminum companies for damages sustained by plants, animals, and humans attributed to emissions from the companies. It is concluded that the Raritan Bay area, which already has an air pollution problem, cannot tolerate the additional burden that the aluminum reduction plant would impose on the atmosphere.

Emission Testing Branch

ALCOA ALUMINUM. BADIN, NORTH CAROLINA. (FINAL
REPORT). Rept. 72-MM-12, 135p., 1972. 1 ret.

Results are presented from an Office of Air Programs emissions test conducted at Alcoa Aluminum in Badin, North Carolina. The plant was considered a well-controlled stationary source in the aluminum reduction industry. Three particulate runs were made at the inlet and outlet of aluminum reduction control system (hood, fluidized bed, and baghouse). The probe, cyclone, and filter catch for this method ranged from 48.49 Ibs/ton feed to 60.27 Ibs/ton feed at the inlet and from 0.330-0.765 Ibs/ton feed at the outlet. The total particulate catch ranged from 63.83 Ibs/ton feed to 83.23 Ibs/ton feed at the inlet and from 5.04-6.80 Ibs/ton feed at the outlet. The standard Environmental Protection Agency method was used at the outlet only. The probe, cyclone, and filter catch ranged from 0.236-0.264 Ibs/ton feed, while the total catch ranged from 2.22-2.30 Ibs/ton feed. The standard EPA train was also used for three runs at the inlet and outlet for fluorides. Soluble fluorides at the inlet ranged from 48.20-58.50 Ibs/ton feed, while total fluoride catch ranged from 56.20-65.90 Ibs/ton feed. The soluble fluoride catch at the outlet ranged from 0.099-0.520 Ibs/ton feed, while the total fluoride catch ranged from 0.327-1.656 Ibs/ton feed. Soluble fluorides at the roof monitor as measured by the standard EPA train ranged from 0.734-1.334 Ibs/ton feed, while the total fluoride catch ranged from 85.18- 90.42 Ibs/ton feed. Other methods employing a non-heated filter between the last impinger and the silica gel or a viton tube for connecting the probe to the standard sample box were also utilized for fluoride measurements at the aluminum reduction control system.

TEXAS GULF SULPHUR COMPANY WET PROCESS
PHOSPHORIC ACID PLANT, AURORA, NORTH

CAROLINA. Environmental Engineering, Inc., Gainesville,
Fla., Environmental Protection Agency Contract, Rept. 71-CI-
31, 3Sp., Nov. 17-18, 1971.

Emission tests were conducted by Environmental Engineering, Inc. under the direction of the Environmental Protection Agency at the Texas Gulf Sulphur Company wet process phosphoric acid plant in order to obtain data for use by the Industrial Studies Branch and the Standards Development Implementation Division. Measurements were made in the outlet stack (following scrubbers) for total fluorides, while observations of visible emissions were made by a member of the Industrial Studies Branch. Fluoride emissions ranged from 0.0034-0.0016 Ibs/ton P2O5 fed. One test result showed an emission rate of 0.0007 Ibs of fluoride/ ton phosphorus pentoxide fed which was unrealistically low and hence should be voided. Visible emissions were 0%. FUNDAMENTAL PROBLEMS OF INDUSTRIAL HYGIENE
IN PROCESSING OF POLYFLUORETHYLENE RESINS.

((Osnovnye voprosy gigieny truda pri pererabotke ftoroplastov.))
Text in Russian. Gigiena Truda i Prof. Zabolevaniya (Moscow),
10(11):12-18, Nov. 1966. 9 refs.

A literature survey is presented on processes involved in the degradation of polyfluoroethylene resins. Studies of operating conditions during heat treatment of polyfluoroethylene showed that the atmosphere may be polluted with perfluoroisobutylene, tetrafluoroethylene, oxyfluorides, hydrogen fluoride, carbon monoxide, and polymer aerosols. A system of prophylactic measures has been developed which drastically reduces toxic air pollution. Heat processing of polyfluoroethylene resins requires the special attention of hygienists and engineers.

EMISSIONS FROM ANODE BAKE PLANT AT REVERE
COPPER AND BRASS, INC., SCOTTSBORO, ALABAMA.

(FINAL REPORT). Environmental Protection Agency, Research
Triangle Park, N. C., Emission Testing Branch, Office of Air
Programs, Rept. 72-MM-24, S6p., 1972 (?). 2 refs.

A final report is presented on emission tests by the Office of Air Programs on the anode bake plant of Revere Copper and Brass, Inc. in Scottsboro, Alabama. Pollutants sampled were fluorides, particulates, hydrocarbons, and sulfur dioxide. Total fluoride emissions ranged from 0.35-0.48 lb/ton, and soluble fluoride ranged from 0.32-0.44 lb/ton. Particulates on and in front of the filter ranged from 0.36-0.41 lb/ton, while total particulate ranged from 0.70-0.87 lb/ton. Results were expressed as pounds of pollutant emitted per ton of aluminum produced. This data will be used to establish performance standards for the aluminum reduction industry. Fans and electrostatic precipitators are used. (Author summary modified)

WILL TRASH REMOVAL BE A MARKETING FACTOR FOR
THE GLASS CONTAINER INDUSTRY AND PRODUCERS OF
OTHER PACKAGING MATERIAL?

((Wird die Abfallbeseitigung zu eineni Marktfaktor fur die Verpackungsglas- Industrie und die Hersteller anderer Verpackungsmittel? Text in German. Glastech. Ber., 40(11):438-438, Nov. 1967.

While the removal of discarded glass containers presents a problem, it is not insurmountable, particularly if refuse crushing plants and techniques are developed which will refuse the silicon from waste glass. The substitution of plastic packaging materials for glass has the disadvantage that during incineration of polyvinylchloride-containing material, corrosive gases are evolved, which cause severe damage to the boiler units of the incinerator plant. Furthermore, the emission of hydrochloric and hydrofluoric acids from these plastics causes dangerous air pollution to such an extent, that in the United States the incineration of plastic waste is forbidden in the vicinity of large cities.

NATURE AND SOURCES OF AIR POLLUTION. Preprint,
39p., 1966. 24 refs. (Presented at the National Conference on
Pollution and Our Environment, Montreal, Quebec, Oct. 31-
Nov. 4, 1966, Paper A2-2.

The nature and properties of pollutants are discussed, including major sources and projected future trends. Seasonal variation in the deposition of total solids, the formation of aerosols by condensation and dispersion, the collection of aerosols and particulate matter, and atmospheric concentrations of suspended particulate matter are discussed. Properties of light

scattering and optical absorbance of aerosols are cited. Condensation nuclei and ions are discussed, as well as the major chemical components of particulate pollution. Sulfur dioxide, hydrogen sulfide, organic sulfides, hydrogen fluoride and other halides, oxides of nitrogen, ozone and oxidants, carbon monoxide, aldehydes, and other organic vapor contaminants are considered. The photochemical theory of smog formation is discussed, and motor vehicle operation and emissions are considered. Dust fall and concentrations of suspended particulates, smoke, and selected pollutants in the urban atmospheres of several Canadian and United States cities are tabulated and correlated with respect to seasons and meteorological parameters.

DICALCIUM PHOSPHATE BORDEN CHEMICAL COMPANY, PLANT CITY, FLORIDA. PEDCo-Environmental Specialists, Inc., Cincinnati, Ohio, Environmental Protection Agency Contract 68-02-0237, Task 1, Rept. 72-CI-15, 37p., Feb. 1972. 1 ref.

Stack emission tests were conducted, and related process samples were taken at the Borden Chemical Co.'s phosphate animal feed plant in Plant City, Fla. during the period Feb. 22-25, 1972. Stack gas samples were taken in the duct leaving the kiln (before the cyclones) and in the stack after the scrubber. Three simultaneous sets of samples were taken at these sites to determine the total fluoride content of the gas streams. Moisture, carbon dioxide, and oxygen content of the gas streams were also measured; velocity, temperature, and total gas flow were determined for each test. Samples of phosphate rock feed, Limestone, phosphoric acid, product and scrubber water were also taken during each run. Each stack gas sample on the dicalcium process extended over a 2-hour period. A complete summary of stack gas conditions and emission levels for each test run are tabulated.

FARMLAND INDUSTRIES INC. WET PROCESS PHOSPHORIC ACID, PIERCE, FLORIDA. PEDCo-Environmental Specialists, Inc., Cincinnati, Ohio, Environmental Protection Agency Contract 68-02-0237, Task 2, Rept. 72-CI-17, 39p., March 1972.

Stack emission tests were conducted and related process samples were taken during the period March 1 and 2, 1972 at the Farmland Industries phosphoric acid plant in Pierce, Fla. Three tests were made to determine total fluoride emissions entering the atmosphere from the phosphoric acid manufacturing process after a primary and secondary scrubbing system. Stack gas samples were taken in the duct after the scrubber. Three sets of samples were taken to determine the total fluoride content of the gas stream. Moisture, carbon dioxide, and oxygen content of the gas stream were also measured; velocity, temperature, and total gas flow were determined for each test. Samples of feed materials, the phosphoric acid product, and scrubber water were also taken during each run. Each stack gas sample extended over a 2-hour period except for the last test which was cut short because of a process malfunction.

INTERNATIONAL MINERALS AND CHEMICALS SUPER
PHOSPHORIC ACID, BARTOW, FLORIDA. PEDCo.-Environ-
mental Specialists, Inc., Cincinnati, Ohio, Environmental Pro-
tection Agency Contract 68-02-0237, Task 2, Rept. 72-CI-16,
54p., March 1972.

Stack emission tests were conducted, and related process sam-
ples were taken during the period Feb. 28-March 1, 1972, at
the International Mineral and Chemical Co. superphosphoric
acid plant in Bartow, Fla. Three tests were made to determine
total fluoride emissions before and after the scrubber serving
the superphosphoric acid plant. Fumes from the plant acid
recycle tank, and the vent serving the product storage tank
and barometric seal tank are directed into a combination ven-
turi scrubber and packed bed scrubber in series before enter-
ing the atmosphere. Samples were taken simultaneously in the
two lines entering the scrubber system, and in the single duct
leaving the scrubber. The equipment layout and the locations
of the sampling sites are included. Three sets of samples were
taken to determine the total fluoride content of the gas
streams. Moisture, carbon dioxide, and oxygen contents of the
gas streams were also measured; velocity, temperature, and
total gas flow were determined for each test. Samples of feed,
product, and recycled acid were taken during each run, as well
as scrubber water samples.

FLUORINE BALANCE AND FLUORINE EMISSION FROM
CEMENT KILNS. ((Flu- orhaushalt und Fluoremission von Ze-
mentofen.)) Text in German. Zement-Kalk-Gips (Wiesbaden),
21(1):18, Jan. 1968. 20 refs

In the burning of Portland cement clinker, fluorine is partly
driven out of the raw materials and fuel. To determine
whether gaseous fluorine is emitted along with the other kiln
gases, complete fluorine determinations were performed for 11
cement kilns of varying design. No gaseous fluorides could be
detected in the cleaned gas from these kilns; the significance
of electrofilters in the removal of solid fluorides is discussed.
In conclusion, cement kilns cannot emit gaseous fluorides
because, in the presence of an excess of CaO, they produce
CaF₂. The negligible level of fluorides in the dust from the
cleaned gas (0.009-1.420 mg. F/Nm to 3rd power) is thus not
dependent upon the magnitude of the fluorine balance, but
upon the efficiency of the electrostatic precipitators. The
amount of fluorine combined in the clinker ranges from 88-98
percent of the total fluorine intake, and this percentage in-
creases with a decrease in dust load of the emitted gas.
Fluorine appears as CaF₂ in clinker and kiln dust and, as
such, is harmless since CaF₂ is relatively insoluble in water.

EMISSION TESTING REPORT. STAUFFER CHEMICAL
COMPANY, TARPON SPRINGS, FLORIDA. (FINAL RE-
PORT). PEDCo.-Environmental Specialists, Inc., Cincinnati,
Ohio, Office of Air Quality and Planning Contract 68-02-0237,
Task 4, Rept. 72-MM-05, Sep., 1972. 1 ref.

Atmospheric emissions of fluorides, phosphorus pentoxide
(P₂O₅), total particulates, and sulfur dioxide from Stauffer
Chemical Company's elemental phosphorus plant at Tarpon
Springs, Florida were sampled to form a data base for New
Source Performance Standards. Tests were made to determine
fluoride and P₂O₅ concentrations before and after the venturi
scrubber serving a furnace slag tapping operation. Fluoride,
P₂O₅, total particulates, and sulfur dioxide concentrations
were also measured before and after the spray chamber serv-
ing the feed nodulizing kiln. Additionally, the fluoride and
P₂O₅ concentrations in the air return line and the carbon
monoxide line leading to the kiln were measured. Composite

stack gas total fluoride emissions were equal to 0.0262 gr/DSCF, while the total P2O5 emissions from the same source were between 0.264 and 0.408 gr/DSCF. Composite values for emissions from the nodulizing kiln-scrubber spray chamber outlet C were 0.00660 gr/DSCF for total fluorides and 0.0150 for total P2O5; those for chamber outlet B were, respectively, 0.00656 and 0.0185 gr/DSCF. The total particulate catch (weighted average) for the nodulizing kiln-scrubber spray chamber outlet was 0.0993 gr/DSCF. Sulfur dioxide emissions at the spray chamber outlet ranged from 144-415 ppm. Orsat analyses were also performed.

INTERNATIONAL MINERALS AND CHEMICALS, AMER-
ICUS, GEORGIA. Office of Air Quality Planning and Stan-
dards, Research Triangle Park, N. C., Emission Testing Branch,
Rept. 73-FRT-15, 34p., 1973. 1 ref.
Emission tests were performed at the International Minerals
and Chemicals plant in Americus, Georgia for the purpose of
setting standards for phosphate fertilizer plants. The normal
superphosphate plant was tested for particulates and fluorides,
while the ammoniator-granulator plant was tested for am-
monia, particulates, and fluorides. Values were recorded for
both inlet and outlet scrubber concentrations. Total particu-
lates for the superphosphate plant ranged from 0.0965-0.1726
gr/DSCF at the outlet, while the concentrations at the am-
moniator scrubber outlet ranged from 0.01304-0.02339
gr/DSCF. Total fluorides at the outlets ranged from 0.0527-
0.120 gr/DSCF and from 0.000201- 0.000543 gr/DSCF at the su-
perphosphate and ammoniator plants, respectively. Ammonia
concentrations at the ammoniator scrubber outlet varied
between 0.912 and 1.49 gr/DSCF.

FMC CORPORATION, POCATELLO, IDAHO. PEDCo-En-
vironmental Specialists, Cincinnati, Ohio, Office of Air Pro-
grams Contract 68-02-0237, Task 15, Rept. 72-MM-26, 26p.,
1972. 1 ref.
Emission tests were conducted before and after the No. 1
scrubber serving the No. 2 calcining kiln at the FMC Corpora-
tion plant in Pocatello, Idaho which was designated as a well-
controlled stationary source in the elemental phosphorus
reduction industry. Samples were collected to determine the
filterable and total particulate emissions, fluorides, phosphorus
pentoxide (P2O5), and nitrogen oxides at each sampling loca-
tion. Particulates (probe, cyclone, and filter catch) ranged
from 0.0478-0.162 gr/DSCF at the outlet and from 0.183-0.873
gr/DSCF at the inlet. Total catch at the outlet was 0.141-0.285
gr/DSCF. Total fluorides at the outlet ranged from 0.00187-
0.00893 gr/DSCF and from 0.03328-0.1576 gr/DSCF at the in-
let. Total average P2O5 was .00647 gr/DSCF at the outlet and
.0372 gr/DSCF at the inlet. The average outlet emission of
NOx was 155 lbs/hr, while that for the inlet was 142 lbs/hr.

A. EMISSION SOURCES

Ohio, Office of Air Programs Contract 68-02-0237, Task 15, Rept. 72fMM-27, 35p., 1972. 1 ref.

A series of emission tests were conducted at the elemental phosphorus plant of Monsanto Chemical Company in Soda Springs, Idaho. Fluoride, phosphorus pentoxide (P2O5), sulfur trioxide, and sulfur dioxide concentrations before and after the venturi scrubber serving the slag tapping operation of the No. 8 electric furnace were measured. Average emission results for the fluoride tests in Ib/hr fluoride were .21 at the outlet and 2.1 at the inlet, indicating and efficiency of 90.0%. The P2O5 emission rate was .00610 Ib/hr at the outlet and .11195 Ib/hr at the inlet for an efficiency of 94.8%. Average emission results for the P2O5 tests were .00771 Ib/hr of P2O5 at the outlet and .08784 Ib/hr P2O5 at the inlet (efficiency of 90.4%). Fluorides measured .00124 Ib/hr at the outlet and .01807 Ib/hr at the inlet (efficiency of 92.0%). Sulfur trioxide outlet and inlet concentrations, respectively, were: 2.5 and 74 ppm (efficiency of 96.6%). Sulfur dioxide removal showed an efficiency of 29.6% with an outlet concentration of 3.8 ppm and an inlet concentration of 5.4 ppm. These data will be used to set performance standards.

Kulujian, Norman and Richard W. Gerstle
INTERNATIONAL MINERALS AND CHEMICAL CORP.,
KINGSFORD, FLORIDA. PEDCo-Environmental, Cincinnati,
Ohio, Office of Air Programs Contract 68-02-0237, Task 12,
Rept. 73-ROC-1, 28p., Feb. 1973. 1 ref.

Atmospheric emissions of particulates and fluorides from the International Minerals and Chemical corporation phosphate rock dryer in Kingsford, Florida were sampled to establish a guide for New Source Performance Standards. Triplicate tests were performed to determine particulate and fluoride concentrations at the inlet and outlet of the dryer scrubber. Total particulate concentrations in Ib/hr averaged out to 945.5 for the inlet and 32.51 for the outlet. Total fluoride concentration was 21.76 Ibs/hr at the inlet and 2.3 Ibs/hr at the outlet. Outlet flow rates for all cases except one particulate run were slightly higher than volumes sampled at the inlet. This may have been caused by cyclonic flow distribution; but, since the maximum difference was only three percent, other factors may have contributed to the variation.

Bell, Carl D.
EMISSION TESTING REPORT. INTERNATIONAL
MINERALS AND CHEMICALS (IMC), WINSTON-SALEM,
NORTH CAROLINA. York Research Corp., Stamford, Conn.,
and the Office of Air Quality Planning and Standards, Research
Triangle Park, N. C., Emission Testing Branch, Office of Air
Quality Planning and Standards Contract, Rept. 73-FRT-14,
21p., 1973. 2 refs.

An Office of Air Quality Planning and Standards emission testing program was conducted at the International Minerals and Chemicals (IMC) plant in Winston-Salem, North Carolina, selected as a well-controlled stationary source in the phosphate fertilizer industry. Particulates, fluorides, phosphorus pentoxide (P2O5), and ammonia were sampled at the inlet to the dryer, the inlet to the cooler, and the outlet of the scrubber. Total particulate catches at the dryer inlet, cooler inlet, and scrubber outlet were: 10.6-20.9 Ibs/hr (average 17.1); 8.44-17.4 Ibs/hr (average 13.4); and 10.9-20.4 Ibs/hr (average 15.1), respectively. Total fluoride catches for the dryer inlet, cooler inlet, and scrubber outlet were respectively: 0.06-0.34 Ibs/hr (average 0.16); 0.58-1.19 Ibs/hr (average 0.90); and 0.06-0.16 Ibs/hr (average 0.11). Total P2O5 for the dryer inlet, cooler inlet, and scrubber outlet were respectively: 13.7-73.7 mg; 340.0-651.0 mg; and 12.7-40.4 mg. Ammonia results for the same three sampling points were respectively: less than 0.3-21.3 mg; 1.8-2.9 mg; and less than 0.3 to 13.0 mg. Results for trace metals and mercury analysis for the second fluoride

run are also presented. (Author summary modified)

Midwest Research Inst., Kansas City, Mo.
SOURCE TESTING REPORT. ARCO CHEMICAL COMPANY, FORT MADISON, IOWA. (FINAL REPORT). Office of Air Programs Contract 68-02-0228, Proj. 358S-C, Task 22, MRI Task 23, Rept. 73-FRT-1, 20p., 1973. 2 refs.
Fluoride and ammonia emissions were determined for the ARCO Chemical Company plant at Fort Madison, Iowa, designated by the Environmental Protection Agency as a well-controlled fertilizer plant. The fluoride caught in the cyclone ranged from 0.00-0.2 Ib/hr with an average of 0.108. Fluoride per ton of P2O5 ranged from 0.0-0.0123 Ib/ton with an average of 0.007. Detected fluoride was present in the soluble form for the cyclone catch for all five runs; and analysis for insoluble fluoride showed less than 0.06 mg, the lower limit of detection for the method employed. The total fluoride emitted ranged from 0.39-0.85 Ib/hr with an average emission of 0.554. All ammonia analyses showed less than 0.3 mg, the lower detection limit; and there was no detectable ammonia discharged from the stack for the period. Results were also collected for moisture and Orsat analysis of the stack gases for each fluoride run. (Author summary modified)

09697

Environmental Science and Engineering, Inc., Gainesville, Fla.

SOURCE TEST REPORT ON MEASUREMENT OF EMISSIONS FROM OCCIDENTAL CHEMICAL COMPANY, WHITE SPRINGS, FLORIDA. (FINAL REPORT). Office of Air Programs Contract 68-02-0232, Task 12, Task Change 3, Rept. 73-ROC-3, 38p., 1973. 2 refs.
Fluoride and particulate emission tests were performed at the phosphate rock drying operation located at the Occidental Chemical Company, White Springs, Florida for the purpose of obtaining data for use by both the Industrial Studies Branch and the Performance Standards Branch of the Environmental Protection Agency. All emission tests were performed simultaneously at the inlet and outlet of a Dorrco Cyclonic Wet Scrubber; fluoride emissions were determined by a method currently being studied by the Environmental Protection Agency, while particulate emissions were determined by the EPA Method No. 5. Grab samples of the stack gases at each sampling site were obtained by an Orsat analyzer, and the concentrations of carbon dioxide, oxygen, and carbon monoxide were determined. Fluoride, trace metals, and mercury content in rock dryer process reactants and products were also determined. Total fluoride emissions in lbs/ton of feed ranged from 0.000596-0.000958 for the rock dryer scrubber outlet and from 0.0218-0.0269 for the inlet. Total phosphates ranged from 2.46-6.5 mg for the outlet and 236.4-347.4 mg for the inlet. Total particulate emissions in lbs/ton of feed were 0.130-0.177 for the outlet and 0.535-1.075 for the inlet.

Danielson (comp. and ed.), Public Health Service, Cincinnati, Ohio, National Center for Air Pollution Control, PHS-Pub-999-AP-40, p. 11-21, 1967. GPO: 806-614-30

The parameters of an air pollution problem, particularly the problem in Los Angeles County; the measures taken to eliminate the problem; and control measures still needed are described. The air contaminants include: organic gases (hydrocarbons, hydrocarbon derivatives); inorganic gases (NO_x, SO_x, CO); miscellaneous inorganic gases (NH₃, H₂S, Cl₂, F₂); particulates (carbon or soot particles, metallic oxides and salts, oily or tarry droplets, acid droplets, metallic fumes). Each is discussed indicating the sources and significance in the air pollution problem.

Hammond, William F. and Herbert Simon
SECONDARY ALUMINUM-MELTING PROCESSES. In: Air Pollution Engineering Manual. (Air Pollution Control District, County of Los Angeles.) John A. Danielson (comp. and ed.), Public Health Service, Cincinnati, Ohio, National Center for Air Pollution Control, PHS-Pub-999-AP-40, p. 284-292, 1967. GPO: 806-614-30

The secondary aluminum melting process is described in detail indicating the type of furnaces used, charging practices, pouring practices, and fluxing. Frequently a large part of the material charged is low-grade scrap and chips. Paint, dirt, oil, grease, and other contaminants from this scrap cause large quantities of smoke and fumes to be discharged. Even if the scrap is clean, large surface to volume ratios require the use of more fluxes which can cause serious air pollution problems. The emissions from aluminum fluxing may consist of hydrogen fluoride, hydrogen chloride, chlorine in the gaseous state, aluminum chloride, magnesium chloride, aluminum fluoride, magnesium fluoride, aluminum oxide, magnesium oxide, zinc chloride, zinc oxide, calcium fluoride, calcium chloride and sodium chloride in the solid state. Because of the widely divergent properties of these air contaminants the problem of control is complicated. A canopy hood is usually used for capturing the emissions from the charging well of aluminum reverberatory furnaces. Calculation of the quantity of air required can be accomplished as shown in an example. Some type of scrubber is required to remove the soluble gaseous fraction of the effluent, and either a baghouse or an electrical precipitator is needed to control the solids. In order to maintain adequate collection efficiency, the use of high efficiency scrubbers with a caustic solution as the scrubbing medium has been found necessary. Typical test data on collection efficiency for both ordinary and high-efficiency scrubbers are outlined. Average collection efficiencies obtained on various devices on emissions from chlorinating aluminum are outlined. The devices are horizontal multipass wet cyclone, single-pass wet dynamic collector, packed-column water scrubber with limestone packing, ultrasonic agglomerator followed by a multitube dry cyclone, and an electrical precipitator. The trend in control equipment for aluminum-fluxing emissions appears to be away from electrical precipitators and toward the scrubber-baghouse combination.

COMBUSTION AND THERMAL DECOMPOSITION PRODUCTS OF ORGANO-PHOSPHORUS INSECTICIDES. Preprint, Texas Univ., Austin Environmental Health Engineering Research Lab., Dept. of Civil (Env. Health) Engineering, 1968. (3) refs. (Presented at the 61st Annual Meeting of the Air Pollution Control Association, St. Paul, Minn., June 23-28, (11)p., 1968. Paper 68-9.)
Research was done on the oxidation and thermal decomposition products of some common organophosphorus pesticides to shed light on toxic hazards resulting from fires involving pesticides, those either stored in warehouses or those freshly

sprayed in fields. The data presented are mostly directed toward demonstrating how much of the organic phosphorus escapes to the air as unconverted pesticide and how much as 'other' compounds. There are only a few reactions which would produce compounds with a toxicity comparable to the original pesticides, while most would reduce its toxicity by a factor of 100 to 1000. EMISSIONS FROM WATER SPRAY TOWER AND WET
ELECTROSTATIC PRECIPITATOR SYSTEM AT ALU-
MINUM COMPANY OF AMERICA, ALCOA, TENNESSEE.
Office of Air Programs Contract, Rept. 71-MM-14, York Rept.
Y-7730-A, 138p., June 26, 1972. 1 ref.
The source test was performed at the Alcoa primary aluminum plant for the purpose of gathering emission data for the Performance Standards Branch and control unit efficiency data for the Industrial Studies Branch. The aluminum cells were of the vertical stud Soderberg type. Emissions from thirty cells were manifolded to a particulate knockout chamber followed by a forty foot redwood water spray tower in series with a wet electrostatic precipitator before being released to the atmosphere. The standard Environmental Protection Agency particulate train was used to sample both particulate matter and fluorides. Six simultaneous samples were taken across the control system using paper filters in three of the runs and glass fiber filters in the other three runs. In addition, three samples were taken at the outlet using membrane filters. Triplicate gaseous samples of fluorides, sulfur dioxide, and nitrogen oxides were also taken at both the inlet and outlet. Experimentation with two types of absorbing media in the midget impingers of the fluoride gas train was performed by collecting three fluoride samples in water and three in sodium hydroxide at both the inlet and outlet.

AIR POLLUTION. *Chambres d Agriculture*, 35(304; Suppl.):1-16, Nov. 1964. 7 refs. Translated from French by Information Interscience, Inc., TR 0416.
The sources and effects of air pollution in the country and in urban communities of France are reviewed. Air pollution causes important losses of crops, contaminates the soil, vegetables and livestock, and ultimately poisons the consumers of these agricultural products. Fluorine, sulfur dioxide, and organic peroxide compounds are particularly noxious. Specific examples of damage caused by these compounds to plants and livestock in France are given. In Paris the air contains approximately 180 mineral products/cu m as well as residues of combustion, soot, ashes, dust, and wastes of all types. The principle sources of air pollution in Paris are presently due to emanations from domestic furnaces, emissions from industrial fumes, and exhaust gas from automobiles. Domestic furnaces are responsible for 70% of the sulfur pollution in the center of Paris. Anti-pollution legislation is summarized.

A. EMISSION SOURCES

11

cialists, Inc., Cincinnati, Ohio, Environmental Protection Agency Contract 68-02-0237, Task 1, Rept. 72-CI-14, 48p., Feb. 1972. 1 ref.

Stack emission tests were conducted and related process samples were taken at the Borden Chemical Co.'s phosphate animal feed plant in Plant City, Fla., Feb. 22-25, 1972. Three tests were made to determine total fluoride emissions on the rock defluorination operations. The total fluoride from the kiln exit gases at the scrubber inlet averaged 2.96 gr/SCF which is equivalent to 417.6 lb/hr. The total fluoride at the scrubber outlet averaged .0016 gr/SCF which is equivalent to .57 lb/hr. Moisture, carbon dioxide, and oxygen contents of the gas stream were also measured as well as gas velocity, temperature and total volume.

NORTHWEST BERGEN COUNTY SEWER AUTHORITY
SLUDGE INCINERATOR, WALDWICK, NEW JERSEY. Office of Air Programs Contract 68-02-0225, Task 7, Rept. 72-C1-2, 133p., May 1972. 2 refs.

Source emission tests were conducted at the Northwest Bergen County Sewer Authority Sludge Incinerator to aid in the establishment of federal emission standards for new sources in this category. Three tests were conducted on the fluidized bed sludge incinerator equipped with an Impinget scrubber. Samples were taken after the scrubber for particulates, moisture, sulfur dioxide, nitrogen oxides, hydrogen chloride, mercury, and fluorides. Also sampled were carbon monoxide, carbon dioxide, and oxygen for excess air determinations. All tests were performed according to the recommended source test procedures of the Office of Air Programs, Environmental Protection Agency. Examination of the particulate loadings indicated an 80% difference between test NBS-1 (0.583 lb/hr) and either of the last two tests, 0.116 lb/hr and 0.099 lb/hr, respectively. There is no clear explanation for the reduced loadings on the second day's tests.

EMISSION SURVEY OF THE LOWER POTOMAC SLUDGE
INCINERATOR, FAIRFAX COUNTY, VIRGINIA. York
Research Corp., Stamford, Conn., Air Pollution Control Office
Contract, Rept. 71-CI-20, York Rept. Y-7394-I, 72p., Sept. 1,
1971.

The purpose of this program was to obtain the total emissions from the sludge incinerator. This information will be used for the establishment of Federal performance standards. Representative particulate samples were collected from the stack flue gas at the scrubber exhaust, using the Air Pollution Control Office Method. Nitrogen oxides, sulfur dioxide, hydrogen chloride, metals, mercury, and fluorides were sampled by APCO Methods. Sludge at inlet, inlet-outlet scrubber water, hydrocarbons, odors, and ash were also sampled. Scrubber outlet results are: SO₂, 2.013, 2.069, and 2.125 ppm; NO_x, 62.8-46.0, 83.3-75.8, and 44.3-54.7 ppm; HCl, 11.9, 6.83, and 10.9 ppm; Hg times 10 to the -6 power, .1956, .7073, and .2184 ppm; fluorides, .469; HC, 7.875-3.375-4.50, 3.375-3.375-9.0, and 2.25-3.375-7.875 ppm; odor, 80-120-5120, 40-20-640, and 160-40-20 odor units/CF; filter particulates, .0260, .0136, and .0134 gr/SCFD; and total particulates, .0335, .0221, and .0170 gr/SCFD.

EMISSIONS FOR PRIMARY ALUMINUM SMELTING
PLANT (SPECIAL EMISSION CONTROL SYSTEM) AT ALU-
MINUM COMPANY OF AMERICA, WENATCHEE,
WASHINGTON. Office of Air Programs Contract, Rept. 71-
MM-16, York Rept. Y-7730-B, 104p., June 8, 1972. 1 ref.

The source tests were performed for the purpose of gathering

emission data for the Performance Standards Branch and control unit efficiency data for the Industrial Studies Branch of the Environmental Protection Agency. Emissions from the primary aluminum cells were recirculated through the process via a specially developed system designed by Alcoa to improve the quality of aluminum produced and drastically reduced emissions. The standard EPA particulate train was used to sample both particulates and fluorides. Six simultaneous samples were taken across the control system using paper filters in three runs and glass fiber filters in the other three runs. Also, three outlet tests were run using membrane filters. Triplicate gaseous samples of fluorides, sulfur dioxide, and nitrogen oxides were also taken at both inlet and outlet. Experimentation with two types of absorbing media in the midget impingers of the fluoride gas train was performed by collecting three samples in water and three in sodium hydroxide. Outlet results are: particulates (lb/ton) paper filter, .365, .353, and .707; glass fiber filter, .587, .353, and .617; membrane filter, .350, .414, and .222, total fluorides (lb/ton) paper filter, .000812, .000867, and .000433; glass fiber filter, .000503, .000580, and .000509; membrane filter, .000638, .000689, and .001111; gaseous fluorides (lb/ton), .132, .300, .233, and .270; and SO₂, 10.5, 7.2, 10.5, 9.3, 11.6, and 9.9 ppm.

BLOOD PROTEIN AMIDE NITROGEN AND ITS POSSIBLE

DIAGNOSTIC VALUE IN INTOXICATION WITH ELECTRO-

WELDING AEROSOL. (Amidnii azot belkov krovi i ego voz-

mozhnoe diagnosticheskoe znachenie pri vozdeistvii na organizm

electrosvarochnogo aerosolya.) Text in Russian. Gigien. Truda i

Prof. Zabolevaniya, 12(8):56-58, Aug. 1968. 16 refs.

The aerosol obtained from automatic electro-welding, using

An 60 agents, contained in mg/cu m 0.83-1.15 HF, 2-3.18

N₂O₅, and 120-150 dust-of which 14.4 mg/cu m was Mn, 72-

90 mg/cu m Fe, 6-7.5 mg/cu m CaF, and 8.6-10.5 mg/cu m

SiO₂. Rats placed in exposure chambers were subjected to

daily 4 hr aerosol inhalations for 1, 3, 6, or 9 months. The

blood from the animals was subjected to acid (IN H₂SO₄)

hydrolysis during which ammonia derived from the blood

protein amide groups was measured. The one-month aerosol

inhalation reduced the amide group stability: of the total amide

N, in the first 10 minutes of hydrolysis, 31% was released as

ammonia in controls, as compared to 41-54% in the treated

animals. Complete hydrolysis was obtained in the controls in 2

hr and in the treated animals in 30 min. These changes are be-

lieved to be caused by Mn. The hydrolysis curves show a

characteristic pattern of change in the 1-month period, and sta-

bility in the 3, 6, or 9-month period. The curves may be of

diagnostic value in cases of intoxication with the electro-weld-

ing aerosol.

NEW DEVELOPMENTS IN FLUORIDE EMISSIONS FROM

PHOSPHATE PROCESSING PLANTS. J. Air Pollution Control

Assoc., 19(1):15-17, Jan. 1969. 5 refs.

<xref image="2000WVAB.TIF|V3|2006:09:28:01:17:08.00|115304|0"> image: </xref>

The problem of monitoring for ambient fluoride emissions near a phosphate fertilizer processing plant in Manatee County, Florida, are discussed. Results of a study conducted to determine the emission of fluorides from the surface of a gypsum settling pond at the Borden Chemical Company plant are given. Conclusions reached as a result of the study are: (1) That fluorides are emitted from such a pond at a minimum rate of about 0.16 pound per acre of surface area per day, (2) that a breakpoint of about one-half mile from the pond occurs in concentration of fluoride in the ambient air, (3) that concentrations of fluorides in excess of 75 ppm were found in young citrus leaves in groves near the gypsum pond, and (4) that, although a one-mile protective buffer zone for a phosphate plant might be considered adequate for citrus groves, it would not necessarily be adequate for row crops or ornamental flowers such as gladiolas. EMISSIONS FROM WET SCRUBBER SYSTEM AT
REYNOLDS METALS, INC., TROUTDALE, OREGON. Office
of Air Programs Contract, York Rept. Y-7730-E, GAP Rept. 71-
MM-20, 148p., May 31, 1972.

A source test was performed at the Reynolds Metals Primary Aluminum Plant to gather emission data for the Performance Standards Branch and control unit efficiency data for the Industrial Studies Branch. Emissions from the cells passed through a wet scrubber system before being released to the atmosphere. The standard Environmental Protection Agency particulate train was used to sample both particulate matter and fluorides. Three simultaneous samples were taken across the control system using glass fiber filters. Triplicate gaseous samples of fluorides, sulfur dioxide, nitrogen oxides were also taken at both the inlet and outlet. Gaseous fluoride samples were collected in midget impingers using water as the scrubbing solution. Three samples were collected on the inlet and three on the outlet.

EMISSIONS FROM THE WET SCRUBBER SYSTEM AT
HARVEY ALUMINUM, THE DALLES, OREGON. Office of
Air Programs Contract, Emission Testing Rept. 71-MM-21,
York Rept. Y-7730-F, 167p., June 7, 1972.

A source test was performed at the Harvey Primary Aluminum Plant for the purpose of gathering emission data for the Performance Standards Branch and control unit efficiency data for the Industrial Studies Branch. Emissions from the cells were manifolded to a wet scrubber system before being released to the atmosphere. The standard Environmental Protection Agency particulate train was used to sample both particulate matter and fluorides. Six simultaneous samples were taken across the control system using paper filters in three of the runs and glass fiber filters in the other three runs. In addition, three samples were taken at the outlet using membrane filters. Triplicate gaseous samples of fluorides, sulfur dioxide, and nitrogen oxides were also taken at both the inlet and outlet. Experimentation with two types of absorbing media in the midget impingers of the fluoride gas train was performed by collecting three fluoride samples in water and three in sodium hydroxide at both the inlet and the outlet. At the primary inlet, total fluorides were 42.24, 56.01, and 62.70 Ibs/ton Al, gaseous fluorides were 38.59, 38.57, and 31.73 Ibs/ton Al, and SO₂ was 25.3, 124, and 27.5 ppm. At the primary outlet, total fluorides were 1.266, 1.666, and 1.945 Ibs/ton Al, gaseous fluorides were .877, 1.418, and 1.647 Ibs/ton Al, and SO₂ was 107.3, 23.5, and 165 ppm. At the secondary inlet, total fluorides were .642, 2.43, and 1.89 Ib/ton Al. At the secondary outlet, they were 1526, 18.34, and 1.102 Ib/ton Al.

ATMOSPHERIC EMISSION EVALUATION, MARTIN
MARIETTA ALUMINUM PRIMARY REDUCTION PLANT,
THE DALLES, OREGON. Office of Air Programs Contract 68-
02-0236, Rept. 73-ALR-1, 83p., Dec. 1972. 1 ref.
The exhaust gases of the primary and secondary emission con-
trol systems on the Soderburg cells at Martin Marietta Alu-
minum in Dalles, Oregon were sampled and evaluated Oct. 2-
5, 1972 in order to set performance standards. The three sam-
ples taken from the primary outlet had a fluoride concentra-
tion of 0.000087, 0.000164, and 0.000289 grains/standard cu ft.
The three samples taken from the secondary outlet had a
fluoride concentration of 0.000348, 0.000168, and 0.000209
grains/standard cu ft. The standard cu ft is reported at 70 F, 1
atmosphere pressure, and dry. The following information is in-
cluded: discussion of results, description of the process, loca-
tion of sampling point, operation and production data on cells
sampled during emission tests, and sampling and analytical
procedures. Control equipment includes afterburners, bub-
blers, electrostatic precipitator, mist eliminator, and a spray
chamber. (Author summary modified)

Crate, C.

FLUORIC POISONING. X. THE JURIDICAL PROBLEM. ((L-
'intoxication Fluoree. X. Le probleme juridique.)) Text in
French. Rev Med Veterinaire, 194:13-20, 1953.
The problem includes (a) the p. oof of fluoric poisoning and (b)
the estimate of damages, (a) The proof must rest on both clini-
cal and chemical criteria. After a review of early procedures,
the following factors are given as pertinent: 1. disease symp-
toms in an animal do not necessarily imply high fluorine con-
tent in the bones; 2. an animal must always be considered as
having been a victim of fluorosis when its bone ashes contain
more than 0.5% of fluorine (in CaF₂); 3. when the fluorine
content is less than 0.25, the subject is free from the specific
poisoning; 4. between 0.25 and 0.50, the animal may show
costal nodosities, and these are not incompatible with the es-
sential osteomalacia. Tooth enamel is particularly sensitive to
fluoric poisoning. Blood and muscle laboratory tests are nega-
tive. Urine tests are valueless unless supported by fluorine and
fluoride tests of air and fodder. Urine tests on humans, how-
ever, may point to further useful research applicable to
animals, (b) Losses due to 'factory disease' may be direct or
indirect. The former include damages due to the settlement or
death of the sick animals. Settlement, by mutual agreement, is
subject to the positive results of the tests, and this is a source
of conflict. The indemnity must cover the replacement value
plus medical and other expenses. Indirect losses include cost
of substitution fodder during the illness, and the loss in value
of the establishment permanently exposed to fluoric pollution.
Further remarks must await the outcome of instances cur-
rently before the courts.

A. EMISSION SOURCES

13

the USA. These or their precursors emanate from transportation, industry, or generation of electricity. The increase in population and in our demands for energy will result in increased activity within each of these categories and attendant increases in pollutant emissions. Thus, in all instances, the problem is going to worsen within the next 20 years. By 2000 AD or shortly thereafter, there should be a reduction in the levels of SO₂ to present levels; the fluoride pollution problem will probably be worse; and, unless a power plant such as the electric engine is developed to take the place of the gasoline engine, our major problem will probably be one of photochemical air pollutants. It is also quite likely that pollutants such as hydrogen chloride and chlorine will increase in importance in the future. Finally, it should be kept in mind that the accuracy of predictions of this type is subject to changes in attitudes and technology. (Author's summary)

Kelso, Gary

EMISSIONS FROM A CARBON ANODE BAKE PLANT AT CONSOLIDATED ALUMINUM CORPORATION, LAKE CHARLES, LOUISIANA. Midwest Research Institute, Kansas City, Mo., Office of Air Programs Contract 68-02-0228, Proj. 3585-C, Task 19, MRI Task 20, Rept. 73-ALR-3, 84p., Jan. 29, 1973. 2 refs.

Source emission tests were conducted at the Consolidated Aluminum Corp.'s aluminum reduction plant at Lake Charles, La. A summary of results from the fluoride and mass particulate tests conducted on the stack (behind an electrostatic precipitator), and the Orsat analysis of the stack gas are tabulated. Three fluoride tests were run. There was close agreement (16.58 Ib/hr and 16.81 Ib/hr, respectively), in the first two tests, while the third test had a lower value (15.69 Ib/hr). The total mass particulate emissions test which was run with the third fluoride test had a value of 74.77 Ib/hr. Twelve separate Orsat analyses were run on the gas sample and are tabulated. Results of the tests are carbon dioxide-average-1.1%; oxygen-average-19.0%; and carbon monoxide-average-0.0%. These data will be used to establish performance standards for the industry. (Author summary modified)

12622

Boehlen, B.

FLUORINE EMISSION AT ALUMINIUM WORKS. Chem. Eng., No 221, CE266-268, Sept. 1968.

The most important of the extraneous substances in the air which arise from alumina reduction are inorganic fluorine compounds, alumina, tar, carbon, sulfur dioxide, and carbon monoxide. The fluorine compounds are particularly important because of their toxicity to livestock and plants. Waste gas purification systems must be of two types: One for purification of the furnace waste gas and the other for purification of air from the premises. The first system for use with the Soderberg furnace consists of a combustion step with cyclone and electrostatic precipitator dust removal, and spray-type scrubbers or filter-plate columns for hydrogen fluoride removal. The system for purification of air from the premises consists of a spray chamber with synthetic fabric lining mounted on the roof. Purification of waste furnace gases from Soderberg furnaces results in a fluorine concentration in the pure gas of less than 10 mg/cu m, while the purification of air from the premises results in a fluorine concentration in the pure gas less than 2 mg/cu m.

Valentine, Fisher, and Tomlinson, Seattle, Wash., and Office of Air Programs, Research Triangle Park, N. C., Emission Testing Branch and Industrial Studies Branch
HARVEY ALUMINUM, THE DALLES, OREGON. OAP Contract 68-02-0236, Rept. 72-MM-07, 121p., 1973.
Harvey Aluminum was considered a well controlled stationary source in the aluminum reduction industry and was, therefore selected by the Office of Air Programs for the emission testing program to determine performance standards. Testing at the bubbler- electrostatic precipitator (ESP) site included determination of particulate and fluoride emissions. Samples were collected at the inlet to the bubbler and at the stack outlet of the ESP. Testing was also conducted for fluorides and particulates in the secondary system. This included sampling sites before and after the spray chambers in the spray tower. Three particulate and three fluoride runs were made at each inlet and outlet sampling site for both the primary and secondary systems. The particulate emission data indicated that the major portion of the reaction cell exhaust was going through the primary system while the remaining exhaust went through the secondary control system. The combined probe and filter catch at the primary system inlet ranged from 42.41 Ibs/ton feed to 136.80 Ibs/ton feed while at the primary dsystem outlet the range was from 0.0395 Ibs/ton feed to 0.0736 Ibs/ton feed. The total catch, which includes the impinger portion of the train, ranged from 44.90 Ibs/ton feed to 138.63 Ibs/ton feed at the inlet and from 0.100 Ibs/ton feed to 0.1325 Ibs/ton feed at the outlet. The particulate emissions in the probe and filter catch at the inlet of the secondary system ranged from 16.46 Ibs/ton feed to 27.19 Ibs/ton feed while the outlet ranged from 2.61 Ibs/ton feed to 12.46 Ibs/ton feed. The total catch at the inlet had a range of 22.38 Ibs/ton feed to 30.90 Ibs/ton feed while the outlet ranged from 4.77 Ibs/ton feed to 16.91 Ibs/ton feed. The fluoride emission results were divided into soluble and total fluorides. The soluble fluoride emissions at the inlet of the primary system ranged from 30.97 Ibs/ton feed to 41.44 Ibs/ton feed and at the outlet from 0.101 Ibs/ton feed to 0.0140 Ibs/ton feed. The total fluorides at the inlet ranged from 32.57 Ibs/ton feed to 92.80 Ibs/ton feed while at the outlet the range was from 0.0101 Ibs/ton feed to 0.0161 Ibs/ton feed. The secondary system (spray tower) ranges for soluble fluorides were 0.639 Ibs/ton feed to 0.839 Ibs/ton feed for the inlet, and 0.551 Ibs/ton feed to 1.026 Ibs/ton feed for the outlet. The total fluorides for the inlet and outlet of the secondary system ranged from 0.638 Ibs/ton feed to 0.873 Ibs/ton feed and from 0.164 Ibs/ton feed to 0.273 Ibs/ton feed respectively.

To set realistic performance standards for the aluminum reduction industry, Reynolds Aluminum, a well-controlled source, was studied. Three particulate and three fluoride runs were made at the inlet and outlet of the electrostatic precipitator (ESP). Four fluoride runs were made at the roof monitor. Almost all of the exhaust from the aluminum reduction reaction cell is caught by the hood. Therefore, to be assured of an adequate amount of sample at the roof, it had to be sampled for approximately 10-15 hr at a high sampling rate. The combined probe, cyclone and filter particulate catch at the ESP inlet ranged from 60.8 lbs/ton feed to 73.5 lbs/ton feed while at the outlet it ranged from 1.39 lbs/ton feed to 4.98 lbs/ton feed. The total particulate catch ranged from 74.5 lbs/ton feed to 90.8 lbs/ton feed at the inlet and 3.21 lbs/ton feed to 8.91 lbs/ton feed at the outlet. The fluoride emissions results were analyzed as solution fluorides and total fluorides. The soluble fluoride emissions at the inlet of the ESP ranged from 24.4 lbs/ton feed to 36.6 lbs/ton feed and at the outlet from 0.365 lbs/ton feed to 0.422 lbs/ton feed. The total fluoride catch at the inlet ranged from 35.0 lbs/ton feed to 50.4 lbs/ton feed while at the outlet it ranged from 0.382 lbs/ton feed to 0.422 lbs/ton feed. The soluble fluorides at the roof monitor ranged from 1.09 lbs/ton feed to 2.76 lbs/ton feed. The total fluoride catch at the roof monitor ranged from 1.10 lbs/ton feed to 2.85 lbs/ton feed. Valentine, Fisher, and Tomlinson, Seattle, Wash.
ALCOA, ALUMINUM, WENATCHEE, WASHINGTON.
FINAL REPORT. Office of Air Programs Contract 68-02-0236,
Kept. 72-MM-06, 104p., 1972. 1 ret.
Alcoa Aluminum in Wenatchee was considered a well controlled stationary source in the aluminum reduction industry and was, therefore, selected for the emission testing program to determine reasonable performance standards. Testing at the A-398 site included determination of particulate and fluoride emissions. Samples were collected at the inlet to the fluidized bed and at the outlet of the baghouse. Sampling for fluorides was also conducted at the roof monitor using a portable roof takeoff system which Alcoa uses in its own testing program. The combined probe, cyclone, and filter catch for the particulate emissions at the inlet of the A-398 ranged from 95.8 lbs/ton feed to 1.39 lbs/ton feed. The total particulate catch, which includes the impinger portion of the train, at the A-398 ranged from 97.4 lbs/ton feed to 101 lbs/ton feed at the inlet and 1.32 lbs/ton feed to 2.54 lbs/ton feed at the outlet. The soluble fluoride emissions at the inlet and outlet of the A-398 ranged from 17.3 lbs/ton feed to 36.8 lbs/ton feed and 0.0547 lbs/ton feed to 0.260 lbs/ton feed respectively. The roof monitor soluble fluoride emissions ranged from 1.09 lbs/ton feed to 1.34 lbs/ton feed. The total fluoride emissions at the inlet of the A-398 ranged from 17.4 lbs/ton feed to 51.7 lbs/ton feed while at the outlet they ranged from 0.0547 lbs/ton feed to 0.267 lbs/ton feed. The total fluoride emissions at the roof monitor ranged from 1.10 lbs/ton feed to 1.37 lbs/ton feed.

Environmental Engineering, Inc., Gainesville, Fla.
C. F. CHEMICALS, INC. DIAMMONIUM PHOSPHATE,
BARTOW, FLORIDA. Environmental Protection Agency Contract CPA-70-82, Rept. 71-CI-37, 135p., Dec. 1971. 1 ref.
Emission tests were conducted at the C. F. Chemicals, Inc. diammonium phosphate plant No. 3 located in Bartow, Fla. Dec. 16-20, 1971. Using separate sample trains, measurements were made for both total fluorides and ammonia in the inlet and outlet ducts of the reactor, cooler, and dryer scrubbers. Grab samples of the scrubbing liquids, the process reactants, and the process products were taken and analyzed for fluoride and phosphorus pentoxide content. Pertinent results of the tests are tabulated. The plant operated under normal process conditions during the three test runs. However, minor irregu-

larities occurred in the sampling and there are irregularities in the test data. The data was obtained for use by the Industrial Studies Branch and Performance Standards Branch of the Environmental Protection Agency.

Environmental Engineering, Inc., Gainesville, Fla.
ROYSTER COMPANY DIAMMONIUM PHOSPHATE, MULBERRY, FLORIDA. Environmental Protection Agency Contract 68-02-0232, Rept. 72-CI-25, 165p., May 1972. 1 ref.
Emission tests were conducted at the Royster Co. diammonium phosphate production facilities in Mulberry, Fla., May 17-18, 1972 for the Industrial Studies Branch and the Performance Standards Branch of Environmental Protection Agency. Using separate sample trains, measurements were made for both total fluorides and ammonia. Emission tests were conducted in the inlet and outlet ducts of the reactor, cooler, and dryer scrubbers as well as in the common outlet to the atmosphere. Grab samples of the scrubbing liquid, the process reactants, and the process products were analyzed for fluoride and P2O5 (phosphorus pentoxide) content. Although scrubber operation appeared normal during the tests, it was subsequently determined that an abnormal acid mist entrainment problem existed. This resulted in higher than normal fluoride emissions to the atmosphere and also explains why in all cases fluoride concentrations measured at the scrubber outlets were greater than the concentrations measured at the inlets. A complete summary of the gas conditions, fluoride concentrations, and ammonia emission levels are tabulated. (Author summary modified)

C. F. CHEMICALS, INC. WET PROCESS PHOSPHORIC ACID, BARTOW, FLORIDA. Environmental Engineering, Inc., Gainesville, Fla., Environmental Protection Agency Contract CPA-70-82, 72p., Dec. 1971. 1 ref.
Emission tests were conducted at the C. F. Chemicals Inc., wet process phosphoric acid plant no. 3 located in Bartow, Fla. Three tests runs were conducted on Dec. 14-15, 1971. The scrubber inlet from the attack tank showed fluoride emissions ranging from .452-.907 Ib/ton P2O5 (phosphorus pentoxide) fed. At the inlet from the filtration system, the fluoride emissions ranged from .0025-.0042 Ib/ton P2O5 fed, while emissions at the inlet from the condenser ranged from .005-.006 Ib/ton P2O5 fed. At the scrubber outlet, total fluoride emissions ranged from .011-.064 Ib/ton P2O5 fed. Compared to the other two test runs, the value obtained for the first run (.064 Ib/ton P2O5 fed) is extremely high. This irregularity is unexplainable, except for the possibility that the sample for run 1 was contaminated. Scrubber efficiency was calculated and ranged for 93.0% to 98.7%. A complete summary of the test results are tabulated.

S. W. BROOKLYN MUNICIPAL INCINERATOR, NEW YORK, NEW YORK. FINAL REPORT. Environmental Protection Agency Contract CPA-70-82, Task 1, Rept. 71-CI-15, 160p., 1972. 2 refs.

Source tests for the determination of particulates, sulfur dioxide, nitrogen oxides, hydrogen chloride, fluoride, special metals, and mercury emissions were performed at Unit Number 1 of the Southwest Brooklyn Municipal Incinerator. Control equipment utilized in Brooklyn was a Wheelabrator electrostatic precipitator. Three particulate test runs were performed at the inlet and outlet of the incinerator. Several gaseous emission tests were performed at the outlet only. Only Orsat analyses for carbon dioxide, oxygen, and carbon monoxide were performed at both inlet and outlet. Inlet particulates (probe, cyclone, and filter catch) measured 0.3744, 0.3783, and 0.3714 gr/SCFD. Particulate total catch was 0.3814, 0.3822, and 0.3790 gr/SCFD. At the outlet SO₂ was 1.1, 0.3, and 0.3 ppm, NO_x was 28.9, 44.3, and 44.8 ppm, and HCl was 63.1, 15.4, and 38.2 ppm. Outlet particulates (probe, cyclone, and filter catch) were 0.1642, 0.1679, and 0.0983 gr/SCFD, and total particulates were 0.2013, 0.2048, and 0.1347 gr/SCFD. Data will be used to determine realistic performance standards.

TEXAS GULF, INC. SUPERPHOSPHORIC ACID, AURORA, NORTH CAROLINA. AUGUST 29-30, 1972. Environmental Protection Agency Contract 68-02-0232, Rept. 73-PSA-1, 43p., Aug. 1972. 1 ref.

Emission tests were conducted at the Texas Gulf, Inc. superphosphoric acid production facilities in Aurora, N. C., Aug. 29-30, 1972 for the Industrial Studies Branch and the Performance Standards Branch of the Environmental Protection Agency. Three 2 hr tests were made and the outlet stack of the off-gas scrubber was measured for soluble and insoluble fluorides. Grab samples of the scrubbing liquid, the process reactant, and the process product were analyzed for fluoride and phosphorus pentoxide content. The total fluoride for the three runs was 0.002 gr/SCF, 0.002 gr/SCF, and 0.003 gr/SCF respectively. This is equivalent to total fluoride in lb/hr of 0.005, 0.005, and 0.007 for the three runs.

TEXAS GULF, INC., WET PROCESS PHOSPHORIC ACID, AURORA, NORTH CAROLINA. Environmental Protection Agency Contract 68-02-0232, Rept. 73-PSA-2, 62p., Sept. 1972. 1 ref.

Emission tests were conducted at the Texas Gulf, Inc. phosphoric acid plant in Aurora, N. C. Aug. 31-Sept. 1, 1972 for use in setting performance standards. Measurements for soluble and insoluble fluorides were made in the inlet ducts and outlet stack of the fume scrubber. The inlet leading from the attack tank and the combined inlet leading from the filtration system-condenser hotwell system were sampled. Numerous grab samples of the process reactants and products were analyzed for fluoride and phosphorus pentoxide content. There are two identical production lines—the East Train and the West Train. The first two test runs (1W, 2W) were per-

formed on the West Train; the third test (3E) was conducted on the East Tram. At the outlet, total fluoride was 13.9 mg, 14 mg, and 2.2 mg for Runs 1W, 2W, and 3E respectively; in the reactor scrubber inlet the total fluoride was 178.3 mg, 121.1 mg, and 283.4 mg; at the filter and miscellaneous scrubber inlet, total fluoride was 138.2 mg, 6.7 mg, and 1.4 mg.

W. R. GRACE AND COMPANY. GRANULAR TRIPLE SUPERPHOSPHATE STORAGE. BARTOW, FLORIDA. Environmental Protection Agency Contract 68-02-0232, Rept. 73-FRT-12, 42p., Sept. 21-22, 1972. 1 ref.
Three test runs of 2 hr each were conducted at a granular triple superphosphate storage building at the W. R. Grace and Company phosphate works. Measurements for soluble and insoluble fluorides were made at the outlet stack of the storage building scrubber. Grab samples of the scrubbing liquid and storage product were analyzed for fluoride and phosphate (P2O5) content. A schematic flow diagram of the process operation and the sampling location, pertinent test results, and complete test data are given. The amount of granular triple superphosphate located in storage during the test runs was approximately 2000 tons P2O5 product. Normal production and shipping operations were taking place during the test runs. No problems were encountered during the sampling. Locations of sampling points, sampling and analytical procedures, and laboratory analysis procedures are described. The data will be used by the Industrial Studies Branch and the Performance Standards Branch of the Environmental Protection Agency.

ROYSTER COMPANY. RUN-OF-PILE TRIPLE SUPERPHOSPHATE. MULBERRY, FLORIDA. Environmental Protection Agency Contract 68-02-0232, Rept. 73-FRT-11, 48p., Sept. 19-20, 1972. 1 ref.
Emission tests were conducted at the Royster Chemical phosphate works. Royster's scrubbing system is designed so that the stack gas from the scrubber is split into the streams and vented to the atmosphere by two stacks. Both stacks were tested simultaneously for soluble and insoluble fluorides. In addition, grab samples of the scrubbing liquids, the process reactants, and the product were analyzed for fluoride and phosphorus pentoxide content. A schematic flow diagram of the process operation and the sample locations and pertinent test results are presented. The total fluoride emissions for the three runs were 0.18, 0.30, and 0.15 lbs/ton P2O5. The process, sampling points, and sampling and analytical methods are described. The data will be used by the Industrial Studies Branch and the Performance Standards Branch of the Environmental Protection Agency.

W. R. GRACE AND COMPANY GRANULAR TRIPLE SUPERPHOSPHATE, BARTOW, FLORIDA. Environmental Protection Agency Contract 68-02-0232, Rept. 72-CI-30, 66p., June 1972. 1 ref.

Emission tests were conducted at the W. R. Grace and Co. phosphate works in Bartow, Fla. On June 14-15, 1972, three test runs of approximately 2 hr each were conducted on the granular triple superphosphate process in order to get data for determining performance standards. Measurements were made for total fluorides at the outlet stack and at the inlet ducts to the dryer and miscellaneous scrubbers. Grab samples of the scrubbing liquids, the process reactants, and the process products were analyzed for fluoride and phosphorus pentoxide content. At the outlet, the total fluoride was the three runs was 9.07 mg, 6.7 mg, and 6.9 mg; at the dryer scrubber inlet, total fluoride was 5116.7 mg, 1212.6 mg, and 72.0 mg; at the miscellaneous scrubber inlet, total fluoride was 472 mg, 7.3 mg, and 153.8 mg. No explanation for these irregularities could be confirmed. A complete summary of stack gas conditions, emission concentrations, and system efficiency is tabulated. (Author summary modified)

W. R. GRACE AND COMPANY. GRANULAR TRIPLE SUPERPHOSPHATE STORAGE. BARTOW, FLORIDA. Environmental Protection Agency Contract 68-02-0232, Rept. 72-CI-30B, 36p., June 14-15, 1972. 1 ref.

Emission tests were conducted at the W. R. Grace and Company phosphate runs to obtain emission data for the Industrial Studies Branch and Performance Standards Branch of the Environmental Protection Agency. Measurements for soluble and insoluble fluorides were made at the outlet stack of the storage building scrubber. Grab samples of the scrubbing liquid and storage product were analyzed for fluoride and triple superphosphate. A schematic flow diagram of the process operation and sampling location is given. The amount of granular triple superphosphate located in storage during the test runs was approximately 4500 tons. Normal production and shipping operations took place during test runs. No irregularities occurred during the sample. A summary is given of stack conditions and emission levels for each test, and complete results are listed. The location of sampling points, sampling and analytical procedures, and emission calculations and results are described.

Environmental Engineering, Inc.
SEVENTY-THIRD STREET MUNICIPAL INCINERATOR, NEW YORK, NEW YORK. FINAL REPORT. Environmental Protection Agency Contract CPA-70-82, Task 1, Rept. 71-CI-14, ISOp., 1972. 1 ref.

Source tests for the determination of particulates, sulfur dioxide, nitrogen oxides, hydrogen chloride, fluoride, special

metals, and mercury emissions were performed. Control equipment utilized was a venturi water scrubber. One particulate emission test was performed at the inlet to the control unit, while three particulate test runs were performed at the outlet. Several gaseous emission tests were performed at the outlet only. Only Orsat analyses for carbon dioxide, oxygen, and carbon monoxide were performed at both the inlet and outlet. Inlet particulates at probe, cyclone, and filter were 1.0856 gr/SCFD; the total catch was 1.2382 gr/SCFD. Outlet particulates at probe, cyclone, and filter were 0.0842, 0.0888, and 0.0830 gr/SCFD; total catch was 0.1026, 0.1088, and 0.1067 gr/SCFD. Outlet SO₂ emissions were 3.6 and 1.4 ppm; NO_x were 32.7, 51.8, and 69.1 ppm; and HCl were 170, 97.1, and 108.0 ppm. Data will be utilized to determine realistic performance standards.

12919

Environmental Engineering, Inc., Gainesville, Fla.
INTERNATIONAL MINERALS AND CHEMICALS DICALCIUM PHOSPHATE, BARTOW, FLORIDA. Environmental Protection Agency Contract CPA-70-82, Rept. 72-CI-21, 90p., March 1972. 1 ref.

Emission tests were conducted at the International Minerals and Chemicals dicalcium phosphate production facilities in Bartow, Fla. March 13-14, 1972 for the Industrial Studies Branch and the Performance Standards Branch of the Environmental Protection Agency. Measurements for total fluorides were made at the inlet and outlet ducts of the reactor-granulator, dryer, and screen-mill scrubbers. Grab samples of the scrubbing liquids, the process reactants and the process product were analyzed for fluorides and phosphorus pentoxide content. A complete summary of stack conditions, emission levels, and scrubber efficiencies for each test run and test location is tabulated.

12929

Environmental Engineering, Inc., Gainesville, Fla.
ROYSTER COMPANY. RUN OF PILE TRIPLE SUPERPHOSPHATE. MULBERRY, FLORIDA. Environmental Protection Agency Contract 68-02-0232, Rept. 72-CI-18, 77p., Feb. 29-March 1, 1972. 1 ref.

Emission tests were conducted at the Royster Company triple superphosphate plant. Total fluorides were measured at the scrubber inlet duct and at the two outlet stacks to the scrubber. The emissions from the mixing cone were also measured. Grab samples of the scrubbing liquid, the process reactants, and the process product were analyzed for fluoride and phosphorus pentoxide (P₂O₅) content. A schematic flow diagram of all sampling locations and complete test results are given. All process and scrubber operating conditions were normal during the three test runs. No major sampling problems were encountered. For the third test run, both the percent stack gas moisture and the fluoride concentration for the north and south outlet stacks were extremely low compared to the other two test runs. No explanation was available for this anomaly. Stack gas conditions, fluoride emission levels, and scrubber efficiencies for each test run are given. Process

BORDEN CHEMICAL, INC. GRANULAR TRIPLE SUPERPHOSPHATE STORAGE. PINEY POINT. Environmental Protection Agency Contract CPA-70-82, Rept. 72-CI-5B, 52p., Jan. 24, 1972. 2 refs.

Emission tests were conducted at the Borden Chemical, Inc. phosphate works. Total fluorides were measured at the inlet and outlet ducts of the storage off-gas scrubber and grab samples of the scrubbing liquid were taken during the test runs and analyzed for fluoride content. A schematic flow diagram of the process operation and the sampling locations are given. The amount of granular triple superphosphate located in storage during the test runs was approximately 1400 tons. Loading of the product into rail cars took place during test runs. No major problems were encountered during the sampling. Stack conditions and fluoride concentrations for each test point, sampling and analytical procedures, emission calculations, and results are presented. The data will be used by the Industrial Studies Branch and the Performance Standards Branch of the Environmental Protection Agency.

12933

Environmental Engineering, Inc., Gainesville, Fla.
W. R. GRACE AND COMPANY WET PROCESS PHOSPHORIC ACID, BARTOW, FLORIDA. Environmental Protection Agency Contract CPA-70-82, Rept. 72-CI-1, 81p., Jan. 1972. 1 ref.

Emission tests were conducted at the W. R. Grace and Co. wet process phosphoric acid plant located in Bartow, Fla., Jan. 4-5, 1972 for the Industrial Studies Branch and the Performance Standards Branch of the Environmental Protection Agency. Measurements for soluble and insoluble fluorides were made in the inlet ducts and outlet stack of the crossflow scrubber. The inlet leading from the attack tank and the inlet leading from the filtration system were sampled. Numerous grab samples of the process reactants and products were taken and analyzed for fluoride and phosphorus pentoxide (P₂O₅) content. For runs one, two, and three, respectively, the scrubber inlet from the attack tank showed fluoride emissions of 0.0333, 0.182, and 0.187 lb/ton P₂O₅ fed. Emissions at the inlet from the filtration system were 0.031, 0.025, and 0.024 lb/ton P₂O₅ fed, while at the scrubber outlet to the atmosphere, total fluoride emissions were 0.004, 0.008, and 0.004 lb/ton P₂O₅ fed. From this data, scrubber efficiency was calculated to be 93.3%, 96.0%, and 97.7% for runs one, two, and three, respectively. A complete summary of stack gas conditions, sample volumes collected, and fluoride emissions are tabulated. (Author summary modified)

Hollander, Egon
CONDITIONS FOR RELEASING FLUORINE DURING THE DECOMPOSITION OF PHOSPHATES WITH SULFURIC ACID. (Podmienky uvolnovania fluoru pri rozklade fosfatov kyseliny sirovou). Text in Czech. Chem. Prumysl (Prague), 18(2):65-67, 1968. 14 refs.
Conditions were determined for releasing fluorine, during the decomposition of the most commonly used natural phosphates by means of acids. In the decomposition of fluoride phosphate, relatively little fluorine is released: 31% in the USA, 40 to 45% in the USSR, and 33.7 to 42.8% in Czechoslovakia. In manufacturing concentrated and combined fertilizers, where the amount of fluorine released is con-

siderably less, additional fluorine is released through the manufacture of the superphosphate. Factors that influence the process include type of phosphate, temperature, concentration, fineness of the grain, and the amount of acid used. The higher the concentration of sulfuric acid, the greater the concentration of phosphoric acid. When concentrations of phosphoric acid range to 30% P2O5 at temperatures of 95 to 100 C, evaporation of the acid is low; with more than 40% of P2O5, evaporation rises sharply. The amount of fluorine released is directly proportional to the temperature, the amount of acid used for the reaction, and the fineness of phosphor grain. The reaction is also facilitated by using active matter with the acid.

Cross, F. L., Jr. and R. W. Ross
FLUORIDE EMISSIONS FROM PHOSPHATE PROCESSING
PLANTS. Fluoride Quarterly, J. Intern. Soc. Fluoride Res.,
2(2):97-105, April 1969. 4 refs.

A three-part study to determine the extent of an area affected by fluoride emissions from a phosphate plant gypsum pond led to the following conclusions: Monitoring of fluorides by static air samplers at distances up to 8000 ft from the pond indicates a break point in concentration at one-half mile. The F levels drop off rapidly to this break point. In citrus leaves from groves close to the pond, fluoride concentrations up to 75 ppm were found in spring flush. Similar amounts were found in young leaves at one-half mile from the pond. Concentrations taken before November may serve as an indicator of air pollution which can result in a reduction of citrus yield. A one-mile protective buffer zone for a phosphate plant might be considered adequate for citrus groves but would not necessarily be adequate for row crops or ornamental flowers such as gladioli. Studies conducted on the surface of the pond by means of a specially constructed sampling shelter demonstrated fluoride emissions up to 0.16 lb/acre/day. At least 26 lbs of fluoride/day were emitted from the 160-acre pond. (Author conclusions modified)

Knabe, Wilhelm
EXPERIMENTAL STUDY OF THE FLUORINE CONCENTRATION IN NEEDLES AND LEAVES OF PLANTS AS FUNCTION OF THEIR HEIGHT ABOVE GROUND. (Experimentelle Pruefung der Fluoranreicherung in Nadeln und Blaettern von Pflanzen in Abhaengigkeit von deren Expositionshoehe ueber Grund.) Translated from German. Landesanstalt fuer Immissions und Bodennutzungsschutz des Landes Nordrhein-Westfalen, Essen (Germany), p. 101-116, Sept. 1968. 6 refs.

The ability of many types of plants to absorb fluorine from the air and store it in the leaves makes this pollutant particularly well suited for studies of the pollutant intake by plants, as function of the immissions in ground level atmospheric layers. Therefore, field tests were performed of a distance of 4.6 km from a fluorine emitting aluminum factory. The plants were set up in containers at various heights above ground. The factory emits approximately 30 kg F/h, about 80 percent in the gaseous state and 20 percent as dust. The wider aim of the experiments was to find correlations between the amount of excessive fluorine in plants and characteristic immission parameters. In the narrower range of our field experiments, the fluorine in-

<xref image="2000WVAH.TIF|V3|2006:09:28:01:17:26.00|117810|0"> image: </xref>

take of overground plant organisms as a function of the height of the plant above ground was studied. All plants had the same soil and the same water supply. A detailed description is given of the experimental procedures and equipment. The results pertain only to the period from October to November, and October to February, respectively, and only to fluorine containing emissions from one aluminum plant. The increase of the fluorine content in plant organisms with increasing height above ground or in the first row facing the aluminum plant in the fall and winter of 1967/68 confirms earlier field experiments. For further analyses of the fluorine content in plant organisms it must be kept in mind that not only the physiological age and the sampling time but also the height above ground and the position toward the emission source ought to be comparable.

MacDonald, H. E.

FLUORIDE AS AIR POLLUTANT, Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 2(1):4-12, Jan. 1969. 31 refs. Fluoride compounds reach the air from two sources: volcanic action and man's industrial activities. The two greatest acute air pollution episodes occurred in Belgium's Mouse Valley and in Donora, Pa. In both disasters, there was evidence of acute fluoride poisoning. The sources of industrial fluoride pollution are coal, clay, cryolite, fluorspar, hydrogen fluoride, and phosphate rock. About half the bituminous coal consumption in the United States for 1963 was utilized by electric power utilities. Vegetation in several counties in California has been adversely affected by fluoride emissions from brick, tile, and pottery factories. Cryolite, used in the production of aluminum, has been traced as a source of damage to vegetation, livestock, and human health. Fluorspar and hydrogen fluoride are used in steel production, and the latter is also used in the production of high-octane gasoline. Many cases of eye irritation were recorded shortly after a Los Angeles refinery began using hydrogen fluoride. Fluoride emissions from the production of phosphate fertilizer, phosphoric acid, and phosphorus have been responsible for damage to vegetation and livestock, and respiratory ailments in people. Control of fluoride emission may be achieved by a variety of scrubbers and electrostatic precipitators

Colombini, M., C. Mauri, R. Olivo, and G. Vivoh

OBSERVATIONS ON FLUORINE POLLUTION DUE TO EMISSIONS FROM AN ALUMINUM PLANT IN TRENTINO.

Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 2(1):40-48, Jan. 1969. 5 refs.

For many years, women and children complained of skin lesions similar to suffusions in an area of Trentino, near an aluminum plant. These lesions were first observed in the same place about 30 years ago. The symptomatology is related to damage to the vegetation due to emission of fluorine compounds. Since March 1966, three permanent stations were installed in the area in order to collect volatile fluorine compounds. Since February 1967, five deposit gauges were established at progressively increasing distances from the source. Fluorine air pollution has reached values close to and sometimes above 10 micrograms/cu m of air. Rain water collected for two weeks in the deposit gauges showed decreasing concentrations of fluorine the greater the distance from the source. The highest value of 7.13 mg/L was found in the deposit gauge closest to the factory. In the inhabited area, the fluorine content ranged between 0.14 and 2.55 mg/L. Since May 1967, the degree of fluorine pollution has decreased following installation of modern purification equipment at the plant. (Author summary modified)

Smith, Ralph I.

AIR-POLLUTION PROBLEMS OF THE PHOSPHATE INDUSTRY. (Bureau of Mines and Geology, Montana, Western Phosphate Region, Proc. Ind. Seminar West. Phosphate Reg., Butte, Mont., 1966, p. 46-48, June 1967. (Special Pub. 42). Materials from the phosphate industry which contribute to air pollution are listed as follows: solids, such as natural dust and organic particles, industrial dusts such as carbon and fly ash from the combustion of fuels, and fine dusts; gases, such as sulfur dioxide and trioxide, hydrogen fluoride, silicon tetrafluoride, chlorine, hydrogen chloride, carbon monoxide and dioxide, nitrous and nitric oxide, ammonia, alcohols, and ozone; and water vapor and mists, which are liquid from condensation of water and acids on suitable nuclei. The noxious gases come from two sources in the phosphate industry: a wet process called denning, and from calcination processes. As the gases or smoke come out of the stack, they may either continue upward, spread out and diffuse, or an inversion or turbulence may cause a rapid downward trend a short distance from the stack. Smoke and fumes have both psychological effects (depression and general irritation) and physiological effects (the irritation of membranes of the nose, throat, and lungs by the inhalation of gases; a toxic effect in the stomach of animals who eat contaminated vegetation). Methods for the removal of solids are listed as follows: a long flue equipped with baffles and settling chambers; a filtering system such as a bag house; and the cyclone. The most economical and effective way of removing noxious gases is by scrubbing. Sulfur gases may also be sent through a sulfuric acid plant. Fluorine gases may be removed by forcing the gases through a bed of limestone; the absorption causes a chemical reaction to take place, forming inert calcium fluoride. Other removal methods mentioned include the following; electrostatic precipitation, and sonic precipitation.

SANITARY PROTECTION OF AIR IN VINNITSA. U.S.S.R.

Literature on Air Pollution and Related Occupational Diseases, vol. 8:241-246, 1963. (B. S. Levine, ed.) (Also: *Gigiena i Sanitariya*, 26(1):73-76, 1961. CFSTI: 63-11570)

Plans are presented for the purification of discharges from different shops and departments of a superphosphate plant which currently emits 10.5 tons of sulfur dioxide, 6.5 tons of nitric acid, 1.2 tons of sulfuric acid, 0.5 tons of fluorides, and one ton of superphosphate and tricalcium dust each day. Even at a distance of 2000 meters from the plant, the maximum fluorine concentrations are 13 times in excess of the allowable limit. Similarly, sulfur dioxide concentrations at 1000 meters and sulfuric acid aerosols at 500 meters have been found to exceed allowable limits. The maximum concentration of dust at 200 m from the plant is 15.4 mg/cum, or thirty times in excess of the allowable limit. Dust samples collected at 200-1000 meters from the plant showed a fluorine content of 0.8 to 1.4%. Soil samples at 200, 500, and 1000 meters contained 16.9, 9.61, and 8.7 mg of fluorine per 100 g of soil. Among the measures being taken to reduce pollution are the elimination of gas leaks by equipment hermetization, the installation of dust catching and gas purification equipment, and the construction of high stacks for greater dispersion of pollutants. It is further recommended that the sulfuric acid department build a separate housing for its exhaust fans, use filters to raise tail-gas utilization efficiency, and build a warehouse to store the apatite concentration.

EVALUATION OF FLUOR CONTENT IN LIVING ORGAN-
ISM STANDING UNDER THE EFFECT OF FLUOR EX-
HALATIONS. (Zhodnotenie hladiny fluoru v zivom organizme
ovplyvnovanom fluorovymi exhalatmi). Text in Czech. Cesk.
Hyg. (Prague), 13(1): 12-17, 1968. 21 refs.

Such parameters as air quality, atmospheric fluor content, and content of fluor in dust fall, drinking water, and agricultural products were evaluated in a long-term study carried out in the vicinity of an aluminum plant. At the same time, the fluor content in the teeth, hair, nails, and urine of children living close to the plant was assessed. The mean values of the total fluor content in the air fluctuated from 0.02 to 0.14 mg/F per cu m, and in fallen dust reached up to 7.34 tons of fluor per sq m per yr. The mean fluor content in the drinking water was 0.2 mg/liter. Fluor content in food produced from plants grown in the region fluctuated within 0.5 and 10.0 mg/F/kg, in foods of animal origin within 0.5 and 1.2 mg/F/kg. The fluor content in bones of sparrows, frogs, and rats was two to fourteen times higher than in the controls. The teeth, nails, hairs, and urine of children living in the nearest residential quarter contained an amount of fluor which was twice to three times as large as that of the control children. Examinations in children living in the neighborhood of the plant did not reveal any signs of endemic fluorosis. (Author summary modified)

Knop, Wilhelm
INDUSTRIAL DUSTS AND WASTE GASES. (Industriestaube und-abgase). Text in German. Wasser Luft Betrieb, 14(1):20-23, Jan. 1970.

The major sources of dangerous and annoying industrial dusts or gaseous pollutants are enumerated. In mines, coking plants, and gas works, dusts develop at the sorting, crushing, and mixing processes. The extent of dust development depends on the water content, the grain size, and the strength of the material. Waste gas and vapor develops behind driers, transportation facilities, and in the quenching of coke. The chemical industry produces the dangerous halogen gases, of which chlorine and bromine are the most harmful. The maximum allowable long-term emission concentration for chlorine is 0.1 cu cm/cu m air; the short-term value is three times daily 0.5 cu cm/cu m air. Hydrogen chloride develops at the manufacture of dyes. The maximum allowable emission concentration for fluorine is 0.5 cu cm/cu m air. Fluorine compounds (in gaseous form or dust) develop in aluminum production, fertilizer manufacture, and at the polishing stations for quartz and glass. With sulfuric acid production in a Claus furnace or in the manufacture of dyes SO₂ and SO₃ develop. The maximum allowable concentration for these pollutants is 0.2 cu cm/cu m air. Hydrogen sulfide has been limited to 0.1 cu cm/cu m air. It develops in refineries in dye and viscose manufacture. A particularly noxious gas is carbon monoxide which develops in phosphorus and carbide plants. Quarries, cement factories, the ceramic industry, mixers for asphaltting highways, iron ore sintering plants, blast furnaces, and foundries all are large contributors of dust and gaseous emissions.

Chovin, Paul
CHEMICAL POLLUTION OF THE ATMOSPHERE. (La pollution chimique de l'atmosphere). Text in French. Sci. Progr. Decour., no. 3417; 35-40, Jan. 1970. 6 refs.

A systematic general review is presented of the origin and nature of chemical pollutants of the atmosphere, of their action on living beings, and of the battle against atmospheric pollution. Principle sources of pollutants are the industrial and domestic heating plants. In regions of high industry concentration, steel plants and chemical plants emit specific pollutants.

Principal pollutants are sulfur dioxide, sulfur trioxide, carbon dioxide, carbon monoxide, nitric oxide, nitrogen dioxide, fluorine, and light and heavy hydrocarbons. Sulfur dioxide is a byproduct of combustion of fossil fuels containing, on the average, 3% S (coal in France has about 1% S, some foreign coals have up to 6% S). Estimated emission of S is as follows: in France, 2 million tons, in England, 5 million tons, and in the U. S., 40 million tons a S per year. Sulfur trioxide is largely due to oxidation of SO₂; it combines with moisture to form H₂SO₄ which is very noxious. Rain has a beneficial effect by scrubbing the polluted air. Carbon dioxide is the product of complete combustion of C; 500 to 600 million tons are estimated to be emitted in England. Carbon monoxide is the product of incomplete combustion, rather rare in industry, but invariably present in automobile exhaust gas. Nitric oxide and NO₂ are present in low concentrations, but a complex photochemical reaction produces one type of smog, ozone, and new chemical compounds such as peracetylnitrate, CH₃-CO-OO-NO₂, which has a very strong physiological effect. Fluorine and its compounds, such as HF, are emitted by fertilizer and by aluminum plants. Dusts are emitted by industrial and domestic heating plants. The action of air pollutants on bronchi and lungs is discussed at length. The reaction of the cardio-vascular system and the incidence of broncho-pulmonary cancer are also considered. In the battle against atmospheric pollution laws alone are insufficient, means of measuring emissions, and enforcing compliance are essential.

17377

Rowden, E.

OUTSTANDING AIR POLLUTION PROBLEMS. Brit. Clayworker, 78(930):36-46, Nov. 1969. 7 refs. (Presented at the Clean Air Conference, Eastbourne, Oct. 22.)

The most serious pollution problem in the heavy clay and refractories industries is the brown smoke produced by the firing on blue bricks, roofing tiles, and floor quarries and the firing of salt-glazed pipes in intermittent and continuous grate-fired kilns that are hand fired with coal. In recent years, dark smoke emission has been reduced considerably by the incorporation of oil-fired continuous car tunnel kilns or the conversion of continuous or intermittent kilns to oil- or natural gas-firing. To reduce emissions for existing coal-fired intermittent kilns, modifications of the coal-charging procedure are suggested. Other outstanding problems of the industries concern the new minimum kiln chimney height established by the Alkali Inspectorate and the emission of fumes and acid soots. Many existing stacks will need to have height increases or be replaced by mid-1970. If natural gas becomes available, existing chimneys of small height would be sufficient, except when firing high sulfur or fluorine-bearing clays, or where salt glazing is carried out. The acid soot emission is related to the firing of oil in continuous kilns. Methods for its reduction depend on achieving and maintaining efficient combustion, limiting the sulfur content of the fuel or clay, and preventing acid deposition. Fume emissions are more difficult to deal with than smoke emissions. They present serious problems in the firing of fletton bricks and in the firing in continuous kilns of clays containing sulfur and fluorine compounds. A practical commercial solution has not yet been found for this problem.

Tsunoda, Fumio

A NEW ASPECT OF AIR POLLUTION - FLUORIDES.

(Taikiosen mondai no aratano ichi kyokumen - fukkabutsu ni yoru bai o reini). Text in Japanese. Igaku No Ayumi (Progr. Med.), 70(2):621-622, Sept. 27, 1969. 2 refs.

As a result of industrial growth, atmospheric contamination by mercury, lead, fluorine and other compounds is becoming noteworthy. An aluminum refinery in Aizu basin was blamed for the death of all silkworms in the area. Trees shed their fruit prematurely. The harmful compound was: $3\text{NaF}-\text{AlF}_3$. The fluorine contained in it contaminated the atmosphere and badly damaged plants. Some plant species were sensitive to only a few ppm. Many accumulate fluorine, paddy and gladiolus. This is the reason why cows and silkworms were poisoned. Also, there is a possibility that human beings accumulate too much fluorine in their bodies. Even a few ppm in the air may exert a direct influence. In the Aizu district, inquiries were made into the effects of long-term exposure to fluorine. Persons who had accumulated fluorine for many years were examined with regards to the quantity of fluorine in urine, lung function, existence of spotted teeth, and bone softening especially the pelvis and the limbs). Results of the study have not yet been issued. The major sources of fluorine are aluminum refineries whose number is expected to increase. In the near future, fluorine will be also used for atomic power industries. It is concluded that the air pollution research has arrived at the stage where not only the atmosphere but also water, soil, and food are objects of study because of an indirect contamination through air.

17464

REMARKABLE MEASURES FOR THE IMPROVEMENT OF

AIR QUALITY. (Beachtliche Massnahmen zur Verbesserung der Luft). Text in German. Wasser Luft Betrieb, 14(1):33-36, Jan. 1970.

In 1967, a total of 4 million tons of sulfur dioxide were emitted from industrial sources, particularly power plants. Until 1975, an increase to 5 million tons is anticipated; from then on, the SO_2 emission will stagnate and eventually decline, due to the use of nuclear power. Contrary to this downward trend, fluorine, chlorine, hydrocarbons and numerous odorous pollutants are on an upward trend, due to the expanding chemical industry. In the metallurgical industry, the sinter capacity has been doubled; thus, the larger units will emit HCl and larger quantities of gaseous fluorine compounds along with SO_2 . It is estimated that sintering plants presently already emit as much fluorine compounds as the aluminum plants. No fluorine removal method from the waste gases of the ore sintering plants is yet available. Traffic will further increase, as well as vehicle emissions. Emissions by domestic heaters will decrease because electric or central heating will take the place of old coal or oil fired heaters. To combat the increasing pollution of air by an overall increase of emissions, the state of North-Rhine-Westphalia plans to establish emission inventories. Such inventories have been made in the area around Cologne; other large cities will soon follow.

17471

Knop, Wilhelm

INDUSTRIAL DUSTS AND WASTE GASES. (Industriestaube und-abgase). Text in German. Wasser Luft Betrieb, 14(2):63-66, Feb. 1970. 22 refs.

The most dangerous and annoying pollutants emitted by various industries are enumerated. Steel mills emit primarily iron oxides and fluorine compounds. Half of the original fluorine input is emitted; the other half goes into the slag. The iron oxide emissions, primarily the small particles below 5 micron, form the brown smoke. The non-ferrous metal fabricating and

finishing plants emit metal oxides (cadmium oxide). When inhaled, the latter may be extremely harmful. The TLV (threshold limit value) is 0.1 mg/cu m air. In aluminum production, dust-laden waste gases develop, despite the wet process. The aluminum oxide dust content in the rotary furnace is 300-400 g/standard cu m. In electrolytic reduction of aluminum oxide, cryolite also dissociates. As a consequence, hydrogen fluoride and dusts of fluorine compounds are found in the waste gas. The TLV for fluorides is 2.5 mg/cu m; for hydrogen fluoride, 2 mg/cu m. In lead plants 3 to 3.5 cu m waste gases per kg sinter develop in the sintering and roasting station. They contain 1.5 to 5% by volume SO₂ and up to 15 g/cu m dust. The dust contains lead, zinc, sulfur, and small amounts of other elements. Considerable amounts of metal vapors develop. In the fly dust of the shaft furnaces, cadmium oxide or sulfate, arsenic, zinc, and thallium compounds may be found. In copper smelting plants, the waste gases contain fly dust and SO₂. In zinc refining, fly dust (0.1 g/standard cu m) and SO₂ are emitted to the waste gas. In ferro-alloy production, dusts of various kinds are carried along in the waste gases. The waste gas quantity of a 10 MW furnace amounts to 70,000-250,000 cu m/h; the dust content, to 0.25-2.5 g/cu m.

Kiss, Istvan

INDUSTRIAL METHODS FOR ENRICHMENT OF U-235. (Az IJ-235 dúsítástanak ipari módszerei). Text in Hungarian. Energia Atomtech. (Budapest), 11(7-8):466-473, 1958.

Various methods are reviewed for increasing the U-235 concentration of uranium ore. The various procedures for separating a particular isotope include distillation, chemical reaction, thermal diffusion, electrolysis, gas diffusion, and the ultracentrifuge; however, the two last-mentioned methods have been found by statistical studies to be the most suitable. In addition to a study of the theoretical principles of gas diffusion and centrifugation, the isotope enrichment is discussed. Formulas are given for the time required for a cascade to reach equilibrium and for the amount of power required to operate the gas diffusion cascade. The gas diffusion method of separating uranium isotopes uses uranium fluoride (UF₆), which sublimates at 56 C. Only one isotope of fluorine occurs naturally, so that the UF₆ molecule will have a weight of either 352 or 349, if one neglects the 0.005% content of U-234 that occurs naturally in uranium ore. When the K25 type of diffusion plant is used, the pressure of the entire system has to be kept below atmospheric pressure for the following reasons: the smaller the pressure, the larger the enrichment factor, due to the longer free path of the molecules; there is less possibility of an impact between the UF₆ and the tubing; and if a leak were to develop in the equipment, the UF₆ would not escape. Uranium fluoride is in itself a poisonous compound, and when diluted by the atmosphere, it is prone to react with the moisture in the air to form hydrogen fluoride gas.

A. EMISSION SOURCES

21

fur and more stringent legislation preventing the discharge of gases containing sulfur dioxide to the atmosphere has generated interest in the utilization of gases from various sources as an alternate raw material. The important characteristics of gases relative to sulfuric acid production are particulate matter, volatile impurities, temperature, SO₃ content, acid mist content, and SO₂ content. Desirability of the possible sources depends on the relative economy with which each can be handled. Particulate matter and volatile impurities must be removed from the gases before entering the acid plant to prevent corrosion and deactivation of the catalysts. Acid mist also poses a corrosion problem. Chlorides and fluorides present a problem with stainless steel equipment. It is desirable to keep the SO₃ content in the gases to a minimum because it represents a yield loss. The SO₂ content is the most important economic factor. It should be between 3.5 and 7.5%. Below 3.5% heat must be added to keep the plant in operation. Air must be added if the concentration is above the upper limit.

Webster, Stewart H.

VOLATILE HYDRIDES OF TOXICOLOGICAL IMPORTANCE. J. Ind. Hyg. Toxicol., 28(5): 167-182, Sept. 1947. 63 refs. (Presented at the American Industrial Hygiene Association, Annual Meeting, 9th, Chicago, 111., April 9-11, 1946.) Among the hydrides of the twenty elements forming volatile hydrogen compounds are some of the most toxic gases, having few uses and generally occurring accidentally. The tendency to form complex hydrides is greatest with carbon but is shown also in the neighboring elements (boron, nitrogen, silicon, phosphorus, germanium, and arsenic). Some of the most important physical and chemical properties of the hydrides are summarized, together with useful data, such as formula, molecular weight, and conversion factors. Stability, solubility, odor characteristics, and reducing action are mentioned. With the exception of methane, ammonia, and water, all of the simple volatile hydrides give precipitates with silver nitrate, all except silver chloride being colored. Filter paper can also be used for determinations. Toxicity of the volatile hydrides is discussed. Effects are cited of hydrogen chloride, hydrogen fluoride, sodium fluoride, ammonia, ethylene, acetylene, phosphine, arsine, boron, silicon, hydrogen sulfide, stibine (antimony hydride), hydrogen selenide, and tin hydride.

Henry, Jack L.

A STUDY OF FACTORS AFFECTING FLUORIDE EMISSION FROM 10,000 AMPERE EXPERIMENTAL ALUMINUM REDUCTION CELLS. In: Extractive Metallurgy of Aluminum. (Gary Gerard, ed.), Vol. 2, New York, Interscience, 1962. p. 67-81. 5 refs.

Results are described of experiments aimed at obtaining a better understanding of factors affecting fluoride emission from aluminum reduction cells. The general nature of fume generation is considered with the emphasis placed on the effect of cell operating variables on fluoride emission rate. The study, carried out with 10,000 amp experimental reduction cells with prebaked anodes, showed that cell temperature, bath ratio, and alumina concentration are the most important factors affecting fluoride emission rate. Gaseous hydrogen fluoride generation results principally from the reaction of molten or vaporized bath materials with moisture in the air and hydrocarbons in the carbon anodes. Relatively little hydrogen fluoride is formed from the reaction with moisture in the alumina fed to the cells. The large number of variables involved in aluminum reduction cell operation make it difficult to establish with a high degree of certainty the correlation of operating factors with fluoride emission. This difficulty exists even with small-scale experimental reduction cells operated by

research personnel. (Author abstract modified)

Kenneth N. Ports

ATMOSPHERIC SAMPLING STUDY OF NF ROCKET
PROPELLANT, REDSTONE ARSENAL, HUNTSVILLE,
ALABAMA, 26 MAY-16 JUNE 1969. Army Environmental Hy-
giene Agency, Kdewood Arsenal, Md., Rept. 99-003-69/70,
32p., Nov. 14, 1969. 2 refs. CFSTI, DDC: AD 699360

A field study was conducted at Redstone Arsenal, Huntsville,
Alabama to measure the concentration of and determine areas
of exposure to total fluorides in the exhaust cloud of statically
fired six pound motors utilizing a developmental NF propel-
lant. Results of the study gave strong indications that only
areas exposed to the visible exhaust would be contaminated by
fluorides. The study results also indicated that all fluorides in
the exhaust were predominantly in the gaseous state. Areas of
greatest exhaust cloud total fluoride concentration were found
to be at the approximate location where the cloud was initially
formed. In the firing tests conducted, exposure to the cloud at
any point within its path was determined to be less than one
minute in all cases observed. It was estimated that areas at
distances greater than 150 meters from the firing point of the
six-pound motors would not be significantly exposed to
fluorides from the exhaust. (Author abstract)

20134

Sullivan, J. L.

AIR POLLUTION-CAUSES AND CONTROL. Occupational
Health Rev. (Ottawa), 20(3-4):9-23, 1968-69.

Pollution due to the burning of liquid and gaseous fuels, and
industrial emissions is discussed; methods for measuring solid
particles and gases are described, and their prevention or
elimination is considered. Gasoline internal combustion en-
gines seldom burn fuel completely, resulting in discharges of
carbon monoxide and hydrocarbons, while nitrogen oxides
occur as the combination of nitrogen and oxygen in air under
the influence of high temperatures inside the cylinders of the
engine. These compounds are significant as components of
sunlight-induced or photo-chemical pollution, causing eye ir-
ritation, and damage to vegetation and materials. Diesel ex-
hausts discharge greater quantities of carbon particulates and
odorous materials, partly attributable to aldehydes and other
fuel decomposition products, than the emissions of the
gasoline engine. Lead, zinc, copper and nickel smelting release
large quantities of sulfur dioxide, while the manufacture of
iron and steel causes visible fine particulate plumes. Gaseous
and solid fluoride compounds are evolved by the electrolysis
of aluminum oxide, and paper manufacturing results in the
escape of odorous sulfide and mercaptan compounds. Soot or
dust-fall can be collected very simply in open-top gauges,
separated from the water by filtration, then dried and weighed;
dust can be measured by means of a device similar to a
vacuum cleaner, in which a sample of air is drawn through a
filter, composed usually of paper or fibre-glass, and the quan-
tity of dust is determined by subtracting the previously-deter-
mined weight of the filter. Gases are often measured continu-
ously by absorption of infrared or ultra violet electromagnetic
rays. Legislation for the reduction of emissions has two main
objectives: to establish standards and to enforce them. It is
preferable to employ methods which do not create pollution,
<xref image="2000WVAL.TIF|V3|2006:09:28:01:17:38.00|125117|0"> image: </xref>

but filters are mentioned for the many processes which cannot avoid generating dust. Pollution control has been a provincial responsibility in Canada, and specific acts of legislation are cited.

Crane, G. B., D. R. Goodwin, and J. F. Rook
ATMOSPHERIC EMISSIONS FROM WET-PROCESS
PHOSPHORIC ACID MANUFACTURING. Preprint, National
Air Pollution Control Administration, Washington, D. C., 19p.,
1969.

The raw materials, chemical reactions, and plant design for the manufacture of wet-process phosphoric acid are described, and a flow diagram is given. All such plants emit SiF₄ and probably to a lesser extent HF. The digester where phosphate rock is decomposed by sulfuric acid is the main source of fluoride emissions; the evaporator where the phosphoric acid is concentrated is a second source; and the filter for the reaction slurry, a third. Other sources are vacuum and flash evaporator hot wells, acid splitter boxes, sumps, and phosphoric acid tanks. Modern designs for emissions control include provisions for sending the various streams to scrubbers adapted to handle each stream. Spray-crossflow packed scrubbers, venturi scrubbers, and others are suitable for these applications. Summaries of the results of a stack testing program carried out at 10 plants are given. It is concluded that it should be possible to operate these plants within acceptable emission ranges at the least if the plants are designed, operated, and maintained to prevent or collect emissions.

Hendnckson, E. R.
THE FLUORIDE PROBLEM. Preprint, Ontario Dept. of Energy and Resources Management, Toronto, Air Management Branch; Air Pollution Control Assoc., Pittsburgh, Pa., TR-7 Agricultural Committee; and Air Pollution Control Assoc., Toronto, Ontario, Ontario Section, 13p., 1970. 3 refs. (Presented at the Proceedings on the Impact of Air Pollution on Vegetation, Toronto, Ontario, April 7-9, 1970, Paper 12856.)
Fluorine is discussed in terms of kinds of compounds, sources, control procedures, and regulations in various parts of the United States. The majority of problems relating to fluorides in the atmosphere involve vegetation, animals through ingestion of vegetation, and materials. Fluorides may be discharged into the atmosphere by combustion of coal, the production of phosphate chemicals and fertilizers, and by several other metallurgical manufacturing processes. The processing of phosphate rock contributes a substantial portion of the total fluoride contamination. Most of the reactive fluorides are readily absorbed in conventional scrubbing systems. Regulations and air quality standards relating to fluoride gases and particulates are discussed.

Spencer, John D.
REVIEW OF BUREAU OF MINES COAL PROGRAM, 1967.
Bureau of Mines Information Circ., no. 8385, 99p., June 1968.
72 refs.
Details of environmental studies featured in research and technological work on coal, and other research relating to the mining and utilization of coal are presented. Fly ash is evaluated for use in land reclamation and agriculture. Investigations of desulfurization methods include lime additives, centrifugation, wet tabling, and others. Programs to locate low-sulfur coal have been initiated. Sulfur dioxide recovery from stack gases is accomplished by absorption by alkalized aluminum, chromatographic sorption, manganese oxide absorption, limestone addition, catalytic oxidation, and the Reinluft process. The effectiveness of various methods for decomposing nitric oxide are tested. Costs for cleaning stack gases are estimated. Chlorine removal from gases and stack sampling

methods are mentioned. The use of coal as a purification method for sewage is investigated. Studies to determine particle size ranges in mining operations are discussed. Occupational health as it relates to mining is studied. The relationship between coal dust and pneumoconiosis is studied, as well as methane-coal dust explosions. Gas chromatographic methods and ventilating systems used in mines are described. Coal processing and storing methods are discussed. Combustion research on coal as a fuel for power generation is reviewed, and catalysts for hydrogen-oxygen fuel cells are tested. Coke production represents a large market for coal. Gasification research and hydrogenation methods are disclosed. New uses for coal include the production of hydrogen cyanide, carbon black, lignite, and synthetic food for microbes. Composition and properties of coal and coal products are analyzed, and arsenic and fluorine content of coal are determined analytically.

Jensen, Robert M.
INTRODUCTION TO AIR QUALITY CONTROL. Pacer,
1(5): 1-14, 1970.

The hazard of and the harm caused by air pollution depend upon concentration and exposure. As can be demonstrated statistically, the incidence of health hazards due to air pollution is about 100 times greater in a city than in a rural area. Transportation contributes nearly 60% of the total atmospheric pollution and yields 74,800,000 tons of pollutants per year; manufacturing is the next biggest producer at 23,400,000 tons per year. The biggest single pollutant is the 65,000,000 tons of deadly carbon monoxide which we pump into our atmosphere each year. There is a large and rapidly increasing amount of evidence which relates air pollution to chronic bronchitis and respiratory cancer. Air pollution damages crops, livestock, shrubbery, and trees. Fluorine compounds in forage will cause cattle to lose teeth and to have an overgrowth of leg bones and ribs. Odor from a rendering plant or from some chemical plants can depress the value of land for both commercial and residential use. New York City estimates that corrosion costs the city about \$6 million per year. Alternatives in sulfur dioxide control include the use of fuels with no sulfur, removal of the sulfur from the fuel, and removal from the gaseous products of combustion.

COMPUTATIONAL METHOD OF DETERMINING
FLUORINE BALANCE DURING ALUMINUM ELECTROLY-
SIS. (Raschetnyy metod opredeleniya balansa ftora pri elek-
trolize alyuminiya). Text in Russian. Tesvetn. Metal., 40(2):59-
62, 1967. 8 refs.

The following quasiempirical formulas for fluorine loss during electrolytic production of aluminum are presented: 1) loss with exhaust gases as a function of cryolite content of the electrolyte and electrolyte temperature; 2) loss with fettlings as a function of service interval; 3) loss in the form of CF₄ as a function of the number of anode effects, duration of anode effect, and % yield in terms of current; 4) mechanical loss as a function of the fluoride content of the raw material; and 5) loss with the coal ash. Fluorine loss through exhaust gases is reported for three installations and ranges from 18.97 to 25.63

Morgan, George B. and Guntis Ozolins
THE IMPACT OF AIR POLLUTION ON THE ENVIRONMENT. Preprint, National Air Pollution Control Administration, Cincinnati, Ohio, Div. of Air Quality and Emission Data, Up., 1970.

The population of a large part of the world has been exposed to polluted air for many decades and, in some cases, centuries. Significant increases are forecast for the future. If control actions are not intensified, air pollution may increase by a factor of six to ten by the year 2000. Before any meaningful control efforts can be carried out, we must know what the ambient levels of pollution are and how they relate to levels established as causing health or economic effects. Many pollutants have always been a part of the natural atmosphere. They are now called pollutants because, with man's help, they are now excessive in quantity. Particulate pollution is the most recognized and pervasive. Its health effects are functions of both particle size and composition. Another significant effect is that, suspended in the atmosphere, particulates reflect away part of the sun's energy and could result in an over-all lowering of the earth's temperature. Gases, 90% of all pollutants, are the second class of pollutant. Examples are sulfur dioxide, nitric oxide, nitrogen dioxide, carbon monoxide, and hydrogen fluoride. A third major pollutant class is the family of hydrocarbons. These participate in photochemical reactions which result in the formation of secondary pollutants such as peroxyacyl nitrates, ozone, formaldehyde, other aldehydes, and ketones. It is from these secondary pollutants that the primary danger to both animal (including the human animal) and vegetable life arises. Numerous industrial processes and the ubiquitous automobile emit these assorted products that are a serious problem in the environment surrounding their source. Almost all human activity results in some form of air pollution, direct or indirect, particulate or gaseous. High-temperature combustion, automotive, industrial, and domestic, is the principal offender. Parameters that must be considered when evaluating effects of pollution include quantity, distribution, and environmental tolerance for pollutants, individually and in concert. Locally, micrometeorology and topography also require consideration. Of all identified pollutants, suspended particulates and sulfur dioxide have been the most extensively measured and studied. As analytical techniques become available, other pollutants will come under programmed surveillance. Among these are asbestos, mercury, lead, pesticides, fluorides, and biologically active metals. International assessment of these problems is necessary for the preservation of the biosphere.

Mammarella, Luigi
EVALUATION OF POLLUTION EMISSIONS IN ITALY.
(Valutazione delle effluenze inquinanti in Italia). Text in Italian.
In: L'inquinamento atmosferico in Italia. Rept. 27, p. 70-95,
1970. 110 refs.

An attempt is made to estimate the development of the pollution problem in the near future on the basis of current statistics. Figures are given on the responsibility of the main sources of pollution for the various types of pollutants found in the atmosphere. The emission of materials related to air pollution is given for six of the main industrial sources and for 4 types of fuel used. Meteorological conditions are summarized for 7 important areas of Italy: Turin, Milan, Venice, Bologna, Rome, Naples and Taranto. This is correlated with the consumption of fuel oil and gasoline, and a hypothesis is worked

out for predicting possible pollution levels up to the year 1980. It is estimated that in the period 1970-1980, one could expect an average annual increase for all types of pollutants of 6.7%.

Drinker, Philip

AIR POLLUTION PROBLEMS IN THE UNITED STATES.

World Health Organization, Copenhagen (Denmark), Regional Office for Europe, Proc. Conf. Public Health Aspects Air Pollution Europe, Milan, Italy, 1957, p. 21-36. 11 refs. (Nov. 6-14.) As in other countries, the demand for power in the U. S. is increasing steadily, at an estimated 3% annually. Bituminous coal is still the most used fuel, followed in order by oil and gas. Some of the coals used in the mid- and far-west have a sulfur content as high as 5%; thus some very large power stations emit sulfur dioxide in amounts comparable to those from smelters roasting sulfide ores. There is a general rule in the U. S. requiring power stations that burn coal in powdered form to clean their stack effluents of grit and ash before discharge. It is also common practice to make an extensive meteorological survey before building a tall chimney, to insure an adequate height for dispersion of smoke plumes. Pollution from ore smelters, by fluorides, and from vehicle exhausts, with emphasis on smog effects is discussed. Attention has not been paid to date to nitrogen oxides in chimney gases; these concentrations increase with furnace temperatures, so that the better the plant is run the more oxides of nitrogen are given off. Although the technology for control of the more well known pollutants has made considerable progress, no practical method has yet been devised for control of nitrogen oxides.

Stuewe, A. Howard

HYDROGEN FLUORIDE: WHERE IT GOES, HOW IT'S MADE, WHY IT'S GROWING. Chem. Eng. News., vol. 36:34-38, 57, Dec. 22, 1958.

Consumption of hydrogen fluoride is expected to reach 215,000 tons in 1963. Grouped under four major categories, the principal market for HF are primary aluminum production, fluorocarbons (refrigerants aerosols), uranium production, and petroleum alkylation (in the production of high octane blending components for gasoline). All HF production is dependent on the reaction of sulfuric acid with fluorspar, domestic reserves of which could become exhausted by the end of the century. Fractional distillation is employed to remove high-boiling impurities (sulfuric acid and water) and lower-boiling impurities (silicon tetrafluoride, carbon dioxide, and sulfur dioxide) from HF.

AIR POLLUTION IN AN AREA OF RAPID INDUSTRIALIZA-

TION. World Health Organization, Copenhagen (Denmark), Regional Office (or Europe Proc. Public Health Aspects Air Pollution Europe, Milan, Italy, 1957, p. 208-218. 3 refs. (Nov. 6-14.)

Complaints about air pollution in Rotterdam led to the establishment of the Rotterdam Soil, Water and Air Committee with special subgroups to investigate emissions from fluoride-producing industries, incinerator plants, oil refineries, smoke-producing installations, and small industries and restaurants. Each group advises management about the possible hazards

<xref image="2000WVAN.TIF|V3|2006:09:28:01:17:44.00|118368|0"> image: </xref>

posed by emissions and suggests appropriate control measures. Other activities of the Committee include regular pollutant measurements, rainwater analyses, twice weekly air sampling, hourly smoke sampling, mortality studies, clinical studies of patients with chronic bronchitis, and examinations of diseased cattle and damaged vegetation. Despite measures of eliminate fluorides from stack gases, their presence in even small concentrations is harmful to plants. Since rain-gauge samples near two phosphate plants contained less fluorides than samples collected in the center of Rotterdam, the presence of another source of fluoride pollution is suspected. Investigations are under way to determine if it is the coal used by power plants and several industries.

PRESENT SITUATION AND OUTLOOK OF FLUORIDES
AIR POLLUTION PREVENTION TECHNOLOGY-TACK-
LING WITH ALUMINUM SMELTING POLLUTION. (Fuk-
kabutsu ni yoru taiki osen boshi gijutsu no genjo to tenbo -
arumi seiren kogai ni torikumu). Text in Japanese. Kinzoku
(Metals) (Tokyo), 41(1): 122-125, Jan. 1 and 15, 1971. 9 refs.
Sources of fluoride pollution and the effects of fluorides on
man and plants are reviewed. Aluminum electrolysis uses
cryolite which is 54% fluoride. Raw materials containing
fluorides are also used in the production of phosphate fertil-
izers and iron and steel. Raw materials containing smaller
amounts of fluorides are required for the production of glass
fibers, bricks, tiles, cement, and porcelain. Coal burned by
thermal power stations can be a problem since coals contain
20-295 ppm of fluorides, averaging 120 ppm. Fluorides affect
plants more than any other atmospheric pollutant, accumulati-
ng in a large number of species in polluted areas. Fluorides
affect man in two ways, directly through air pollution or in-
directly through contaminated vegetation. They are present in
considerable amounts in both green vegetables and rice. Symp-
toms of chronic fluoride poisoning in man are abnormal
hardening of bones and spots on teeth. Cases of chronic
poisoning have appeared among workers exposed to cryolite
dust and among individuals whose drinking water contains
more than 6 ppm fluorides Existing technology, the use of
scrubbers for controlling fluoride emissions from aluminum
electrolysis or electric furnaces, is effective only with concen-
trations up to 1 ppm. New production technologies should be
developed which dispense with the use of raw materials con-
taining fluorides.

MISCELLANEOUS INDUSTRIAL EMISSIONS. In: Project
Clean Air. California, Univ., Berkeley, Task Force 5, Vol. 1,
Section 14, 5p., Sept. 1, 1970. 3 refs.
Five broad categories of industrial polluters are briefly con-
sidered, as well as their kinds of emissions and control
problems. The inorganic chemical industry has problems with
hydrochloric acid, hydrofluoric acid, nitric acid, sulfuric acid,
calcium oxide, chlorine, soaps and detergents. Steel produc-
tion is a major industry, but the open hearth furnaces are
gradually being replaced by the basic oxygen furnace.
Although this also produces fumes, the new plants can be con-
structed with proper control equipment. Foundries may change
the work they do from day to day so that control problems are
at their worst, but methods to trap particles and fumes are
available. The handling of large volumes of minerals normally
involves problems with dust, while the special biological ef-
fects of asbestos must be noted. Glass fibers can also be a
problem, as well as fluoride-containing ores. Copper lead, and
zinc mining and milling operations involve dust problems,
while sulfur oxides may be released during smelting. Hydrogen
sulfide, mercaptans, sulfide and polysulfides which have very
bad odors, and other noxious gases are emitted during wood

pulp processing. Typical gaseous emissions from Kraft pulping are presented tabularly. Coffee roasting plants, slaughterhouses, and pickle plants emit strong odors. An area of concern is new processes to break down waste and return it to a state useful in natural processes without problems of storage. A particularly important point which needs to be considered is site location.

Williams, Charles R.

AIR POLLUTION FROM FLUORIDES. J. Air Pollution Control Assoc., 6(2):100-102, Aug. 1956. (Presented at the Air Pollution Control Association, 49th Annual Meeting, Buffalo, May 20-24, 1956.)

There has been a long history in the country of severe crop and cattle damage in several areas caused by air pollution from fluorides. Rock phosphate and fluorspar and other ores of fluorine compounds are the major sources responsible for this pollution problem. A brief review of production figures for these materials defines the extent of the problem. Phosphate rock is utilized primarily for the production of superphosphates (fertilizers), food and medicinal phosphates, elemental phosphorus, phosphoric acid, ferro-phosphorus, and stock and poultry feed. The important sources are in Florida, Tennessee, Idaho, Montana, Utah, and Wyoming. Utilization of fluorides, particularly in production of aluminum and steel, provides another large-scale source of fluoride pollution. The use of fluorides in the production of aluminum is discussed, as well as the release of fluoride in the production of elemental phosphorus and superphosphates.

ATMOSPHERIC POLLUTION IN A SUPERPHOSPHATE

PLANT. (Zagryazneniye atmosfernogo vozdukha superfosfatnym

zavodom). Text in Russian. Gigiena i Sanit., no. 10:85-87, 1970.

2 refs.

Air pollution from a fertilizer plant with a total daily emission of 0.36-1.08 tons of phosphorus compounds, 1.85-2.59 tons of ammonia, 10-17 tons of sulfur oxides, and 20-34 tons of nitrogen oxides was studied. The sulfuric acid plant has a 100-meter stack and the superphosphate plant, a 40-meter stack; both are equipped with electrofilters. A 1967 survey revealed that school children living in the vicinity of this plant showed increased incidence of fluorosis as a result of exposure to hydrogen fluoride emissions which reached levels as high as 3 mg/cu m. Reduced yields from fruit trees, grape vines, and other plantings within a 500-meter radius were also reported.

A. EMISSION SOURCES

25

tions are compared with the corresponding Threshold Limit Value. The results make it clear that zinc and iron fumes are general hazards; nitrogen dioxide is a severe hazard in enclosed flame-cutting processes; copper, vanadium, and fluoride fumes are likely hazards in welding; and sulfur dioxide and ozone are hazards in specific processes. Workers should be protected against these substances by both general and local exhaust ventilation. Where local exhaust ventilation is not possible, operators should be equipped with positive pressure-air line respirators.

Carroll, Robert E.

TRACE ELEMENT POLLUTION OF AIR. Missouri Univ., Columbia, Environmental Health Center and Missouri Univ., Columbia, Extension Div., Proc. Missouri Univ. Third Annu. Conf. Trace Substances Environ. Health, Columbia, Mo., 1969, p. 227-231. 6 refs. (June 24-26.)

Trace elements constituting a present or potential community health hazard include lead, cadmium, beryllium, barium, nickel, and fluorides. As a contaminant from motor vehicle fuel, lead is known to be present in amounts sufficient to raise the body burden. Cadmium has been linked to hypertensive diseases, and high air levels seem to be correlated with increased mortality. Beryllium is recognized as a serious industrial hazard that can produce disease at very low concentrations. Because of its use in rocket and missile fuels, community beryllium levels must also be carefully monitored. Barium has become a community concern because of its increasing use as a motor vehicle and diesel fuel additive. No health effects have been demonstrated from current nickel levels, but further research is needed. Excess fluoride in air may pose regional problems involving contamination of animal forage or plant damage. A major problem in evaluating trace elements is that very little is known about the ecological cycles from air-to-food chains and water supplies. (Author abstract modified)

Stockham, John D.

THE COMPOSITION OF GLASS FURNACE EMISSIONS.

Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 30p., 1970. 4 refs. (Presented at the Air Pollution Control Association, Annual Meeting 63rd, St. Louis, Mo., June 14-18, 1970, Paper 70-72.J)

The concentrations of sulfur oxides, nitrogen oxides, fluorine, chlorine, and carbon monoxide from two furnaces, one melting flint glass and the other melting amber glass, were determined either by adsorption on silica gel impregnations or by scrubbing the gases in liquid impingers, while grain loading of particulate matter was determined by filtering a sample of the effluent and weighing the collected material. The volume of effluent discharged was determined from velocity data obtained by a pilot tube traverse across a stack diameter. Solids loadings averaged 2.1 and 5.4 lbs/hr or 0.029 and 0.041 grains/scfm of exhaust gas for the flint and amber glass emissions, respectively. SO₃ averaged 17 and 15 ppm, by volume, while the SO₂ concentrations averaged 250 and 315 ppm. F and Cl concentrations were about 2 and 4 ppm, respectively. Nitrogen oxides concentration averaged 340 and 640 ppm. CO content in the flint glass effluent was 375 ppm and in the amber glass effluent, 40 ppm. Particle size, shape, and composition were determined using electron microscopic and spectroscopic techniques. The geometric median particle diameter, based on a size-frequency distribution by number, was about 0.12 micron. Three forms of sodium sulfate were identified; other elements identified as being present in major proportions were calcium, magnesium, silicon, barium, and chromium. (Author abstract modified)

Roe, J. W.

GASES AND FUMES PRODUCED IN FUSION WELDING
AND CUTTING. Ann. Occupational Hyg., vol. 2:75-84, 1959. 16
refs.

What is known about the nature and amount of fumes and gases evolved from oxyacetylene welding, arc welding, oxygas cutting, and arc cutting is summarized. Arc welding presents the greatest range of possible toxic by-products, with the nature of the fumes and gases evolved depending to a large extent upon the means adopted to protect the molten weld from the atmosphere. Thus, when the electrode consists of a bare steel rod, the fume consists of iron oxide with more or less manganese oxide; nitrogen oxides are also formed from the air as a result of the high temperature and the ultraviolet radiation from the arc. For a given type and size of electrode, the total weight of fume evolved depends upon the rate at which it is melted down (i.e. upon the current). The quantity of nitrogen oxides and ozone produced depend upon the energy dissipated in the arc and upon the degree of its exposure; thus deep penetration welding and welding with a bare electrode produce larger quantities while the so-called 'dead soft' electrodes, in which the end of the rod is in a cup formed by the unmelted coating produce less than average. Types of electrodes, constituents of the coating, and notes on the fumes evolved are presented tabularly. Small quantities of gaseous fluorine compounds are evolved during the normal use of low hydrogen electrodes and these quantities become appreciable if abnormally high welding currents are employed. The rate of production of nitrogen oxides is mentioned, including their toxicity. Submerged arc welding and the fumes which may be evolved are also indicated. Fumes formed from inert gas shielded welding are cited. The vapor of trichlorethylene yields phosgene both directly as a result of photochemical decomposition and indirectly by reaction with ozone. Maximum allowable concentrations and the control of nitrogen oxides, fumes, and ozone are discussed. Good ventilation is indicated.

Johnstone, H. F.

PROPERTIES AND BEHAVIOR OF AIR CONTAMINANTS.

Ind. Med. Surg., 19(3):107-115, March 1950. 19 refs.

Some of the obnoxious gases known to be present in industrial atmospheres and their physiological effects observed at low concentrations are described, and their threshold values indicated. Chief sources of sulfur dioxide in industrial cities are the combustion of fuels, smelting operations, refineries, and chemical plants. SO₂ in the air is known to be injurious to vegetation above 0.5 ppm, to contribute extensively to the corrosion of buildings and metal objects, and to cause irritation of the throat at 10 ppm. Hydrogen sulfide is one of the constituents of the waste gases from pulp mills, and is prevalent around sewage disposal plants, gas plants, and mine seepages. It rapidly discolors lead paints. Sources and effects of sulfur trioxide or sulfuric acid mist and other sulfur compounds are also indicated. The principal methods for treating gases containing SO₂ are absorption in a liquid absorbent followed by regeneration by heating, neutralization with ammonia and recovery of ammonium sulfate, neutralization by lime slurry, absorption in water or aqueous solutions, and recovery of hydrogen sulfide. Formation of the oxides of nitrogen and its control are mentioned; as well as ammonia. Hydrogen fluoride may be produced from aluminum plants and phosphate fertil-

<xref image="2000WVAP.TIF|V3|2006:09:28:01:17:50.00|123757|0"> image: </xref>

izer plants, and causes irritation of the throat, coughing, fluorosis in cattle, and mottled teeth in man. Sources and effects are included for hydrogen chloride, organic chlorides, carbon dioxide and monoxide, exhaust gases, peroxides, and zone. Optical properties of aerosols and their effect on visibility are discussed, as well as their deposition, coagulation, stability, diffusion in the atmosphere, electrostatic properties, and physiological effects. In many ways the physical properties of aerosols are more important in atmospheric pollution than the chemical nature of their constituents.

FLUORINE POISONING RESULTING FROM THE AIR POLLUTION CREATED BY A SUPERPHOSPHATE PLANT.

(Fluoorvergiftiging tengevolge van luchtverontreiniging door een superfosphaatfabriek). Text in Dutch. Chem. Weekblad, 38:583-584, 1941. 4 refs.

A complaint made to the public health agency that window panes in buildings located near a superphosphate plant were strongly etched indicated the presence of hydrogen fluoride in the atmosphere, which was traceable to the high content (3%) of fluorine compounds in the raw phosphate used at the plant. For a number of years there had been technical knowledge of wet processes by which the HF gas could be recovered and used in the manufacture of sodium fluorosilicate, a highly marketable byproduct. It was found that while the phosphate used as raw material contained 3% fluorine, the superphosphate product contained only 1%. Two rainwater sampling stations were set up, on 100 m from the plant, the other 300 m, and the chemical composition of the samples from these two locations were compared with that of a study made elsewhere. This comparison revealed a relatively high concentration of chloride, nitrate, calcium, and phosphate ions, as well as a 2.0% content of fluoride ions at the 100 m station, and 1.3% at 300 m. The study further demonstrated that milk poisoning, traceable to dairy animals who were pastured in the vicinity of the plant, could be derived from this excessive concentration of fluorine in the atmosphere. Earlier complaints of milk poisoning had been attributed to pollution from sulfur dioxide and nitrogen compounds, and to a fine dust that was emitted from the plant.

EFFECTS OF FLUORIDE EMISSIONS FROM ROOF-TILE-

KILN ON PLANTS. (Uwagusurigawara seizo kojo haigasuchu fusso kagobutsu ni yoru shokubutsu haigai ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 5(1):226, 1970. (Proceedings of the Japan Society of Air Pollution, Annual Meeting, 11th, 1970.)

Two ceramic plants which manufacture glazed shingles were investigated for fluoride emissions that were suspected of causing damages to agricultural products in the neighborhood. The items investigated were the original shingle material before glazing and firing and the exhaust gas from the kiln. In one plant, 1.7 to 4.1 ppm of fluorides were determined in the exhaust gas, and 3.0 to 4.4 ppm were found for the emissions from the other plant. Fluorides in air were measured by the JIS K 0105 method; from one plant, 20 ppb were recorded 210 m downwind. For the other plant, 43 ppb were discovered 73 m downwind. Further measurements were taken at six locations in a fan-shaped area downwind from the plant in the main wind direction, and 258 micrograms F(-)/100 sq cu/30 days were found 140 m southwest of the plants. The concentrations decreased with the distance from the source. When plants were analyzed, significantly larger amounts of fluorine were seen compared to those plants that were not damaged.

THE INFLUENCE OF ENVIRONMENTAL PROTECTION ON
PLANNING, OPERATION AND ECONOMY OF STEAM
POWER PLANTS. I. MAINTENANCE OF CLEAN AIR. (Ein-
fluss des Nachbarschutzes auf Planung, Betrieb und Wirtschaft-
lichkeit von Dampfkraftwerken. Teil 1: Reinhaltung der Luft).
Text in German. Tech. Ueberwach. (Duesseldorf), 12(4):106-112,
April 1971. 29 refs.

Steam power plants emit solid matter such as fly ash and soot,
and gases such as sulfur and nitrogen oxides, hydrocarbons,
and fluorine compounds. The VDI guideline 2091 limits dust
emissions of power plants with a capacity of 70,000 cu m/hr to
150 mg/cu m dry flue gas volume. Only electrostatic precipita-
tors achieve this value in the cleaned gas. For heavy fuel oil,
soot emissions are limited to a smoke shade 3, which is to be
measured by the Bacharach filter paper method. The VDI
commission has worked out a limit value for soot according to
which not more than 70 mg soot may be emitted/cu m solid
matter (oil, coke, etc.). During soot blowing, not more than
200 mg/cu m may be emitted. Over the entire operating period,
not more than 1.5 g soot/kg oil may be emitted on the average.
For soot collection, centrifugal separators are widely used. Of
the gaseous pollutants from steam plants, sulfur dioxide is the
most important. Since no efficient flue in gas desulfurization
process is yet available, efforts are under way to obtain low-
sulfur fuel oils. No measurements have yet been taken of the
gaseous fluorine compounds emitted by steam boiler plants. It
is assumed that most of the fluorine is bound to alkaline ash
components. The nitrogen dioxide emission has been limited to
a long-term maximum allowable concentration of 1 mg/cu m.
Cooling towers 100 m high and more are emitters of droplets
which contaminate the environment. In some power plants,
droplet separators have been installed with great success.

29532

Koizumi, Mutsuo

AIR POLLUTANTS GENERATED IN INTRA-FURNACE
COMBUSTION. (Ronai nensh ni okeru taikiosen hus.shit.su no
hassei). Text in Japanese. Japan Society of Mechanical Engineer-
ing, Tokyo, Proc. Special Symp. Air Pollution, 27th, 1971, p.
23-42. (April.)

The generation mechanism of air pollutants formed during the
intra-furnace combustion of solid, liquid, and gaseous fuels
was discussed with respect to the type of combustion equip-
ment and other conditions. Dust containing unburned carbon is
emitted as a result of solid fuel combustion, when combustion
gas is used for heating, and by the combustion of liquid and
gaseous fuels. Most of the sulfur content in fuel becomes sul-
fur dioxide during combustion. Part of the sulfur contained in
the fuel is oxidized to form sulfur trioxide which, combined
with water, often becomes sulfuric acid mist. The SO₂ in the
emission gas sometimes changes to form SO₃ through at-
mospheric oxidation. When the combustion gas allows the for-
mation of sulfuric acid, it causes the soot in the gas to con-
dense into masses. These masses of soot fall onto neighboring
areas. The nitrogen oxides discharged from an intra-furnace
combustion device are usually nitric oxide and nitrogen diox-
ide. The NO is first generated during combustion and is par-
tially transformed to NO₂ as it goes through the furnace and
heating device. In some combustion devices such as a cupola
or diffusion flame annealing furnace which require a reducing
<xref image="2000WVAQ.TIF|V3|2006:09:28:01:17:54.00|124336|0"> image: </xref>

A. EMISSION SOURCES

27

atmosphere, the exhaust gas contains carbon monoxide and hydrogen. An incinerator discharges aluminum, aldehyde, and organic acid if the combustion temperature is not high enough. Hydrogen chloride is generated from the incineration of vinyl chloride, hydrogen fluoride from the incineration of fluorine resins or from tank furnaces of special glass, and metal compounds from the combustion accompanying metal processing or from incineration of plastics-containing additives.

Becker, Karl H.

PHYSICAL-CHEMICAL PROBLEMS OF AIR POLLUTION.

(Physikalisch- chemische probleme der Luftverunreinigung). Text in German. Chem. Unserer Zeit., 5(1):9-18, Feb. 1971. 46 refs.

Principal air pollutants are reviewed. Carbon monoxide is generated by the incomplete combustion of fossil fuels, for instance in an automobile engine which emits 0.5 to one ton of carbon monoxide per automobile per year. Since CO is converted to the harmless carbon dioxide at elevated temperatures only, it can stay in the atmosphere for two to three years. Sulfur dioxide is produced when heavy fuel oils and coal, containing sulfur in various concentrations are burned. When in the air, sulfur dioxide is oxidized to sulfur trioxide, which can combine with water vapor to form sulfuric acid and can cause the formation of smog which disappears from the atmosphere with rain. Hydrocarbons are emitted by petrochemical industrial plants and are also components of automobile exhausts. Automobile exhausts also emit nitric oxide and nitrogen dioxide. Halides as pollutants usually occur in small concentrations, except in some areas of steel and aluminum producing plants where greater concentrations of hydrochloric and hydrofluoric acids may occur. The incineration of scrap synthetic materials, such as polyvinyl chloride and teflon also cause pollution from the chlorine and fluorine compounds. Other pollutants mentioned are carcinogens such as benzpyrene and other polycyclic hydrocarbons contained in the soot emitted by diesel engines and lead compounds present in automobile exhaust gases, if gasoline containing tetraethyl lead as antiknock agent is used.

Tichatschke, J.

STUDIES OF THE EMISSIONS FROM REFUSE INCINERATORS.

(Untersuchungen ueber Emissionen aus Muellverbrennungsanlagen). Text in German. Mitt. Ver. Grosskesselbesitzer, 51(3)219-223, June 1971. (Presented at the VGB - Fachtagung Muellverbrennung 1970, Salzburg, Austria Aug. 28, 1970, Hamburg, West Germany, Sept. 11, 1970, and Koln, West Germany, Sept. 25, 1970.)

In an experimental refuse combustion furnace, with a throughput of 20 t/hr at a heating value of 1600 kcal/kg, measurements of the gaseous emissions were taken over a three year period with an electrically heated quartz probe and a subsequent electrically heated quartz wool filter. The sampling point was at the boiler end after the economizer. The waste gas temperature at this point was 220 C. For determination of sulfur trioxide, absorption in 80% isopropanol and photometric methods were used. Sulfur dioxide was absorbed in an iodine solution. Prior to this method, the gravimetric method was used. The chloride content of the flue gases was determined with the mercury(II)-oxide-cyanide method. For this purpose, 50 to 100 liters of flue gas were drawn through a scrubber. For hydrogen fluoride measurements 500 liters of flue gas were drawn through a fritted gas scrubber. Diluted sodium lye was used as absorption solution. The volatile organic acids and aldehydes were also determined. The hydrogen chloride, hydrogen fluoride, and sulfur dioxide concentrations rose gradually over the years. For HCl, a maximum concentration of 18 mg/cu m was measured. For SO₂, the frequency max-

imum ranged from 0.8 to one g/cu m. The most frequently measured SO₃ concentration was 0.03 g/cu m. For CH₃COOH, a maximum concentration of 120 mg was measured, and for HCHO, of 200 mg/cu m. The ammonia content, which was measured over a period of two years, ranged from 0.5 to 4.5 mg/cu m. No hydrogen sulfide, chlorine, or phosgene could be detected. The odor of the gases became more pronounced as the temperatures dropped to below 650 C. Rain water samples taken just beneath the smoke plume from an incinerator revealed that the rain is influenced by the waste gas, but is not a concentrated acid.

Teworte, W.

THE USE OF FLUORINE-BEARING MATERIALS IN THE

GERMAN FEDERAL REPUBLIC. (Einsatz von fluorhaltigen

Materialien in der BRD). Text in German. VIM (Ver. Deut.

Ingr.) Ber., no. 164:11-18, 1971. 13 refs.

Before World War II, Germany was the world's largest supplier of fluorine. In 1938, it produced 30% or 140,000 tons out of a total world production of 462,000 tons. Since then, the situation has changed completely. In 1969, the world consumption amounted to about 3.6 million tons, out of which Mexico as the largest producer provided one million tons; Germany's participation was only 90,000 tons which placed it eighth after Mexico. This latter production was practically used up completely by the domestic industry; in addition, some 160,000 tons were imported to cover the overall demand of 250,000 tons. Of the world's consumption of fluorine in 1969, 45% were used for steel manufacturing, 15% for aluminum, 33% for producing chemicals, and 7% for glass and ceramics. The chemical industry requires fluorite, CaF₂, primarily for producing hydrofluoric acid, HF. Two tons of CaF₂ are needed for producing one ton of HF. Hydrofluoric acid in turn is used as an intermediate product for the manufacture of numerous inorganic and organic fluorine compounds. Among the inorganic compounds are aluminum fluorides, used as flux material in the production of primary aluminum. The organic fluorine compounds include the aliphatic chlorine-fluorine-hydrocarbons, such as freon, which are used as spraying and cooling substances. Other important fluorine-bearing products are synthetic materials, such as teflon. Direct applications for fluorspar can be found in the manufacture of steel, of welding electrodes, enamel, glass wool, and other industrial products.

Nelson, Kenneth W.

NONFERROUS METALLURGICAL OPERATIONS. In: Air

Pollution. Arthur C. Stern (ed.), Vol. 3, 2nd ed., New York,

Academic Press, 1968, Chapt. 37, p. 171-190. 16 refs.

While sulfur dioxide from the smelting of copper, lead, and zinc has been the principal pollutant of interest in nonferrous metallurgy, gaseous and particulate fluorides from aluminum smelting are also of concern. Fluoride problems first came to attention because of adverse effects on grazing animals rather than effects on vegetation, as with SO₂. The mining, milling, and concentrating of copper, lead, and zinc are discussed, as well as their refining and smelting, emissions, and controls. The mining and ore treatment of aluminum is considered, its electrolysis, and emissions and controls. Copper, lead, zinc, and aluminum produced from scrap are also discussed. The production of nonferrous alloys is noted.

Baiulescu, G. and P. Marcuja
ASPECTS REGARDING THE STUDIES ON AIR POLLUTION. (Aspecte referitoare la studiile asupra poluarii atmosferei). Text in Rumanian. Rev. Chim., 22(1):51-55, Jan. 1971. 19 refs.

A general review is given of the subject of air pollution. A list of 10 major pollution sources is given, figures on the emission of specific substances by the various sources, a general review of inorganic and organic pollutants, methods of determining the major pollutants (including automated systems), and efforts to set standards and establish legislative controls. The following are some of the data given on emissions from specific sources. Ammonia plants emit about 90.7 grams of ammonia and 90 kg of carbon monoxide per ton of ammonia produced. Chlorine plants give off 45.3-544 kg of chlorine gas per 100 tons of liquid chlorine produced. Hydrochloric acid plants emit organic chlorine compounds at the rate of 0.5 vol% of exhaust gases. The manufacture of nitric acid is responsible for about 27 kg of nitrogen dioxide per ton of acid, with an effective recovery of 36-99.8%, depending on the process used. Phosphoric acid plants emit 9-27 kg of silicon tetrafluoride and hydrofluoric acid per ton of phosphorus pentoxide produced, and emits 0.09-4.5 kg of pentoxide aerosol for each ton of acid produced. The manufacture of sulphuric acid results in emissions of 9-31.5 kg SO₂ and 0.09-0.9 kg SO₃ per ton, depending on the type of control equipment used. This type of data is given for a large number of pollution sources.

Luxon, S. G.
FLUORIDE EMISSION DURING FIRING OF POTTERY IN CONTINUOUS KILNS. Fluoride, 3(2):61-65, April 1971.
In the manufacture of pottery with continuous kilns, the windows of the building and of some adjoining buildings were noticed to have become etched and no longer transparent due to the formation of ammoniumsilicofluoride. The calcium fluoride which is in china-stone was converted in the presence of organic matter into ammonium fluosilicate. Acid gases, arising from products of combustion used to heat the kiln, liberated hydrofluoric acid which accounts for the etching of glass. Air samples in the kiln workroom showed fluoride concentrations up to 3.5 mg/cu m. (Author abstract modified)

Hasegawa, Toshio
AIR POLLUTION PROBLEMS OF A GLASSWORKS. (Garasu kojo no kogai mondai). Text in Japanese. Kagaku to Kogyo (Tokyo) (Chem. Chem. Ind.), 45(2):28-35, 1971.
The main air pollutant discharged from glassworks is smoke dust, the main source of which is the cubicle furnace. The results of surveys made at two glass factories for dust emission and at another glass factory suspected of emitting noxious gas damaging to crops are discussed. The two factories surveyed for dust emission were a physical and chemical glasswares manufacturing firm and a vacuum bottle manufacturing firm. In the former, four 500 Ib. cubicle furnaces with a maximum fuel consumption of 35 l/hr and a normal consumption of 26 l/hr, a 1.7 cu m combustion chamber, and rotary-type burners using B heavy oil were inspected. The dust density was 1.21 g/N cu m at maximum, 0.13 g/N cu m at minimum, and 0.46 g/N cu m on the average. In the second factory, eight 750 Ib cubicle furnaces were surveyed. The ratings included the fuel consumption, 62.6 l/hr of B heavy oil, and the 1.94 cu m combustion chamber. The dust density was 1.24 g/N cu m at maximum, 0.12 g/N cu m at minimum, and 0.66 g/N cu m on the average. Crop damage had been reported in the vicinity of a glassworks manufacturing fancy bottles. An investigation was conducted to determine the cause. It was a fluorine compound, such as hydrogen fluoride, generated during the processing of fluorite. The damage to the crops included foliar

burns or dead leaves in rice plants on a long, narrow strip of land in the 20-300 m range west of the factory. Soybeans in the area were most seriously damaged, suffering from chlorosis. The total acreage of damage amounted to 20 acres of rice plants and 15 acres of soybean. Sampling and measurement of the noxious gas at the source in the atmosphere, and in nun-falls, and chemical analysis of the damaged crops were conducted. The results of the measurement and analysis are shown in tables and charts. Fluorine, detected from the crust of soy bean, amounted to 299.2 ppm at the nearest point from the factory, while that detected from the rice-bran was 26.4 ppm at the point farther than the first point and 6.0 ppm at the farthest point.

Birse, E. A. B.

PROBLEMS IN ALUMINIUM REFINING. Smokeless Air (London), 40(151): 19-22, Autumn 1969. (Presented at the Scottish Division, Annual Conference, Largs, Great Britain, May 22, 1969.)

Aluminum is smelted by dissolving alumina in molten cryolite (sodium aluminum fluoride) and passing an electric current from a carbon electrode (anode), which is suspended in the molten solution, to the carbon lining of the containing pot (cathode). The process itself does not evolve fluorides; but when fluoride additions are made to the molten cryolite, fluoride vapors escape to the ambient air above the pot. Total fluoride losses from a large pot are only 23-35 lb/24 hr, but in a modern smelter with 340 pots the overall emission is significant. New smelters are achieving 95% fume collection by enclosing pots within hoods and by using electrolytic pots with prebaked instead of self-baking anodes.

Strunz, W.

CHEMISTRY AND ENVIRONMENTAL HYGIENE. (Chemie und Umwelthygiene). Text in German. Allgem. Prak. Chem. (Vienna), 22(2):25-31, Feb. 1971. (Presented at the Bundesin-nungstagung des chemischen Gewerbes, Wien, West Germany, Oct. 23, 1970.)

There are 300 chemical substances which are termed air pollutants. Some of the most common air pollutants are sulfur dioxide, sulfur trioxide, hydrogen fluoride, fluorine, chlorine, nitrogen oxides, aldehydes, ketones, lead, hydrogen chloride, carbon dioxide, and carbon monoxide and tetraethyl lead. Among the heaviest polluters are power plants. In a thermal power plant with a capacity of 300,000 kW/hr, 70 tons of oil are burned and one million cu m flue gases are produced. The rain water in industrial centers has, at times, a pH of five. Automobiles are also heavy polluters. In Vienna, 90,000 tons of CO are emitted into the air/day. The emissions of hydrocarbons, lead, and SO₂ are 9000, 0.55, and 180 tons respectively. The maximum allowable concentration for nitrogen oxides is one mg/cu m air, for C12 0.3 mg/cu m air, for hydrogen sulfide 0.15 mg/cu m, for SO₂ 0.40 mg/cu m, for lead 0.004 mg/cu m, for 0.1 mg lead/day. The atmospheric pollution affects humans, animals, and plants.

Dreyhaupt, F. J.

CONCLUDING REMARKS. (Schlussbemerkingen). Text in German. VDI (Ver. Deut. Ingr.), Ber., no. 164:110-112, 1971. No limit values on permissible fluorine concentration have been decided upon and released by the German Authorities. This is a matter of urgency, considering the fact that the phytotoxicity of fluorine is approximately 100 times greater than that of sulfur dioxide, and that fluorine emissions are steadily on the increase because new sources of emission continue to arise, for instance in ore sintering plants and aluminum works. Sufficient information is by now available to determine maximum permissible concentrations. Doubts have been expressed concerning whether the results of induced plant intoxication by fluorine gas in test enclosures are directly comparable with field conditions. More preliminary experimentation is not needed. Very conservative emission limits based on the results of the enclosure tests and on the various information available from international research are needed. Any regulations eventually issued should not be applicable on days of weather inversions.

Carotti, Arrigo A. and Elmer R. Kaiser

CONCENTRATIONS OF 20 GASEOUS CHEMICAL SPECIES

IN THE FLUE GAS OF A MUNICIPAL INCINERATOR.

Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 25p., 1971. 5 refs. (Presented at the Air Pollution Control Association Annual Meeting, 64th, Atlantic City, N. J., June 27-July 2, 1971, Paper 71-67.)

Tests were undertaken at the incinerator plant of the Town of Babylon, Long Island, to determine the physical composition of the emitted pollutants. Nitrogen dioxide was collected in evacuated flasks of known volume and measured spectrophotometrically via the reaction with the Griess-Saltzman reagent. Acid gases and mists were collected in appropriate impingers containing aqueous alkali, and each species conventionally quantitated according to accepted methods of appropriate sensitivity. Aldehydes and ketones were quantitatively absorbed in sodium bisulfite and quantitated iodimetrically. Sulfur dioxide was collected in hydrogen peroxide and determined as the sulfate. Hydrocarbons and phosgene were quantitated gas chromatographically. On the basis of the data recorded, hydrochloric acid is a major constituent of municipal incinerator gaseous emissions. The variations in the concentrations of the most predominant chemical species (HCl, NO_x, SO₂, organic acids) normally found in municipal incinerator emissions are significant and are probably the result of variations in the composition of the fuel charge. Hydrocarbons (C₁-C₅), cyanide, fluoride, phosphate, aldehydes, and chlorine are relatively minor constituents of municipal incinerator gaseous emissions. Water scrubbing appears to be effective in removing chlorides from flue gas. (Author abstract modified)

Sholtes, R. S. and B. S. Tatera

PARAMETERS WHICH INFLUENCE FLUORIDE EMISSIONS FROM GYPSUM PONDS.

Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 43p., 1971. 19 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 64th, Atlantic City, N. J., June 27-July 2, 1971, Paper 71-19.)

The suspicion that gypsum ponds used in mineral mining and processing may be a major source of fluoride emissions is investigated. A laboratory based study examined the vapor pressure of gaseous fluoride in equilibrium with dilute solutions of hydrofluoric acid, fluosilicic acid, and mixtures of these and commercially obtained gypsum water. A modified gas saturation method produced samples that were analyzed for fluoride concentration by ion and reference electrodes. The effect of temperature, air velocity, and fluoride concentration on gase-

ous fluoride emissions from gypsum ponds were evaluated using a laboratory scale gypsum pond. Both gypsum slurry water and process water were examined. Measurements of air velocity were provided by a velometer and to types of anemometers. The relative humidity of the intake and exhaust air were measured by a sling psychrometer. The analysis gave a series of predictive equations for fluoride emission as a function of fluoride concentration, wind speed, water temperature, relative humidity, and evaporation rate. The vapor pressure studies predicted that for all solutions studied, HF gas would be the source of highest percentage fluoride in the saturated gas. They also showed that the fluorides present in gypsum water can act as if they were in equilibrium with fluosilicic acid. Laboratory gypsum pond studies revealed a buildup of fluorides in the gypsum water, which is not true for actual gypsum ponds, thus discounting fluoride emissions from the surface as the only means of releasing fluorides from gypsum ponds. Processes not occurring in the laboratory, i.e., percolation, rainfall dilution, and photochemical reaction, may therefore have a major part in preventing the buildup of fluorides in field gypsum ponds. Air velocity and temperature strongly influence fluoride emissions from gypsum slurry and process waters; the effects of concentration were relatively less. Charts and figures demonstrating the relationships are included.

Nakamura, Keigo

ON AIR POLLUTION CAUSED BY HYDROGEN FLUORIDE.

(Fukka suiso ni yoru taiki osen ni tsuite). Text in Japanese. Kogai To Taisaku (J. Pollution Control), 6(4):50-58, July 1971. 9 refs.

When the atmosphere contains as little as 10 ppb of hydrogen fluoride, crops can be damaged, because the HF is accumulated in the leaves. Teeth and bones are also affected when cattle eat feed containing 30-50 ppm HF over an extended period of time. Fluoride emissions are issued from plants which process ores containing fluoride compounds. Steel mills in Japan are using about four kg fluorspar/ton steel. Various types of scrubbers are utilized to recover fluoride from aluminum smelter and phosphorus fertilizer exhaust gases. Collectors are then used to trap fluoride and sulfuric acid mists.

Chambers, Leslie A.

CLASSIFICATION AND EXTENT OF AIR POLLUTION

PROBLEMS. In: Air Pollution. Arthur C. Stern (ed.), Vol. 1, 2nd ed., New York, Academic Press, 1968, Chapt. 1, p. 1-21.

This history of air pollution is discussed, including natural causes, decaying refuse, and wood smoke. The use of coal from the beginning of the 14th century to the early part of the 20th led to air pollution by coal smoke and gases. Various English kings, legislation, and committees attempted to regulate its use. In 1952, the death of 4000 persons in London led to strict controls. Smog also caused deaths in England. In America, the incident at Donora, Pennsylvania spurred pollution control efforts. In Poza Rica, near Mexico City, hydrogen sulfide caused deaths and illness. Other pollutants, such as metallic fumes, acid mists, fluorides, and odors, have also caused health problems. While oil and gas have replaced coal, they have caused further pollution. Evidently, photochemical reac-

<xref image="2000WVAT.TIF|V3|2006:09:28:01:18:04.00|120216|0"> image: </xref>

lions in automobile engine exhausts have caused Los Angeles smog. Air pollution is directly related to energy sources; a major change in energy sources could change the quality of air pollution. Carbon dioxide in the atmosphere has increased with the use of fossil fuels. Pollutants can be emitted directly from identifiable sources or can be produced in the air by an interaction between two or more primary pollutants, or by a reaction with normal atmospheric constituents. The first group includes aerosols, coarse particles, and sulfur, organic, nitrogen, carbon, halogen, and radioactive compounds. Secondary pollutants include halide salts, sulfuric acid mist, photochemical reactions, and the absorption of gases by surfaces of liquid and solid particles. Nucleation, condensation, sedimentation, and meteorological processes also effect the formation and impact of primary and secondary pollutants. Air pollution can cause a reduction in visibility, material damage, agricultural damage, physiological effects on man and domestic animals, and psychological effects. Air pollution will be a larger problem in the future. Its emergence as a global phenomenon will effect many governmental and administrative procedures.

Gartrell, F. E.

WATER POLLUTION POTENTIAL OF AIR POLLUTION

CONTROL DEVICES. In: Air Pollution. Arthur C. Stern (ed.),

Vol 3, 2nd ed., New York, Academic Press, 1968, Chapt. 49, p.

535-549. 22 refs.

Devices for air pollution control which reduce the amount of waste material discharged to the atmosphere usually increase the quantities of such materials that must be disposed of by other means. Wet collectors of many types are used for air cleaning and all types contribute to the total quantity of liquid wastes which may be discharged to waterways, with or without treatment. With industrial development, urban population growth, and rapidly expanding use of water for all purposes, the accompanying need for stream pollution control has led to the establishment of agencies with the authority to regulate the discharge of waste materials to surface waters. From a review of water quality standards, it is obvious that many waste materials considered as air pollutants of major concern are likewise objectionable for many water uses, when present in even fairly low concentrations. This is particularly true of wastes involving fluorides, sulfur compounds, and radioactive materials. The control of fluorine wastes from uranium ore processing, phosphate fertilizer production, and steel mills, is discussed. Radioactive waste disposal practices at the Oak Ridge National, the Argonne National Laboratory, and at the Los Alamos Scientific Laboratory are described. The control of sulfurous wastes is indicated for copper smelters and electric power plants. The control of fly ash, dust, and other particulate wastes from calcium carbide plants, blast furnace operations, power plants, and chemical plants is reviewed.

Hartkopf, Guenter

ENVIRONMENTAL PROTECTION AND POWER PRODUC-

TION. (Umweltschutz und Elektrizitaetswirtschaft). Text in Ger-

man. Elektrizitaetswirtschaft, 70(17):507-511, 1971. (Presented

at the VDEW Jahrestagung, Mainz, West Germany, May 27,

1971.)

The conversion to electricity as a source of energy in households, trade, industry, and transportation (railroads) transferred the burden of the air pollution problem from several sources to one large-scale source. Power plants emit dust, sulfur dioxide, nitrogen oxides, carbon monoxide, hydrocarbons, fluorine, and chlorine. Processes for SO₂ removal from waste gases, desulfurization of fuels, and siting of power plants are investigated as air pollution control methods.

Vitaliano, Dorothy B.

FLUORINE-BEARING ASH FROM THE HEKLA ERUPTION,
1970: DISTRIBUTION, EFFECT ON ENVIORNMENT, AND
IMPLICATIONS FOR MEDITERRANEAN ARCHEOLOGY
AND GEOMYTHOLOGY. In: Boston College Environmental
Center Summer Institute on Surtsey and Iceland. National
Aeronautics and Space Administration, Moffett Field, Calif.,
Ames Research Center, NASA TM X-62,009, p. 65-68, Feb.
1971. 3 refs. NTIS: N71-17982

In addition to its effect on the environment in Iceland, the oc-
currence of fluorine-bearing ash in the 1970 eruption of Hekla,
as in the 1947 eruption of that volcano, has interesting implica-
tions in connection with Mediterranean archeology and geo-
mythology. It seems likely that the 1970 eruption of Hekla
may furnish a clue as to how the Santorin eruption of 1450
B.C. could have been responsible for the adverse effects
caused to the plants, cattle, horses, asses, camels, oxen, and
sheep of the Egyptians who were downwind of the eruption.

32702

CONTAMINANTS IN THE AIR. WHAT THEY ARE: Ind.

Power, 62(1):68-70, Jan. 1952.

Smoke, dusts, fumes, mists, vapors, and gases are defined in
terms set forth by the American Standards Association. Com-
mon sources of contaminants are discussed and shown on a
chart, and common airborne particles are listed according to
size in micron. Pollutants include pollens, bacteria, viruses,
metal dusts and fumes, magnesium oxide fumes, cement dust,
foundry dust, pulverized coal fly ash, zinc oxide fume, sulfur
trioxide, carbon black, sulfuric acid mist, particles of coal and
ash from furnaces, organic matter, and industrial wastes. In
addition, the particle sizes of various contaminants are com-
pared according to both micron diameter and Tyyler scales.
The effects of, or atmospheric reactions involving, sulfur diox-
ide, hydrogen sulfide, nitrogen oxides, and fluorine com-
pounds are briefly reviewed. The physical properties of parti-
cles are contrasted with the chemical nature of their con-
stituents and are noted to be even more important in at-
mospheric pollution. Inversions and wind can effect the dis-
tribution of pollutants.

PRESENT STATE OF PUBLIC NUSIANCE CAUSED BY OF-
FENSIVE ODORS IN TOKYO. (Tokyo ni okeru akushu kogai
no genjo). Text in Japanese. Yosui To Haisui (J. Water Waste),
13(8):972-978, Aug. 1971.

Control criteria were designated for emissions of smoke,
gases, and offensive odors in Tokyo. The harmful gases in-
cluded ammonia, fluorine and its compounds, hydrogen cya-
nide, carbon monoxide, formaldehyde, methanol, isoamyl
alcohol, isopropyl alcohol, hydrogen sulfide, hydrogen
chloride, acrolein, acetone, sulfur dioxide, benzene, nitrogen
oxides, toluene, phenol, sulfuric acid, and chromic acid. The
public Nuisance Bureau received 2751 complaints about offen-
sive odors and 416 complaints about deleterious gases during
1970. The major sources of the offensive odors were plants
processing fish guts and bones, animal bones and fat, and

Hellwig, A. and D. Hempel

STUDIES OF THE RELATIONSHIP BETWEEN THE EMISSION OF FLUORINE COMPOUNDS AND THEIR CONCENTRATION IN ATMOSPHERIC AIR AND WATER. (Untersuchungen ueber den Zusammenhang zwischen der Emission von

Fluorverbindungen und ihrem Gehalt in der atmosphaerischen Luft und im Wasser). Text in German. Z. Ges. Hyg. Ihre Grenzgebiete (Berlin), 17(9):651-655, Sept. 1971. 20 refs.

Fluoride compounds are frequently components of industrial emissions. Hydrogen fluoride is emitted in the manufacturing of bricks and clay. The most important source for fluorine-containing emissions is the chemical industry. Fluorine is a natural component of human and animal tissue. Man needs a daily dose of 1.5 to 1.8 mg fluorine which is supplied by the water (0.1 mg) and by food (0.4 mg). In the vicinity of a superphosphate plant, the fluorine content of the atmosphere was determined at eight measuring stations. More measuring stations were set-up in the main direction, i.e., east and north-east of the emission source. All stations were arranged in distances of 200 to 3000 m from the emission source. The measurements were taken every two weeks with the aid of an automobile. At each station, 40 individual measurements were taken between July 1968 and June 1970. The air was drawn through two subsequent absorption vessels at a speed of 5 l/min each of which was filled with 15 ml 0.05 N NaOH. The fluorine concentration was determined by measurement of the extinction at a wave length of 530 nm. The highest concentrations were measured at a distance of 300 and 1000 m from the stack in a south-eastern direction. The maximum allowable emission concentration for fluorine (0.03 mg/cu m short-term value, 0.1 mg/cu m long-term value) has not been exceeded at any one time or at any point.

33853

Ryder, R. J. and J. J. McMackin

SOME FACTORS AFFECTING STACK EMISSIONS FROM A

GLASS CONTAINER FURNACE. PART I. Glass Ind., 50(6):307-310, June 1969. (Presented at the Conference on Glass Problems, 29th, Nov. 21, 22, 1968.) PART II. Ibid., 50(7):346, 348-350, July 1969. 4 refs.

A glass melting furnace can give off emissions from the flame and from volatilization. Sulfates, fluorides, and borates are major constituents that contribute to volatilization. A small percentage of these materials becomes stack gas and can cause air pollution. A glass furnace was tested to determine the amounts of particulate matter, sulfur dioxide, sulfur trioxide, carbon monoxide, hydrocarbons, and nitrogen oxides in the stack gas. Also, the plume's opacity was determined. Variation in the furnace load, temperature, fuel-air ratio, and make-up of minor ingredients could effect stack emission. The particulate emission (primarily sodium sulfite), SO₂, SO₃, and nitrogen oxides increased as the furnace load (and thus temperature) increased. An increase in excess air from 20-25% to 30-35% produced decreases in the level of particulate emission. The addition of carbon to the minor-ingredient mix eliminated this. Also, the addition of carbon was the most effective single factor in decreasing particulate emission. The apparent opacity was influenced by the fuel-air ratio but was not affected by the minor-ingredient mix. Furthermore, increases

in excess air in the 20-40% range caused significant opacity decreases. As expected, the opacity increased as the furnace load increased. Because of Los Angeles regulations, the maximum load is dictated by the level of particulate emission and stack plume opacity.

Bernhart, A. P.

NOTES ON AIR POLLUTION: THE INGREDIENTS

DEFINED. PART I. Water Pollution Control (Toronto), 109(10):41-42, Oct. 1971. 19 refs.

The problem of air pollution in Canada is reviewed with respect to effects on human health (respiratory diseases), animals, plants, buildings (soiling and deterioration), traffic (visibility), and economy; breakdown by individual pollutant; and major sources. The major pollutants and their sources included suspended particulates and dust fall from furnaces, incineration, and cement plants; pollen from grasses and trees; sulfur oxides from coal furnaces, carbon monoxide from cars; hydrocarbons from engine exhausts and gasoline evaporation; aldehydes from diesel exhausts and dry cleaners; nitrogen oxides from power plants; oxidants; odors from slaughterhouses, garment factories, glue factories, and diesel buses; fluorides from aluminum and fertilizer plants; lead from car exhausts; benzopyrene; carbon dioxide; and other minor pollutants, i.e., organic acids, hydrogen sulfide, ammonia, chlorine, and bromine.

Schmidt, E.

FORMATION AND EMISSION OF AIR-POLLUTING SUB-

STANCES IN BRICKWORKS KILNS. (Auswurf und Entstehung luftverunreinigender Stoffe bei Ziegelofen). Text in German. Ziegelind. (Weisbaden), no. 24:560-571, 1968. 14 refs.

Emission measurements for 60 brick ovens revealed that soot emission levels from old ovens with simple combustion installations often exceed maximum permissible levels while modern kilns easily conform to prescribed standards. The median sulfur dioxide emission was 0.5 g/N cu m, but emission levels varied rather widely. Sulfur oxides from brick kilns contained a considerably higher share of SO₃ than emissions from other types of furnaces. Fluorine concentrations ranged from 1 to 184 mg/N cu m (median level, 48 mg/N cu m). The emission of sulfur oxides and fluorine is governed by the composition of the materials used in brick manufacture, especially the lime content, and by the firing temperature. Emissions increase with higher firing temperature and decrease with lime content. A higher emission of sulfur oxides is usually accompanied by higher fluorine emissions. To comply with prescribed emission standards for sulfur oxides, stack heights of 20 to 40 m are necessary; for fluorine, from 20 to 50 m. In special cases high stacks will not suffice and the blowing of powdered magnesite or of dolomite into the furnace may be necessary.

Porteous, A.

SOME ASPECTS OF AIRBORNE POLLUTANTS AND THEIR EFFECTS ON LIVE SUPPORT SYSTEMS. Public Cleansing (London), 61(10):485-492, Oct. 1971. 4 refs.

Increases in population and affluence have combined to produce wastes and environmental tampering on an un-

<xref image="2000WVAV.TIF|V3|2006:09:28:01:18:10.00|118370|0"> image: </xref>

preceder.ted scale. The decompositon of these wastes through incineration produces air pollutants that are potentially damaging to life support systems. Domestic refuse, for example, has a composition of roughly 30% ash clinkers and coal dust, which is a potential source of sulfur dioxide when incinerated. Sulfur dioxide and fluorides can affect life and even small concentrations cause selective damage to vegetation. The decomposition of plastics under high-temperature condition gives rise to the possibility of acid mists and the emission of polychlorinated biphenyls. Low concentrations of PCBs can be concentrated biologically until they affect living systems. Atmospheric dust from combustion and other industrial processes is linked to the decrease in atmospheric temperature which has shortened the average growing season since 1950 by about two weeks. There are three SO₂-removal processes which may be feasible on a large scale: Remluft, Cat-ox, and alkalized alumina.

National Materials Advisory Board, Washington, I). C., Panel on Fluorspar

TRENDS IN THE USAGE OF FLUORSPAR. National Academy of Sciences - National Academy of Engineering, Washington, D. C., Pub. NMAB-269, 54p., Dec. 1970. 21 refs. NTIS: PB 198339

Three major segments of American industry (steel, aluminum, and fluorocarbon producers) use approximately 939? of the fluorspar consumed in the United States and will probably continue to require large and assured supplies well beyond the next decade. The fluorspar demand of the aluminum industiy may decrease because of fluorine recovered from waste products and phosphate production. However, the overall fluorspar demand should contine to grow as the result of increasing requirements for the product of steel and fluorcai-bons. The total fluorspar demand was 1.24 million tons in 1968 and is projected to increase to 1.8 million in 1975 and to 2.2 million in 1980. Due to environmental concern, secondary sources of fluoroine are beginning to be exploited in greater volume. The principal source is a by-rooduct from the production of phosphates. POLLUTION CONTROL AT A LARGER FERTILIZER COM-
PLEX. Safety Air Ammonia Plants, vol. 13:23-28, 1971.
Although the pollution abatement facilities at a fertilizer com-
plex of Canadian Industries Ltd. were expected to enable air
quality regulations to be met, CIL decided that it would be
desirable to monitor its operations to ensure that this was
being accomplished, to indicate the malfunction of pollution
control equipment, and to enable repair of such equipment be-
fore environmental damage could occur. A survey sampling
grid was set up to measure fluorides, sulfur dioxide, and par-
ticulate matter. The major source of fluoride emission to the
atmosphere is the diammonium phosphate plant, where
phosphoric acid is reacted with ammonia. Ground level concen-
tration data are indicated, and a model to simulate any com-
bination of circumstances by mathematical means is presented.
A venturi scrubber was installed between the ammonia
scrubber and the dust scrubber stack, using gypsum pound
water as the scrubbing medium, thus lowennq the fluoride
emissions. Water quality monitoring, particulate emissions,
ammonia plant condensate, and solid waste disposal are also
discussed.

CHEMISTRY AND DETERMINATION OF AIR POLLU-
TANTS. (Scheikunde en analyse van luchtpollutie). Text in
Dutch. Ind. Chim. Beige, 36(7):S89-626, 1971. 231 refs.
Gaseous pollutants include sulfur compounds, hydrocarbons,
nitrogen compounds, ozone, fluoride compounds and chlorine

compounds. Sampling methods are explained. The term Residence Time is defined. Sources of sulfur containing gases are tabulated, and chemical reactions of sulfur dioxide formation are given. Methods of analysis of sulfur dioxide are described. Biological and toxicological effects of hydrogen sulfide are described. The sources, measurement, formation, and possible effects of carbon dioxide, fluorine and chlorine compounds, carbon monoxide, and nitrogen oxides are discussed. The natural cycle of ozone in atmosphere and polluting effects of ozone are described. The phenomenon of photochemical mist formation in London and Los Angeles is described. Also mentioned are: Reduction of visibility through smoke, aerosols and photochemical generation of mists; effects on materials; effects on agricultural products through sulfur dioxide, fluorides, or ozone; and physiological and psychological effects

Schmidt, E

THE FORMATION AND EMISSION OF AIR POLLUTING SUBSTANCES BY BRICK KILNS. (Auswurf und Entstehung luftverunreinigender Stoffe bei Ziegelofen). Text in German. Bcr. Deut. Keram. Ges., 45(11):S79, Nov. 1968.

Measurements of emissions from 60 brick factories revealed that the emission of particulates from old kilns of simple construction often exceeded maximum permissible levels while modern easily conformed to prescribed limits. Sulfur dioxide emissions fluctuated widely within 0.1 and 1.8 g/N cu in. SO₃ comprised 5-50% of the total sulfur oxides emitted; thus, the emission of SO₃ from brick ovens is higher than from other types of furnaces. All brick clays contained small amounts of fluorine compounds with 0.02 to 0.1% F. Fluorine emission levels fluctuated from 1 to 125 mg/N cu m. Dispersion of SO₂ requires stacks 20 to 40 m high stacks; for F, 20 to 50 m stacks are necessary. Emissions increased with increasing combustion temperature and decreased with increasing lime content in the brick clay. High SO₂ emission is usually coupled with high emission of F

Taga, Tahakide

CONTINENTAL REPORT: ASIA. International Union of Air Pollution Prevention Associations, Intern. Clean Air Congr., Proc. London, England, 1966, p. 22-24. (Oct. 4-7 Paper II/4.) The problem of air pollution in Formosa, the Korean Republic, the Philippines, Thailand, India, and Japan is reviewed with respect to pollutants, emission sources, control agencies, air quality measurements, and legislation. Cities with the greatest pollution problem are listed. Standards were established for dust fall from fuel combustion and incinerators, oxidants, carbon oxides, nitrogen oxides, and sulfides from commercial and industrial activities (Formosa); smoke, fumes, and dusts (including cyanides, fluorides, phosphorus compounds (Korea); soot, dust particles, sulfur dioxide, hydrogen fluoride, hydrogen sulfide, hydrogen chloride, nitrogen dioxide, chlorine, carbon dioxide, hydrogen cyanide, and ammonia (Japan). The major sources of pollution in Asia include automobiles, power plants, unpaved roads, lumber mills, chemical processing, cement factories, domestic ovens, and pulping.

ENVIRONMENTAL PROTECTION AND CULTIVATION OF THE ENVIRONMENT IN LOWER SAXONY. (Umweltschutz und Umweltpflege in Niedersachsen). Text in German. Staedtehygiene (Uel7.cn/Hamburg). 22(11):266-267, Nov. 1971. The emission limit values for sulfur dioxide and dust are exceeded in Lower Saxony during normal weather conditions only in individual critical areas. In the Nordenham area the soil and the vegetation are heavily enriched with lead and zinc dust, sulfur dioxide, and fluorine. The lead content of the soil has reached 120 times and zinc has reached 150 times the normal values. The milk of animals grazing in this area has to be heavily mixed with other milk in order to make it drinkable. In Delmhorst, the natural composition of the air is changed by the emissions of a linoleum plant and a lacquer-resin plant. During the oxidation of linseed oil and the melting of resins, acrolein, formic acid, acetic acid, and phenols are liberated. In Osterwald, the fluorine emissions of a ceramic plant has destroyed a large forest. Injuries in forests were also observed in Bad Salzdetfurth from the emissions of a potassium plant and near Munich by a cellulose plant. Animal mass breeding stations cause unbearable odor emissions in Suedoldenburg, Bersenbrueck, Diepholz, Bassum, and Nienburg.

Reimer, Hans
REMOVAL OF PLASTIC WASTE BY MEANS OF INCINERATION. (Beseitigen von Kunststoffhaltigem Muell durch Verbrennen). Text in German. Muell Abfall, 4(1):19-21, Jan. 1972. 7 refs. (Presented at the Muelltechnischen Kolloquium des Forschungund Entwicklungs-Instituts fuer Industrie- und Siedlungswasser wirtschaft der Technischen Universitaet, Stuttgart, West Germany, Oct. 15, 1971.) The incineration of plastic waste causes problems deriving from the fact that plastic material develops gases. Since the combustion temperature in the incineration plant has to exceed 850 C in order to avoid bad odors and the temperature level must not exceed 350 C for dedusting the flue gas, the flue gases have to be cooled down by water or air. In this case, however, the flue gases get into direct contact with metallic material causing corrosion because of the content of chloride in the plastic waste, forming ferrochloride in a reducing atmosphere, and peeling the material. Methods against corrosion are adding of secondary air which prevents the formation of inhomogeneous flue gas concentrations and avoiding the use of metallic material up to a grate height of 2m. Tests are given to bind the developing chloride by physical or chemical means like dolomite. Concerning the emissions of hydrochloric acid, the concentration in the flue gases rarely exceeds 1000 mg/N cu m, and is expected to raise to 2000 mg/cu m in 1980. The emission concentration of hydrofluoric acid amounts to 8 - 10 mg/cu m.

Ministry of Health and Welfare (Japan) Dept. of Environmental Pollution Control
ABOUT THE NATURE AND EFFECT OF HARMFUL SUBSTANCES (POISONOUS AND DELETERIOUS SUBSTANCES CONTROL LAW. Article 2, Item 1, No. 3. (Yugai busshitsu (Hodai 2 no, Dai 1 ko, Dai 3 go) no seijo oyobi eikyo ni (suite)). Text in Japanese. 44p., May 1971. The nature, permissible concentration, and measurement methods of cadmium, chlorine, fluorine, lead, nitrogen, and their compounds. Cadmium and its compounds include metallic cadmium, cadmium oxides, and cadmium salts. Oral and inhaled toxicities are mentioned. The dithizone method is used to measure cadmium. The rhodanic mercury method is used to measure hydrogen chloride and the detecting tube method and the orthotolizine method is used to measure chlorine. Acute

and chronic effects of chlorine compounds are discussed. Fluorine, hydrogen fluoride, difluoric oxides, and fluorides are measured by the alizarin complexon method. Lead, inorganic lead compounds, metallic lead, lead oxide, lead chloride, and organic lead each have unique toxic properties. The dithizone method is used to measure lead. Nitric oxide, nitric anhydride, nitrous oxide and nitrogen dioxide are discussed. The detecting tube and naphthylethylene-diamine methods are explained.

REACTIONS ASSOCIATED WITH THE KILN GASES.
CYCLIC PROCESSES OF VOLATILE SUBSTANCES,
COATINGS, REMOVAL OF RINGS. (Zement-Kalk-Gips
(Wiesbaden), 2S(1):1-12, Jan. 1972. 46 refs. (Presented at the
Verein Deutscher Zementwerke Congress, Duesseldorf, West
Germany, Sept. 28-Oct. 1, 1971.)

In addition to dust from the process material the gas stream in a cement kiln contains mainly alkali sulfates, alkali chlorides, and calcium fluoride formed by reaction in the kiln gas after vaporization from the material. If these compounds react with or are precipitated on the material in the colder parts of the kiln, they will form an internal cycle. If they are precipitated in the gas cleaning installation and are then returned to the process, they will form a closed external cycle which will be broken if the substances in question are discarded with the dust collected in the precipitator. Material balance investigations on 11 kilns with suspension preheaters and 10 kilns with grate-type preheaters determined that the internal alkali and sulfur cycles are approximately equal. Approximately equal amounts of alkali and sulfate are also precipitated with the dust; dust quantities for the suspension preheater are 50-117 g/kg of clinker as compared with up to 20 g/kg for the grate-type preheater. The reaction with the alkalies is of decisive importance with regard to sulfur dioxide emissions. The internal chloride cycle increase? steadily if the chloride content of the raw meal exceeds 0.01-0.015% by weight. The fluoride is combined mainly in the clinker. Objectional coatings and meal, sinter, and clinker rings can be obviated by appropriate reduction of the cycles in question (coatings and meal rings) or by reduction of the proportion of fusible matter in the clinker (sinter and clinker rings). A further condition to minimize the formation of objectionable coatings is proper routine operation of the kiln. Effective methods for the removal of coatings and rings include cutting with high- or low-pressure water jets, dislodging with a gun, or destroying by explosive action with the Carbox process.

Escourrou, R.
THE SCOURGE OF POLLUTION. (Le fleau de la pollution).
Text in French. Papeterie, 93(11):102S-1026, 1029-1032, 1035-1038, 1041-1045, Nov. 1971.
Air, water, and noise pollution are discussed. Dust generation is discussed, with particular emphasis on cement works. Gaseous pollutants include sulfur dioxide, fluorine derivatives, carbon monoxide, and odors (from spray painting shops, animal food production, and motor vehicle exhausts). The sampling of air is briefly described, as well as methods of determining concentrations of sulfur dioxide, fluorine, and dust. Water pollution, effects on fish, and sources of water pollution are discussed. Pollution of the sea by atomic fallout, residual oil,
<xref image="2000WVAX.TIF|V3|2006:09:28:01:18:16.00|124277|0"> image: </xref>

effluents from coastal industries, and the discharge from sewers is discussed. A suggested permissible noise limit for city conditions would be 80 to 85 decibels. A motor vehicle traveling at 50 mi/hr exceeds this noise level.

PROBLEMS OF ENVIRONMENTAL PROTECTION IN BASIC-INDUSTRY PROCESSING PLANTS. (Probleme des Umweltschutzes bei verfahrenstechnischen Anlagen der Grundstoffindustrie unter besonderer Beruecksichtigung gesetzlicher Vorschriften zur Luftreinhaltung und Laermbeakaempfung). Text in German. *Aufbereitungs-Technik*, 12(12):757-763, Dec. 1971. 25 refs.

Branches of industries such as cement plants, soft and hard coal briquetting plants, cokeries, and iron ore sintering plants are large air polluters. Great efforts have been undertaken to reduce emission. In the cement industry, for instance, the average dust emission dropped from about 3.5% in the year 1950 to 0.15% of the clinker production in 1967. Over the same period the clinker production rose from 11 million tons to 33 million tons. The technical directives limit the dust emissions by cement grinding stations to 150 mg/cu m. The gaseous emissions from cement plants are negligible. The soft coal briquetting plants of the German Democratic Republic emitted about 260,000 tons of dust in 1967. In hard coal briquetting plants the emission of benzo-3,4-pyrene must be mentioned in addition to the dust emission. Cokeries emit dusts, tar aerosols, and gases, particularly hydrogen sulfide and sulfur dioxide. In 1956 the SO₂ emission by these plants amounted to 56,000 tons. Through scavenging of the gases, the SO₂ emissions can be greatly reduced. In iron ore sintering plants, dust and SO₂ are emitted. The SO₂ concentration in the uncleaned gas may reach 10 g/cu m. At an annual production of 20 million tons of sinter, about 210,000 tons of SO₂ are emitted. These plants also emit fluorine. The federal government drafted a law expanding its constitutional rights to include the fields of water pollution, maintenance of clean air, and noise abatement. Emission limits for basic industry processing plants are included in the technical directives pertaining to air.

PARTICIPATE POLLUTANT SYSTEM STUDY. VOLUME I -

MASS EMISSIONS. Midwest Research Inst., Kansas City, Mo., Air Pollution Control Office Contract CPA 22-69-104, MRI Proj. 3326-C, 372p., May 1, 1971. 198 refs.

A program to assess particulate air pollution from stationary sources in the continental United States and to advance the capability of control equipment for particulates was conducted. All significant sources of particulate pollutants are identified, and the most important sources are evaluated. Future problem particulate emission sources, determined by projecting production trends, control efficiency, and control equipment application trends, were identified. Research and development plans were formulated to fill in the knowledge gaps pinpointed during the study. From the list of significant sources, a ranking of the most important sources by total tonnage emitted was developed by calculating total emissions using emission factor techniques and other calculation methods. Important sources by tonnage are fuel combustion in stationary sources; crushed stone, sand, and gravel; operations related to agriculture; iron and steel manufacturing; cement plants; forest products; lime; clay products; primary nonferrous metals; fertilizer manufacturing; asphalt; ferroalloys; iron foundries; secondary nonferrous metals; coal preparation plants; carbon black; petroleum refining; and acid manufacturing. Sources and air pollutants were ranked by objectionable properties. In order they were: carcinogens, beryllium and mercury, toxic metals, mercaptans, isocyanates, asbestos and silicates, very toxic metals, fluorides, alkyl amines, hydrogen

sulfide, calcium oxide, mineral acids (hydrochloric, nitric, sulfuric, and phosphoric acids), sulfates, nitrates, sulfur oxides, organic sulfides, pyridines, nitrogen oxides, chlorine, soot, smoke, carbon black, less toxic metals, fly ash, inert particulates, oxidants such as ozone, olefins, aldehydes, phenols, aniline, aromatics, chlorocarbons, mixed organics, ammonia, hydrocarbons, and carbon monoxide.

Marier, J. R.

THE ECOLOGICAL ASPECT OF FLUORIDE. Fluoride, 5(2):92-97, April 28, 1972. 21 refs. (Presented at the International Society for Fluoride Research, Annual Conference, 4th, the Hague, Netherlands, Oct. 24-27, 1971.)

Research results have shown that fluorides tend to be the major atmospheric pollutant involved in a situation that also involves sulfur dioxide. The possible synergism involving more than one pollutant must be thoroughly investigated since a simple additive effect would underestimate the condition if a synergism magnifies the combined effect of the two pollutants. Another example of synergism involves the magnitude of fluoride uptake in vegetation, arising from the use of fluoride-containing phosphate fertilizers. The presence of only 0.11 mg/l of available boron doubles the uptake of fluoride via the root-system of vegetation. A study determined that exposure of aquatic vegetation to 100 ppm of water-borne fluoride for 5 days increased the vegetation fluoride content 50-fold, whereas exposure to 20 ppm for 14 days increased it 38-fold. No information is available concerning exposure to lower level of water-borne fluoride for longer periods of time. The possibility that vegetation exposed to fluorine air-pollution are able to convert inorganic fluoride to the much more toxic fluoroacetate and fluorocitrate forms is considered. Recycling of the emitted fluorides for use in syntheses of useful compounds would benefit the industries and the ecosystem.

FLUORINE CONTENT OF REFRACTORY CLAYS AND
FLUORINE EMISSION DURING FIRING OF FIRE-CLAY

PRODUCTS. (Der Gehalt an Fluor in feuerfesten Tonen und Schamotte und die Beeinflussung der Fluorabgabe beim Brand der Schamotteergebnis.se). Text in German. Sprcchsaal Keram. Glas Email Silikate, 103(20):901-906, Oct. 2, 1970. 10 refs.

The influence of different factors on the final fluorine content in refractory clays was studied. During firing, 40% of the total (0.03-0.06%) fluorine content is volatilized. Fluorine removal starts at 400-500 C and is intensified with increased temperature until sintering processes start. High sulfur dioxide concentrations and mainly water vapor in the atmosphere have enhancing effects. The volatilization during firing is influenced by the sintering of the raw material and the porosity. Fluorine removal is additionally influenced by both shape and wall thickness of the products. The removal from the near-surface layer, at a temperature of 900-1000 C, is more intense than from the core, where it occurs at 1200 C. The fluorine removal is considerably less intense in production than in experimental firing.

SOME CHEMICAL OBSERVATIONS ON THE VOLCANIC
EMANATIONS AND INCRUSTATIONS IN THE VALLEY OF

10,000 SMOKE, KATMAI, ALASKA. Amer. J. Sci.,
50(296):14M53, 1920. 12 refs.

Volcanic gases have been pouring out continuously from vents distributed over a 50-square-mile area since the eruption of the Katmai crater in southwestern Alaska in 1912; in the course of time they have built up large masses of incrustations around the vents. Examination of the incrustations revealed the presence of the following compounds: sulfur, arsenic, fluorides, corundum, silica, boron, gypsum and apatite, potassium alum, iron, vivianite, pyrite, manganese, and aromatic hydrocarbons. Water vapor was the major component of the issuing gases, but hydrogen sulfide, sulfur dioxide, volatile ammonium compounds, and hydrochloric and hydrofluoric acids were also detected. While the majority of incrustations were secondary products arising from decomposition of ash by volcanic gases, the great volume of escaping vapors had a magmatic origin. The mineralization going on in the area may be due to water liberated by contact of the crystallized crust of earth with heated magma.

MEASURES AGAINST AIR POLLUTION CAUSED BY INDUSTRIAL SOURCES. (De strijd tegen de luchtvervuiling afkomstig van industriële bronnen). Text in Dutch. Polytech. Tijdschr., Ed. Procestechiek (The Hague), 27(7):231-237, 1972. 26 refs. (Presented at the Environmental Control Seminar, Rotterdam, Netherlands, May 25-26, 1971).

A general survey is given of air pollution from industrial sources in the United States, with special regard to particulate, gaseous, and fluorine pollution. The contribution of industry to air pollution was 14% with 30 million tons in 1968. Particulate pollutants are most important, followed by sulfur dioxide, hydrocarbons, carbon monoxide, and gaseous and particulate fluorine compounds. To effectively control air pollution, improved source localization techniques are required. General principles and uses of pollution control equipment such as cyclones, tissue filters, scrubbers, and electrostatic filters are reviewed. Contributions of several industries to particulate and gaseous pollution in 1967 are reviewed. Quarrying, gravel, and sand processing was the major source of particulate emissions with 4.6 million tons, followed by grain mills with 2.952 million tons. Compared to other industries, a high proportion of the emission sources is localized in the iron and steel industry, (1.490 million tons). Cokeries are a major source of HC emissions. The respective contributions by the paper and asphalt industries were 633,000 and 522,000 tons. The joint share of the cement and lime industries is 744,000 tons, followed by foundries with 217,000 tons. Brick manufacturing was responsible for the bulk of fluorine emissions. The chief sources of sulfur dioxide, carbon monoxide, and hydrocarbon emissions were primary nonferrous smelting (2,940,000 tons from the copper industry alone), petroleum refining (6.2 million tons), and petroleum products processing (1.1 million tons), respectively.

Kearney (A. T.) and Co., Inc., Chicago, 111.

AIR POLLUTION ASPECTS OF THE IRON FOUNDRY INDUSTRY. Office of Air Programs Contract CPA 22-69-106, Rept. APTD-0806, 260p., Feb. 1971. 18 refs.

A study was made of the iron foundry industry, with particular emphasis on the melting area, was undertaken in order to examine those aspects pertinent to air pollution. Pollutants commonly discharged by such industries include smoke, metallic oxides, oil vapors, carbon monoxide, sand fines, metal dust,

and coke dust, odors, fluoride fumes, vapors, and facing fumes. Particulate emissions have been a point of focus for concentrated efforts in air pollution; however, gaseous emissions and odors from the foundries have not been given much attention, and the foundry industry now has to take steps to suppress these discharges into the atmosphere. The physical difficulties of satisfactory collection of pollutants are not easily solved and, in most cases, costs of satisfactory collection are quite high. A lack of correlation between standard furnace design factors and emission levels indicates a variance in operating factors. One group of variables is related directly to cupola operation, including specific blast rate, blast temperature, type of lining, and operating variables of the afterburner. A second group of variables concerns the quantity and quality of charge materials. Reproducibility of test results is difficult with any given technique, even for a stable emissions producing system. Compounded further by the use of different techniques, equipment, and testing companies to obtain data for comparison and analysis, the confidence level of the data must suffer, despite the high degree of professionalism of the laboratories performing the tests. Control methods include centrifuges, scrubbers, filters, afterburners, preheaters, hoods, and electrostatic precipitators.

Takahashi, Noboru

ENVIRONMENTAL POLLUTION BY METAL INDUSTRIES.

(Kinzoku sangyo ni yoru kankyo osen). Text in Japanese.

Kagaku (Science), 41(10):551-556, Oct. 1971.

Iron works produce mineral powder and coke powder as particulates and sulfur dioxide. More than 50% of the SO₂ is from the sintering process. By an approximate calculation, a plant with a capacity of annual production of 1000 tons crude steel produces 7,000,000 cu m SO₂ every year. The SO₂ gas from an iron works also contains extremely poisonous arsenic trioxide. The same plant discharges about 2400 tons of waste water yearly. Casting industries generate approximately 6000 tons of particulates yearly, of which about 50% are silicon dioxide. In zinc production industries, cadmium is generated since its contamination in zinc mineral is approximately 0.25%. It is discharged as dust into air and as waste in waste water. In aluminum refining, fluorides are generated, and for a production of 1 ton aluminum about 20 to 30 kg of fluorine are also produced as fluorides. Cyanides are largely used in metal gilding and thermal treatment, approximately 50% for the former and 30% for the latter. These cyanides, accompanied with cadmium, have been the major pollutants in the rivers in large cities.

control regions. For each source category, gas flow rate, temperature, and velocity and stack height were evaluated and the operation of the industry, process description, and input-output relation were reviewed. Collection efficiencies were calculated for baghouses, electrostatic precipitators, high- and low-energy scrubbers, mechanical collectors, afterburners, adsorption methods, and scrubbers. Complete data are presented for exhaust gases from combustion of coal, fuel oils, natural gas, and wood wastes within power plants, and industrial processes; domestic heating; incineration; open burning; solid waste disposal; chemical processes; paint and varnish manufacturing; soap and detergent manufacturing; synthetic rubber and fiber plants; food and feed operations; primary and secondary metallurgical processes; sintering; mineral processing; petroleum refining; pulp mills; dry cleaning; surface coating operations; and gasoline marketing. Pollutants emitted by the various processes include solvents, alumina, copper oxides, metal fumes, chlorides, lead oxides silica, fly ash, particulates, sulfur oxides, nitrogen oxides, sulfur dioxide, soot, chlorine gas, carbon dioxide, carbon monoxide, hydrogen fluoride, hydrogen sulfide, ammonia, organic vapors, fluorides, phosphoric acid mist, aldehydes, hydrogen chloride, hydrocarbons, zinc oxides, dusts, and odors.

Brocke, Werner

FORECASTING OF POWER PLANT-, INDUSTRY- AND DOMESTIC HEATING-CAUSED AIR POLLUTION. (Prognose der Luftbelastung durch Emissionen stationärer Feuerungsanlagen in Kraftwerken, Industrie und Haushalt). Text in German. Luftverunreinigung, 1971:20-25, Dec. 1971. 12 refs. Forecasts are given for the air pollution caused by fossil fuel-based stationary firings in power plants, industry, and domestic heating in the German Federal Republic in the period from 1969 to 1980. While the primary energy consumption will rise by about 60%, the demand for fossil fuels will increase by about 44%. The pit coal consumption shows a drastic downward trend, while the demand for brown coal will be practically unchanged, and brown coal will be consumed by power plants only in 1980. Great increase in fuel oil and gas consumption will continue. Fuel specific emissions are secured for particulate pollutants and sulfur dioxide only, and the forecasts do not consider anti-pollution measures to be taken in the meantime. Particulate emissions, 50% of which are caused by stationary firings, will decrease by 25% by 1980. The respective shares of power plants, industry, and domestic heating will be 26%, 10% and 15%. Sulfur dioxide emissions from stationary firings, now 88% of the total, will increase by 50%. Against 70% in 1970, 83% of the total fluorine emissions will be caused by stationary firings in 1980, while the corresponding percentage for nitrogen oxides will be 42%. The carbon monoxide emissions from stationary firings will decrease from 2.5 million tons in 1970 to 1 million tons in 1980. Domestic heating and especially the chemical industry will be primarily responsible for organic pollutants. Communal incinerators, now emitting 1000 tons of particulate pollutants and 10,000 tons of sulfur dioxide yearly, will possibly cause local or regional pollution problems. As a result of fuel and waste gas desulfurization, SO₂ emissions will drop three million tons below the 1969 level. Due to dust separation techniques, and the use of adequate fuels, a total particulate emission of 230,000 tons, instead of 800,000 tons, is expected.

Baum, F., J. Giebel, and H. Brell

THE ANALYSIS OF GASEOUS POLLUTANTS AT HARD COAL FIRED INDIVIDUAL HEATERS. (Ueber die Erfassung gasförmiger Schadstoffe bei steinkohlegefeuerten Einzelöfen). Text in German. Gesundh. Ingr. 93(4):102-108, April 1972. 27 refs.

Emissions of sulfur dioxide, hydrogen sulfide, fluorine and oxides of nitrogen from individual hard coal-fired heaters were

measured. For determination of the total sulfur and fluorine emission the gas samples (1.67 cu dm/min) were passed through a quartz impinger for soot and tar separation and through two quartz-fritted scrubbers. The impinger and scrubbers contained 75 cu cm IN NaOH, 10 cu cm 3% H₂O₂ solution, and 5 drops of n-butanol. The same sampling set-up was used for determination of the other pollutants. As absorption fluids, however, 20 cu cm cadmium acetate solution (consisting of 50 g Cd(CH₃COO)₂·2H₂O and 100 cu cm CH₃COOH in 850 cu cm H₂O) was used for the H₂S determination and 120 cu cm Saltzmann solution (25 g sulfanilic acid, 250 mg alpha-naphthalamine, and 250 cu cm CH₃COOH in 4 cu dm H₂O) was used for determination of NO_x. The ash and unburned residues from the combustion were also analyzed. Two types of heaters were examined. In the first one the combustion air enters at the bottom. The waste gases pass the entire fuel charge from bottom to the top. In the second one the combustion air is supplied at various points of the heater. Anthracite briquettes were used for firing. Each combustion test lasted 2, to 3-2/3 hr. The average CO₂ concentrations measured in the waste gas during one combustion period of the bottom-fed heater ranged from 4.96% by volume to a maximum of 7.73 vol %. In the second heater they ranged from 6.83 to 7.88 vol %. The concentration of SO₂ emissions ranged from 270 to 848 mg/cu m in the first heater and from 495 to 677 mg/cu m in the second. The H₂S emission of the bottom heater was considerably higher than that of the multi-point type. The opposite was true for the fluorine and the NO_x emission. Based on the number of such heaters in the Ruhr area, their contribution to the total fluorine emission was estimated. Over the half-year of winter, 0.1 to 0.2 microgram fluorine/cu m air comes from domestic heaters.

Gautier, Armand

FLUORINE IS AN ELEMENT ALWAYS PRESENT IN EMIS-
SIONS FROM THE EARTH CORE. (Le fluor est un element
constant de emanations du noyau terrestre). Text in French.
Compt. Rend., vol. 157:820-825, Nov. 10, 1913. 5 refs.
On-site collection of samples of the gases issuing from the volcano Mt Vesuvius shortly after its eruptions, was started in 1906 in order to establish their fluorine content. In 1913 a sampling method was successfully applied using a 1-liter bottle containing lime, in which a small tube was inserted. The tube was sealed into the bottle neck and protruded well beyond it, so that the bottle could be placed into a suitable fumarole with the tube reaching inside. The fluorine reacted with the lime, and subsequent laboratory tests of this sample showed a fluorine content of 0.110 mg/1 gas, corresponding to 0.116 mg hydrofluoric acid or 0.150 mg silicon fluoride. Hydrofluoric acid is estimated to form about 1/8000 part of the total gaseous emission of volcanic fumaroles. Another set of tests was made at a location in Italy where burning gases emerge perpetually through surface cracks. A surface-cooled lead spiral was used on which the water vapor of the emission condensed, permitting collection of the non-condensable gases. These contained carbon dioxide, hydrogen sulfide, ammonia, methane,

A. EMISSION SOURCES

37

oxygen, hydrogen, nitrogen, and traces of argon and helium. The fluorine content of these gases was 0.255 mg, corresponding to 0.268 mg hydrofluoric acid/l gas. Most natural mineral waters contain fluorine. For example, the fluorine content of Vichy water is 3.72 mg/l indicating a volcanic origin.

BACKGROUND INFORMATION FOR ESTABLISHMENT OF NATIONAL STANDARDS OF PERFORMANCE FOR NEW SOURCES. GRAY IRON FOUNDRIES. Air Pollution Control Office Contract CPA eO-142, Task 2, 63p., March 15, 1971. 31 refs.

Gray iron foundries produce metal castings by mixing gray iron, pig iron, scrap, and trace additives. The need for particulate controls is great, but average profits of approximately 6-9% do not provide much margin for elaborate controls. New plants seem to be able to economically justify air pollution control; old plants cannot. All devices now in use are designed to control particulate matter. No attempt is made to control nitrogen oxides, and in many cases emission levels have not been determined. The only sulfur dioxide removal is that which takes place during particulate scrubbing. The concentrations of SO₂ in top gases from cupola furnaces range from 300 to 470 ppm. Quantitative analyses of fluoride emissions are not reported. Reduced S compounds are not generated in any gray iron processes. Odors originating from the oil, wax, and resins used in molding have not been measured. Uncontrolled cupola melting results in variable opacity which approaches 100%. Electric arc melting also produces a visible plume. Other processes have plumes during charging and when fluxes are added. Four foundries are either planned or in production within stringent particulate emission regulations; eleven foundries operate with 99% efficient controls. Emission limits recommended for new or modified sources are: sulfur oxides--500 ppm, NO_x--325 ppm, particulates--0.03g/scf, and visible emissions--less than 10% equivalent opacity. Control methods include venturi scrubbers, fabric filters, baghouses, afterburners, and electrostatic precipitators.

Hernick, R. A.
BACKGROUND INFORMATION FOR ESTABLISHMENT OF NATIONAL STANDARDS OF PERFORMANCE FOR NEW SOURCES: IRON AND STEEL INDUSTRY. Environmental Engineering, Inc., Gainesville, Fla., and Herrick Associates, Reston, Va., Environmental Protection Agency, Division of Abatement Contract CPA-70-142. 107p., March 8, 1971. 40 refs.

Process conditions common in iron and steelmaking are outlined. Emissions of particulates, sulfur oxides, nitrogen oxides, fluorides, polycyclic organic matter, total reduced sulfur, odors, carbon monoxide, and visible emissions are discussed for the processes and the optimum control devices are identified where possible. The basic oxygen furnace and the electric furnace are expected to become the only significant factors in steel production over the next 20 years. There are no BOF installations in the U.S. that do not have air pollution control devices. Control in electric furnace steelmaking is usually handled by canopy heads and sometimes by roof evacuation. The gases from both processes are usually conducted to gas cleaning systems. Recommended standards of performance for the BOF can be written in terms of particulate emissions. A concentration no greater than 0.020 gis/scf should be the maximum. Gas cleaning installations cannot in most cases maintain acceptance specifications. Electric furnace steelmaking should be restricted to a standard of one lb/t of steel produced.

PUBLIC NUISANCE AND THE PROBLEMS OF EVALUA-

TION. (Kogai to sono keisoku ni okeru mondaiten). Text in Japanese. Hyouunka to Hishitsu Kanri (Stand. Qual. Control), 25(5):14-17, p. 14-17. May 1972.

Fluorine causes injury to humans. Rice and vegetables should not contain fluorine. Lead also enters the human body through food. In the city of Tokyo, 460,000 tons of sulfur oxides per year (1967) are discharged. About 99% is from industry and 1% from automobiles and aircraft. Nitrogen oxides are discharged at the rate of 180,000 tons/yr. About 63.5% is from industry, 35.9% from automobiles, and 0.6% from aircraft. Carbon monoxide is discharged at the rate of 880,000 tons/yr. About 997% are from automobiles, 0.1% from industry, and 0.2% from aircraft. The transport and diffusion of pollution are mentioned.

CLEAN AIR FOR TOMORROW. UTOPIA OR REALITY?

(Reine Luft fuer morgen. Utopie oder Wirklichkeit)? Text in German. 81p., 1972.

Trends in different branches of industry, domestic heating, and transportation and related problems involved in air-pollution control in North Rhine-Westphalia for the period ending 1985 are detailed. Air pollution control as now applied in the chemical industry is not satisfactory. While processes associated with odorous and toxic emissions will increasingly prevail, multi-stage cleaning and systematic measurements by means of recording instruments will be required. Air-pollution control at a rate of 80% will be required for new and existing plants as of 1973 and 1978, respectively. Hydrocarbon and sulfur dioxide emissions should be controlled by the petrochemical industry. The chief pollutants to be controlled in iron and steel works are carbon monoxide, dust, and fluorine compounds, and the specific dust emissions from melting furnaces* should be lowered from 1.5 kg to 1.0 kg/ton of iron. Dust emissions in nonferrous metallurgy should be reduced to one third the present limit. Solids, sulfur dioxide, nitrogen oxides, and flue gas emissions from power plants should be reduced. Techniques for desulfurizing fuels and waste gases are available. Fluorine, chlorine, and sulfur compounds are the basic components of emissions from waste incinerator plants. Long-distance heating offers an ideal solution to pollution from domestic heating. The growth of transportation-generated emissions is outlined. Diesel exhaust, though containing no lead and less CO than Otto engine emissions, is nearly as harmful as the latter. Strict new standards for CO, hydrocarbon, and nitrogen oxide emissions should be implemented in 1976 (3 g of CO, 0.3 g of hydrocarbons and 0.25 g of nitrogen oxides per km).

NONFERROUS METALLURGY. (NE-Metallerzeugung). Text

in German. In: Reine Luft fuer morgen. Utopie oder Wirklichkeit. Moehnesee-Wamt'I, West Germany, K. von Saint George, 1972, p. 60-65.

<xref image="2000WVB1.TIF|V3|2006:09:28:01:18:32.00|110842|0"> image: </xref>

The present situation and future trends in the output and emissions in the nonferrous metallurgy of North Rhine-Westphalia are described. The aluminum industry, which accounts for more than 50% of the total output of West Germany, will experience rapid growth. The basic pollutants are gaseous fluorine compounds (0.8-1.5 kg/I), aluminum- and fluorine-bearing dust (9-20 kg/t), sulfur dioxide (3-15 kg/t), and carbon monoxide. Aluminum remelting is expected to increase 100% by 1980. Chloride aerosols, metal oxides, and gaseous fluorine compounds are the chief pollutants. Dust separation at a rate of 15% was applied to rotary furnaces in 1970. Dust emissions will decrease from 1320 tons in 1970 to 680 tons in 1980 by lowering the dust concentration to 150 mg/N cu m and 100 mg/N cu m for rotary furnaces and thermal chips treatment facilities, respectively. Gaseous fluorine emissions, 90 tons in 1970, will be reduced to 50 tons in 1980 by applying wet-type gas cleaning. Sulfur dioxide emissions from lead manufacturing will be reduced 90% due to waste-gas desulfurization. The efficiency of SO₂ separation at sulfuric acid production facilities is 98%. Lead and zinc emissions, amounting to 350 and 180 tons in 1970, will decrease to 50 tons each in 1975. Sulfur dioxide emissions from copper manufacturing, for which a 2% yearly rate of growth is predicted, will rise from 900 tons in 1970 to 1100 tons in 1980, the waste-gas SO₂ concentration being 0.2 g/N cu m. Hydrochloric acid emissions, now 500 tons, will decrease by 50%. While total dust emission will be reduced from 600 to 300 tons, no further reduction in lead, zinc, and copper emissions is possible. The dust emissions from copper alloy manufacturing will be 10% of the 1970 level by 1980, as an upper limit of 50 mg/N cu m will be set in 1973. Sulfur dioxide emissions from zinc manufacturing, for which electrolytic processes are increasingly used, will decrease from 1800 tons in 1970 to about 1500 tons in 1980. The imposition of a maximum allowable dust emission of 50 mg/N cu m in 1973 will result in zinc and lead emissions, now 160 and 40 tons, decreasing to 80 and 20 tons, respectively, despite a growth rate of 40%.

 STONE AND EARTH. (Steine und Erden). Text in German. In: Reine Luft fuer morgen Utopie oder Wirklichkeit. Moehnesee-Wamel, West Germany, K. von Saint-George, 1972, p. 65-66
 The present situation and future trends in the stone and earth industry of North Rhine-Westphalia are described. The general growth in production, as anticipated through 1980, is characterized by a trend toward centralization and large-capacity units with resulting increased specific emissions. The basic pollutants are dust (cement and limeworks), fluorine compounds (brickworks and enamel industry) as well as fluorine, chlorine, and metal oxides (glass manufacturing). No changes in the amount and composition of refractory plant emissions are expected, but the proportion of volatile and toxic components (lead, zinc, barium, fluorine, cadmium, boron, selenium, strontium, and chromium) in brickwork emissions will increase. Dust emissions from cement manufacturing plants will decrease slightly over the next few years. Strict supervision of dust separators and recording instruments for automatic dust measurements providing automatic shutoff of rotary kilns in case of emergency, should be required for cement works. High-efficiency separation of dust, fluorine, lead, zinc, and other volatile and toxic substances at brickworks, enamel processing, and wall and floor covering manufacturing plants is necessary. The need for the separation of toxic substances in glass manufacturing is emphasized.

 THE EMISSION SOURCE INDUSTRY GROUP CHEMISTRY.
 (Die Emittentengruppe Industrie). Text in German. In: Reine

Luft fuer morgen. Utopie oder Wirklichkeit. Moehnesee-Wamel, West Germany, K. von Saint-George, 1972, p. 14-26.

The problem of chemical plant emissions and the necessary measures to be taken during the period ending 1985 are outlined. The chief pollutants emitted by the plants are organic vapors and gases (hydrocarbons and their halogen derivatives, aldehydes, ketones, organic acids, amines, mercaptans, and disulfides), inorganic vapors and gases such as hydrogen sulfide, sulfur dioxide, hydrochloric acid, fluorine compounds as well as toxic dusts of carbides, fluorides, ferroalloys, arsenic, and asbestos. The pollution-control techniques presently applied in the chemical industry may be inadequate to control emissions from new processes. In addition, the rate of growth in production is highest for products involving high emissions, partly of odorous substances. An 80% reduction in emissions from new and old facilities as of 1973 and 1978, respectively, will be required in plastic and synthetic fiber processing, and will apply to old and new pesticides manufacturing plants alike as of 1973. Adoption of the double-contact process in sulfuric acid production reduced SO₂ emissions by about 85% decrease in sulfur dioxide emissions, while the nitrogen oxide emission abatement in nitric acid manufacturing due to catalytic hydrogen reduction was 88%. Guidelines regarding emission abatement in chemistry are presented. Odorous and toxic discharges should undergo multistage treatment.

IRON AND STEEL. (Eisen und Stahl). Text in German. In: Reine Luft fuer morgen. Utopie oder Wirklichkeit. Moehnesee-Wamel, West Germany, K. von Saint-George, 1972, p. 32-37. Future trends, air pollution problems, and related measures envisaged for the period ending 1985 in iron and steel manufacturing in North Rhine-Westphalia are outlined. North Rhine-Westphalia is responsible for 70% of the total steel output of West Germany, and further growth is expected. Thomas steel will be fully and Siemens-Martin steel largely replaced by oxygen converter steel by 1980. Dust emissions from ore yards should be controlled. Sintering plants, emitting toxic metal oxides and fluorine and chlorine compounds, should be equipped with proper pollution-control equipment. While blast furnaces, discharging dust, carbon monoxide, nitrogen oxides, sulfur dioxide, and hydrogen sulfide, will prevail during the rest of the decade, processes for direct reduction have been developed. The toxic oxides emitted by oxygen converters call for wet dust separators, electrostatic, and continuously operating tissue filters. The present emission standards should be replaced by stricter ones, and excess-air coefficients of 0.3-0.1 should be applied to abate CO emissions. Electric arc furnaces using the ultra-high-power technique should be covered by total dust separation. A limit value of 50 mg/N cu m and the use of tissue filters should be required. Open-hearth furnaces still in use after 1976 should be equipped with dust separators. The recycling of nontreated dust, containing iron and toxic or volatile compounds of lead, cadmium, zinc, arsenic, manganese, copper, antimony, chromium, and fluorine, should be abandoned. The shutdown of obsolete facilities and improvements in pollution-control techniques are further necessary measures. Special attention should be paid to controlling emissions from ore yards, sintering plants (where combined desulfurization and defluorination techniques should be adopted),

IRON AND TEMPERING FOUNDRIES. (Eisen- und Tempergiessereien). Text in German. In: Reine Luft fuer morgen. Utopie oder Wirklichkeit, Moehnesee-Wamel, West Germany, Vcrlag K. von Saint-George, 1972, p. 38-40.

The present situation and future trends for a penod ending in 1980 in the output and emissions of iron and tempering foundries in North Rhine-Westphalia are described. The iron and tempering foundries in North Rhine-Westphalia now account for 44% of the total production volume in West Germany, their growth is expected to slow down during the next decade. The basic pollutants emitted by foundries are dust, sulfur dioxide, and gaseous fluorine compounds, and melting furnaces as well as mold preparation represent the chief emission sources. The maximum allowable specific dust emission from melting furnaces will be lowered from 1.5 to 1.0 kg/I of iron by 1980. New furnaces can be now provided with total dust separation, and the proportion of such furnaces is expected to rise to 20% by 1980. Cupola furnace throat gases contain, on an average, 700 ppm of SO₂, corresponding to a specific emission of 1.6 kg/t. A decrease of about 33%, in SO₂ emission by 1980 can be expected, as coke will be increasingly replaced by natural gas and electricity. The gaseous fluorine emissions are due to fluorine contents in coke (20 ppm) and in dolomite and lime (about 100 ppm). While the fluorine emissions (less than 10 t/year are relatively low), separation techniques with a minimum efficiency of 90% are available. A further decrease in fluorine emissions due to the decreasing proportion of basic hot-blast cupola furnaces is predicted

42685

Ministerium fuer Arbeits, Gesundheit und Soziales des Landes Nordrhein-Westfalen, Duesseldorf (West German[^])

POWER PRODUCTION. (Energieerzeugung). Text in German. In: Reine Luft fuer morgen. Utopic oder Wirklichkeit, Moehnesee-Wamel, West Germany, K. von Saint-George, 1972, p. 40-51.

Trends in fuel use by thermal power plants and industry in North Rhine-Westphalia and resulting changes in emissions (solids, sulfur dioxide, nitrogen oxides, and gaseous fluorine compounds) are described. Assuming no further improvements in air-pollution control techniques, emissions of solids will increase by 12.5% by 1985, the share of power plants rising from 65% to 72%-. Fuel oil will account for 23% of all energy sources. 60-73% increase in nitrogen oxides emissions from 1969 to 1985 is expected, but the contribution of power plants and industry will remain about the same. Sulfur dioxide emissions will increase by 75% from 1.2 million tons in 1969 to 2.1 million tons in 1985. While the proportion of brown coal will be unchanged, it will be consumed almost exclusively by power plants, and the increase in fuel-oil consumption will be most important in industry. Fluorine emissions will be up 179; from 7500 tons in 1969 to 8800 tons in 1985. The contribution of powpr plants to total fluorine emissions will rise from 84% to 93% as a result of increased brown coal consumption. Optional emission-control measures with regard to solids, SO₂, and fluorine emissions are suggested As dust emission standards are violated as a consequence of continuous operation, the installation of automatic measuring instruments may be necessary A specific emission of 0.6 kg/ton of heavy oil should be reached by applying centrifugal dust separators, while the dust emission standards for coal firings should be lowered to 50-100 mg/N cu m. In 1969, 64% of the heavy oil consumed contained less than 1% sulfur; in 1985, the proportion of heavy oil with 0.46% S will be 40% Waste gas desul-

furization, resulting in an 80% decrease, will be applied as of 1974, and appropriate means for desulfurizing fuels are available. The total reduction in SO₂ emissions by 1985 will be some 30%. Fluorine emissions are expected to decrease from 7500 to 4600 tons in 1985 by 25%. The efficiency of wet separation techniques and alkaline absorbents is 80%>.

Safonov, V. N., V. A. Limanskii, V. P. Klyushkin, E. G. Levkov, N. G. Bulgakova, G. I. Iinskaya, N. A. Borisenko, and A. S. Ievkova

THE PHYSICAL PROPERTIES AND CHEMICAL COMPOSITION OF DUST FORMED DURING THE PRODUCTION OF ALUMINUM AND SILUMIN. Tsvetn. Metal., 44(4):42-44, 1971.

12 refs. Translated from Russian. Trans-Chem, Inc., Knoxville, Tenn., 6p.

The physical properties and chemical composition of dust have a significant effect on the basic operating character of dust removal devices, and these determine the expediency of using a specific type of dust removal system. Hence, methods for the determination of physical properties and chemical composition of dusts are reviewed. The dispersion of dust particles by particle size at four different plant locations was determined by methods of three dust extractors and an impactor (a multistage jet precipitator) Both methods measure the dispersion of dust particles directly in a gas conduit; the latter, however, gives more reliable results. For measuring the specific electrical resistance of electrolyzer and silumm dust, a device was used in which a dust layer is formed between two filtering surfaces under conditions found in a gas conduit. An advantage of this method for forming the dust layer lies in the fact that it is not necessary to measure the thickness of the dust layer, since it is always constant and equal to the distance between the discs. Regarding chemical composition, fluorine components are of special interest since they are harmful to the attendant personnel as well as being valuable components. Fluorine which is tied up in the form of complex fluorides was determined by a gravimetric method on lead fluorochloride and also by a mercurous and mercuric method using diphenyl carba/one as an indicator. Results are also given for the fluorine determination by a thorium method using alizarin red S as an indicator. Aluminum, calcium, and magnesium were determined by complexometric methods. Silicon was determined photometrically by the dark blue silicomolybdenum complex with elimination of the interference of fluoride ion by boric acid. The basic method for determining the resinous material requires the extraction of polynuclear aromatics with non-fluorescing benzene and then measuring the fluorescence of the extracts. Iron was determined by an orthophenantholine method after the fluorine was extracted by fusing with potassium pyrosulfate.

AIR POLLUTION ASPECTS OF THE IRON FOUNDRY INDUSTRY-FEBRUARY, 1971. Air Pollution Control Office Contract CPA 22-69-106, 156p., Feb. 1971. 18 refs. NTIS: PB 204712

Despite recent advancements in the technology of making iron castings, the cupola is still the predominant melting unit employed in the iron foundry industry. Emissions from the industry include metallic oxides, oil vapors, and carbon monoxide

<xref image="2000WVB3.TIF|V3|2006:09:28:01:18:38.00|119299|0"> image: </xref>

from melting furnace operations; from other dust-producing operations come sand fines, metal dust, and coke dust. Odors and gaseous compounds such as fluoride fumes, vapors, and facing fumes come from both sources. The lack of correlation between standard furnace design factors and emissions levels requires that the explanation for the wide variance in type and quantity of emissions lie with cupola operating factors, rather than cupola design. Operating factors are broken down into two distinct groups: methods of operations, such as blast rate and temperature, type of lining, and operating variables of the afterburner; and the quality of charge materials, including metal to coke ratio, use of oxygen or natural gas, and the use of briquettes. Recommended practices for testing particulate emissions from cupolas are also included. Control devices include centrifuges, scrubbers, fabric filters, afterburners, preheaters, electrostatic precipitators, furnace hoods, and ventilation.

43014

BACKGROUND INFORMATION FOR ESTABLISHMENT OF NATIONAL STANDARDS OF PERFORMANCE FOR NEW SOURCES. PRIMARY SMELTING OF COPPER, LEAD, AND ZINC. Environmental Engineering, Inc., Gainesville, Fla. and PEDCo Environmental Specialists, Inc., Cincinnati, Ohio, Air Pollution Control Office Contract CPA 70-142, Task 2, 82p., March 15, 1971. 33 refs.

The primary nonferrous smelting industry consists of smelting copper, zinc, and lead bearing ores. Because of the high sulfur content, sulfur dioxide emissions are copious. In 1966, nonferrous smelters emitted approximately 3.8 million tons of SO₂, or 12% of the total SO₂ emissions in the nation. The main processes in the extraction of copper, lead, and zinc from their ores are dressing or concentrating, roasting, sintering, melting and refining carried out in different types of equipment, depending upon the nature of the ore and the particular plant design. Emissions from primary smelters include, in addition to SO₂, nitrogen oxides, solid particulates including toxic metals, and minor amounts of fluorides. Primary control emphasis is placed upon sulfur dioxide and particulate emission. Control technology, including electrostatic precipitators, fabric filters, SO₂ removal processes (contact, alkaline additive, absorption, Claus, and scrubber methods), and mist eliminators, is examined. Most of the SO₂ source streams are of sufficient concentration to justify sulfur value recovery. Smelting operations which control SO₂ emissions to a high degree, both those presently in use and projected designs for the future, are described. Specific regulations currently pertaining to emissions from primary nonferrous smelters are summarized, and the growth of the industry is projected to the year 1980.

Stoiber, Richard L. and William I. Rose, Jr.

THE GEOCHEMISTRY OF CENTRAL AMERICAN VOLCANIC GAS CONDENSATES. Geol. Soc. Am. Bull., 81(10):2891-2912, Oct. 1970. 49 refs.

Chemical data on fumarolic exhalation from high-temperature fumaroles were obtained from 132 gas condensates sampled at six Central American volcanoes. The data are from sufficiently varied locations and cover a long enough time span to permit generalizations regarding the variations in quantity of the seven components for which analyses were made, namely, chlorine, fluorine, sulfate radical, calcium, magnesium, sodium, and potassium. Fumaroles on lava flows have chloride-rich emanations, and fumaroles at active central vents have high SO₄. Quantitative data suggest decrease of Cl/SO₄ ratio at fumaroles at or near active vents before an eruptive period and a rise in the ratio afterward. Regular observations of trends of Cl/SO₄ in condensates from high-temperature fumaroles near central vents appear to allow prediction of the onset of a new eruptive period. The seasonal rains in Central America aid in confirming the effect of groundwater dilution on concentration. Cl and F concentrations and Cl/F, unlike SO₄ or Cl/SO₄, are time and temperature dependent. Changes in concentration with time or temperature appear due to increased ground-water dilution, reduction in the volume of chlorine from the magmatic source with time and, for F, extraction by reaction with the wallrock. Alkalis and alkaline earths appear to be the products of reaction with the wallrock. Part of the K and Na, whose chlorides, unlike those of Ca and Mg, are volatile, appears to have a magmatic source. Estimates of the Na/K ratios in emanations from basaltic to dacitic magma cover a range of 0.5 to 3.0. Suggestions are made for improved data collection when an appropriate opportunity is offered. (Author summary modified)

ENVIRONMENTAL POLLUTION BY SULFUR PROCESSING
FACTORY WASTE GAS AND ITS CONTROL TREATMENT.

(Seirin kojo haigasu ni yoru kankyo osen to jogai taisaku). Text in Japanese. Fukushima-ken Eisei Kenkyusho Kenkyu Hokoku (Fukushima Prefect. Inst. Public Health, Rept.), 19(2):39-41, June 1971. 9 refs.

The hydrogen fluoride and phosphorus content in flue gases from a yellow phosphorus manufacturer are determined by the JIS method and the molybdenum blue method, respectively. An air sampler is used for the gas sampling by placing 10 ml of N/100 potassium permanganate in a gas impinger and sampling at a rate of 2 l/min. Results show that the HF content in flue gas from a melt phosphorus fertilizer plant is 10.2 ppm, and that from a yellow phosphorus plant is 6.29 to 12.72 ppm. The phosphorus content in flue gas from the melt phosphorus fertilizer plant is 0.22 to 0.35 mg/cu m, that from a phosphoric acid fertilizer plant is 10.4 to 37.2 mg/cu m, and that from the yellow phosphorus plant is 0.54 mg/cu m as an average of two stacks. Methods that have been used for the control of the two pollutants are described.

BACKGROUND INFORMATION FOR ESTABLISHMENT OF
NATIONAL STANDARDS OF PERFORMANCE FOR NEW

SOURCES: PRIMARY ALUMINUM INDUSTRY. Environmental Protection Agency, Div. of Abatement Contract CPA-70-142, Task Order 2, 55p., March 1971. 25 refs.

Aluminum processes are reviewed, and emissions from primary aluminum smelters are listed. Sulfur oxides are generally considered to be an insignificant air pollution problem in the smelting process. Nitrogen oxides are also insignificant, except as developed in ancillary activities. No information is available on the emission of alumina dust. Fluorides are the emissions of greatest concern. Total fluoride emission increases with temperature. Total fluoride emissions from the best run plants are reported at 2.3 to 6 lb/t of aluminum with 16 to 48% in the gaseous form. Particulates from these same sources range from 9 to 50 lb/t of aluminum. Some gaseous hydrogen fluoride is evolved. Reduced sulfur compounds have not been found. Odors are not thought to present a problem. The recommended standard for gaseous and particulate fluorides is 2.4 lb/t Al; total particulates, 5 lb/t Al; and visible emissions, Ringelmann No. 1.

44566

American Assoc. for the Advancement of Science,
Washington, D. C., Air Conservation Commission
SUMMARY OF THE FACTS. In: Air Conservation. AAAS Pub.
80, p. 23-46, 1965.

Sources, atmospheric behavior and health effects are reviewed for carbon dioxide, carbon monoxide, sulfur dioxide, sulfuric acid, hydrogen sulfide, nitrogen oxides, hydrogen fluoride, ethylene, olefins, aldehydes, mercaptans, solvents, dust, soot, insecticides and herbicides, and radioactive materials. Factors affecting long transport of pollutants are particle size, gravity, turbulent diffusion, aggregation and condensation, lapse rate, and temperature inversion. Pollutants are removed from the atmosphere by rain, snow, oxidation, and washout. Pollutant control is achieved by elevated stacks, removal of pollutants from effluent streams, and modification of industrial processes, raw materials, and fuels. The importance of scientific investigation, dissemination of information, public opinion leadership, and effective legislation are discussed.

THE CHARACTERISATION OF ALUMINUM REDUCTION

CELL FUME. Preprint, American Inst. of Mining, Metallurgi-

cal, and Petroleum Engineers (AIME), New York, N. Y., 10p., 1971. (Presented at the American Institute of Mining, Metallurgical, and Petroleum Engineers, Annual Meeting, New York, Feb. 26-March 4, 1971.)

The nature of the fume emitted by aluminum reduction cells with prebaked anodes was investigated. The gaseous and particulate contributions under different conditions of cell operation were assessed, and the constitution and particle size distribution of the dust determined by chemical and X-ray examination, together with optical and scanning electron microscopy. Approximately 50% of the fluorine emission is in the form of hydrogen fluoride. The particulate material exhibits a double size distribution with one fraction consisting substantially of dust greater than 5 micron diameter and the other of fine material considerably less than 1 micron diameter. The principal components of the coarse fraction are alumina, carbon, and frozen droplets of cryolite; the fine fraction appears to consist mainly of condensed fluoride vapor approximating in composition to chiolite ($5\text{NaF} \cdot 3\text{AlF}_3$). This fine particulate material accounts for about 35% of the total fluorine emission from the cells. Some parallel observations on the character of the fume evolved from vertical stub Soderberg cells are also discussed. The principal differences are that approximately 90% of the fluorine is present as HF, and that the dust, and particularly the alumina content, is lower than from a prebake cell. (Author abstract)

COMPOSITION AND PROPERTIES OF SUPERPHOSPHATE-VOLATILIZATION OF FLUORINE IN SUPERPHOSPHATE MANUFACTURE. (Ind. Eng. Chem., 34(6): 722-727, June 1942.

Production of ordinary superphosphate results in the volatilization of fluorine which is allowed to escape to the atmosphere or is absorbed in water. At some plants that manufacture ordinary superphosphate, as well as at some that manufacture double superphosphate, the volatilized fluorine is recovered as hydrofluosilicic acid and is marketed chiefly as sodium fluosilicates. In the production of ordinary superphosphate, 11 to 42% of the fluorine in the phosphate rock is volatilized during the mixing and denning operations. The percentage volatilization of the fluorine tends to decrease with an increase in the phosphorous content of the rock. With rocks of the same phosphorous content, the fluorine volatilization is somewhat higher from Tennessee brown rock than from Florida land pebble. Studies of the distribution of fluorine among the calcium sulfate waste and the intermediate and final products of the manufacture of double superphosphates by the wet method showed cumulative volatilizations of fluorine ranging from 36 to 54% of the total fluorine in all the phosphate rock used throughout the process. pounds (sulfur oxides, mercaptans, and hydrogen sulfide), carbon monoxide, carbon dioxide, nitrogen oxides (nitric oxide and nitrogen dioxide), photochemicals (hydrocarbons, aromatics, and aldehydes), particulate matter, lead and other metals, fluorides, radioactive pollutants, and economic poisons such as pesticides and fungicides. The epidemiological relationship between lung cancer and exposure to air pollutants is discussed. Incomplete combustion of organic materials is a primary source of airborne carcinogenic aromatic hydrocarbons. Agricultural uses, including ground and aerial application and nonagricultural uses of economic poisons are described. Radioactive contamination of the atmosphere results from the reactor fuel cycle; the use of nuclear energy as a source of propulsive power; the use of radioisotopes in industry, agriculture, medicine, and scientific research; and from nuclear weapons testing. The radionuclides that are present in the radioactive debris from fallout and that have the greatest significance in terms of their effects on man are strontium-90 and strontium-89, which are beta emitters and principally irradiate the skeleton; cesium-137, which is a beta-gamma emitter and concentrates in soft tissues, resulting in internal whole-body irradiation; carbon-14, a beta-gamma emitter, which accumulates in the body and delivers whole-body irradiation; iodine-131, a beta-gamma emitter, which concentrates in the thyroid gland; and a number of short-lived fission products that produce external whole-body irradiation when deposited on the ground. The behavior of these materials in the food chain is examined. Monitoring systems and countermeasures for radiation pollution are described.

EXHAUST GAS CONVERSION FACTORS. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 16p., 1972. (Presented at the Air Pollution Control Association, Annual Meeting, 65th, Miami, Fla., June 18-20, 1972, Paper 72-88.)

The exhaust gas parameters from 76 combustion and industrial sources are given including fuel combustion processes, refuse incineration, mineral industries, chemical industries, metallurgical processes, pulp mills, and refineries. The main objective of the study was to define a relationship of the exhaust gases being emitted, to the process weights. Each of the 76 industrial source factors includes a process description, the potential air contaminants, operating time, abatement equipment, an input-output relationship, and the exhaust gas parameters: gas flow rate, gas temperature, gas velocity, and stack height. An attempt was made to relate the exhaust gas parameters to an input or output quantity. Thus by knowing the production rate of a plant, one can use these exhaust gas source factors and pollutant emission factors to obtain engineering estimates of specific plant emission and its community impact through modeling. Sources include coal, oil, natural gas, and wood combustion, incineration; burners; chemical processes such as ammonia, carbon black, chlorine, hydrofluoric acid, paint, phosphoric acid, plastics, ink, soap, sulfuric acid, synthetic fibers, and rubber production; food and agricultural processes; primary metallurgy; steel, lead, zinc, and aluminum production including sintering, blast furnaces, electric furnaces, and open hearth furnaces; petroleum refining, pulp mills; dry cleaning; and surface coating.

STUDYING FLUORINE EMISSIONS FROM PHOSPHORIC ACID AND FERTILIZER MANUFACTURING SOURCES.

(Etude des émissions fluorées lors de la fabrication de l'acide phosphorique et d'engrais). Text in French. Tribune CEBEDEAU (Centre Beige Etude Doc. Eaux), 25(343-344): 321-324, June-July 1972.

Emission measurements were carried out around a phosphoric acid and fertilizer manufacturing plant. The waste gases from

the phosphoric acid manufacturing plant, containing 3.8% fluorine, were cleaned by scrubbers at an efficiency of 99%. The daily F discharge was 1.4 kg. The fluorine to silicon ratios ranged from 2.7 to 3.2. The phosphorus pentoxide concentrations were below 3 mg/cu m. The fluorine emissions from the ammonium phosphate production were in a range of 2-50 mg/cu m with an average of 16.4 mg/cu m corresponding to a daily output of 50 kg. Ammonia and its derivatives bound in phosphate, fluoride, and fluosilicate were discharged at a rate of 2 t/day corresponding to a concentration of 550 mg/cu m (50 to 2000 mg/cu m). The superphosphate manufacturing plant, of a capacity of 400 t/day, discharged 150,000 cu m of waste gas with an F concentration of 22.5 mg/cu m daily, corresponding to a daily emission of 80 kg. The superphosphate granulation plant discharged F mostly in the form of hydrofluoric acid, at a rate of 80 kg/day; it was served by three cyclones to reduce the discharge rate to 15 kg/day. The fluorine concentrations measured within a 2-kilometer-radius around the plant ranged from zero to 30 micrograms/cu m. Necrotic manifestations in the vegetation were observed. Fluorine, along with sulfur dioxide and ammonia emissions, may be responsible for the elevated fog frequency in the neighborhood.

Hoshino, Yoshiro

THE MAIN SOURCES OF ENVIRONMENTAL POLLUTION

IN THE INLAND SEA AREA. (Seto Naikai chiiki ni okeru shuyo na kankyo osengen). Text in Japanese. In: The Inland Sea - Report on General Investigations of Pollution. (Seto Naikai - osen sogo chosa hokoku). General Investigation Committee on the Inland Sea Pollution, Tokyo (Japan), p. 390-414, 1972. The main pollutant sources in the coastal areas of the Inland Sea are discussed by type of industry. Storage by the Fukuyama Plant of Japan Steel Pipe of approximately 23 million tons of iron ore, coal, and lime creates a tremendous amount of dust. The Mizushima Plant of Kawasaki Ironworks stores 15 million tons of material, and the nearby village of Takashima has a serious problem of dust pollution. The Fukuyama Plant produces approximately 24,000 tons of sulfur dioxide annually at its sintering plant from the iron ore alone. In addition, at least 650,000 tons of SO₂ from coal and at least 40,000-50,000 tons from fuel pollute the area. A copper refinery plant that annually produces 100,000 tons requires 500,000 tons of copper and emits 20,000-30,000 tons of SO₂. The principal air pollutant produced at an aluminum plant is hydrogen fluoride created during aluminum electrolysis. The Sumitomo Chemical Toyama Plant reportedly pollutes an area of 3-kilometer radius around the factory. The Mizushima Plant of Japan Mining produces approximately 21,000 tons of SO₂ annually, and the Mitsubishi Petroleum Mizushima Plant produces 19,000 tons. Together with the thermal electric plants of the Chugoku Electric and Kawasaki Iron in the Mizushima area, the total SO₂ emitted from the thermal electric plants in the Mizushima area is approximately 92,000 tons annually. The total sum of SO₂ from the thermal electric plants and iron refineries is approximately 240,000 tons in the area.

WASTE GAS COMPOSITION AND MAINTENANCE OF CLEAN AIR WITH OIL AND GAS HEATING. (Abgasfragen und Luftreinhaltung bei Oel- und Gasfeuerungen). Text in German. VDI (Ver. Deut. Ingr.) Z. (Duesseldorf), 114(14):1043-1047, Oct. 1972. 16 refs.

The majority of substances composing fuel oils are formed by carbon and hydrogen. They also contain organic compounds such as sulfur, nitrogen, oxygen, and various metals. The combustion gases contain sulfur in organic or inorganic form such as mercaptans, hydrogen sulfide, or carbonyl sulfide. The problem of sulfur dioxide emission is discussed. The most widely used method of avoiding these emissions is the desulfurization of fuels. In the German Federal Republic this method is practiced with natural gases and with light fuel oils. The sulfur production from these two sources will exceed 500,000 tons/yr by the mid-seventies. The desulfurization of heavy fuel oils has been tested since 1967 in experimental plants on a commercial scale. The results so far have not been very encouraging but give hope. The emission of ash plays a negligible role with light and heavy fuel oils and fuel gas. Also, the fluorine emissions by these fuels are low; light fuel oil and natural gas contain no fluorine; heavy fuel oil is assumed to contain 1 to 10 mg/kg. There are also process-dependent emissions such as carbon monoxide, soot, fly ash, hydrocarbons, polynuclear aromatics, and the oxides of nitrogen. The most important cause for such emissions is the lack of air or oxygen. Another cause is an air surplus. Measures for reducing these emissions are reviewed, e.g., the proper fuel oil for the size of the heating system, good adjustment of fuel oil atomization, good agreement between the shape of the flame and the shape of the combustion chamber, proper supply of combustion air, and avoidance of temperature drops below the dew point.

PROBLEM: REFUSE INCINERATION. (Problem: Muellverbrennung). Text in German. Staedtehygiene (Uelzen/Hamburg), no. 10:236-237, Oct. 1972. 8 refs.

According to recent investigations, the incineration of refuse can endanger human health. The incineration plant at Hamburg, for example, emits 6 million cu m of flue gases daily containing about 900 kg of very fine-grained dust. The dust particle surface absorbs metal chlorides and organic compounds causing cancer if the dust penetrates into the lungs. Besides the dust, great quantities of harmful gases like carbon monoxide, hydrochloric acid, heavy metal chlorides, and many organic compounds are emitted from incineration plants. These gases are only completely destroyed if burned at temperatures exceeding 1400 C, which, however, are not reached in incineration plants, since the linings of the furnaces would be seriously damaged. Polychlorinated biphenyls which are frequently used in hydraulics, constructional engineering, and as softener in lacquers raise a new problem since they are not decomposed by burning and have a dangerous biological effect when being emitted. Another great problem arises by the increasing production of substances containing fluorine, such as teflon, which forms highly toxic gases when being burned. Considering the problems connected with refuse incineration, emphasis should be laid on research work in the recycling and sanitary landfill field.

Dobbs, C. G.

FLUORINE, THE FAVOURED POLLUTANT. *Protectio Vitae*, no. 3:105-109, 1972. 37 refs.

The annual average fluorine content in rainwater of 0.16 mg/l was raised to a range varying from 0.28 mg/l to 10 mg/l in the neighborhood of industries using fluorine. Test plants with a

normal F-ion content of 7-15 mg/kg dry weight could have had as much as 500 to 1850 mg/kg in the polluted areas. Also, a direct correlation between the F-ion level in the rainwater and in the test plants was found. A much higher F-ion content in food plants such as lettuce, leeks, parsley, and various fruits grown in industrial areas was found. The hazards of pollution are of two main types - intensive and extensive. The intensive type usually causes acute and visible damage which result, eventually, in some sort of action to eliminate it. Unfortunately, the action often consists in the transformation of intensive into extensive pollution, as with the high stack policy. All it did was to spread the pollutant over a wider area where its effects will be more difficult or impossible to distinguish from those of other factors. A case in point is the large aluminum plant near Holyhead in North Wales. At the Public Enquiry in 1968 the estimated total emission was 928 Ibs/day of fluoride. By 1970 this amount had risen to 1436 Ibs. The stack was raised from 300 ft to 400 ft and provided with an additional rise from an internal hot pipe from the anode plant.

Stanford Univ., Calif., Stanford Workshop on Air Pollution
AIR POLLUTION IN THE SAN FRANCISCO BAY AREA.
(FINAL REPORT). 385p., 1970. 72 refs.

The state of the air pollution problem in the San Francisco Bay area, with respect to the chemical nature, potential effects, sources, and occurrence of air contaminants, administrative aspects, public affairs, air pollution control devices, and research projects, is examined. The major pollutants include particulate matter; sulfur oxides; carbon monoxide; nitrogen oxides; organics (hydrocarbons); photochemical reaction products, e.g., smog, ozone, and peroxyacyl nitrates; and other pollutants such as lead particles, hydrogen sulfide, fluorides, and various metals. The sources considered included automobiles, petroleum operations, chemical plants, metallurgical and mineral industries, combustion operations, electric power production, and organic solvent users. Complete air quality and emission data are included. Other sources of pollution, collectively significant, consist of automobile service stations, incineration, domestic heating, agricultural burning, and non-highway transportation. The administration of the control district and citizens groups were examined and rated; suggested plans for future activities are presented.

COMPARATIVE MODEL THEORY OF ATMOSPHERIC
POLLUTION BY POWER PLANTS. (Vergleichende
Modelltheorie der atmosphaerischen Schadstoffbelastung durch
Kraftwerke). Text in German. Staub, Reinhaltung Luft,
32(11):454-458, 1972. 33 refs. (Presented at the Colloque IRCHA
sur les Atmospheres polluees, 10th, Paris, France, May 3-5,
1972.)

On the basis of maximum permissible concentrations, simplified box models were developed to compare air pollution from nuclear- and fossil-fueled power plants. Assuming exponential decay of the pollutants, body burden functions for the main pollutants from different types of power plants were calculated and compared. These pollutants include dust, sulfur dioxide, nitrogen oxides, fluorine compounds, xenon(133), and krypton(85). The pollutant body burden of nuclear power plants was found to be much smaller than that of fossil fueled plants. Power stations fueled with natural gas gave relative body burdens which are smaller than those from power plants fueled with hard coal, brown coal, and oil, but larger than those from nuclear power plants. Krypton(85) released from reprocessing plants was the main pollutant of nuclear power systems.

Niigata Prefectural Health Research Inst. (Japan) and Niigata Prefectural Research Inst. for Public Nuisances (Japan)
INVESTIGATIONS OF FLUE DUST AND FLUORINE, AUTOMOTIVE EXHAUST GAS AND OTHERS. (End nado no baijin, fusso chosa, hoka). Text in Japanese. In: 1971 Annual Report. No. 6. p. 40-44, Aug. 1972.
The dust and fluorine content of flue gases were investigated at 30 spots in four companies operating in Niigata Prefecture to find that they were all below the regulatory criteria. Atmospheric concentration of sulfur oxides in the Yahiko-mura area was measured at seven selected spots for total of 70 times. The values obtained were generally very low. At the Aoumi-cho and Niigata Higashi-ko districts, suspended dust was measured by hi-volume samplers three times a month for total of 108 times. Analysis of automotive exhaust gas was conducted at Joetsu City, Kameda Town, and Kashiwazaki City where automotive traffic is generally congested. In a few selected districts of Niigata City, sulfur dioxide in the atmosphere was measured by the pararosaniline method, fluoride by the alkaline filter paper method, and suspended dust by the hi-volume sampler method, for 4 days from July 5 to July 8. An air pollution survey for the old Naoetsu district was also conducted. Other investigations performed during the year include surveys on effects of air pollution on plants, surveys on emission sources of harmful substances, and radioactivity in rain, suspended dusts, soils, and water. The results obtained from these investigations are tabulated.

Just, Jan
ATMOSPHERIC AIR POLLUTION AS AN ECONOMIC,
NATURAL SCIENCE, AND HEALTH PROBLEM. (Zanieczenie powietrza atmosferycznego jako problem gospodarczy, przyrodniczy i zdrowotny). Text in Polish. Gaz, Woda Tech. Sani. (Warsaw), 46(6): 195-198, 1972. 1 ret.

Air pollution sources include exhaust gases and particulates generated by technological processes during combustion; gases and dust from industrial installations; gases and dusts drawn

from production areas and storage places; and pollutants produced by open-air sources, such as dumps, storage sites, heaps, and vehicles. The pollutants exist as gases, fog, or particulates in the atmospheric air. They are aerosols (0.1 micron) or suspended particles (larger than 0.1 micron). They can represent a hazard to human health. The speed of dust deposition depends on the grain diameter. It varies between 54,900 cm/sec for dust with a 100-micron diameter to 0.000059 cm/sec for 0.1 micron. The pollutants most frequently found are sulfur dioxide and its compounds (in Poland 2,500,000 ton/yr in concentrations ranging from 0.01 to over 1 mg/cu m). Sulfur dioxide and its derivatives are highly corrosive, so at 0.5 mg/cu m in England they cause great economic losses. Nitrogen oxides are generated by electrical discharges and high temperature combustion processes (combustion motors). Their concentration in air should not exceed 0.2 mg/cu m. Fluoride and its compounds are generated by facilities producing phosphates, aluminum works, the glass industry, and the ceramic industry. They are highly poisonous, and their concentration should not exceed 0.01 mg/cu m/day. Carbon monoxide is generated by incomplete burning of combustibles containing carbon. Its concentration should not exceed 10 mg/cu m. Carbon dioxide is generated by the natural processes of rotating, breathing, and combustion. Its concentration is 620 mg/cu m. A constant increase by 1.37 mg/cu m/yr has been observed. The permanent danger of polluting the troposphere is imminent. The methods of atmospheric air protection are planning, technological, technical, and administrative-educational.

Bundesministerium des Inneren, Bonn (West Germany),
Projekt gruppe Umweltchemikalien und biozide
CONTRIBUTION OF THE ENVIRONMENTAL CHEMICALS
AND PESTICIDES PROJECT GROUP. (Beitrag der Projekt-
gruppe Umweltchemikalien und Biozide). Text in German. In:
Materialien zum Umweltprogramm der Bundesregierung 1971.
Umweltplanung. Lower House of Parliament, 6th Session, Docu-
ment 6/2710, p. 65-107, Oct. 1971.
Environmental aspects of the use of fertilizers, pesticides, and
other environmental chemicals, and of exhaust lead emissions
are reviewed. The amount of automobile-generated lead emis-
sions in West Germany is estimated at 7000 t/yr in 1970. The
lead concentrations in the air in places with high traffic densi-
ty ranges from 0.5 to 15 micrograms/cu m, against a
background concentration of 0.03-0.1 micrograms/cu m. The
sedimentation rate of lead ranged from 0.18 to 4.8 mg/sq
m/day in the 1967-1968 period. Correlation between the lead
concentrations in plants and their distance from highways was
determined. The maximum allowable workplace lead concen-
trations are 0.200 mg/cu m for metallic lead, 0.015 mg/cu m for
lead arsenate, and 0.75 mg/cu m for both lead tetraethyl and
lead tetramethyl. Emissions of nitrogen dioxide, sulfur diox-
ide, fluorine, pesticides, mercury, cadmium, fuel additives,
and other pollutants are discussed.

Bundesministerium des Inneren, Bonn (West Germany),
Arbeitsgruppe Montanindustrie
CONTRIBUTION OF THE MINING INDUSTRY PROJECT
GROUP. (Beitrag der Arbeitsgruppe Montanindustrie). Text in
German. In: Materialien zum Umweltprogramm der Bundesregierung 1971. Umweltplanung. Lower House of Parliament,
6th Session, Document 6-2710, p. 357-394, Oct. 1971. 17 refs.
Environmental protection-related problems and objectives in
the mining industry are outlined. The potassium salt industry
has invested 6 million dollars for the control of sulfur dioxide
and dust emissions over the last 10 years. Coke gases from
brown coal coking are partly desulfurized to a residual
hydrogen sulfide content of 2 g/cu m and to an organic sulfur
content of 0.5 g/cu m. The afterburning of carbon monoxide
by auxiliary air, and the partial replacement of coke by natural
gas or oil in cupola furnaces are among the emission control
possibilities of practical interest. The decreasing proportion of
open-hearth furnaces in the iron and steel industry is of a
beneficial effect regarding emissions. A three-stage steel
manufacturing process now under study, which consists of ag-
glomeration, direct reduction, and electric smelting, will also
reduce emissions. Dry absorbents are best for binding fluorine
emissions from nonferrous metallurgical plants where the SO₂
emitted should be converted into marketable sulfur instead of
into sulfuric acid. Electrostatic dust precipitators, tissue fil-
ters, and venturi scrubbers are used for dust separation in the
ferroalloy industry.

JECT GROUP. (Beitrag der Arbeitsgruppe Chemische Indus-
trie). Text in German. In: Materialien zum Umweltprogramm
der Bundesregierung 1971. Umweltplanung. Lower House of
Parliament, 6th Session, Document 6/2710, p. 395-461, Oct.
1971.
Environmental protection-related problems and objectives in
the chemical industry of West Germany are reviewed. The
total sulfur dioxide, nitrogen oxide, carbon monoxide,
chlorine, hydrochloric acid, fluorine compound, hydrocarbon,
and dust emission concentrations in 1969 were 60,000, 25,000,
50,000, less than 100, 1000, 200, 100,000, and 10,000 tons,
respectively. Qualitative and quantitative determination
method, and emission standards for various pollutants, and
means of pollution control (such as cyclones, electrostatic dust
precipitators, tissue fillers, scrubbers, fiber filters, and ther-
mal, catalytic, and wet inhibitors) are reviewed. Problems
and pollution control area in various branches of
the chemical industry (inorganic raw materials, petroleum and
natural gas, organic intermediaries, organic paints, monomers,
pesticides, pharmaceutical products, detergents, pulp and
paper, leather, textiles, starch, sugar, and beer) are outlined

47965

Bundesministerium des Inneren, Bonn (West Germany),
Arbeitsgruppe Glas, Keramik, Steine und Erden
CONTRIBUTION OF THE GLASS, CERAMICS, STONE AND
EARTH WORKING GROUP. (Beitrag der Arbeitsgruppe Glas,
Keramik, Steine und Erden). Text in German. In: Materialien
zum Umweltprogramm der Bundesregierung 1971. Umwelt-
planung. Lower House of Parliament, 6th Session, Document
6/2710, p. 509-520, Oct. 1971. 5 refs.
Problems and efforts in the glass, ceramics, stone, and earth
industries in the environmental protection area are outlined.
The contribution by this branch of industry to pollutant emis-
sions in 1969 was 70,000 tons of particulate matter, 50,000 tons
of sulfur dioxide, and 200 tons of gaseous fluorine compounds.
The specific dust emission from cement works is about 0.11%

of the cement output, compared to 3.5% in 1950. While it is possible to limit dust emission concentrations to 150 mg/N cu m by means of electrostatic and mechanical dust separators, there are no economically acceptable solutions to the SO2 and F emission problems. The extensive use of low-sulfur fuel for glass smelting has a positive effect regarding SO2 emissions.

47966

Bundesministerium des Inneren, Bonn (West Germany),
Arbeitsgruppe Energie

CONTRIBUTION OF THE ENERGY WORKING GROUP.

(Beitrag der Arbeitsgruppe Energie). Text in German. In: Materialien zum Umweltschutzprogramm der Bundesregierung 1971. Umweltplanung. Lower House of Parliament, 6th Session, Document 6/2710, p. 521-547, Oct. 1971.

General environmental problems of energy production are reviewed. Thermal power plants emit varying amounts of dust, sulfur dioxide, nitrogen oxides, carbon monoxide, hydrocarbons, fluorine, and chlorine compounds which, unlike nuclear power plant emissions, will continue to create acute environmental problems. The efficiency of electrostatic dust precipitators has increased from 90 to 99.89% during the last 10 years. Flue gas desulfurization, with an efficiency of 80%, entails specific investments in the range of 5-13 dollars/KWh, and an increase of 1 cent/kWh in the cost of electricity. Future research and development will focus on diffusion mechanisms, the effects of various pollutant concentrations, heat, and vapor on living organisms and on the atmosphere, waste heat utilization, fine dust separation techniques, fuel and flue gas desulfurization processes, wet and dry cooling towers, and possibilities to reduce radioactive emissions.

Public Health Service, National Center for Air Pollution Control

POWELL COUNTY, MONTANA AIR POLLUTION ABATEMENT ACTIVITY. Sip., July 1967. 12 refs.

The air pollution problem in Powell County, Montana, emission sources, and control measures enacted are examined. The major emission sources in the area is a phosphate rock defluorination plant which emits particulates, hydrogen fluoride, and silicon tetrafluoride. Design, operation, and maintenance deficiencies of the plant are reviewed. To determine the severity of air pollution due to plant operations, topography, climatology, and fluoride distribution in grasses, foliage, water, and soil were examined. Data on temperature, precipitation, atmospheric stability, and wind speed and direction are included. Fluoride emission control activity is also reviewed.

TEST METHOD FOR THE ANALYSIS OF TOXIC PRODUCTS FROM BURNING MATERIALS - PHENOLIC

FOAM. Fire Technol., 8(3):22S-236, Aug. 1972. 4 refs.

(Presented at the National Fire Protection Association, Annual Meeting, 76th, Philadelphia, Pa., May 17, 1972.)

<xref image="2000WVB9.TIF|V3|2006:09:28:01:19:00.00|106025|0"> image: </xref>

The toxic products given off by organic materials exposed to a large fire cannot be realistically assessed by conventional laboratory techniques such as pyrolyzing small or powdered samples in an oven pyrolysis chamber and analyzing the gases given off, because the high surface temperatures and large internal temperature gradients that these materials experience when exposed to a fire are not properly simulated in such a chamber. Toxic products evolved from burning phenolic foam were determined in an experimental fire simulation facility. The experimental set-up, specimen preparation, and test procedure are described. Analysis of the gases by infrared spectrophotometry, gas chromatography, mass spectrometry, and colorimetry revealed that carbon monoxide, hydrogen fluoride, hydrogen chloride, hydrogen cyanide, and phenol were evolved in small amounts. A method of extending these results to actual field situations, based on mass loss rates of the foam measured in the fire simulation facility is presented.

Dotreppe-Grisard, N.
PLASTICS AND THE ENVIRONMENT. DISPOSAL OF DOMESTIC REFUSE. (Matières plastiques et environnement. L'élimination des ordures ménagères). Text in French. Tribune CEBEDEAU (Centre Beige Etude Doc. Eaux), 25(341): 190-197, April 1972. 18 refs.

Problems of solid waste disposal and waste incineration-related air pollution are described with regard to Belgium. Air pollution, including odorous emissions, and corrosion are the basic problems of waste incineration. Some 2% of the domestic waste in Belgium consists of plastics, including 1.75% of polyethylene, 0.30% of polystyrene, and 0.20% of polyvinyl chloride (PVC). While PVC is the only plastic material to give rise to hydrochloric acid emissions, such emissions are generated by other components of the domestic waste, such as paper and wood. Since a considerable part of the HCl formed during incineration is adsorbed by alkaline buildups and fly ash, the gaseous HCl emission is much less than the theoretical amount liberated. The formation of HCl may be due to mineral chlorides and silicates forming highly volatile iron and aluminum chlorides, and to reactions of alkaline chlorides with acid sulfates. Incinerator waste gas analyses performed in the U.S.A. revealed the following pollutant concentrations- 1-330 ppm of HCl, 0.6-1.1 ppm of hydrofluoric acid, up to 106 ppm of sulfur dioxide, 57-138 ppm of nitrogen oxides, up to 45 ppm of carbon monoxide, 25-58 ppm of aldehydes, and other hydrocarbon contents below 10 ppm. The dust concentrations in the flue gases may range from 300 to 1000 mg/N cu m, and can be effectively reduced by electrostatic precipitators to as low a value as 120 mg/N cu m. Gaseous pollutants require scrubbers for their removal. Odorous components can be removed best by afterburning, while methods such as adsorption on graphite and masking by other compounds are prohibitively expensive or unacceptable. The best method, however, is to maintain the combustion chamber temperature above 750 C. Corrosion hazards in incinerators can be lessened by maintaining the gas temperature in a range of 900-1000 C, flow rates of 6-8 m/sec, applying secondary air, and by minimizing changes in the flow direction.

Weisburd, Melvin I.
FERTILIZER INDUSTRY. In: Field Operations and Enforcement Manual for Air Pollution Control. Volume III: Inspection Procedures for Specific Industries. Pacific Environmental Services, Inc., Santa Monica, Calif., Office of Air Programs Contract CPA 70-122, Rept. APTD-1102, p. 7.14.1-7.14.17, Aug. 1972. 8 refs.

Two major sub-groupings of the chemical fertilizer industry are of particular importance as air pollutant sources and are considered in detail: the phosphatic compounds produced from

phosphate rock, and ammonium nitrate produced by the reaction of ammonia with nitric acid. Processes, control methods, and inspection points are considered. Fluorine compounds are usually removed by scrubbers; particulate matter is removed by cyclones, cloth filters, and scrubbers; proper control and ventilation can reduce dust; baghouses and electrostatic precipitators can also be used to reduce pollutants.

Schmitt, C. R.

THERMAL DEGRADATION CHARACTERISTICS OF VARIOUS POLYMERIC MATERIALS. J. Fire Flammability, vol. 3:303-315, Oct. 1972. 8 refs.

The toxic gaseous products evolved from the thermal degradation of various polymeric packaging materials were studied by mass spectrographic analyses. Vapors liberated from a flexible urethane foam at the temperature of melting and just prior to ignition contained toxic hydrogen cyanide gases; after ignition, the hydrogen cyanide content increased significantly. Analytical data were also compiled on the pyrolysis products of polyethylene, pigmented polystyrene, and fluorohalocarbon material. Thermal degradation products from the fluorohalocarbon at 250 C showed the presence of atomic mass units 20 and 36, indicative of hydrogen fluoride and hydrogen chloride, respectively. At 305 C, atomic mass units 47 and 66, corresponding to decomposition fragments Cl-C and C-Cl-F, respectively, were very prevalent (Author abstract modified)

AIR POLLUTION AND HEALTH - A PROGRAM OF 1960.

(Luftreinhaltung und Gesundheit - ein Programmi von 1960).

Text in German. Staedtehygiene (Uelzen/Hamburg), 23(12):273-275, 1972.

The European Committee for Diagnostics of Health Damages (Eurotox) and for the Protection of the Population met in Paris in 1960 to investigate the air pollution problem. A resolution was passed calling for the improvement of domestic heating systems by promotion of central heating, for the reduction of toxic components in automobile exhausts, for the separation of industrial and residential areas by green belts, and for reducing the railroad emissions by turning to electric and diesel drives. Twelve years after this conference, it can be said that much has been done since 1960 for the reduction of air pollution. In the Ruhr area, the sulfur dioxide and dust emissions have been continuously monitored since 1964. The dust emission was reduced considerably, and the SO₂ emission also went down markedly due to better electrostatic precipitators and the use of low-sulfur fuels. Gas and electricity are increasingly used for heat production. Oil central heating systems are being annually inspected in North Rhine Westphalia. The emission of hydrogen fluoride has received great attention, aluminum plants are now required to clean their waste gasen satisfactorily. For decontamination of automobile exhausts, the lead concentration in gasolines is being reduced. The afterburning of carbon monoxide and hydrocarbons will become indispensable soon. Much has been done for electrification of the railroads.

ENVIRONMENTAL PROBLEMS ON THE INDUSTRY. (Die Umweltprobleme der Industrie). Text in German. Perg-Huettenmaenn. Monatsh., 117(8):275-280, Aug. 1972. (Presented at the Oesterrische Bergbautag, Baden, Austria, April 25-28, 1972.) General problems of industrial air pollution as encountered in industrialized countries are reviewed. The sulfur dioxide emissions show a downward trend in most industrialized countries, which is primarily attributable to the increasing use of low-sulfur fuels. Dry and wet processes for the separation and conversion of SO₂ in waste gases are expected to reach the stage of technological maturity before long. Nitrogen oxide emissions, determined by flame temperature and air excess, originate primarily in industrial and internal combustion engines processes. While industry generates practically no carbon monoxide due to near-complete combustion, automotive exhaust and domestic heating emit sizable proportions of this pollutant. A survey of the recent trends in the development of industrial and other emissions shows that coarse dust and SO₂ as pollutants will be replaced, along with the associated problems, by such industrial pollutants as fluorine, chlorine, hydrocarbons, toxic and malodorous gases, vapors, and aerosols.

Hata, Akio, Yutaka Kawano, Akio Yamaguchi, and Teruo Tanabe
AIR POLLUTION BY IRON AND STEEL PLANTS (TECHNICAL CONSIDERATION OF SOURCES). (Seitetsusho no taiki osen ni tsuite gijutsu men kara mita mondaiten (bo seitetsusho no gutairei yori)). Text in Japanese. Japan Society of Air Pollution, Proc. Symp. Japan Soc. Air Pollut., 13th, 1972, p. 161. (Nov. 7-9, Paper 116.)
Pollutants emitted by various types of furnaces of iron and steel works are discussed from the example of one plant. The dusts from the blast furnace generally contain 5-30 g/cu m dusts of iron oxide, sulfides and carbon. The emission concentration is 0.1 g/cu m and the total of more than 40 tons of dust are emitted monthly. At this plant, if the dust collectors are not operating for any reason, all of the dusts are discharged in the environment. From the blast furnace, 16.2% of the carbon monoxide content leaks into the atmosphere, and this is about 13 million cu m/mo CO. This is equivalent to exhaust emissions from 240,000 automobiles. A converter produces 10-15 kg/ton of dusts. Most dusts are ferrous oxide in the size of 0.3-1 micron. From three 60-ton furnaces, about 7 tons/mo of dusts are emitted. The soot leakage incidents are numerous, sometimes as often 184 incidents/mo. Six open hearth furnaces were operating until March 1971. The operation was discontinued, but after the dust collection, the emission concentration was as high as 0.5 g/cu m. Also, because of the addition of 300 kg fluoride per charge, 187 cu m/charge of hydrogen fluoride used to be created. One electric furnace of a 60-ton capacity produces 120-240 kg/ton/charge of dusts. The dusts contain chromium, nickel, manganese, molybdenum, and vanadium. The sintering pellet plant dusts contain a great quantity of sulfide and sulfur oxides. The amount of sulfur contained in the fuel at this plant is relatively low, but the total consumption is very large, and therefore, SO_x emission is also large.

ORGANIC COMPOUNDS IN VOLCANIC GAS FROM SAN-TIAGUITO VOLCANO, GUATEMALA. Geol. Soc. Amer. Bull., vol. 82:2299-2302, Aug. 1971. 7 refs.
Gas samples collected at Sapper fumarole of the Santiaguito, Guatemala, volcano on Dec. 5, 1969, were analyzed by gas chromatography-mass spectrometry. The samples were com-

posed of 95% air, presumably of atmospheric origin, water vapor, and both organic and inorganic gases. The total organic content was about 100 ppm, and the methane content was fairly high (14 ppm). The compounds identified in the gas samples were methane, xenon, nitrogen dioxide, ethylene, tetrafluoroethylene, ethane, carbonyl sulfide, hexafluoropropene, propene, propane, chlorodifluoromethane, chlorotrifluoroethylene, chloromethane, methanol, acetaldehyde, methanol, isobutene, butene, dichlorofluoromethane, ethanol, carbon disulfide, isopentene, propanol, acetone, trichlorofluoromethane, pentane, isopropanol, methyl acrolein, n-propanol, methylethyl ketone, hexenes, hexanes, benzene, cyclohexane, trichloroethylene, heptenes, methyl cyclohexane, toluene, octenes, octanes, 1,1,2-trichloro-1,2,2-trifluoroethane, hydrochloric acid, and hydrofluoric acid. The compounds are probably produced by heating of fossil soil or sedimentary layers by the magma.

EXHALATION OF HARMFUL SUBSTANCES FROM

BRICKWORK KILNS. (Exhalace škodlivin z cihlarských pecí).

Text in Czech. Stavivo, 50(3): 69-70, 1972. 3 refs.

Measurements of particulate emissions from brickwork kilns disclosed that they do not as a rule exceed prescribed norms, but excessive emission does occur in the case of old oil-fired kilns where the injection of oil into areas below 900 C or deficiency of air causes excessive soot formation. This defect can be removed by the injection of secondary air into the burners. Similar excessive emissions of soot by coal-fired kilns cannot be remedied. Hydrogen sulfide is rarely emitted as a pollutant, the real problem is sulfur dioxide. Measurements of SO₂ emissions from 59 brickwork kilns were earned out in the German Democratic Republic. Maximal sulfur oxide concentrations were below 3 g/N cu m; the mean value of emissions from all kilns was 0.49 g/N cu m with an average stack height of 30-50 m. Sulfur trioxide is more harmful than SO₂ and its noxious effect cannot be underrated because the bricks inside the kilns act as catalysts; consequently brickwork kilns emit a greater share of SO₃ than other furnaces. The sulfuric acid formed is absorbed by the soot flakes. The share of SO₃ of total sulfur oxides emission is on the average 25% but can reach 50%. Sulfur oxides can originate occasionally from brick clay; on the other hand, calcium carbonate dispersed in bricks in the course of firing combines with sulfur and prevents part of it from forming oxides. Many clays contain calcium fluoride, the mean content is 0.063%. In the firing 16% is emitted. 80% of the fluorine remains in the material. Fluorine emission fluctuates between 1 and 180 mg/N cu m with an average of 48 mg/N cu m. The sulfur oxides emission problem could be solved by using oil with a low sulfur content.

THE FORMATION AND COMPOSITION OF THE

FLUORIDE EMISSIONS FROM ALUMINUM CELLS.

<xref image="2000WVBB.TIF|V3|2006:09:28:01:19:06.00|113953|0"> image: </xref>

Preprint, Norwegian Society of Professional Engineers, Oslo, 44p., 1972. 42 refs. (Paper presented at the International Symposium on the Fluoride Problem in the Aluminum Industry, Trondheim, Norway, May 24-26, 1972.)

Data available on the fluoride consumption per ton of aluminum produced, the amount of fluorides retrieved from the anode gas, possible causes of the fluoride emissions, and possible reactions between the moisture content of the feed and the molten fluorides are surveyed. Quantitative calculation is presented for the emissions generated by vaporization from the melt, based on data for vapor pressures of sodium fluoride - aluminum fluoride melts. While vaporization is a significant source of fluoride emissions, other and equally important mechanisms must also contribute to the emission rates. The water introduced with the feed may in part lead to hydrolysis reactions in the fluoride melt, while it may also in part be reduced to hydrogen. Another source of hydrogen is the materials of the anode. Part of the hydrogen may be anodically oxidized to hydrogen fluoride which gives a significant contribution to the total fluoride emission rate. The reactions of water vapor with the fluoride-containing vapor from the melt, on the other hand, will alter the chemical composition of the emissions but will not contribute to the emission rate. The observed fluoride emission rates may be ascribed to three principal mechanisms, i.e., vaporization from the molten electrolyte, primary generation of hydrogen fluoride in the cell, and the entrainment of liquid droplets and solid dust. The available evidence indicates that these three mechanisms are of about equal significance.

AIR POLLUTION. PART I. Provincia de Buenos Aires (Argentina), Comision de Investigaciones Cientificas, Reunion Probl. Kfluentes Ind. Contain. Ambiental, La Plata, Argentina, 1971, p. 1-18. (July 12-17.)

A general survey of the main problems developing because of air pollution is presented. The important emission sources discussed include industrial combustion and production processes in coking plants, the iron and steel industry, metal fabricating, copper melting plants, cement works, zinc production, sulfuric and nitric acid production, chemical plants, metallurgical production, mineral oil industries, viscose factories, power plants, domestic heating, and traffic with emissions from petrol and diesel engines. Emissions from each of these processes are reviewed, including aerosols, dusts, soot, carbon monoxide, sulfur dioxide, hydrocarbons, nitrogen oxides, fluorine compounds, hydrogen sulfide, carbon disulfide, and lead. Effects of these pollutants on the skin, eyes, lungs, respiratory system, heart, circulation system, liver, nerves, bones, stomach, and the intestinal system are listed. Harmful effects on plants, animals, and material objects are also considered.

STUDY OF FINE DUSTS WITH AN ANALYTICAL ELECTRON MICROSCOPE. (Die Untersuchung von Feinstaeuben durch ein analytisches Elektronenmikroskop). Text in German. VGB Kraftwerkstechnik, 53(3): 195-199, March 1973.

Dust samples from electrostatic precipitators of four incinerators burning industrial refuse were examined as to their concentration of fluorine compounds. An analytical electron microscope which combined the properties of electron microscope with those of an electron microprobe was used for the examinations. The electron beam passed a double condenser system and electromagnetic detectors. A mini lens behind the detector focused the electron beam on the sample producing an X-ray fluorescence radiation emitted in all directions. But only the radiation leaving at an angle of 45 deg was recorded by the non-dispersive detector and the two spec-

trometers. Each spectrometer had four analyzing crystals. The chemical and fine structure micro-analyses were carried out at 80 kV. In more than 20 individual samples from each incinerator, sodium fluoride was the most frequent fluorine compound. In the fly dust from incinerators for domestic refuse, calcium and lithium fluoride were most frequently identified.

Sutler, Ernst

FLUORIDE MEASUREMENTS IN ALUMINUM PLANTS.

(Fluoridmessungen in Aluminiumhuetten). Text in German.

Staub, Reinhaltung Luft, 33(3): 114-117, March 1973.

Fluorides were measured in Swiss aluminium smelting plants to assess the fluorosis hazard. Atmospheric conditions affected the efficiency of artificial ventilation. Ion selective electrodes were used to determine fluorides in personal samplers attached to workers. Measurements were taken during various seasons. The average values fluctuated between 0.2 and 1.5 mgF/cu m. No statistically proved dependence on the weather could be detected, but the wind around the furnace workshop did exert a considerable influence. By cutting out the influence of the wind on the ventilation system of the workshop, the fluoride concentration could be reduced. Adequate conduction of the air inflow into the electrolysis workshop is of great importance for a low fluoride concentration.

TOXICITY STUDY OF MK 50 MOD O ROCKET MOTOR

EXHAUST. Naval Weapons Center, China Lake, Calif., Propulsion Development Dept., 14p., Aug. 1968. 4 refs. ORD Task 008-084-001/200-1/127-00-01, Rept. NWC-TP-4638. NTIS, DDC: AD 842118

A fluorocarbon base propellant, N-34, is used in the Mk 50 Mod O rocket. Toxic gases, hydrogen chloride, and hydrogen fluoride are exhausted during combustion. Exhaust clouds were sampled during rocket firings and to determine HCl and HF concentrations in the atmosphere in the vicinity of the launcher during firing. Topside HCl concentration was above the threshold limit value but below the tolerable limit for short duration exposures. Topside HF concentration at the launcher was above both the threshold and short duration limits; and 60 ft from the launcher, was above the threshold but below the tolerable limit for short exposures. Both the HCl and HF concentrations in the magazine were below their respective threshold limit values for extended and repeated exposures. (Author abstract modified)

A. EMISSION SOURCES

49

complete combustion is difficult to achieve in small incinerators. Therefore, they should not be allowed in residential areas. In large incinerators complete combustion is achieved by uniform charging, continuous operation, and high combustion chamber temperature. Analyses in the large incinerator in Duesseldorf revealed that the amount of volatile organic acids in the waste gases were on the lower detection limit. Of the 4,000,000 t/yr sulfur dioxide emitted in West Germany, 12,000 tons come from incinerators. The latter emit 5000 t/yr nitrogen oxides, 8000 t/yr hydrogen chloride, 50,000 t/yr hydrogen fluoride and 4,000,000 t/a dust. Nothing is known about the emission of heavy metals. An examination in power plants and incinerators has shown that toxic heavy metals such as lead, zinc, arsenic, and others are deposited in various sections of the heat exchanger which means that a considerable portion is not emitted into the environment with fly dust.

Dauids, P.

AIR POLLUTION THROUGH POLLUTANT EMISSION FROM INCINERATORS. (Die Luftbelastung durch die Schadstoffemission aus Muellverbrennungsanlagen). Text in German. Muell Abfall, 5(3):61-68, 1973. 17 refs. (Presented at the Muell-technische KoIIoquium, Stuttgart, West Germany, March 8, 1973.)

The incinerators in operation in the Federal Republic of Germany today are all similar in their design with the exception of individual components. For dust cleaning of the effluents, electrostatic precipitators are mostly used. A removal of gaseous pollutants is generally not pursued. In six incinerators a 1-week measurement program was launched to determine the type and quantity of the components of trash and their distribution in the gaseous and solid combustion residues which are important for air pollution. The dust measurements were taken behind the electrostatic precipitator to determine the dust composition in the cleaned gas. Main components were silicon aluminum, and iron compounds. The measured lead concentrations were below 1%, the zinc concentrations below 5.3%. In two samples none of these two components could be determined. Concentrations of chlorine, phosgene, hydrogen cyanide, hydrogen sulfide, and ammonia were about 1 mg/cu m (detection limit) or they were not detectable at all. For C12 and COC12 this was also true in cases where 6% polyvinyl chloride had been added to the trash. Correlation of the measurement results yielded a significant relationship between hydrogen chloride and hydrogen fluoride emissions. Five hundred values for HCl and sulfur dioxide were available taken in one incinerator since 1966. For the period 1966 to 1972 a steady decline of the SO2 emission by about 1/3 was discernible. The HCl emission rose between 1967 and the beginning of 1970 by about 100%. Since then it remained constant.

SYNTHETIC WASTE IN TRASH AND ITS EMISSIONS FROM INCINERATORS. STUDIES AND DEVELOPMENT TRENDS. (Kunststoffabfaelle im Muell und ihre Emissionen aus Muellverbrennungsanlagen. Untersuchungen und Entwicklungstendenzen). Text in German. Muell Abfall, 5(3).-68-71, 1973. 4 refs. (Presented at the Muelltechnische KoIIoquium, Stuttgart, West Germany, March 8, 1973.)

In the year 1971 six 1-week measurement series were conducted with the aim of determining weight, type, and amount of synthetics in domestic refuse. Each resident throws away 4.1 kg of synthetic wastes/yr. A number of synthetics, primarily polyamides and polyurethanes, contain up to 19% nitrogen. Of the synthetic wastes in domestic refuse, polyamid contained 4.9%. Between 0.1 and 0.2 kg nitrogen/ton refuse are disposed of. The contribution of synthetics to the emission of nitrogen oxides is rather insignificant. None of the more im-

portant synthetics contain sulfur. The most important fluorine containing synthetic is polytetrafluorethylene, but its fraction among the synthetics is so small that no fluorine could be detected. Chlorine is an essential component of chlorinated polyethylene, polyvinylchloride, and polyvinylidenechloride. In domestic refuse from Bochum a chlorine fraction of 5.0% was found. The total chlorine fraction in the Bochum domestic refuse amounted to 3.45 kg/ton refuse, the fraction constituted by the synthetics alone 0.95 kg/ton refuse. Based on this data, the synthetic s share to hydrogen chloride emission for domestic refuse is 32%. Based on an estimated specific domestic refuse accumulation of 256 kg/resident/yr by 1980, an industrial refuse quantity of 116 kg/resident/yr, a bulky and communal refuse quantity of 34 kg/resident/yr synthetic quantity of 5.9%, the average chlorine emission will be 5.7 kg/ton waste. This is 50% more than in 1971.

Davids, P.

AIR POLLUTION DUE TO THE EMISSION OF NOXIOUS
SUBSTANCES FROM REFUSE INCINERATION PLANTS.

(Die Luftbelastung durch die Schadstoff Emission aus Muellverbrennungsanlagen). Preprint, 1973. 38 refs. (Presented at the Refuse Meetioug, 24th, Stuttgart, West Germany, March 8, 1973.) Translated from German, 36p.

The quantity and quality of emissions from refuse incineration plants are examined. Gaseous emissions include hydrocarbons, e.g., aldehydes and organic acids, chlorine and fluorine compounds, sulfur dioxide, nitrogen oxides, and carbon monoxide. The dusts contain various metal compounds, including silver, aluminum, boron, calcium, cadmium, chromium, copper, iron, potassium, magnesium, manganese, sodium, nickel, lead, silicon, tin, strontium, titanium, and zinc. Waste composition and controls to prevent emissions were examined.

Gerhards, K.

PLASTIC SCRAP IN TRASH AND ITS EMISSIONS FROM
TRASH INCINERATORS. INVESTIGATIONS AND TENDENCIES
IN DEVELOPMENT. (Kunststoffabfaelle im Muell

und ihre Emissionen aus Muellverbrennungsanlagen. Untersuchungen und Entwicklungstendenzen). Preprint, 1973. 4 refs. (Presented at the Refuse Meeting, 24th, Stuttgart, West Germany, March 8, 1973.) Translated from German, 14p.

The weight, type, and proportion of plastics in house trash are determined to study the contribution of plastics in refuse to emissions from incinerators. Based on 1971 data, plastics contents of trash and subsequent emissions are predicted for 1980. The major plastic components are polyolefins, polyvinylchlorides, and polystyrenes. Plastics combustion contribution to nitrogen oxide, sulfur, and fluorine compound emissions is negligible. The major pollutant related to plastics incineration is hydrogen chloride.

THE GLASS CONTAINER INDUSTRY IN THE FUTURE:
MARKETING, TECHNICAL ECONOMIC AND POLITICAL

ASPECTS. (Die Hohlglasindustrie der Zukunft unter marktmaessigen, technischen und gesellschaftspolitischen Aspekten). Text in German. Glastechn. Ber., 46(5):71-83, May 1973.

<xref image="2000WVBD.TIF|V3|2006:09:28:01:19:14.00|120338|0"> image: </xref>

(Presented at the Glastechnischen Tagung, Wiesbaden, West Germany, July 5, 1972.)

The development of the container industry is considered, and market trends, structural changes in wares, packaging, production methods, and economics are discussed. Each industry has to cope with the problems of environmental pollution. The glass industry has eliminated, to a large extent, the fluorine components from its emissions. Further reductions of the emission were achieved through improved trough construction, reduced flow speeds, reduced use of fuels, and increased use of electricity, use of pelleted and granulated raw products, and addition of sodium lye for the maintenance of a residual moisture for transport. About 75% of the produced glass containers are no return bottles. They pose no problems with any of the waste disposal methods from the sanitary landfill and incineration to composting.

51282

Wood, R.

FLUORINE AS A POLLUTANT. 8. Trans. Brit. Ceram. Soc., 72(1):35-37, Jan. 1973. 11 refs.

Fluorine as a contaminant in the environment, as well as the beneficial effects of this element to man, are described. Sources of fluorine contamination such as steelmaking, metal alloy production, brick, tile, and ceramic industries, aluminum production, phosphate fertilizer industry, phosphoric acid production, cement industry, and burning coal are discussed. A variety of other minor possible sources of airborne fluorine contaminants are described. A panel of the American Association for the Advancement of Science placed fluorine as the third in a list of five pollutants. Gaseous hydrofluoric acid and silicon tetrafluoride are the main fluorine compounds in polluted atmospheres which damage plants. Fluorosis in animal and humans is discussed. Legislation and standards in the United Kingdom are mentioned. The threshold limit values for hydrofluoric acid and inorganic fluoride are 2 and 2.5 milligram/cu m, respectively. A sampling procedure has been developed, based on the use of a membrane filter to collect particulate, and an alkali-impregnated paper to trap gaseous fluoride.

INVESTIGATION OF LOCAL AIR POLLUTION IN CONCENTRATED AREA OF TILE MAKING INDUSTRY IN FU-

KUYAMA DISTRICT, KORIYAMA CITY. (Koriyama-shi Fu-

kuyama chiku ni okeru kawara kojo chitai no taiki osen (SOx oyobi HF) chosa ni tsuite). Text in Japanese. Fukushima-ken Eisei Kenkyusho Kenkyu Hokoku (Fukushima Prefect. Inst. Public Health, Rept.), 20(4):91-98, Oct. 1972. 14 refs.

The efficiency of an exhaust gas treatment method in the tile making industry was investigated as well as the concentration of hydrogen fluoride in the atmosphere around tile making plants. Four plants were investigated. The rate of treatment efficiency of exhaust gas (sulfur oxides) from the tile making industries was 87% (A), 77.8% (F), 75% (C), 74.7% (D), and 69.4% (B). The rate of treatment efficiency for hydrogen fluoride was 96.2%, 91.3%, 90%, and 89.7% respectively. The average concentration of hydrogen fluoride in the atmosphere around the plants was determined to be 0.025 ppm (C and F), 0.005 ppm (D), and 0.00 ppm (E). Atmospheric hydrogen fluoride concentrations were measured continuously by automatic apparatuses for five days and nights. The average HF concentration in homes near the industries was 0.05 ppm near D, 0.04 ppm near A, 0.03 ppm near B, and 0.01 ppm near C.

52508

Schneider, Werner

CORROSION AND INJURIES FROM EMISSIONS CAUSED BY THE WASTE GASES OF INCINERATORS. (Korrosionen und Immissionsschaeden durch Muellrauchgase). Text in German. *Energietechnik*, 23(6):277-280, June 1973. 31 refs. In the German Democratic Republic at present about five million tons of waste accumulate annually which are dumped. Since this amount will increase, incineration will gain increasing importance. Dusts and odors from incinerators can be satisfactorily treated. Great problems are still posed by gaseous pollutants and by corrosion. Since the waste gases from incinerators contain only about 0.03% of sulfur dioxide and the developing sulfur trioxide is bound by the high amount of fly dust (10 to 40 g/cu m), high temperature corrosion by alkali iron sulfate melts can be ruled out. Studies revealed that high-temperature corrosion in incinerators is mainly caused by hydrogen chloride in a reducing atmosphere. Low-temperature corrosion may be caused in incinerators by hygroscopic and easily melting zinc chloride and iron chloride hydrates. The emission of HCl at present amounts to between 0.5 and 1 g/cu m. The maximum allowable emission concentration for HCl is 0.015 or 0.05 mg/standard cu m. Efforts concerning the reduction of the emission of this pollutant are aimed at the replacement of polyvinyl chloride by other chlorine-free synthetics. The binding of HCl to calcium oxide or the removal by scavenging processes are also methods under consideration. Apart from this pollutant, the incineration waste gases also contain hydrogen fluoride in quantities up to 10 mg/cu m. This pollutant deserves special attention in future at the planning of new incinerators.

52664

Kanamaru, Go, Hirohisa Shima, Takaetsu Matsui, and Tamaki Hashizume
AN EXAMPLE OF ATMOSPHERIC POLLUTION BY FLUORIDES. (Hukkabutsu ni yoru taiki osen no ichirei ni tsuite). Text in Japanese. Mie-ken Kogai Senta Nenpo (Mie Prefect. Pub. Nuisance Center Annu. Rep.), no. 1:134-137, March 1973. 6 refs.

A ceramic plant emitted hydrogen fluoride gas which caused silkworms raised nearby to die, show poor growth, or stop preparing cocoons. Hydrogen fluoride from another ceramics plant in another city caused damage to cedars and pines. Hydrogen fluoride in these areas was collected on a filter paper, extracted with distilled water, and determined colorimetrically. Sulfur dioxide and phenol were simultaneously determined by the rosaniline-formalin method and 4-aminoantipyrin method, respectively. The highest HF value in the first city in 1970 was 78 micrograms/day/100 sq cm. After the detection of this high concentration, a jet scrubber replaced a water spray as the air treatment method. In the second city, the highest HF value was 58.3 micrograms/cu m; the highest SO₂ concentration was 0.70 ppm; the highest phenol concentration was 0.156 ppm.

(Die Einbindung von Spurenelementen, insbesondere des Fluors, in Aschen und Staeben von Muellverbrennungsanlagen). Text in German. VGB Kraftwerkstechnik, 53(6):408-414, June 1973. 9 refs.

Seven samples from domestic and communal refuse incinerators and eight samples from industrial incinerators were obtained. From each incinerator several ash samples from the combustion chamber and from the flue gas ducts through the boiler to the electrostatic precipitator were taken. The fluorine concentration in the ash samples was determined by water vapor distillation and subsequent determination of the formed hexafluoride (H_2SiF_6) silicic acid in the distillate by a specific electrode. The elements aluminum, barium, calcium, cobalt, chromium, copper, potassium, lithium, magnesium, manganese, molybdenum, sodium, nickel, lead, antimony, vanadium, and zinc, were determined by atomic absorption spectrophotometry. Phosphorus and iron were determined by photometry, silicon and sulfur by gravimetry, and chlorine by titration. The analyses indicated that both chlorine and fluorine enrich in depositions and the dust at a drop of the flue gas temperature to below 600 C. The fluorine enrichment is highest in the dusts from the electrostatic precipitator. This indicates that the hydrogen fluoride of the flue gas is bound to the dust particles. Of the fluorine compounds, most frequently calcium fluoride was found, whose low solubility is 0.16 g/l water at 20 C. The sodium fluoride was found only in samples from industrial incinerators. In the incinerators equipped with travelling grates, the binding of fluorine in the form of CaF_2 is low because the ash remains in the combustion zone for a long time at high temperature. Most of the fluorine is bound in the electrostatic precipitator.

ENVIRONMENTAL PROBLEMS OF MODERN HIGH-CAPACITY ARC FURNACES. (Umweltprobleme moderner Hochleistungs-Lichtbogenofen). Text in German. Rade Rundschau (Austria), no. 3:556-557, 1973. (Presented at the Electric Steel Industry Conference, Zurich, Switzerland, Oct. 25-28, 1973.)

The decrease of environmental pollution by the steel industry despite the production increase by 16% between 1960 and 1971 is mainly due to the replacement of the Thomas process by electric melting and by the oxygen lancing process. With both processes, dust collectors reduce the dust emission to less than 150 mg/cu m waste gas. With the electric arc furnace a problem remains, that of the emission of carbon monoxide and fluorides. The CO can be removed by afterburning and the calcium fluoride can be replaced by other fluxing agents such as clay.

THE BINDING OF TRACE ELEMENTS, ESPECIALLY FLUORINE, BY ASHES AND DUSTS RESULTING FROM REFUSE INCINERATING PLANTS. (Die Einbindung von Spurenelementen, insbesondere des Fluors, in Aschen und Staeben von Muellverbrennungsanlagen). Text in German. VGB Kraftwerkstechnik, 53(6):408-414, June 1973. 9 refs. The incorporation of fluorine and other trace elements in the ashes and flue gases which result from the incineration of refuse is described. Analyses of samples of house and city refuse and of industrial sweepings are presented. Samples were obtained from various areas in the combustion chamber of the incinerators and from the flue pipes and were subjected to the following analyses: ashes were analyzed chemically for trace elements; all samples were subjected to a roentgenographic phase analysis; and samples with high fluorine content, usually fine particulate matter which filtered through the electrofilter, were analyzed by means of the electron

microscope and with the aid of electron rays. The chemical analysis revealed that the ashes and other products of incineration differed considerably from the raw refuse and that the products of combustion interacted among themselves. Both chlorine and fluorine were found in sediments of dust when the temperature of the smoke was below 600 C. Fluorine was particularly concentrated in the particles in the electrofilter, most frequently occurring as calcium fluoride. Sodium fluoride was relatively rare, occurring only in industrial incinerator sediments.

STUDIES OF THE FLUORINE EMISSIONS FROM SOFT
COAL-FIRED POWER PLANTS. (Untersuchungen ueber
Fluor-Immissionen ans Braunkohlen-Kraftwerken). Text in Ger-
man. Z. Ges. Hyg. Ihre Grenzgebiete (Berlin), 19(8):568-570,
1973. 19 refs.

Because of reports of massive bee-kills in the vicinity of soft-coal operated power plants, the fluorine concentration in soft coal samples as well as in filter ash from these power plants was determined. From 10 strip mines in East Germany, 68 soft coal samples were taken according to geological aspects. After drying and grinding of the samples, the fluorine was separated by distillation and determined by colorimetry. The filter ash samples were distilled without ashing. In all examined soft coal samples, fluorine was found. The fluorine concentration was between 6 and 50 g/ton in East Elbe soft coal and between 2 and 178 g/ton in West-Elbe soft coal. At the combustion only part of the fluorine remains in the ash, the rest leaves in gaseous form. The filter ashes contained fluoride up to more than 400 ppm fluoride, chloride, and high quantities of sulfide.

AIR POLLUTION CONTROL BY FLUORIDES FROM PRI-
MARY ALUMINUM SMELTING. (Aruminyumu seiren kogyo
ni okeru fukkabutsu ni yoru taikiosen boshitaisaku). Text in
Japanese. Kogai to Taisaku (J. Pollution Control), 9(4):376-381,
April 1973. 12 refs.

A prebake aluminum smelter gives easier air pollution control than the Soderberg automatic continuous burning anode system. The fluoride emitted from the electrolytic bath is removed by the double system of a bath-hood cleaner and chamber-ceiling cleaner. Hydrogen fluoride and tetrafluorosilicon are mostly emitted. Removal for the Soderberg and Prebake systems are 92-99% and 80-97% of the fluoride, respectively. A wind tunnel study was used to estimate the ground level concentration of gaseous fluoride dispersed by a line emission source. There is a close relationship between ground level and wind velocity and direction. The effects of fluorides on plants and animals and the composition of fluoride compounds emitted by aluminum smelters are reviewed.

MASS-SPECTROMETRIC INVESTIGATION OF GASEOUS

FLUORIDES FORMED DURING ARC-WELDING. (Mass-spektrometricheskoye issledovaniye gazoobraznykh ftoridov, dydelyayushchikhsya pri dugovoy svarke). Text in Russian. Avtomat. Svarka, 24(6):10-12, 1972. 9 refs.

Ion fragments of silicon tetrafluoride, SiF_3^+ , SiF_2^+ , HF^+ , and F^+ ions were identified mass-spectrometrically in the mass spectrum of the gases formed during arc-welding by means of carbonate-fluorite type welding wires. Other mass-spectrometric investigations of titanium tetrafluoride and zirconium tetrafluoride revealed that the mass spectrum of TiF_4 is composed of TiF_2^+ , TiF_3^+ and TiF^+ ions, and that of ZrF_4 of ZrF_4^+ , ZrF^+ and ZrF_3^+ ions.

REFUSE INCINERATOR FLUE GAS-INFLICTED CORRO-

SION AND EMISSION DAMAGES. (Korrosionen und Immissionsschaeden durch Muehlrauchgase). Text in German. Energietechnik, 23(6):277-280, June 1973. 31 refs.

General problems of corrosion and plant (flora) damage due to refuse incinerator-generated flue gases are described. Corrosion occurring at temperatures above 400 C is due to a combination of hydrochloric acid as formed during the incineration of polyvinyl chloride and common salt with reducing atmosphere in overheater and steam generator zones of refuse incinerators. Quantitative volatilization of the iron chloride formed on metal surfaces above 400 C was observed. High-temperature corrosion can be avoided or reduced by feeding homogenized batches, the use of secondary air, and by limiting the steam temperature to 250-300 C. Corrosion at temperatures around 200 C is due to the formation of low-melting, hygroscopic hydrates of zinc and iron chlorides which predominantly precipitate in electrostatic dust separators. Watery condensates, containing HCl, sulfur dioxide, and sulfur trioxide, can cause low-temperature corrosion in small-capacity incinerators with wet type dust separation. Odorous emissions from incinerators can be avoided by the application of temperatures above 800 C, and combustion air intake from refuse bunkers. The SO_2 emission concentrations from refuse incineration plants range from 0.5 to 1.0 g/N cu m. The HCl concentrations, being in the same range, are much more critical, and can easily cause plant damages around waste incineration plants. The HCl concentrations can be reduced by proper siting of the incinerators, and proper choice of the stack height. No phosgene is formed during waste incineration processes, while the hydrofluoric acid concentrations may reach up to 10 mg/N cu m.

Burchard, John K.

SURVEY OF THE AIR POLLUTION PROBLEMS ARISING

IN THE NON-FERROUS METALLURGICAL INDUSTRIES.

Preprint, 10p., 1973. (Presented at the Seminar Control of Emissions from the Non-Ferrous Metallurgical Industries, Dubrovnik, Yugoslavia, Nov. 19-24, 1973.)

A survey of the air pollution problems arising in the non-ferrous metallurgical industries in 11 countries is summarized. The nonferrous metallurgical industry is a prime contributor to air pollution in all the countries. Sulfur oxides, particulates, fluorides, and hazardous metals are the main pollutants from the aluminum, zinc, copper, and lead industries. There are many significant differences which affect the capability of controlling smelter pollutants. Factors such as type of metallurgical process used, degree of use of existing control technology, age of facilities, ability of smelter to bear cost of control, physical layout of smelter, market for byproducts of control process, and many others have resulted in control effi-

ciency in countries ranging from no control to over 90% control for some pollutants. Even within a single country, there are significant differences in control efficiencies from smelter to smelter. The primary SOx control technique is the contact sulfuric acid plant, although its use varies from country to country. All types of conventional equipment, precipitators, scrubbers, and bag filters are used for particulate control. Several countries report use of both wet and dry adsorption systems for control of fluorides from aluminum smelting. Sulfur oxide emissions from nonferrous smelting ranged from 1-13% of total country SOx emissions, ranking behind electric utilities in all cases. Particulates were a smaller percentage at 1-5%. Continuous research efforts in three areas are being conducted: problem identification, process modification, and gas cleaning equipment improvement.

Grjotheim, K., H. Kvande, K. Motzfeldt, and B. J. Welch
THE FORMATION AND COMPOSITION OF THE
FLUORIDE EMISSIONS FROM ALUMINUM CELLS. Can.
Met. Quart., 11(4):585-599, 1972. 42 refs.

A survey of information in the literature regarding the total fluoride consumption per ton of aluminum produced in many plants and the amount of fluorides retrieved from the anode gas is presented, and a quantitative calculation is given for the fluoride emissions generated by vaporization from the melt based on data for vapor pressures of sodium fluoride-aluminum fluoride melts with relevant additions. The observed fluoride emission rates are ascribed to three principal mechanisms: vaporization from the molten electrolyte; primary generation of hydrogen fluoride in the cell; and the entrainment of liquid droplets and solid dust. Available evidence indicates that each mechanism is of about equal significance. Possible reactions between the moisture content of the feed and the molten fluorides include hydrolysis reactions in the fluoride melt and partial reduction to hydrogen as a result of introduction of water with the feed. Another source of hydrogen may be the materials of the anode. Part of the hydrogen may be anodically oxidized to hydrogen fluoride which significantly contributes to the total fluoride emission rate. The reactions of water vapor with the fluoride-containing melt vapor alter the chemical composition of the emissions but will not contribute to the emission rate. (Author abstract modified)

CURRENT TECHNICAL AND ECOLOGICAL PROBLEMS
OF SECONDARY AIR POLLUTANTS. (Attuali problemi tecnici ed ecologici connessi con gli inquinamenti atmosferici secondari). Text in Italian. Inquinamento, 15(5): 16-21, June 1973. 24 refs.

Sources of emission, abatement and control, and maximal permissible secondary pollutant emission levels in force in different countries are reviewed. Included are chlorine, fluorine, hydrochloric acid, hydrofluoric acid, and silicon tetrafluoride, pollutants created primarily localized pollution of relatively short duration. Damage caused to vegetation is primarily chlorosis or loss of chlorophyll; fluorine causes in domestic animals fluorosis or abnormal bone growth. The primary emis-

<xref image="2000WVBG.TIF|V3|2006:09:28:01:19:26.00|121159|0"> image: </xref>

A. EMISSION SOURCES

53

sion sources are chlorine and soda producing plants; hydrochloric acid producing plants; combustion of coal and oil; refuse incinerators; plants producing hydrofluoric acid, phosphoric acid, and phosphate fertilizers; and incinerators burning plastic refuse. Control includes dilution by high stacks, removal of chlorine and fluorine compounds from flue gases by absorption, adsorption, chemical reactions or condensation, or change of process. Most frequently employed is scrubbing with water in venturi towers and absorption by alkaline solutions. Maximal permissible concentrations in different countries differ widely which is not only a reflection of different technological control methods, but also of uncertainty about the toxic effects of the pollutants in question. Many standards are based on maximal allowable concentrations adopted by the American Conference of Governmental Industrial Hygienists.

THE UMWELT PORTRAIT OF A CITY VI: DUESSELDORF.

A COMBAT AGAINST THE WINGS OF A WINDMILL. (Umwelt-Staedteportraet (VI): Duesseldorf. Ein Kampf gegen Windmuehlenfluegel). Text in German. Umwelt (Duesseldorf), 3(5):39-45, 1973.

Duesseldorf is the least polluted city of the Rhine-Ruhr area. Forty percent of its air pollution stems from the 800 industrial complexes, and 40% comes from the 200,000 automobiles. Domestic heaters contribute only 20% to air pollution. Many domestic heaters in Duesseldorf are operated by electric current and natural gas. A large network supplied with remote heat further helps to keep air pollution by domestic heating low. Duesseldorf is included in the measurement program of North Rhine Westphalia. The dust fall is measured at 38 points of the city, the sulfur dioxide concentration is measured at one stationary measuring station, and on 156 further points random samples are taken. The high concentrations of fluorine compounds which exceed the recommended maximum allowable emission concentration of 5 microgram/cu m air causes considerable concern. In the district of Wersten, up to 14.8 microgram were measured. The fluorine concentration later dropped. The sources for the high fluorine emissions are still being sought.

STUDIES OF MINERAL OIL AND MINERAL OIL

PRODUCTS CONCERNING FLUORINE. RESULTS OF A

JOINT TEST. (Untersuchungen von Mineraloel und Mineraloelprodukten hinsichtlich Fluor). Text in German. Erdoel Kohle (Hamburg), 26(11):647-649, Nov. 1973. 3 refs.

Six laboratories in West Germany agreed to employ the same test for determination of the fluorine concentration in crude oil. The crude oil was burned in an oxyhydrogen flame. The electrometric determination of the fluoride concentration in the condensate was carried out with a fluorine sensitive electrode. The detection limit of the method is 0.034 ppm F. The crude oils which were tested are listed in a table. These tests and the analysis of 42 further native crude oils representing more than 90% of the crude oil processed in West Germany yielded that if there is any fluorine present its concentration is lower than the detection limit. Therefore extra light and heavy fuel oil which is produced by simple distillation from the analyzed crude oils provide no source for the emission of fluorine.

THE FATE OF SOME TRACE ELEMENTS DURING COAL

PRETREATMENT AND COMBUSTION. Am. Chem. Soc., Div.

Fuel Chem., Preprints, 18(4):108-113, 1973. (Presented at the American Chemical Society, National Meeting, 166th, Chicago,

111., Aug. 26-31, 1973.)

In one study, selected coals were crushed and separated in organic fluids of known specific gravity. The starting coal and each specific gravity fraction were analyzed for the trace elements mercury, copper, chromium, manganese, nickel, and fluorine. In the second study, coal was combusted in a 100 g/hr combustor, and the ash and flue gases were collected and analyzed for mercury, cadmium, and lead. Then coal and ash were obtained from a 500 lbs/hr furnace and from commercial power plants. Analytical methods and results are described. As much as 40% of the mercury in the coal was associated with the high specific gravity fraction of the coal. Thus, if the pyrite is removed from coal to lower sulfur emissions, a substantial part of the mercury is also removed at no extra cost. About 10-15% of the mercury from the coal may remain in the fly ash in coal-burning power plants. Taking both factors into consideration could reduce the maximum emission of mercury to about 50% of that present in the coal. Cadmium and lead are less volatile than mercury, and thus they are retained in the fly ash to a greater extent than Hg. It is expected that even less volatile elements would be retained in the fly ash to an even greater extent than Pb and Cd. Determinations of fluorine, copper, manganese, chromium, and nickel were only preliminary and emphasized the difficulties inherent in trace analyses of matrices as complex as coal. Trace analysis require extreme vigilance. Coal handling procedures themselves may add trace elements to the coal. (Author summary modified)

Gotsu, Isamu, Hiroshi Kagawa, and Kojiro Shimanuki
INVESTIGATION OF LOCAL AIR POLLUTION IN CON-
CENTRATED AREA OF TILE MAKING INDUSTRY IN FU-
KUYAMA DISTRICT, KORIYAMA CITY. (Koriyama-shi, Fu-
kuyama chiku ni okeru kawara kojo chitai no taiki osen (SOx
oyobi HF) chosa ni tsuite). Text in Japanese. Taiki Osen Kenkyu
(J. Japan. Soc. Air Pollution), 8(3):498, Oct. 1973. (Presented at
the Japan. Society of Air Pollution, Annual Meeting, 14th, Fu-
kushima, Japan, Nov. 6-8, 1973, Paper 228.)

In 1970, unknown causes damaged the rice plants in the vicinity of tile factories in Koriyama. Similar damage in other areas suggested damages by hydrogen fluoride in the stack gas, and in August 1971, stack gas content was measured; 150 ppm of sulfur oxides and 20 ppm of hydrogen fluoride were detected. Seven of 14 tile plants installed stack gas treatment systems under the guidance of Koriyama city, and the systems began operation in January 1972. In April, stack gases were analyzed by the arsenazo III method and spectrophotometry; SOx concentration at the flue exit was 31-40 ppm and showed about 69.4-87% elimination rate; HF measurements were 12-17 ppm and elimination ranged between 98.7 and 96.2%. The SOx maximum was 3.68 ppm and was rather low, but the HF figures were relatively high compared with the figures of similar plants in other prefectures. The daily 8-hour average of environmental HF in the vicinity was 0.02-0.03 ppm and was higher than that of the entire prefecture. The causes may be the low smoke stack, low temperature of the stack gas, and the hilly topography, and poor dispersion. Also, combined pollution with the stack gases from the nearby brick and ceramic factories is suspected.

Fujiyoshi, Kaichi, Takashi Niwa, Masakatsu Kajikawa, and Tomokuni Hayakawa

FLUORIDE EXHAUSTED FROM SEVEN TYPES OF CERAMIC INDUSTRY. (Tojiki kankei kojo no gyoshu betsu ni yoru fusso kagobutsu no haishutsu ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 8(3):360, 1973. (Presented at the Japan. Society of Air Pollution, Annual Meeting, 14th, Fukushima, Japan, Nov. 6-8, 1973, Paper 104.) Emission gases from ceramic factors were investigated by seven classifications of refractory bricks, mosaic tiles, exterior tiles, interior tiles, dishes, glazed roof tiles, and unglazed roof tiles. The JIS method of measurement and analysis were used. The hydrogen fluoride emission from refractory brick kilns were especially high, at 48 ppm. Mosaic tile plants emitted less than 5 ppm of HF. All tiles using glaze (exterior, interior, dishes, glazed tiles) emitted relatively high concentrations of HF (around 10 ppm). The causes were probably the chemical agents used for lowering the melting point. Unglazed tiles are baked in a single-process kiln, and the temperature seemed to affect HF emissions very much. At one kiln, when the kiln top temperature was 500-600 C, HF emission began to increase from 0.66 order to 6.4 ppm order, and reached the highest concentration of 110-320 ppm at 800-900 C. However, at another kiln of the similar type, HF began to decrease at 600 C, and at 800 C, 85% of the total emission was diminished.

ON FLUORIDES IN EXHAUST GAS (1). (Fusso kagobutsu has-scigen chosa ni tsuite - sono 1 - chitsugyo kankei kojo hasseigen chosa). Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 8(3):361, 1973. (Presented at the Japan. Society Air Pollution, Annual Meeting, 14th, Fukushima, Japan, Nov. 6-8, 1973, Paper 105.)

The emission gases from nine ceramic plants producing tiles and bricks in Toyama prefecture were analyzed. Much fluoride, hydrogen chloride, and other chlorine gases were found in the flue gas from the bittern additive, glaze, and the tile materials. Fluoride emissions ranged from 9 to 174 mg/N cu m, and Cl gas from 7 to 516 ppm. At one of the plants, an elimination system was installed for flue gas, and the F content in the flue gas decreased from 131 to 0-1.1 mg, Cl gas from 90 to zero. The environmental concentration of F at 70 m from the plant reduced from 320-410 micrograms F/1000 sq m/month to 0.32, and at 200 m, from 45-56 micrograms to 0-32. Fluorides and HCl gas began to form at 600 C, and reached peaks at 900 for HCl and at 950 C for F.

PRESENT PROBLEMS IN ALUMINUM MELTING PLANTS.

(Aktuelle Probleme der Aluminium-Schmelzhuetten). Text in German. Metall, 27(12): 1228-1231, 1973. (Presented at the Organization of European Aluminum Melting Plants, Annual Meeting. Munich, Sept. 21, 1973.)

The quantity of coated aluminum products for canning and food wrapping purposes such as weather resistant coatings in the construction industry, and coating of kitchen apparatuses of trailers has more than quadrupled between 1962 and 1972 in the U. S. In Europe the increase was even higher. It rose from 57,000 tons in 1970 to 71,000 tons in 1971 to 100,000 tons in 1972. Two types of coated aluminum are of special importance to air pollution, because of fluoride and chloride pollution. Although their fraction is presently still low (about 1%) it is expected to increase. Presently the air pollution problem can be solved with wet collectors. Because of the corroding effect of the waste gases, the construction and material of the scrubber must be carefully selected. All waste water must be cleaned. A closed cycle would be the best solution, but

presently no satisfactory method is yet in operation. Another problem is the high magnesium concentration of the alloys used for the manufacture of cans. A comparison of the capital investment costs for a new secondary coated aluminum melting plant with 20,000 tons annual production with and without facilities for cleaning the waste gases shows that \$3 million are required for a plant with air pollutant cleaning devices and roughly \$2.4 million without such devices.

Magee, E. M., H. J. Hall, and G. M. Varga, Jr.
POTENTIAL POLLUTANTS IN FOSSIL FUELS. (FINAL REPORT). Esso Research and Engineering Co., Linden, N. J., U. S. Environmental Protection Agency Contract 68-02-0629, Program Element 1A2013, EPA-R2-73-249, GRU. 2DJ.73., 300p., June 1973. 110 refs.

Data obtained from the literature on sulfur, nitrogen, and other potential pollutants in fossil fuels in the United States are presented. The data are categorized according to the location of the raw fuels, and are analyzed for geographic effects on composition. Good data and useful correlations with source locations are available for petroleum sulfur, nitrogen, and nickel/vanadium, but not for other potential pollutants. A large amount of data is presented for trace elements in coal and nearly complete data are available for sulfur. Additional data include: spectrochemical analyses of coal ash for trace elements, rare elements in coal, mercury in coal, determination of arsenic in coal, colorimetric determination of beryllium, chemical analysis for germanium and gallium in head samples of fly ash and flue dust, spectrochemical analysis of coal ash, and method for determination of fluorine in coal.

59494

AIR POLLUTION AND ITS SOURCES. (Die Luftverunreinigung und ihre Quellen). Text in German. Bull. Eidgenoess. Gesundheitsamtes, Beilage B, no. 6:311-318, Dec. 1973. The sources of air pollution in Switzerland are surveyed. In Switzerland, regional and local air pollution is due to domestic heating and traffic, as well as to industry and trade. Domestic heating, for which fuel oil is mainly used, is responsible for sulfur dioxide and soot emissions. The SO₂ levels measured in urban areas in winter are 5 to 10 times larger than those measured in summer. Unless adequate measures are taken, the domestic heating-generated air pollution will increase parallel to fuel consumption. Exhaust gases and gasoline vapors constitute the basic pollutants generated by automobiles. While evaporation losses have been minimized by positive crankcase ventilation, exhaust emissions, containing such pollutants as carbon monoxide, nitrogen oxides, unburned hydrocarbons, and lead compounds, continue to be a problem. Industrial firing equipment generates less soot but more SO₂ than domestic heating equipment. Various gases, vapors, dusts, smoke, soot, and fluorides are the major specific industrial emissions. The respective shares of domestic heating, industries, and traffic in the generation of waste gases in Switzerland are 50%, 19%, and 23.5%.

IRON AND MALLEABLE-IRON FOUNDRIES. (Eisen- und Tempergiessereien). Text in German. In: Reine Luft fuer morgen. Utopie oder Wirklichkeit? Ein Konzept fuer das Nordrhein-Westfalen bis 1980. p. 38-40, 1972.

The state of the art and the expected evolution until 1980 of the dust, sulfur dioxide, and gaseous fluoride emissions from iron and malleable-iron foundries in North Rhine-Westphalia are outlined. By reducing the specific dust emission from melting furnaces from 1.5 kg to 1.0 kg/ton of Fe, and by the introduction of total dust separation, covering the entire melting process, the yearly dust emission is expected to decline from 8400 tons to 5000 tons. The SO₂ emission, now 4800 tons/yr at a specific emission of 1.6 kg/ton of Fe, is expected to decline by 33% due to the reduction in the coke consumption, and to the anticipated increase in the use of natural gas, and electric melting furnaces. The gaseous F emission from basic and non-basic furnaces, 100 tons in 1969, is expected to fall to 10 tons in 1980 due to the abandonment of furnaces with basic linings.

ENVIRONMENTAL EFFECTS OF THE CONSTRUCTION AND OPERATION OF A GASEOUS DIFFUSION PLANT.

(FINAL REPORT). Atomic Energy Commission, 33p., July 26, 1973. 8 refs. NTIS: ORO-725

A study was performed to assess the environmental effects of the construction and operation of a gaseous diffusion plant for separation of uranium isotopes. Radioactive contamination, both alpha and beta-gamma, was judged possible only as a result of accidental release or from cleaning of equipment that is removed from the cascade. Alpha radioactivity in air samples from four locations averaged from 0.4-0.5 times 10 to the minus 13 micro Ci/ml, while beta-gamma averaged from 4.0-4.4 times 10 to the minus 13 micro Ci/ml. Small quantities of hydrogen fluoride were present in both the hydrogen and fluorine streams; average concentrations of fluorine found in the ambient environment at the plant examined were less than 1 ppb. Average sulfur dioxide air samples taken at four locations ranged from 28-42 micrograms/cu M, while particulate matter emissions were about 0.17 lb/rmillion Btu input. Emission rates for SO₂ were slightly under 6 lbs/million Btu input and were in excess of the state (Ohio) standards. The use of lower than 3% sulfur fuel is expected to correct the situation

SOURCES CHARACTERISTICS OF LIQUID AND GASEOUS EFFLUENTS FROM FERTILISER PLANT. Indian J. Environ. Health, 15(4):322-328, Oct. 1973.

Air pollutants, liquid effluents, and solid wastes generated from operations in the fertilizer industry are reviewed in terms of their sources; physical and human health effects, and possible control measures. Air pollutants considered include: fall out particulates, suspended particulates, hydrocarbons, oxides of nitrogen, carbon monoxide, sulfur oxides, hydrogen sulfide, and hydrogen fluoride. Appropriate control strategies outlined include: the use of collectors, vapor recovery systems, by-product recovery, combustion techniques, and stack gas scrubbing. Effects range from soiling of property and visibility reduction for particulates to plant damage and adverse human health effects for oxides of nitrogen.

AIR POLLUTION ASPECTS FROM FERTILISER MANUFACTURE. Indian J. Environ. Health, 15(4):283-288, Oct. 1973.

A review of the common pollutants generated by fertilizer

manufacturing and their sources of emission is presented along with some emission data collected from field studies. Pollutants considered are: sulfur dioxide generated from sulfuric acid manufacture, steam generation, and process heaters and furnaces, nitrogen oxides generated from nitric acid production and acidulation (nitrophosphate); dusts generated from grinding and transport of raw materials, raw material storage, escape from drier outlet points, and prilling towers; ammonia generated from its synthesis by reacting hydrogen and nitrogen and in urea production; fluorides generated from phosphoric acid plants and complex fertilizer plants; and sulfur trioxide and acid mists generated from the manufacture of sulfuric acid. Results are presented/ from source sampling during a field visit to a fertilizer plant.

TREATMENT TECHNIQUES FOR AIR POLLUTION-RELATED HARMFUL SUBSTANCES. (Taiki osen kankei yugai busshitsu shori gijutsu). Text in Japanese. PPM (Japan), 5(5):68-93, May 1974.

Chemical and physical information on the formation of pollutants, control methods, and maintenance and inspection of control equipment are reviewed. Cadmium and its compounds, chlorine and hydrogen chloride, fluoride and hydrogen fluoride, and lead and its compounds are described. Various industries and processes creating these substances are. Cd refining; Cd paint drying processes; various soda industries; manufacturing of chlorine, polyvinyl chloride, ferrous chloride, activated carbon, bleach, and chloroform, aluminum refining electric furnaces; and manufacturing of glass, phosphoric acid, calcium superphosphate, phosphate fertilizers, hydrogen fluoride, frosted glass and opaque glass; refining of lead, copper, and zinc; secondary refining of lead; manufacturing of lead paint, glass, nitrogen oxides; ammonia oxidation, and combustion. The forms, properties, toxicity of these substances, and the symptoms of health damages are described.

WASTE INCINERATION. (Muellverbrennung). Text in German. In: Reine Luft fuer morgen. Utopie oder Wirklichkeit? Ein Konzept fuer das Nordrhein-Westfalen bis 1980. p. 55-60, 1972. The state of the art and the expected evolution of the dust, sulfur dioxide, hydrochloric acid, and fluorine emissions from municipal waste incinerator plants in North Rhine-Westphalia are outlined. Dust emissions are expected to play a minor role in the total incinerator-generated emission in 1980 since the total dust emission presently amounts to some 500 tons/yr, and all waste incinerator plants are equipped with dust separators with a minimum efficiency of 95%. The emission of organic compounds can be effectively controlled by optimized combustion conditions. The PVC (polyvinyl chloride) content of domestic refuse, now well under 1%, expected to increase four-fold by 1980, would result in an enormous increase in the HCl emissions because fly ash and slag have reduced adsorption ability for HCl. The HO emissions can be controlled by

<xref image="2000WVBJ.TIF|V3|2006:09:28:01:19:36.00|116098|0"> image: </xref>

wet scrubbing processes, while dry adsorption is both inefficient and costly. The SO₂ emission would also increase rapidly. Slowdown of the increase in the SO₂, HCl, and F emissions is expected from the use of flue gas cleaning devices with a minimum efficiency of 80% for new plants from 1976 on. The introduction of such flue gas cleaning devices also for existing incinerators in 5 more years will result in a net decrease in the pollutant emissions.

60728

Ministry of Labor, Health, and Welfare of North Rhine-Westphalia (West Germany)

NONFERROUS METALLURGY. (NE-Metallerzeugung). Text in German. In: Reine Luft fuer morgen. Utopie oder Wirklichkeit? Ein Konzept fuer das Nordrhein-Westfalen bis 1980. p. 60-65, 1972.

State of the art and the expected evolution of the pollutant emissions from nonferrous metallurgical plants in North Rhine-Westphalia are outlined. Aluminum works cause local air pollution by the emission of gaseous fluorine, dust (alumina and fluorides), sulfur dioxide, and carbon monoxide. The specific fluorine, dust, and SO₂ emissions are 1.5-0.8 kg/ton, 20-9 kg/ton, and 15-3 kg/ton, respectively. Aluminum re-melting plants emit chloride aerosols, metal oxides, gaseous fluorine, and dust. The particulate emission is expected to fall from 1320 tons to 680 tons yearly in 1980, while the re-melting capacity will double. Lead melting plants emit mostly SO₂ and dusts containing zinc, cadmium, arsenic, bismuth, copper, and tin. The Pb and Zn emission will be drastically reduced by 1975. The Pb, Zn, and Cu emissions from Cu melting plants, already below 50 mg/cu m, are not expected to decline further, while the hydrochloric acid emission will be reduced by 50% by 1980. The SO₂ emission will increase from 900 tons in 1970 to 1100 tons in 1980. The SO₂ emission from Zn smelting plants will rise considerably until 1975, and further reduction in the SO₂ emission is expected from the introduction of the double-contact sulfuric acid production process and from flue gas desulfurization. The maximum allowable concentration of dusts containing toxic components in nonferrous metallurgical plants will be reduced from 150 mg/cu m to 50 mg/cu m.

60729

Ministry of Labor, Health, and Welfare of North Rhine-Westphalia (West Germany)

STONE AND EARTH INDUSTRY. (Stein und Erden). Text in German. In: Reine Luft fuer morgen. Utopie oder Wirklichkeit? Ein Konzept fuer das Nordrhein-Westfalen bis 1980. p. 65-66, 1972.

The state of the art and the expected evolution of emission in the stone and earth industry in North Rhine-Westphalia, as well as measures to be taken for pollution abatement in these industries are outlined. Dust, fluorine compounds, lead, zinc, barium, selenium, cadmium, boron, strontium and hexavalent chromium compounds, as well as combustion process-generated sulfur dioxide are the chief pollutants in the stone and earth industry. While measures taken a few years ago have resulted in a decrease in the dust emissions in cement works, the results achieved cannot be regarded as satisfactory. Step-up of cement production, and the trend toward larger production units will most probably result in a disproportionately great increase in the dust emissions due to labile operating conditions. Permanent control of the efficiency of dust-separating equipment, and automatic shutdown of clinker mills during periods of high emission rates in the cement industry, as well as the use of adequate apparatuses for the separation of F₂, Zn, Pb, and other volatile toxic compounds in the brick and glass industries, will be required for emission abatement.

Trefois, M. A.

METALLURGY AS A POLLUTING INDUSTRY. (La Siderur-

gie en tant qu'Industrie polluante). Text in French. Rev. Serv. Publ., 32(1):3-7, 9-16, 1970. 2 refs.

Problems of air pollution and techniques and equipment available for its abatement in metallurgy are surveyed. Sulfur dioxide, arsine, nitrogen oxides, fluorine and chlorine compounds, ozone, carbon monoxide, hydrocarbons, dust, aerosols, and smoke are the principal pollutants emitted by metallurgical plants. Dust chambers, settling chambers, cyclones, multicyclones, scrubbers, venturi scrubbers, and electrostatic precipitators are among the principal dust emission control equipment used in metallurgical plants. The dispersion of the pollutants can be essentially improved by high stacks. Modern metallurgical plants designed with respect to air pollution control include such emission control equipment as Pratt-Daniel dust separators for coke charging and for agglomerate transport equipment, wet methods of coke quenching, Multivortex dust separators for agglomeration lines, Centicell dust separators for agglomerate discharge, cyclone groups for coke handling at the blast-furnaces, and bag filters for the steel melting furnace.

Ministry of Labor, Health, and Welfare of North Rhine-Westphalia (West Germany)

IRON AND STEEL INDUSTRY. (Eisen und Stahl). Text in German. In: Reine Luft fuer morgen. Utopie oder Wirklichkeit? Ein Konzept fuer das Nordrhein-Westfalen bis 1980. p. 32-37, 1972. State of the art and the expected evolution of the particulate, sulfur dioxide, fluoride, and metal oxide emissions from the different processes in the iron and steel industry in North Rhine-Westphalia are outlined. While the electric-arc furnace process, and especially the oxygen converter process, will acquire increased shares in total steel output, the share of the open-hearth furnace process will decrease, and Thomas steel will fade out completely by 1980. Ore dressing operations are responsible for considerable emissions of sulfur dioxide, fluorides, chlorides, and dusts containing lead, manganese, copper, antimony, and other metals. Blast-furnaces are responsible for dust, carbon monoxide, nitrogen oxides, sulfur dioxide, and hydrogen sulfide emissions. Dust separation at oxygen converters is done primarily by means of wet type dust separators and electrostatic precipitators. The dust concentration in the cleaned waste gases from tissue filters and electrostatic precipitators should be limited to 30-40 mg/N cu m and to 50 mg/N cu m, respectively. The considerable CO emissions could be modestly decreased by limiting the air-excess coefficient to 0.1. Electric-arc furnaces should be equipped with suction hoods and tissue filters. Also, fluorine-containing fluxes should be abandoned. The emissions from iron and steel works can be abated by the shutdown of obsolete works, by the use of improved techniques of gas collection and purification for new plants, by the combined removal of sulfur and F₂ from agglomeration plant-generated waste gases, and by the introduction of total dedusting for steel works, including electric-arc furnaces. The maximum allowable dust concentrations should be determined as a function of their content of toxic components.

Brocke, W.

AIR POLLUTION BY EMISSIONS FROM CONVENTIONAL POWER PLANTS. (Die Luftbelastung durch Emissionen konventioneller Kraftwerke). Preprint, Society of German Radiation Protection Physicians and Society for Radiation and Environmental Research, 1971. 9 refs. (Presented at the Society of German Radiation Protection Physicians/Society for Radiation and Environmental Research Joint Meeting, 12th, Environmental Protection in Nuclear and Conventional Power Production, Oct. 8-9, 1971.) Translated from German, 13p.

Conventional power plants produce dusts, sulfur oxides, fluorine compounds, nitrogen oxides, carbon monoxide, and gaseous hydrocarbons. These emissions in the Federal Republic of Germany are estimated for 1970, 1975, and 1980 for bituminous coal, lignite, heating oil, and gas. From 1970 to 1980, particles are expected to increase by 13%, SO_x by 22%, F compounds by 18%, NO_x by 34%, CO by 35%, and HC by 13%. Emissions of sulfur dioxide from stationary sources in power plants, industrial plants, and home heating make up 88% of the total emission of SO₂ in the German Federal Republic. Power plants will produce 41%, 40%, and 36% of the total SO₂ emissions in 1970, 1975, and 1980, respectively. Power plants will produce 70% and 83% of the F emissions in 1970 and 1980, respectively. Power plants in Germany produce 18 to 23% of the NO_x emissions. Half of all particle emissions come from stationary emissions, and 18% came from power plants in 1970. This will rise to 26% by 1980. Different fuels and operating conditions can cause different amounts of emissions. Operating and emission data are given for a 600 MW power plant run on bituminous coal, lignite, heating oil, and gas.

61154

Kremer, Hans

EMISSION FROM FIRING SYSTEMS. (Emission von Feuerungen). Text in German. Umwelt Aktuell., no. 4:29-44, 1973. 38 refs. (Presented at the Congress Umwelt 72, Stuttgart, Germany, June 30-July 9, 1972.)

The particulate and gaseous emissions from firing systems and their causes are reviewed. In the Federal Republic of Germany annually 1 million tons of particulates, 3 million tons of sulfur dioxide, 600,000 tons of carbon monoxide, 600,000 tons of nitrogen oxides, 130,000 tons of hydrocarbons, and about 10 tons of fluorine compounds are emitted by firing systems. Sulfur control measures include the removal of pyrite from coal and the hydration of heavy oil. The costs of these measures are estimated. Dusts can be satisfactorily removed in dust collectors. Nitrogen oxides can be reduced by near stoichiometric combustion, two- or more stage combustion, waste gas recirculation, and water injection.

Schmidt, E.

BALANCE OF AIR POLLUTING FLUORINE FRACTIONS. (Bilanz luftverunreinigender Fluoranteile). Text in German. Bundesverband der Dent. Ziegelind. Forsch., vol. 80:21-24, 1973.

On a brick kiln with a capacity of 3800 kg/hr and a fuel consumption of about 152 kg/hr, measurements of the sulfur dioxide and trioxide and of the fluorine emission were taken. The gas was sampled with a heated quartz tube which was followed by a filter filled with quartz wool for separation of those fractions bound to dust. For analysis of the fluorine concentration, the gas sample was led through a scrubber filled with 2N caustic soda. The samples thus obtained were filled into synthetic bottles for later analysis in the laboratory. The fluorine was determined by water vapor distillation and following colorimetry by the Belcher-West method. The emission of SO₂ and SO₃ was determined separately in an apparatus by

Corbett where SO3 is first absorbed in isopropanol and SO2 next in iodine solution. The concentrations were determined by simple titration. The main measurements were taken over a period of 8 days. They were followed by measurements over 1 day after the furnace operation had been halted. The average concentration of the fluorine emission was 138 mg/cu m. The highest concentration measured was 201 mg F/cu m, the lowest 75 mg/cu m. The sum of SO2 plus SO3 was 328 mg/cu m, with SO3 constituting 71%. On the average, 59% of the fluorine entered with the crude material were driven off. The values fluctuated in dependence of the kiln operation.

Nakagawa, Yoshihiro, Isho Mitsuki, and Takei Takada
ATMOSPHERIC POLLUTION BY FLUORINE COMPOUNDS
IN A DISTRICT AROUND A CERTAIN IRON MAKING FAC-
TORY. (Bo-seitetsu kojo shuhen chiku ni okeru fusso kagobutsu
ni yoru taiki osen). Text in Japanese. Hyogo-ken Kogai Ken-
kyusho Hokoku (Rep. Environ. Sci. Inst., Hyogo Prefect.), no.
5:47-51, Dec. 1973. 6 refs.

Although it is not known popularly, steel making factories usually discharge considerable amounts of fluorine compounds as silicon tetrafluoride or hydrogen fluoride because the factories use calcium fluoride as an extension or slag forming agent. The atmospheric pollution in the neighborhood of a steel plant was examined through the analysis of water soluble hydrogen compound contained in suspended particulates as well as through the determination of fluorine in plant leaves. The method used for the determination was that proposed by Thompson et al. (JAPCA, 21(8) 484-487(1971)). The content in air was 0.211-1.012 micrograms/cu m and the origin of this fluorine was the factory wastes. The correlation between fluorine and various heavy metals such as iron, manganese, and zinc was meaningful. The fluorine content in the leaves of sultan s parasol, Firmiana platanifolia, was 2.30-39.62 micrograms/g leaves. The concentration increases as the location of a tree neared the factory. The values obtained by the colorimetric method and by the ionic electrode method agreed well with each other. Therefore, the ionic electrode method is superior to the other because this method is simpler. Comparison was also made of the Smith method and the Jacobson method.

Kubota, Torahide
DEVELOPMENT OF POLYMER CHEMICAL INDUSTRY
AND ITS ASSESSMENT FROM THE STANDPOINT OF POL-
LUTION. (Kobunshi kagaku kogyo no hattan to kogai kara no
asesumento ni tsuite). Text in Japanese. Kankyo Sozo (Environ.
Creation), 4(4):27-36, April 1974.

Air pollution control plans required of plastic industries include inspections of monomer synthetic process by-products and their toxicity, toxicity of refining low-boiling point gas, photochemically reactive gas, polymer process separation gas, plastic waste incineration combustion gas, and treatment of all these harmful gases. Industries are responsible for producing potentially toxic material by utilizing materials including hydrogen chloride, heavy metals, nitrogen oxide, sulfur oxides, and dusts. Plastic products and potential pollutants, plastic coloring materials and pollution factors, and various polymer compound additives and pollutants are presented in

<xref image="2000WVBL.TIF|V3|2006:09:28:01:19:42.00|122128|0"> image: </xref>

tables. Even with photodegradable plastics and radio-degradable materials, food, air, water, and human health are threatened, especially if degradation occurs while the products are still in use. Degraded materials still produce HCl, hydrogen fluoride, ammonia, COCl₂, carbon monoxide, and formaldehyde. The better the product, the harder the treatment and the more chances for pollution; therefore, the future of polymer products must be based on the environmental safety even if it means inferior products. The distribution-sales flow must include recovery and reuse, and the manufacturing process must include material recovery and recirculation systems.

Beising, R. and H. Kirsch
 THE BEHAVIOR OF THE TRACE ELEMENT FLUORINE
 FROM FOSSIL FUELS AT THE COMBUSTION. (Das Verhalten des Spurenelementes Fluor aus fossilen Brennstoffen bei der Verbrennung). Text in German. VGB Kraftwerkstechnik, 54(4):268-286, April 1974. 61 rets.
 Fluorine is in coal largely bound to the mineral fraction. In the Ruhr coal, the fluorine concentration amounts to between 15 and 210 ppm, soft coal from the lower Rhine contains only 3 to 28 ppm fluorine. Solubility experiments with coal showed a mobility of the F-ions in the water-containing coals. Only a small fraction of the fluorine in the coal stems from the original plant material, the main fraction is found in the illites. In the cyclone melting furnace fired by hard coal which was examined, the fluorine evaporates entirely from the liquid slag. The fluorine concentration in the fly ash collected in the dust collectors may reach as much as 1100 ppm. In soft coal-fired furnaces with dry ash tap-off, about one fourth of the fluorine is retained in the fly ash in the electrostatic precipitator. The largest local fluorine concentration (2200 ppm) was found in the thin deposits on the combustion chamber walls. In the examined furnaces, with the exception of the soft coal fired boilers, the fluorine concentration in the ash increases with decreasing flue gas temperature from zero to 2700 ppm. At a flue gas temperature above 900 C, no fluorine is bound in the deposits. The fluorine ions in the fly ash from soft coal- and hard coal-fired boilers showed a relatively low water solubility. In the literature it is generally assumed that from power plants, the fluorine escapes largely in gaseous form as hydrogen fluoride and silicon fluoride. The formation of HF is promoted by the high water concentration of the flue gases. The present examinations revealed that fluorine is largely bound to the octahedron layer of the clay mineral as a replacement of hydroxyl ions. Under the conditions of the combustion chamber they leave the disintegrating structure and form HF.

Zhukov, V. I., T. N. Livke, P. K. Zaika, I. I. Voldayeva, and M. V. Gavriilyuk
 WAYS OF ABATING GASEOUS AND PARTICULATE POLLUTANT CONCENTRATIONS IN THE AIR IN THE CHEMICAL INDUSTRY. (Puri snizheniya zagazovannosti i zapylennosti vozdukh na predpriyatiyakh khimicheskoy promyshlennosti). Text in Russian. Khirn. Prom. (Moscow), no. 5:371-372, 1974.
 Results of workplace pollutant concentration measurements in chemical plants, and measures planned or taken for emission abatement in such plants are described. The sulfur dioxide, dust, and nitrogen dioxide concentrations measured in a sulfuric acid production plant were in excess of the maximum allowable concentrations in 8.5%, 7.2%, and 37.7% of all cases, respectively. The hydrogen phosphide, dust, hydrofluoric acid concentrations in a phosphate fertilizer plant exceeded the limit values in up to 70% of all cases. An epidemiological survey conducted among the workers revealed that pneumonia was responsible for 30% of all diseases, while the respective shares of the diseases of the upper respiratory tract, of

bronchitis, and gastrointestinal affections were 27%, 2%, and 5%, figures that are indicative of the predominant influence of dust. Wet method and closed cycle operation in a phosphate processing plant, the use of centrifugal scrubbers in a superphosphate manufacturing plant, and alkaline adsorption of phosphates for the reduction of the fluoride emissions, as well as ozone-catalytic purification and the use of fibrous filters for the reduction of the SO₂, sulfur trioxide, and sulfuric acid production plant are among the principal measures taken so far for pollution abatement.

Schoenmaker, Oswald Dirk and Jacobus Philippus Guldenmundt

USE OF PUROFER SPONGE IRON IN A 35-TON ELECTRIC ARC FURNACE. (Einsatz von Purofer-Eisenschwamm in einem 35-t-Elektroofen.) Text in German. Stahl Eisen (Duesseldorf), 94(16):711-728, Aug. 1974. 3 refs.

The emissions from the charging of sponge iron in an electric furnace were examined. Dust emission measurements were taken in the suction tube 26m from the furnace. The furnace waste gases are afterburned and cooled by surplus air. The first portions of the suction tube are water cooled. At the measuring point the temperature was 500 to 700 C. During scrap melting a maximum of 10 to 14 g of dust/cu m and an average of 6 g/cu m were measured. The continuous addition of sponge iron increased the maximum values to 20 to 21 g dust/cu m and the average to 9.0 g/cu m at a sponge iron fraction of 72 to 80%. Of the measured dust during sponge iron melts 60% had a grain size of less than 5 micron, while this fraction was only 30% during scrap melts. Understandably the fractions of silica, alumina, and titanium dioxide, as well as calcium oxide and magnesium oxide were higher during the treatment of sponge iron while the fractions of tin, zinc, lead, manganese, sodium oxide, fluorine, and water soluble chlorine were low.

Gerstle, Richard W. and Robert S. Amick
STAUFFER CHEMICAL COMPANY, MT. PLEASANT, TENNESSEE. PEDCo-Environmental Specialists, Inc., Cincinnati, Ohio, Environmental Protection Agency Contract 68-02-0237, Test 72-MM-04, Task 4, 99p., 1972 (?).

Atmospheric emissions of fluorides and phosphorus pentoxide from Stauffer Chemical Company's elemental phosphorus plant in Mt. Pleasant, Tenn., were sampled to form a data base for New Source Performance Standards as authorized by Celan Air Act of 1970. Tests were made to determine fluoride and P₂O₅ concentrations at the inlet and outlet of the venturi scrubber serving the furnace slag tapping operations. Fluoride concentrations before the venturi scrubber were generally in the range of 0.026 to 0.029 gr/SCF. Phosphorus pentoxide concentrations ranged from about 0.055 to 0.066, gr/SCF. After the scrubber, fluorides ranged from 0.00103 to 0.00131 gr/SCF and P₂O₅ concentrations were in the 0.012 and 0.016 gr/SCF range. Stack gas velocities, temperatures, moisture, carbon dioxide, oxygen, and carbon monoxide content were also measured.

Ministry of International Trade and Industry and Hokkaido-Tomakomai Municipal Government
A REPORT ON THE PRELIMINARY INVESTIGATION FOR THE INDUSTRIAL DEVELOPMENT OF THE TOMAKOMAI AREA (AIR POLLUTION). (Tomakomai chiku sangyo kogai sogo jizen chosa (taiki kankei) hokokusho). Text in Japanese. Sangyo Kogai (Ind. Public Nuisance), 10(8):59- 69, Aug. 1974. Tomakomai city which has been the center of paper pulp, wooden products, and lumber industries is changing into a heavy and chemical industrial area. With the development of industrial conglomerates of aluminum-electric power-oil refinery-petrochemicals, the pollution problems are increasing. The sulfur oxides concentration measured by the lead dioxide method showed a localized pollution in the vicinity of paper mills, and the yearly average SOx concentration measured by the conductimetric method was relatively low and below the environmental standard. The settling particulate concentrations measured in 1971 and 1972 did not show much increase compared to those in preceding years. The high hydrogen fluoride concentration was localized in the vicinity of an aluminum refinery. The relationships between meteorological factors and pollution were analyzed in regard to the wind direction frequency (wind rose) and distribution of wind velocity. The estimation of atmospheric pollutant concentration was based on data on future operations submitted by each industry by means of wind tunnel dispersion tests and theoretical equations of dispersion. The maximum SOx concentrations calculated based on the original industrial development plan were 0.389 ppm at E wind and 0.293 at S wind, exceeding the environmental standard. Recommendations for SOx pollution control by means of conversion to low sulfur content fuel, desulfurization processes, and increase in stack height were issued. With the cooperation of industry, it is now certain that the SOx concentration can be maintained below the environmental standard.

Deysing, Guenter
THE DEVELOPMENT OF POLITICAL ECONOMY IN THE DISTRICT COTTBUS AND THE TASKS RESULTING FROM IT FOR THE SOCIALIST SOCIETY IN THE COUNTRY. (Die Entwicklung der Volkswirtschaft im Bezirk Cottbus und die sich daraus ergebenden Aufgaben fuer die sozialistische I. andeskultur). Text in German. In: Technik und Umweltschutz Luft - Wasser - Boden - Laerm, Luftverunreinigung bestimmter Gebiete und technologische Verfahren zur Emissionsverminderung. Vol. 5, Leipzig, VEB Deutscher Verlag fuer Grundstoffindustrie, 1974, p. 11-18.
The district Cottbus supplied in 1970 35% of East Germany's electric power which by 1975 will have risen to 44%, 51% of the demand for soft coal which will rise to 58% by 1975, and 53% of the city gas which will rise to 65%. The further industrialization and the increasing population density in the cities, primarily in the Eastern part of the district of Cottbus, lead to enormous air pollution problems. Power generation and coal refining cause emission of dust, sulfur dioxide, oxides of nitrogen, phenols, hydrogen sulfide, ammonia, organic sulfur compounds, and other odorous substances. The sizable glass and ceramic industry emits dust, sulfur dioxide, oxides of nitrogen, fluorine compounds, lead, and sulfur trioxide. Other industrial branches operating in the district Cottbus and emitting a broad spectrum of pollutants are the chemical, textile and food industries, and metal working plants. The availability of waste gas cleaning facilities is presently at 75% and great efforts have been made to raise it to 95%. Industry operates 170 measuring stations in the areas Luebbenau, Vetschau, Boxberg, Knappenrode, and Laubusch and the Institute for Hygiene operates 90 measuring stations. The results from these measurements aid the selection of air cleaning

systems.

BACKGROUND INFORMATION FOR STANDARDS OF PER-
FORMANCE: PHOSPHATE FERTILIZER INDUSTRY.
VOLUME 2: TEST DATA SUMMARY (FINAL REPORT).
Rept. EPA 4SO/2-74-019b, 62p., Oct. 1974. 33 rets. NTIS: PB
237607/AS

Background information on the derivation of performance standards for the phosphate fertilizer industry is presented in connection with a first volume which provided a general description of the facilities for which standards were proposed. Summaries of emission testing data cited in Volume I are presented and are concerned principally with tests for fluorides and visible emissions. The facilities, characteristics of the exhaust gas streams, and conditions of operation are also described. Types of facilities covered in the document include: wet-process phosphoric acid plants, superphosphoric acid plants, diammonium phosphate plants, run-of-pile triple superphosphate plants, granular triple superphosphate plants, and storage of granular triple superphosphate. Many of the tests summarized were conducted using the Environmental Protection Agency Method 13 which will be proposed in the Federal Register at or before the time of proposal of the performance standards.

67806

California Air Resources Board
A FINAL REPORT ON AN EMISSION INVENTORY AT
KAISER STEEL. Rept. 73-20-5, 15p., Sept. 18, 1973.
An emission inventory of sources at Kaiser Steel and a schedule for compliance for each source not now in compliance with San Bernardino County Air Pollution Control District regulations were developed. The total emissions from the Kaiser Steel plant in tons/day and tons/yr of the various air pollutants, and the percentage of contribution of most of these emissions to the total emission inventory for San Bernardino County are tabulated. The District has no countrywide information on the emissions of hydrogen sulfide, ammonia, or gaseous fluoride. The total emissions are these: particulate matter 11.4 tons/day, 4161 tons/yr; sulfur dioxide 27.9 tons/day, 10,184 tons/yr; oxides of nitrogen as nitrogen dioxide 13.5 tons/day, 4928 tons/yr; carbon monoxide 98.7 tons/day, 36,026 tons/yr; organic compounds as methane 7.7 tons/day, 2811 tons/yr; H₂S 0.2 tons/day, 73 tons/yr; NH₃ 0.5 tons/day, 183 tons/yr; and gaseous fluoride 1.0 tons/day, 365 tons yr. Most of the emissions of particulate matter, organic compounds, H₂S, and NH₃ are from published emission factors or engineering estimates and most of the emissions of SO₂, NO_x, CO, and gaseous fluorides are from source test data.

A summary is presented of source tests and visible emission measurements which were cited in Technical Report: An investigation of the Best Systems of Emission Reduction for the Primary Aluminum Industry. The summary is concerned principally with tests for fluorides and visible emissions but also describes the facilities, their operating conditions, and characteristics of exhaust gas streams. Average primary outlet emissions (fluorides) for 11 primary aluminum facilities tested were: 0.0122, 0.016, 0.28, 0.405, 0.50, 0.139, 0.448, 0.51, 0.04, 0.74, and 0.31 Ibs/ton of product. Roof emissions (fluorides), secondary outlet fluorides, and visible emissions are also tabulated. Many of the tests were conducted using the Environmental Protection Agency Method 13 which will be proposed in the Federal Register at the time of proposal of the performance standards for new or substantially modified primary aluminum plants.

STATE OF ART, AND CURRENT TASKS AND PROBLEMS
OF ENVIRONMENTAL PROTECTION IN KOMAROM

COUNTY (HUNGARY). (A kornyezetvedelem helyzete, idoszeru kerdesei, feladatai, Komarom megyeben). Text in Hungarian. Tatabanyai Szenbanyak Muzaki-Kozgazdasagi Kozl., no. 2-3:55-60, April-Sept. 1974.

The state of the art of environmental pollution, as well as current achievements and tasks in environmental protection in Komarom county, the most industrialized area in Hungary, are presented. While being one of the most polluted counties in Hungary, Komarom county is in an advanced position in environmental protection, and the measures currently taken are preventive rather than reparative in nature. Dust, sulfur dioxide, fluorine, and malodorous emissions are principally responsible for air pollution. Thermal power plants, cement works, alumina factories, mines, and a vitamin B12 fermenting plant are the chief sources of pollution. A large-capacity cement work is being equipped with electrostatic precipitators for dust emission control. The malodorous substances generated in the vitamin B12 fermenting plant will be destroyed by incineration.

AIR POLLUTION IN TATABANYA AND METHOD OF AIR

POLLUTION STUDY FOR INDUSTRIAL AREAS. (Tatabanya levegoszennyezodesese es az iparvidekek levegoszennyezettsegenek vizsgalati modszerere). Text in Hungarian. Tatabanyai Szenbanyak Muszaki-Kozgazdasagi Kozl., no. 2-3:69-73, April-Sept. 1974. 15 refs.

An inventory is presented of the air pollutant emissions in the Tatabanya region, Hungary, and a general method for the study of air pollution in industrial areas is outlined. Fly ash, dust, sulfur dioxide, and fluorides are the chief pollutants emitted in this industrial area that consumes 1,160,000 tons of coal yearly. A thermal power plant, equipped with electrostatic precipitators for fly ash separation, emits fly ash and SO₂, a gaseous pollutant for whose removal there is currently no economically acceptable method available. It will be possible to abate the dust emission from a large-capacity cement works by the use of electrostatic precipitators. It was possible to reduce the SO₂ concentration peak from 5 mg/cu m to 0.3 mg/cu m by increasing the stack height from 50 m to 160 m at a power plant. This change also resulted in a shift of the site of the peak concentration to a greater distance from the emission source. The automotive exhaust-generated air pollution, though increasing, is well below the allowable level. The expansion of residential areas with long-distance heating systems is a valuable contribution to air pollution abatement. The expectable ground-level concentrations can be estimated from the pollutant discharge on the basis of wind speed and wind direction distribution.

VENTILATION OF ALUMINUM ELECTROLYSIS SHOPS.
(Provetrivaniye tsekhov elektroliza alyuminiya). Text in Russian.
Bezop. Tr. Prom., no. 11:37-38, 1972.

Problems of ventilation and air pollution control in aluminum electrolysis shops are described. In one electrolysis shop, the air discharged contains 2.1 mg fluorides, including 0.7 mg hydrofluoric acid per cu m. Ventilation due to the heat released by the electrolyzers is insufficient as it is controlled mostly by the wind with the aeration pressure not exceeding 0.5 mm of water column. Therefore, mechanical ventilation, especially exhaust ventilation, must be provided for along with conditioning of the incoming air and purification of the exhaust.

BACKGROUND INFORMATION FOR STANDARDS OF PER-
FORMANCE: PRIMARY ALUMINUM INDUSTRY. VOLUME

1: PROPOSED STANDARDS. Rept. EPA-450/2-74-020a, 122p.,
Oct. 1974. 13 refs. NTIS: PB 237612/AS

The proposed standards of performance for primary aluminum plants and the rationale for the degree of control selected are described. Analytical methods for sampling emissions and the environmental and economic impact of the standards are discussed. During initial plant surveys, source measurements, and a later visit to Norway, seven primary aluminum reduction plants were observed to have visible emissions of about 10% opacity or less; four with dry control systems had no visible emissions. One domestic carbon anode bake plant had visible emissions of less than 20% opacity; another domestic plant had 10%. The Norwegian anode bake plant had about 10%. The primary standard was based on primary emissions which averaged less than 0.5 Ibs TF/TAP (total fluoride/ton of aluminum produced) which were achieved on four plants; one foreign plant reported primary emissions of less than 0.5 Ib TF/TAP. Three of the six tests of secondary systems showed average emissions of less than 1.25 TF/TAP, including two plants with elaborate sampling and flow measurement devices. Based on an assumed fluoride control efficiency of only 90%, emissions from carbon bake plants can be controlled to below 0.20 Ib TF/TCAP. Data were obtained from plants in which the collection systems were upgraded and control systems retrofitted to an existing plant. New plants should easily be able to achieve the recommended standard of performance. The economic impact upon the domestic primary aluminum industry of the standards is not considered to be adverse. The economic impact would be adverse if more stringent standards were to be imposed upon the industry. The proposed standard of 2.0 Ib/TF/TAP is supported by measurement of emissions from potrooms. Control technology for anode bake plants is available to achieve 0.20 Ib TF/TCAP. The standard will require installation and proper maintenance of equipment representative of the best technology which has been demonstrated for the industry. (Author summary modified)

SELENIUM, FLUORINE, AND ARSENIC IN SURFICIAL MATERIALS OF THE CONTERMINOUS UNITED STATES.

U. S. Geol. Surv. Circ., no. 692: 1-14, 1974. 33 refs.

Concentrations of selenium, fluorine, and arsenic in 912, 911, and 910 samples, respectively, of soils and other regoliths from sites approximately 50 miles apart throughout the U. S. are represented on maps by symbols showing five ranges of values. Histograms of the concentrations of these elements are also given. The geometric mean concentrations in the samples are 0.31, 0.25, and 0.39 ppm selenium for the entire U. S., the western U. S., and the eastern U. S., respectively; 180, 250, and 115 ppm fluorine, respectively; and 5.8, 6.1, and 5.4 ppm arsenic, respectively. Selenium in soils may be derived from parent material weathered from the underlying rock, from wind- or water-deposited seleniferous materials, from ground or surface water by precipitation, from volcanic emanations brought down by rain, and from sediments derived from mining operations. Fluorine is added to soils from atmospheric fallout from industrial activity, by volcanic ejecta, or by the application of phosphate fertilizers and other fertilizers containing slag. Arsenic in soils can result from agricultural practices, industrial operations, burning of coal ash containing As, smelters, and arsenic insecticides. The analytical methods used to determine selenium, fluorine, and arsenic were X-ray fluorescence, fluoride specific-ion electrode, and spectrophotometric-isotope dilution methods, respectively. FLUORIDE IN THE ENVIRONMENT. Fluoride Quart. Repts., 7(4):220-222, Oct. 1974. 3 refs. (Presented at the Sth I.S.F.R. Conference, April 8-11, 1973.)

Preliminary data on determinations of fluoride in tobacco, detergents and other cleaning materials, certain kinds of dusts (wood, steel, fiberglass, and asbestos), pollen grains, and fertilizers are presented. The data concern mainly items to which one is exposed occupationally. Relatively large amounts of fluoride are found in fiberglass and its presence could be a factor in the irritating action of fiberglass on the mucous lining of the upper respiratory tract. Fluoride contained in steel dust is not likely to induce symptoms in humans, though fluoride might conceivably influence the production of red lung which is primarily caused by airborne iron oxide. Similarly, the presence of fluoride in asbestos might be a factor in the action of asbestos bodies in the lungs. Fluoride is present in minute quantities in pollen grains (approximately 3 ppm); not much pollen is likely to reach the lower air ways due to the size of the pollen (20-60 microns). Fluorides in detergents can reach certain food products when food-handling containers are not sufficiently rinsed. A person who smokes 50 cigarettes per day is estimated to inhale approximately 0.8 mg fluoride as compared to the 8-hour maximum allowable concentration values of 2.5 mg/cu m. Most occupational diseases are aggravated by smoking and even relatively minute amounts of tobacco smoke may, under certain conditions, contribute to respiratory illness.

Vogl, J.

THE EMISSION INVENTORY AND THE NECESSITY OF DETERMINING THE EMISSIONS SPECIFIC TO VARIOUS INDUSTRIAL BRANCHES AND PRODUCTION PROCESSES.

(Das Emissionskataster und die Notwendigkeit der Ermittlung branchen- und produktionspezifischer Emissionen). Text in German. Gesundh.-Ingr., 95(9):251-253, 1974. (Paper presented at the second Symposium on Branch-specific Emissions, Fluorine Emissions by Brick Kilns, Munich, Germany, Feb. 1, 1974.)

In order to gain information on the air quality of a certain area

a detailed emission inventory is required for which extensive data on the spatial distribution as well as size and type of single emission sources must be gathered. Although collection of these data has begun in Bavaria it is reckoned, that it will take several years to complete the emission inventory. For this reason, available sources of information as well as model calculations and approximations have to be used for working out the planned emission protection program. The emission inventory must include the emission sources such as industries, fossil and nuclear fuel-operated power production plants, domestic heaters, and automobiles. For determining the emissions by industrial production facilities existing statistical data such as density of industries in the area and throughput must be used, which is risky with regard to accuracy. The inaccuracy can be reduced somewhat if a differentiation of the various production processes is introduced. The the creation of the emission protection program in Bavaria only sulfur dioxide, oxides of nitrogen, hydrocarbons, carbon monoxide, hydrogen fluoride, and dusts are taken into account. For better comparison of the pollution in various regions an evaluating scheme on the basis of an emission matrix was used which groups the various emission sources according to type and quantity of emitted pollutants into four categories and with which the emissions by each individual industrial branch can be determined.

CHARACTERIZATION OF AIR POLLUTANTS EMITTED
FROM BRICK PLANT KILNS. Preprint, Environmental Protection Agency, Research Triangle Park, N. C., Particulate and Chemical Processes Branch, 15p., 1973 (?). 15 refs.
Stack gases analyses and emission factors were obtained for four brick plants selected as extreme cases of pollutant emitters. Each of the four plants used tunnel kilns fired with natural gas. Average stack gas concentrations for the four plants ranged from 32.0-359 mg/cu m for nitrogen oxides, 121-2690 mg/cu m for sulfur dioxide, 17.9-71.8 mg/cu m for sulfur trioxide, 31.7-162 mg/cu m for fluorides, 2.1-13 mg/cu m for chlorine, and 8-56 mg/cu m for particulates. Chemical analyses of plume particulates presenting visible emissions (opacities as high as 15%) identified the particulate emissions as mixtures of ammonium bisulfate and ammonium sulfate. Emission factors for the four plants ranged from 157-2668 mg/kg brick for sulfur dioxide, 22.5-99.4 mg/kg for sulfur trioxide, 79.9-549 mg/kg for fluorides, and 113-501 mg/kg for chlorine. These factors were computed from chemical analyses of raw and fired materials rather than from the stack analyses and production rates.

ENVIRONMENTAL POLLUTION BY CONVENTIONAL
POWER PLANTS. AIR POLLUTION CAUSED BY CONVENTIONAL
POWER PLANT EMISSIONS. (Umweltbelastung
durch konventionelle Kraftwerke. Die Luftbelastung durch
Emissionen konventioneller Kraftwerke). Text in German.
Strahlenschutz Forsch. Prax., vol. 12:67-76, 1973. (Presented at
the Association of German Radiation Protection Physicians and
<xref image="2000WVBP.TIF|V3|2006:09:28:01:19:56.00|122788|0"> image: </xref>

the Association for Radiation and Environmental Research, 12th Conference, Munich and Neuherberg, West Germany, Oct. 8-9, 1971.)

Data on the contribution of conventional thermal power plants to air pollution is presented. Particulate matter, sulfur dioxide, sulfur trioxide, gaseous fluorine compounds, carbon monoxide, nitric oxide, nitrogen dioxide, and gaseous organic compounds are the chief pollutants emitted by combustion equipment firing fossil fuel. Assuming that no improved emission control measures relative to the current practice will be implemented, the particulate emission is expected to increase by 13% in the 1970-1980 period in West Germany, and increase by 22% for sulfur oxides, 18% for fluorine compounds, 34% for nitrogen oxides, 35% for CO, and 13% for organic compounds. Stationary combustion equipment is responsible for some 88% of the total SO₂ emission in West Germany and power plants are responsible for 70% of all fluorine emissions. The CO and organic emissions by power plants are not significant relative to those generated by automobiles and other industries. The specific pollutant emission is highest for soft coal-fired power plants.

Engineering-Science, Inc., McLean, Va.
AIR POLLUTION EMISSION TEST. U.S.S. AGRI-CHEMICALS. NASHVILLE, TENNESSEE. Office of Air Programs
Contract 68-02-0225, Task 15, Rept. 73-FRT-7, 26p., Nov. 1974.

Source emission tests were conducted at the U.S.S. Agri-Chemical phosphate fertilizer plant in Nashville, Tennessee during the week of May 21, 1973 to provide data for establishing Federal emission standards for new sources in the phosphate fertilizer industry under Section 111 of the Clean Air Act of 1970. The methods used and results obtained in the test series are described. Twelve samples were obtained for each of the following emissions: particulates, ammonia, and total fluorides. Samples were obtained from the dryer kiln/cooler baghouse and from the ammoniator scrubber. Simultaneous sampling of both the inlet and outlet gas streams of each control device was conducted. In addition to these gas stream samples, grab samples of scrubber liquid, phosphate rock, and granulated fertilizer product were periodically taken. The sampling and analytical procedures, process operation, location of sampling ports, and test results are described.

FLUORIDE EMISSIONS FROM TREATMENT OF NATURAL PHOSPHATES IN THE PRODUCTION OF FERTILIZER.
Fluoride Quart. Repts., 8(1):25-33, Jan. 1975. 6 refs.
Emissions from a fertilizer plant manufacturing super, triple, binary MAP and DAP and NPK fertilizer are discussed. The total fluoride emission corresponds to a mean of 100 kg of fluoride/day. The levels of fluoride in the environment were determined during a period of 2 yr at four sampling points situated within a radius of about 1 km from the facility. The values obtained varied between 0 and 10 micron fluoride/cu m. The mean value was close to 2 micron/cu m in total fluoride. Dust analysis in the immediate vicinity showed that about 40% of the collected dust contained apatite derived essentially from the unloading of the minerals. This much fluoride pollution caused necrosis in plants. Fluoride ion ranging from 10 to 200 ppm was found in 50 specimens of sensitive plants. Fluoride ion emission limits are proposed for agricultural areas 1, 2, 3, 5, and 4.5 ppb for periods of 1 mo, 1 wk, 24 hr, and 12 hr, respectively.

Bethea, Robert M.
INTERRELATIONSHIPS BETWEEN AGRICULTURE AND AIR POLLUTION. Air Pollution Control Assoc., Pittsburgh, Pa., Southern Section and Technical Council, Control Technol.

Agric. Air Pollut., Memphis, Tenn., 1974, p. 1-15. 31 refs.
(March 18-19.)

An overview of the interrelationships between agriculture and air pollution is presented. Agricultural sources of particulate and gaseous air pollutants include: rendering operations (odors), confined feeding areas (odorous animal wastes), cotton ginning (particulates), and feed production (particulates). The odor-causing pollutants consist of such compounds as sulfides, mercaptans, ammonia, ketones, and organic acids. Potential control routes for agricultural emissions include: scrubbing processes, incineration, particulate collection with devices such as cyclones or fabric filters, and proper maintenance of agricultural operations. Air pollutants affecting agricultural operations (plants, animals, and agricultural workers) include: sulfur oxides, sulfates, sulfuric acid (acid rains), nitrogen oxides, fluorides, various trace metal compounds, halogens, hydrocarbons, sulfides, mercaptans, cyanides, ozone, ammonia, and halogenated hydrocarbons (e.g., pesticides).

Heggstad, H. E.

AIR POLLUTANTS FROM, AND EFFECTS ON, AGRICULTURE. Air Pollution Control Assoc., Pittsburgh, Pa., Southern Section and Technical Council, Control Technol., Agric. Air Pollut., Memphis, Tenn., 1974, p. 170-177. 8 refs. (March 18-19.)

An overview of the problem of air pollution generation from agriculture and the effects of air pollutants on agricultural activities is presented. The most important air pollutants generated from agricultural operations include: pesticides, dust, smoke from open burning, allergens, odors, and volatilized nitrogen products. Volatilization is a major pathway for the escape of many gaseous pollutants from farm areas. Compared to the effects of air pollutants from transportation, stationary sources, and industry, air pollutants from agricultural processes has relatively little impact on the crops. Over 80% of agricultural losses due to air pollution are caused by photochemical oxidants. Sulfur dioxide is the most important air pollutant affecting vegetation from a point source. Fluoride injury to vegetation is important in localized areas and is responsible for fluorosis in sheep and cattle.

HAZARDS DUE TO GASES, VAPORS, AND SMOKES.

(Gefahren durch Gase, Daempfe, Rauche). Text in German. Schweisstechnik (Vienna), 28(11):228-230, 1974.

Harmful emissions generated during welding operations and appropriate protective measures are described. Arc-welding operations are accompanied by iron oxide, manganese oxide, silica, calcia, and fluoride emissions, depending on the type of the wire used. Smoke generated during arc-welding contains 30-40% iron oxides, 24-26% silica, 7-25% manganese oxides, 15% calcia, and 22% fluorides. In addition, lead and zinc emissions can be generated when welding is performed on surfaces with lead- and zinc-containing finishes. Inhaled iron oxides may cause siderosis and hemosiderosis, while manganese oxides may cause pneumonia and lesions of the nervous system. No free crystalline silica is generated by arc-welding. Shielded arc welding operations generate metal vapors, ozone, nitrous
<xref image="2000WVBQ.TIF|V3|2006:09:28:01:20:00.00|119228|0"> image: </xref>

A. EMISSION SOURCES

63

gases, and fluorides. Carbon dioxide used as a protective gas may form carbon monoxide at high temperature. While CO₂, either as a protective gas or as a combustion product is harmless, it may be hazardous especially in limited spaces by displacing air. Periodic ventilation is necessary during welding operations, and local exhaust systems are required for welding in limited spaces, such as in tanks, to prevent the accumulation of poisonous gases such as CO, nitrogen oxides, and ozone.

REFUSE COMPOST PLANTS: REFUSE COMPOSITION AND
 EMISSIONS FROM INCINERATORS FOR RESIDUAL

MATTER. (Ergebnisse von Muelluntersuchungen und Emission-
 smessungen a Resteverbrennungsanlagen in Muellkompostwer-
 ken). Text in German. Umwelthygiene, 25(12):273-277, 1974. 5
 refs.

Trash composting plants yield residual matter which may reach up to 20% of the composted trash. This residual matter must be either tipped or incinerated. It contains a high amount of plastics which raises the hydrogen chloride emission in incinerators. However, in most cases the residues from trash composting are incinerated together with bulky refuse and industrial waste products so that about the same HCl content has been measured in these special incinerators as in large trash incinerators. The hydrogen fluoride emission was higher in incinerators for composting residues than in normal trash incinerators, which was due to the higher heating value of this matter. The dust removal problem of incinerators for composting residues is identical with that of large trash incinerators. Through installation of electrostatic precipitators the emission limit of 100 mg/cu m (referred to an oxygen content of the waste gas of 11%) can be met. Venturi scrubbers are usually installed for the reduction of HCl and HF emissions. The cleaned gases contained on the average less than 2 mg HF/cu m and less than 100 mg HCl/cu m.

RELATIONSHIPS OF ENVIRONMENTAL PROTECTION

AND PUBLIC HYGIENE. (A kornyezetvedelem es kozegesz-
 segugy osszefuggesei). Text in Hungarian. Tatabanyai Szen-
 banyak Muszaki-Kozgazdasagi Kozl., 14(2-3):89-92, April-Sept.
 1974. 11 refs.

General environmental and hygienic problems of the highly urbanized and industrialized Komarom County in Hungary are described. Industries, mining, power plants, and domestic heating are responsible for very high pollution levels, making this county the most polluted one in the entire country. Air pollution due to settling dust, sulfur dioxide, and fluorides is most problematic, and the situation is aggravated by the promiscuously intertwined industrial and residential areas. The incidence of respiratory tract diseases is highest in this county.

INVESTIGATION OF NOX AND OTHER POLLUTANTS
 EMITTED FROM STATIONARY SOURCES, IV: ELECTRIC

ORE FURNACE. (Kotei hasseigen kara hassei suru chisso
 sankabutsu nado osen bushitsu chosa. (IV) Denkiro). Text in
 Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution),
 9(2):409, Nov. 1974. (Presented at the National Air Pollution
 Research Conference, 15th, Chiba, Japan, Nov. 6-8, 1974, Paper
 260.)

The emission of nitrogen oxides, total hydrocarbons, dust, and hydrogen fluoride from electric ore furnaces was measured. In the case of small scale electric ore furnaces (less than 10 tons/ch), the NO_x concentration was less than 2-10 ppm, total emission quantity was less than 0.1 N cu m/hr, and eF was about 0.096 kg/ton. As for the medium scale furnace (10-30

tons/ch), the NOX concentration increased to 200-300 ppm instantaneously at arcing; however, the average concentration was several ppm, total emission quantity was 0.2-0.3 N cu m/hr, and eF was about 0.033 kg/ton. In the case of large scale furnaces (over 30 tons/ch), the occurrence frequency of instantaneous high NOx concentration (400 ppm) was increased. The average concentration was less than 20 ppm, total emission quantity was 0.7-1.7 N cu m/hr, and eF was about 0.016 kg/ton. The inlet dust concentration was as high as 14-0.4 kg/N cu m, but can be treated effectively by the use of a local hood or direct suction dust collector. The eF was about 2.1-56.9 kg/ton. The total HC emission increased instantaneously at ignition. The average concentration was 2-3 ppm, and eF was about 0.004 kg/ton. The HF measured after the addition of fluorspar showed no sign of HF emission. The variation in NOx dust concentration in one cycle of operation was also measured.

72133

Grimbergen, M. van, G. Reybroeck, and H. van de Voorde
AIR POLLUTION DUE TO THE BURNING OF THERMOPLASTICS II. (Luftverunreinigung, verursacht durch die Verbrennung von Kunststoffen II). Text in German. Zentralbl. Bakteriologie, Hygiene, Infektionskrankheiten, Abteilung B, 160(2):139-147, 1975. 14 refs.

Thirteen chemically pure polymers were burnt in an electric oven to determine the level of solid and gaseous air pollution caused by their stack gases. All 13 polymers are highly combustible but require different burning temperatures (300-900 C) in order to be burnt completely. With the exception of polymethylmethacrylate (PMMA) and polytetrafluoroethylene (PTFE), all plastics leave a very heavy tar and soot deposit after burning. Burning at low temperature (300 C) gives rise to high concentrations of aliphatic aldehydes. The pH of the exhaust gases, dissolved in water, is neutral to strong acid (PTFE) and will cause severe corrosion. The nitrogen-containing polymers pollute by forming cyanides, nitrogen oxides, and ammonia. High concentrations of fluoride are given off by PTFE, PMMA decomposes in its monomer methylmethacrylate and forms large amounts of aliphatic aldehydes, while ABS (acrylonitrile-butadiene-styrene) and SBR (styrene-butadiene-rubber) cause styrene pollution.

Hall, H. J., G. M. Varga, and E. M. Magee
TRACE ELEMENTS AND POTENTIAL POLLUTANT EFFECTS IN FOSSIL FUELS. In: Symposium Proceedings: Environmental Aspects of Fuel Conversion Technology (May 1974, St. Louis, Missouri). Research Triangle Institute, Research Triangle Park, N. C., Environmental Protection Agency Contract 68-02-1325, Task 6, Program Element 1AB013, Rept. EPA-650/2-74-118, ROAP 21 ADD, 21AFJ, p. 35-47, Oct. 1974.

Trace elements in coal and their potential pollutant effects are discussed. Many elements are present at about 1-100 ppm in all regions, and vary by a factor of 3 or less in the averages for different basins or areas. The usual amount of some 20 trace elements measured is about 5-10 ppm. Boron and fluorine are higher, at about 50 to 200 ppm; mercury is lower, about 0.01 to 0.5 ppm. The volatile hazardous elements show the most need for more data. Some or all of these may be related to mineral deposits (beryllium, fluorine, arsenic, seleni-
<xref image="2000WVBR.TIF|V3|2006:09:28:01:20:04.00|120210|0"> image: </xref>

urn, cadmium, mercury, and lead). The hazard of Hg in power plant emissions, in particular, has been grossly exaggerated. Most elements in coal are very close to their crustal abundance, and are not considered toxic at this level. The question of toxicity must be evaluated in relation to actual amounts. The selection of a completely nonpolluting coal is not possible. For a given amount of ash, coals which are low in any one group of elements must be correspondingly high in others. The definition of nonpolluting depends directly on the decision as to which elements are of concern, and which are not. (Author conclusions modified)

Descroix, P.

EFFECT OF AIR POLLUTION ON WATER POLLUTION IN

FRANCE. (L'influence de la pollution atmosphérique sur la pollution de l'eau en France). Text in French. Tech. Sci. Mimic. Rev. Eau, 70(3):127-129, March 1975. 4 refs.

Studies and measurements on water pollution caused by air pollution in France are reviewed. Systematic precipitation pH measurements in and around Paris show an increasing acidification of the precipitation during the last years. However, the acid precipitation is readily neutralized in the sewer system and in the rivers. Vanadium, present in coal and petroleum products, is emitted into the air in detectable quantities, but it is readily and rapidly eliminated from water by spontaneous precipitation and flocculation. Wastewater from flue gas scrubbers in phosphoric acid and superphosphate production plants can be contaminated by large concentrations of fluorine, which represents water contamination hazards.

Heimler, Bo

WASTE INCINERATION. ASSESSMENT OF SAVENAS INCINERATOR PLANT WITH RESPECT TO WASTES, FLUE GASES, ASHES, AND SLAG DURING THE JUNE 1973 -

MAY 1974 PERIOD. (Avfallsförbränning. En kartering av Savenas Förbränningsanläggning med avseende på avfall, rökgas, aska och slag under tiden Juni 1973 - Maj 1974). Text in Swedish. IVL Swedish Water and Air Pollution Research Laboratory, Stockholm (Sweden), Göteborg Municipal Public Health Board and State Environmental Protection Administration Contract 7-172/72, 46p., Sept. 1974.

Complex assessment of the Savenas waste incinerator plant, Sweden, is presented with respect to the composition of the wastes, flue gas, dust emissions, slag, and water pollution during the June 1973 - May 1974 period. The incinerator temperature ranges from 900 to 1000 C. The flue gases are cooled to about 300 C during heat generation, and pass through an electrostatic precipitator and multicyclone for dust separation, after which they are discharged through a 120-meter high stack. The residual dust concentration in the cleaned gas, standardized for dry gas and 10% carbon dioxide, averages 250 mg/cu m. The specific dust emission amounts to 14 kg/hr per furnace, and to 1.2 kg per ton of waste. The residual dust contains 0.17 mg/kg mercury, 0.82 mg/kg cadmium, 22.2 mg/kg lead, 96.1 mg/kg zinc, 1.6 mg/kg manganese, 1.1 mg/kg copper, 0.8 mg/kg chromium, and 0.42 mg/kg nickel. Some 45-55% of the residual dust was larger than 10 micron, and about 10-15 wt% were in the over 40-micron fraction. The sulfur dioxide plus sulfur trioxide, hydrochloric acid, hydrofluoric acid, oxides of nitrogen, and mercury vapor concentrations in the flue gases averaged 223 mg/cu m, 890 mg/cu m, 7.7 mg/cu m, 29 mg/cu m, 76 mg/cu m, and 383 mg/cu m, respectively.

STUDIES ON ENVIRONMENTAL POLLUTION BY FLUORIDE. II. DETERMINATION OF FLUORIDE IN SOIL.

(Fukka butsu ni yoru kankyo osen ni kansuru kenkyu. Dai 2-ho. Dojo chu fusso no teiryō ho no kento). Text in Japanese. Eisei

Kagaku (J. Hyg. Chem.), 21(2):89-92, 1975. 20 refs.
The determination of fluorine in soil by a fusion and distillation technique is described along with measurements near an aluminum smelting plant. The final determination of fluoride ion in the distillate was made the Alizarin-Lanthanum complexation or the Thorium Neothorium Method. Sodium carbonate and zinc oxide were used for the fusion of the soil sample, and nearly 100% fluorine recovery was obtained by the fusion of 1:2:3 (weight/weight) mixture of soil sample, sodium carbonate, and zinc oxide, respectively, at a fusion temperature between 600 and 1000 C. The recovery showed good repeatability. The fused material was then suspended with sulfuric acid solution and distilled. If the distillation was made a temperature between 135 and 145 C which gave a sulfate ion concentration less than 100 ppm in the distillate both the Alizarin-Lanthanum Complexation and the Thorium Neothorium method could be used to determine the fluoride ion in the distillate without interference. Soil samples collected around an aluminum smelting plant showed decreasing fluorine levels at increasing distances from the plant. The fluorine levels were 435 ppm, 322 ppm, and 146 ppm for soil samples collected that 1.5 km, 3.5 km, and 5.0 km, respectively, from the plant.

CAPTURE AND ANALYSIS OF GASEOUS FLUORIDE
EMITTED FROM ALUMINUM REDUCTION CELLS. Aluminum, 51(4):284-288, 1975. 4 refs.
The development of an experimental instrument to monitor both low concentrations of fluoride in effluent gases from the Alcoa 398 fume recovery system and higher concentrations at the inlet of the Alcoa 398 process is described. Gaseous fluoride was removed from the effluent gas sample stream with a unique, continuous aerosol gas scrubber. A fluoride-selective electrode continuously measured the fluoride concentration in the scrubber solution with a permanent record obtained with a strip chart recorder. While testing the efficiency of the Alcoa 398 process, it was found that the gaseous fluoride content of the fluidized alumina bed varied over a large concentration range with time, increasing during crust breaking, anode setting, and metal tapping. The reserve capacity of the Alcoa 398 fume recovery system was able to accommodate large changes in load. Scrubbing efficiencies, the magnitude and duration of the concentration excursions, at the inlet of the Alcoa process, and specific implications for various dry scrubbing fume recovery systems are described.

TRACE POLLUTANT EMISSIONS FROM THE
PROCESSING OF NON-METALLIC ORES (FINAL REPORT).

PEDCo Environmental Specialists, Inc., Cincinnati, Ohio, Environmental Protection Agency Contract 68-02-1321, Program Element 1AB01S, Task 4, ROAP 21AUZ-02a, Rept. EPA-650/2-74-122, 277p., Nov. 1974. 99 refs. NTIS: PB 240117/AS

Significant sources of emissions of potentially hazardous trace pollutants from the mining and processing of non-metallic minerals are identified. Process flow diagrams identifying major processes and material flow as well as pollutant emission sources are provided for operations dealing with cement, clay (including porcelain, refractory, and brick), gypsum, lime, phosphate rock (including fertilizer), potash, boron, mica, and fluorspar. The following processes are recommended for further evaluation because of their potential for emissions of hazardous pollutants or fugitive dust: cement and lime kilns, phosphate rock mining and washing, clay mining, and wet-process as well as thermal phosphoric acid production. Pollutants identified included: fluorides, phosphoric acid mist, carbon dioxide, various metal compounds, fly ash, sulfur dioxide, sulfur trioxide, sulfates, and alkali chlorides.

FLUORIDE EMISSIONS FROM PHOSPHORIC ACID PLANT
GYPSUM PONDS (FINAL REPORT). North Carolina State Univ., Raleigh, Environmental Protection Agency Grant R-800950, Program Element 1AB01S, ROAP 21AFA-07S, Rept. EPA-650/2-74-095, 323p., Oct. 1974. 29 refs. NTIS: PB 241144/AS

Fluoride emissions from gypsum ponds receiving process water from wet-process phosphoric acid plants were measured, and computer simulations of pond emissions and ambient air concentrations were developed. Measured ambient air fluorine concentrations for 95 usable samples obtained at two pond sites ranged from 00000015 to 00000415 moles/cu m. Emission estimates developed from the pond-to-air mass transfer coefficient and the vapor pressure of fluorine over pond water were used along with a standard atmospheric pollutant dispersion model to predict ambient fluorine concentrations. A comparison of the predicted fluorine values with measured fluorine values demonstrated the validity of the emission estimates.

AIR POLLUTION EMISSION TEST. COLORADO FUEL AND IRON. Rept. 75-SEV-5, 71p., Feb. 1976. 4 refs.
Emissions tests were performed at the outlet of an electrostatic precipitator serving the Colorado Fuel and Iron Steel Corporation sintering process in Pueblo, Colorado to obtain data for the development of New Source Performance Stan-

dards. The paniculate emission rate averaged 174.2 kg/hr, and the process basis emission rate was 0.481 kg/million tons of feed. The average fluoride emission rate was 3.85 kg/hr. Very few of the 6-minute average opacity readings were greater than 20%. High readings at the precipitator outlet were noted, however, following periodic rapping of the collecting plates.

AIR POLLUTION EMISSION TEST. SINTER PLANT GRANITE CITY STEEL DIVISION NATIONAL STEEL CORPORATION GRANITE CITY, ILLINOIS (VOLUMES I AND II). Clayton Environmental Consultants, Inc., Southfield, Mich. and York Research Corp., Stamford, Conn., Environmental Protection Agency Contracts 68-02-1408 and 68-02-1401, Tasks 16 and 19, Rept. 75SIN4, Y-8479-19, ISlp., 1975. 2 refs. The emissions from the Granite City Steel sintering facility at Granite City, Illinois were documented. The efficiency of the high energy venturi scrubber used to control emissions was tested. Paniculate, fluoride, hydrocarbon, sulfur oxides, and carbon monoxide were sampled. A trend in opacity decrease occurs as measured total paniculate concentrations decrease. Particle size tests were also performed at the inlet and outlet of the scrubber. A majority of the incoming particles, 52.9%, are less than 1.0 micron in size and of the total paniculate entering the scrubber, 30.6% is above 6.7 micron in size. At the outlet, 93.7% of the particles are below 1.0 micron in size and 1.8% of the particles are above 6.8 micron in size. The average inlet and outlet paniculate concentrations were 0.1599 g/SCFD and 0.01673 g/SCFD, respectively. The inlet concentration ranged from 0.1065 g/SCFD to 0.1887 g/SCFD, while the outlet varied from 0.01673 to 0.01720. (Author abstract modified)

Kumamoto Prefectural Government (Japan)

AUTOMOBILE EMISSION GAS. (Jidosha haishul.su gasu).

Text in Japanese. In: Environmental White Paper in 1974, p. 34-54, June 1975.

Data on automotive exhaust emissions, concentrations of carbon monoxide, nitrogen dioxide, hydrocarbons, oxidant, and particulates, traffic volume, meteorological factors and the results of panaculate composition measured at eight busy inter-sections in three cities in Kumamoto during 1973 were compiled and analyzed. A comparison to 1972 data indicates that pollutant concentrations have generally increased; however, the air pollution problems due to automotive exhaust emissions were not greatly aggravated. Data concerning the registration of flue gas emission sources in compliance with the regulation are compiled and classified by the type of facilities. Air pollution control measures taken in Kumamoto are discussed, and a description of the monitoring system for sedimented dust, sulfur oxides, suspended particulates, and fluorine, and the air pollution emergency procedures are given, with maps of measurement points.

PHYSICO-CHEMICAL INVESTIGATION OF DUST

GENERATED IN DEFLUORINATED PHOSPHATE PRODUCTION

FROM KARATAU PHOSPHORITES. (Fiziko-

khimicheskie issledovaniya pyley, obrazuyushchikhsya pri proizvodstve obesftorennogo fosfata iz fosforitov (Karatu). Text in Russian. Izv. Akad. Nauk Kaz. SSR, Ser. Khim., no. 3:1-5, May-June 1975. 6 refs.

The behavior of dusts separated in electrostatic precipitators in the defluorinated phosphate production from Karatau phosphorites during heating in the 100-1300 C temperature range was studied under laboratory conditions. Heating in the 100-700 C temperature interval caused weight losses ranging from 1 to 13%, depending on the chemical composition of the dust. About 30 to 70% of the fluorine was liberated at temperatures of up to 600 C due to the decomposition of the fluorosilicates. A further increase of the temperature to 1300 C led to an increase in the defluorination rate to 70-95% only in the presence of water vapor. At temperatures over 900 C, potassium compounds volatilized at a rate of 40-60%, while other alkali metal compounds were not affected.

WET PROCESS ACID PLANT WASTEWATER PONDS, AN

ATMOSPHERIC FLUORIDE POLLUTION PROBLEM?

Preprint, FMC Corp., Philadelphia, Pa., and North State Univ., Raleigh, N. C., 18p., July 1975. 7 refs.

A method for estimating the volatile fluorine emissions from phosphoric acid plant waste water ponds was developed and verified by actual downwind measurements. Fluorine emission rates for two actual ponds were estimated from a knowledge of the fluorine concentration and water temperature of the

ponds and atmospheric conditions at the ponds. These emission estimates were then entered into a standard atmospheric dispersion model which predicted ambient air fluorine concentrations downwind of the two ponds. None of the estimates were significantly different from the measured values at the 95% confidence level.

TRACE ELEMENT CONTENT IN SOFT COALS AND IN
THEIR DUSTS. (Ueber Spurenelementgehalte in Steinkohlen
und den daraus entstehenden Reingasstaeben). Text in German.
VGB Kraftwerkstechnik, 55(10):672-676, Oct. 1975.
Twenty-six different coals and dust samples emitted during
their combustion were analyzed for 26 elements. The silver,
beryllium, bismuth, cadmium, mercury, iodine, tin, selenium,
tellurium, tantalum, and tungsten contents in anhydrous coal
were below 10 ppm, while the contents of another 7 elements
(arsenic, boron, cobalt, chromium, copper, molybdenum, and
nickel) were below 100 ppm, averaging below 50 ppm. The
barium, fluorine, phosphorus, lead, strontium, vanadium, and
zinc contents were between 50 ppm and 400 ppm. The silver,
beryllium, bismuth, cadmium, mercury, iodine, thallium, tan-
talum, uranium and tungsten contents in the emitted dust were
below 50 ppm, and the arsenic, boron, cobalt, copper, molyb-
denum, tin, and selenium contents averaged between 100 and
500 ppm. The barium, chromium, fluorine, nickel, phosphorus,
lead, strontium, vanadium, and zinc contents were between
500 and 3000 ppm. Phosphorus contents of up to 14,000 ppm
were measured.

FLUORIDE IN CERAMIC MATERIALS AND FUELS--
MATERIAL MEASURES FOR PREVENTION OF FLUORIDE
EMISSIONS (FINAL REPORT). (Fluor in keramischen Materi-
alien und in Brennstoffen. Stoffliche Massnahmen zur Ver-
meidung von Fluor-Emissionen). (Schluss). Text in German.
Ziegelind. (Weisbaden), (5):210-216, 1974.
Fluoride emissions from the big ceramics industry are
described, and prevention methods of fluoride emissions are
discussed. After describing the properties of fluoride and its
compounds, the effect of fluoride emissions is analyzed. After
presenting measurement methods for fluoride emissions, the
emissions in the earthenware industry are described. Fluoride
appears in ceramics raw materials in various quantities, de-
pending upon the quality of the minerals and the properties of
the compounds. The alloys used and the quality of the fuel
also significantly influence the fluoride emissions. The type of
ovens and chimneys also play an important role, including
oven atmosphere, duration of combustion, and combustion
temperature. Recommendations are made based on literature
and the research results of the Institute for Bricks Research
for decrease of fluoride emissions. They concern fuel quantity,

GAS AND DUST EMISSIONS FROM SUGAR FACTORIES - TECHNICAL POSSIBILITIES OF REDUCING EMISSIONS WITH REFERENCE TO LOCAL AUTHORITY REGULATIONS. (Ges-und Staubemissionen von Zuckerfabriken - Technische Moeglichkeiten zur Emissionsminderung unter Beruecksichtigung der behoerdlichen Vorschriften). Text in German. Zucker, 28(9):491-498, Sept. 1975.

Emissions from sugar factories are grouped under gaseous and dust-type emissions. Main emission sources are the boiler plant and pulp dryer. The various levels and causes of dust emissions from solid fuel and oil firing are described. Gaseous emissions include sulfur oxides, nitrogen oxides, fluorine, and to a certain extent, hydrocarbons (odor emissions). Noxious gaseous emissions are indicated for a model factory with a beet-slicing capacity of 5000 tons/day. The effect of fuel, type of firing and operation is demonstrated. The technical possibilities of reducing emissions are tied up with legal requirements. Gaseous emissions cannot in practice be reduced by technical processes. Suitably high stacks must be erected for the distribution of emissions. With regard to sulfur dioxide, improvements can be made by fuel desulfurization. Dust emissions from pulp drying can be kept within reasonable limits by multi-cyclones.

FLUE GAS INVESTIGATION. (Endo haishutsu gasu no chosa ni tsuite). Text in Japanese. Tochigi-ken Kogai Kenkyusho Nenpo (Annu. Rep. Tochigi Prefect. Res. Inst. Environ. Pollut.), no. 1:91, Jan. 1975.

The flue gas pollution by 109 facilities at 100 factories were investigated and three years of measurement results from 1971 through 1973 summarized for the flue gas emission rate, amount of soot, sulfur oxides, fluoride, chloride, hydrogen chloride, and nitrogen oxides pollutions. The facilities included were 36 boilers, 3 heating furnaces, 20 dissolution furnaces, 16 driers, 26 sintering furnaces, and 8 others. Of the facilities investigated 35.8% (29 facilities) violated the air pollution standards either on the amount of soot or SO_x. In the facilities for driers, only one was within the standards and 15 were in violation. Of 36 boilers, 5 boilers exceeded the standards and 31 boilers were within the standards.

King, William R. and James K. Ferrell

FLUORINE EMISSIONS FROM WET PROCESS PHOSPHORIC ACID PLANT PROCESS WATER PONDS. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 17p., 1975. 8 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 68th, Boston, Mass., June 15-20, 1975, Paper 75-25.7.) Emission estimates for the release of volatile fluorine compounds from process water ponds at phosphate fertilizer plants were developed from the pond-to-air mass transfer coefficient and the vapor pressure of fluorine over pond water. The estimates were compared with measurements of ambient fluorine compound concentrations downwind of process water ponds and the estimates were found to be valid. Emissions from the ponds ranged from 0.7 to 10 lb/acre/day. The emission rate depended on pond temperature, fluorine content of the pond water, and wind speed. (Author abstract modified)

PORTSMOUTH GASEOUS DIFFUSION PLANT ENVIRONMENTAL MONITORING REPORT-1973. Goodyear Atomic Corp., Piketon, Ohio, Atomic Energy Commission Contract AT-(33-2)-1, 27p., May 3, 1974. 5 refs. NTIS: GAT-781

Emissions measurements and ambient air monitoring data for the Portsmouth Gaseous Diffusion Plant are presented. The average environmental concentrations of alpha and beta activity at those locations where the averages were the highest were 0.63% and 0.08%, respectively, of the Atomic Energy Commission's Radioactivity Concentration Guides. The highest single ambient sulfur dioxide concentration was 15% of the Federal standard. Sulfur dioxide emissions from a steam plant burning low and high sulfur coal were 1 lb/million Btu input and 3 lb/million Btu input, respectively. Particulate matter emissions for low and high sulfur coal were 0.4 and 0.2 lb/million Btu input, respectively. Ambient fluoride concentrations in the vicinity of the plant reached a maximum of 5.1 ppb. The overall yearly average of fluoride concentrations in vegetation around the plant boundaries was 6.5 micrograms/g. With the exception of particulate matter, none of the emission levels or ambient concentrations exceeded applicable standards during 1973.

RUBBER, PLASTICS AND GLASS INDUSTRIES ODORS. In: Industrial Odor Technology Assessment. Paul N. Cheremisinoff and Richard A. Young (eds.), Ann Arbor, Mich., Ann Arbor Science Publishers, Inc., 1974 (?), Chapt. 8, p. 101-115. 41 refs.

Odor problems associated with rubber, plastics, and glass industries are reviewed. Odors from the rubber and plastics industry commonly fall into the following groups: nitro compounds (amines and oxides), sulfur oxides, plasticizers, solvents, and phenols, and other alcohols). Operations in the rubber and plastics industry which generate odors include: compounding and formulation, material handling, banbury, mills, curing and vulcanizing, and forming (extruders and presses). Glass industry odors are usually associated with furnace products, mold lubrication maintenance, and coating operations. The odorous emissions include: sulfur oxides, nitrogen oxides, and halide gases. Odors generated by support operations in the glass industry include hydrofluoric acid which is used for glass etching and aromatics which are used as carriers in Teflon coating.

FLUORINE COMPOUNDS IN A SULFUR-PRODUCING INDUSTRIAL REGION. (Związki fluoru w powietrzu atmosferycznym w rejonie zaglebia siarkowego). Text in Polish. Ochrona Powietrza (Warsaw), no. 3:91-92, 1975.

Volatile fluorine compounds have a toxic effect on live organisms and constitute a serious problem in sulfur-producing regions because they frequently exceed permissible concentrations. They are emitted by plants manufacturing powdered and granular superphosphates. These fluorine gases are hydrogen fluoride (HF) and silicon tetrafluoride (SiF₄), which cause a serious irritation of the upper respiratory tract. Chronic intoxication at low concentrations is probably due to the highly toxic fluorine ion (F⁻). Fluorine and its compounds

<xref image="2000WVBV.TIF|V3|2006:09:28:01:20:18.00|116805|0"> image: </xref>

emitted with industrial waste gases can lead to fogs resulting in mass poisoning in an industrial area during adverse atmospheric conditions. Systematic investigations of atmospheric volatile fluorine compounds are therefore necessary. A method is described by which, based on collected annual data, the frequency of excessive permissible 20-min and average daily concentrations over an area of 280 sq km was statistically calculated. The former, higher than permissible concentration (0.03 mg/F/cu m) should not occur more than once a day, the latter (standard 0.01 mg F/cu m) concentration once every 10 days over a period of one year, which corresponds to 1.4% and 10%, respectively. Determination of the fluorine ion content was performed colorimetrically with alizarin and Iantan nitrate. The intensity of the color change in the solution from red to blue is proportionate to the fluorine concentration. The status of air pollution with fluorine compounds for 1972 and 1973 was established and the role of wind direction in the spread of pollution was taken into consideration for the hours of the sample taking. Evaluation of the environmental danger level led to a successful program of limiting fluorine compound emissions.

FUME COMPOSITIONS FOUND AT VARIOUS STAGES OF
ACTIVITY AT KILAUEA VOLCANO, HAWAII. J. Geophys.
Res., 80(21):2963-2966, July 20, 1975. 22 refs.
The panicle and gaseous composition of the fume cloud as it issued from an erupting volcanic vent at Mauna Ulu on the east rift zone of Kilauea Volcano, Hawaii was investigated. Similar measurements were made at Halemaumau, the summit crater of Kilauea, during non-eruptive periods from nearby fissures erupting on the floor of Kilauea caldera. Fume was collected at Kilauea Volcano with equipment patterned after that used in industrial pollution studies. The chief components are sulfur dioxide, sulfur tetraoxide, chlorine, sodium, calcium, potassium, fluorine, magnesium, and iron in that order of decreasing concentration. Content and order of abundance vary depending on the state of activity of the volcanic sources of the fume. Sulfur compounds are preponderant. (Author abstract modified)

Wilson, Hugh H. and Larry D. Johnson
CHARACTERIZATION OF AIR POLLUTANTS EMITTED
FROM BRICK PLANT KILNS. Am. Ceram. Soc. Bull.,
54(11):990-991, 994, Nov. 1975. 10 refs.
The characterization of air pollutants emitted from four brick plant kilns was determined. The emissions vary considerably from plant to plant. The chemical and mineral composition of brick clays and the firing temperatures are widely different from one plant to another. The pollutant concentrations vary because of the different combustion conditions that exist among the plants. Fine particulates, fluorine, and sulfur gases are the pollutants that are most likely to require control in brick manufacturing. In the four plants studied, only sulfur dioxide values at one plant are high enough to cause possible concern as a pollution source.

80334

ECOLOGICAL DIAGNOSIS FOR THE PROVINCE OF EMIGLIA ROMAGNA. (Diagnosi ecologica per l'Emilia Romagna). Text in Italian. *Notizie*, no. 175:30-39, April 1974. The main sources of pollution in Emilia Romagna were divided into 5 broad categories: population, animal rearing, agriculture, industry, and motor vehicles. The distribution of the pollutants particular to each group were analyzed for 341 municipalities. Organic pollution was principally a problem in the area of rivers: the Po, the Po of Volano, and the Rhine. Control procedures for industrial and municipal water pollution are discussed. Sulfur dioxide was the most widespread air pollutant; 57% due to industrial emissions; 28% due to hydroelectric power plants; and 13.5% due to heating. Other emission sources are reviewed: industry is responsible for 81% of dust emissions and 100% of fluoride emissions; motor vehicles account for 92% of carbon monoxide, 80% of lead, and 60% of hydrocarbon emissions. Recovery of materials from solid wastes may be practical, because of the large volume of such wastes.

80507

Berge, Helmut, Erwin King, and Dieter Lorenz
WATER VAPOR IMMISSIONS IN THE AREA OF A CONVENTIONAL THERMAL POWER PLANT. (Wasserdampfmissionen im Bereich eines konventionellen thermischen Kraftwerks). Text in German. *VDI (Ver. Deut. Ingr.) Z. (Duesseldorf)*, 117(15/16):721, 1975. (Full text available from VDI-Verlag GmbH, 4 Duesseldorf 1, Postfach 11 39, West Germany.) Meteorological, agrochemical, and air pollution studies around a conventional thermal power plant with cooling towers in the July 1972 through June 1974 period in the Koeln area in West Germany are summarized. The solar radiation losses due to the cooling towers ranged from 5 to 25% within a 500 m radius, and between 1% and 5% at distances between 500 m and 1000 m. The haze emitted by the cooling towers appears to cause a slight increase in the precipitation in the immediate vicinity, while the waste heat emission caused a slight temperature increase and a reduction of the relative humidity on the lee side. Systematic measurements of fluorine concentrations revealed frequently high concentrations in 1973, sometimes in excess of the 4 microgram/cu m limit, and substantially lower concentrations in 1974. The findings indicate a relatively high background concentration rather than a relationship between the power plant and the fluorine levels.

A. EMISSION SOURCES

69

vers. Refuse Energy Int. Conf. Tech. Exhib., 1st, Montreux, Switzerland, 1975, p. 185-189, (Nov. 3-5.)

The composition of dust in the waste gases of seven incineration plants was analyzed. Thirty-five chemical elements were analyzed quantitatively. Apart from the normal elements, silicon, aluminum, calcium, potassium, sodium, iron, and sulfur, the samples contained lead, zinc, and chlorine with concentrations above 2% by weight. The average content of barium, copper, fluorine, and tin was above 500 ppm. There were huge differences in chemical composition from one plant to another. The concentration of mercury varied within the samples from 1-800 ppm.

Brakhnova, I. T. and S. A. Mosendz
COMPARATIVE HEALTH ASSESSMENT OF POWDER-FILLED WIRES EMPLOYED FOR SURFACING. Weld. Prod., 22(2):78-80, 1975. 5 refs.

The gross emissions of dust and gases formed during surfacing with the powder filled wires used in the welding industry were determined for PP-AN-124, PP-AN-125, PP-AN-G13N4, and PP-AN-170. Fluorides, carbon monoxide, oxides of nitrogen, and ozone form during surfacing with all wires. Dust emission is greatest when surfacing with PP-AN-124. The highest emission of fluoride occurs in surfacing with PP-AN-G13N4. Large quantities of CO form especially with PP-AN-124 and PP-AN-G13N4. Up to 60% of the aerosol component is in the form of carbides of manganese, iron, silicon, and chromium. Changes in the choline esterase activity in the liver and kidney are most pronounced in animals under the action of aerosols from surfacing wires PP-AN-G13N4 and PP-AN-124. Wire grades PP-AN-125 and PN-AN-170 have the least health hazards.

81343

Kautz, K., H. Kirsch, and D. W. Laufhuetten
TRACE ELEMENT CONCENTRATIONS IN HARD COAL AND CLEANED GAS DUSTS DEVELOPING FROM IT. (Ueber Spurenelementgehalte in Steinkohlen und den daraus entstehenden Reingasstaeben). Text in German. VGB Kraftwerkstechnik, 55(10):672-676, 1975.

Twenty-seven hard coal samples of different origin, and 20 dust samples collected after electrostatic precipitators in power plants firing these coal were analyzed for their trace element contents. A comparison of the trace element concentrations in coal ashes, coal, and dust revealed that correlations between the concentrations in the coal or ashes and in the dust do not exist necessarily. The mercury and iodine concentrations in the dust samples were usually lower than in the coal as a result of volatilization during the combustion process. The boron, barium, bismuth, cadmium, cobalt, copper, molybdenum, nickel, titanium, vanadium and tungsten concentrations were about the same in the coal, ashes, and dust samples, while the arsenic, beryllium, chromium, fluorine, phosphorus, and tellurium concentrations were higher in dust than in ashes or coal by 2 to 3 times. The silver, lead, tin, selenium, strontium, uranium, and zinc concentrations were usually up to 10 times higher in dust than in ashes.

Saito, Koichi and Tatsuya Saijo
ON THE TOXIC GAS INVESTIGATION AT THE STATIONARY SOURCE. (Hasseigen ni okeru yudoku gasu no chosa). Text in Japanese. Ibaragi-ken Kogaigijutsu Senta Nenpo (Annu. Rept. Environ. Pollut. Res. Center Ibaragi Pref.), no. 7:44-48, Oct. 1975.

A survey on hydrogen fluoride, hydrochloric acid, chlorine, and sulfur oxides emissions from 8 facilities, and nitrogen oxides emissions from 29 facilities in Ibaragi Prefecture is reported. All determinations were based on the Japan Industrial Standard Method. High HF emissions were expected from

glass manufacturers; however, their emissions were below the standard (at about 1.59 ppm). More than 90% desulfurization was achieved for the flue gases from cement calculation furnaces. Chlorine gas emissions were very small, reflecting the control effort made by the facilities; the highest level found was 1.8 ppm from a copper dissolution furnace. The HCl emissions depended on the type of facilities; municipal refuse incinerators had poor HCl control, and one such facility indicated 13.0 ppm HCl. The NOx emission tended to be higher for larger scale facilities. Those facilities having large boilers showed high levels of NOx emission, which suggested the necessity for thermal NOx control. The NOx level from these facilities was up to 326 ppm.

AIR POLLUTION EMISSION TEST. BETHLEHEM STEEL CORP (FINAL REPORT). York Research Corp., Stamford, Conn., Office of Air and Waste Management Contract 68-02-1401, Task 18, Rept. 75-SIN-1, Y-8479-18, 116p., Dec. 22, 1975. 2 refs.

Emissions tests were performed at the inlet and outlet of an electrostatic precipitator and the outlet of a baghouse located at Bethlehem Steel Corporation's sintering plant in Bethlehem, Pennsylvania. The tests were performed as part of an Environmental Protection Agency effort to develop performance standards for new sintering operations. Average particulate loadings at the precipitator inlet and outlet were 0.2865 grains/standard cu ft and 0.0301 grains/standard cu ft, respectively. Particulate emissions at the baghouse outlet averaged 0.0153 grains/standard cu ft. Average opacities at the precipitator and baghouse stacks were 4% and 1%, respectively. Emission rates at the precipitator outlet for condensable hydrocarbons, non-condensable hydrocarbons, fluoride, carbon monoxide, sulfur dioxide, sulfur trioxide, and nitrogen oxides were 0.778, 609, 2.46, 6837, 1791.3, 28.5, and 102.2 lb/hr, respectively. Kalmon, B.

PORTSMOUTH GASEOUS DIFFUSION PLANT ENVIRONMENTAL MONITORING REPORT - 1974. In: Environmental Monitoring at Major U. S. Energy Research and Development Administration Contractor Sites. Vol. 2, Energy Research and Development Administration, Washington, D. C., Rept. GAT-824, p. 1035-1064, 1975. 3 refs. NTIS: ERDA-54

Environmental monitoring data for the Portsmouth Gaseous Diffusion Plant are presented. The principal process in the plant is the separation of uranium isotopes through gaseous diffusion. The highest single ambient sulfur dioxide concentration measured in the plant's vicinity was 12% of the most recent federal standard, and the average values were less than 3% of the standard. The highest fluoride concentration measured near the plant was 2.65 micrograms/cu m. Sulfur dioxide emissions during the burning of low sulfur coal were slightly less than 1 lb/million Btu, and SO2 emissions during the burning of high sulfur coal amounted to slightly over 3 lb/million Btu. Particulate matter emissions amounted to 0.4 and 0.2 lb/million Btu for low and high sulfur coal, respectively.

Union Carbide Corp., Oak Ridge, Tenn., Office of Safety and Environmental Protection
 ENVIRONMENTAL MONITORING REPORT. UNITED STATES ENERGY RESEARCH AND DEVELOPMENT ADMINISTRATION. PADUCAH GASEOUS DIFFUSION PLANT. CALENDAR YEAR 1974. In: Environmental Monitoring at Major U. S. Energy Research and Development Administration Contractor Sites. Vol. 2, Energy Research and Development Administration, Washington, D. C., Rept. UCC-ND-303, p. 1003-1033, 1975. 5 refs. NTIS: ERDA-54
 Environmental monitoring data obtained in the vicinity of the Paducah Gaseous Diffusion Plant are presented. The plant operations are involved with uranium enrichment and with uranium hexafluoride manufacturing. A steam plant on the grounds burned gas and oil during 1974 and was in compliance with the Kentucky air pollution control regulations for particulates and sulfur oxides. An indicator was taken out of operation during the third quarter of 1974 because visible emissions appeared to violate Kentucky regulations. The incinerator is scheduled for return to service when repairs to its off gas scrubber are complete. Ambient fluoride concentrations in the vicinity of the Paducah installation ranged from less than 0.11 to 4.56 ppm (as hydrogen fluoride) during 1974.

81931

ANNUAL ENVIRONMENTAL REPORT 1974. DUQUESNE LIGHT COMPANY. BEAVER VALLEY POWER STATION AND SHIPPINGPORT ATOMIC POWER STATION. In: Environmental Monitoring at Major U. S. Energy Research and Development Administration Contractor Sites. Vol. 1, Energy Research and Development Administration, Washington, D. C., p. 685-790, 1975. 3 refs. NTIS: ERDA-54
 Environmental monitoring operations involving the sampling of airborne emissions and the measurement of ambient air pollution levels at the Duquesne Light Company's Beaver Valley power station and Shippingport atomic power station are reviewed. A total of 26,530 cu ft of gas was released from the Shippingport station's vent gas system with a total radioactive activity of less than 0.001 curies. There were no other forms of airborne releases at the Shippingport station during 1974. The Beaver Valley power station was not in operation during 1974, and no airborne releases were made during the reporting period. Dust fall measurements made in 1972 at a distance of about 1.5 mi upstream of the Beaver Valley and Shippingport sites indicated that the yearly total dust fall averaged 12 tons/sq mi. The annual arithmetic mean sulfur dioxide level during this period was 0.013 ppm. Other pollutants identified at this upwind site included: fluorides, nitrates, sulfates, manganese, nickel, calcium, zinc, chromium, iron, lead, arsenic, cadmium, vanadium, and beryllium.

81935

Union Carbide Corp., Oak Ridge, Tenn., Office of Safety and Environmental Protection
 ENVIRONMENTAL MONITORING REPORT. UNITED STATES ENERGY RESEARCH AND DEVELOPMENT ADMINISTRATION OAK RIDGE FACILITIES. CALENDAR YEAR 1974. In: Environmental Monitoring at Major U. S. Energy Research and Development Administration Contractor Sites. Vol. 2, Energy Research and Development Administration, Washington, D. C., Rept. UCC-ND-302, p. 945-1001, 1975. 34 refs. NTIS: ERDA-54
 Environmental monitoring data obtained at the Energy Research and Development Administration's Oak Ridge facilities are reported. The average airborne concentrations of particulates and sulfur dioxide were in compliance with applicable standards during 1974, although fluoride concentrations exceeded the standards on several occasions. Annual average fluoride concentrations ranged from 0.9-1.3 ppm. The average

particulate concentrations ranged from 40.9-47.8 microgram/cu m, and the annual arithmetic mean sulfur dioxide concentration was 0.013 ppm. Steam plant operations were in compliance with state emission limits except for the steam plant at the Oak Ridge Gaseous Diffusion Plant. Between 0.8 and 1.0 Ib/million Btu of particulate emissions were released when coal was burned, and the gaseous effluent from this facility exceeded the 1.60 Ib SO₂/million Btu by 0.04 Ib when 1.1% sulfur coal was burned.

82192

WASTE WATER INCINERATION. (Abwasserverbrennung). Text in German. Chem. Ind. (Duesseldorf), 27(6):319-320, 1975. General technical and environmental aspects of wastewater incineration are described. Wastewaters with a minimum calorific value of 450-700 kcal/kg or with a minimum organic matter content of 10% are primarily suitable for incineration. The construction of incinerators without emission control devices can be authorized if the organic carbon, carbon monoxide, hydrochloric acid, hydrofluoric acid, sulfur dioxide, nitrogen oxides and dust emissions are expected to be below the maximum allowable values envisaged in the Technical Guidelines on Clean Air Maintenance. Otherwise, dust, CHI, and SO₂ emissions can be controlled relatively easily, while the removal of aerosols, formed at temperatures of 850 C and over, is problematic. Electrostatic precipitation, cyclone separation, wet scrubbing, and dry gas cleaning can be considered. Wetted tissue filters operating at 95-99% at pressure losses of 200-400 mm water column are best for this purpose. However, they require flue gas cooling to 100-130 C.

Fukuzaki, Norio and Ryuichi Sugai
MEASUREMENTS OF PARTICULATE FLUORIDES IN
NIIGATA PREFECTURE; CHEMICAL COMPOSITION.
(Niigata-kenka ni okeru ryushijo fukkabutsu chosa, funjin no soseibunseki). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):339, 1975. (Presented at the National Air Pollution Research Conference, 16th, Niigata, Nov. 5-7, 1975, Paper 83.)
The chemical composition analysis of airborne dust collected at aluminum refining plants, phosphatic fertilizer plants, and stainless steel plants was done by the X-ray diffraction technique. The sample dust was collected on a millipore filter, or the adsorbed dust within chimneys was collected for analysis. Most of the particle fluorides emitted from aluminum refining factories were sodium aluminum fluoride. Aluminum hexafluorosilicate was not removed by a cleaning tower at the phosphatic fertilizer manufacturer and emitted as the main component of its dust. No particle fluoride could be detected from the stainless steel manufacturer, and ammonium chloride was the major component of its dust.

A. EMISSION SOURCES

71

The protection of workers from fumes likely to be injurious to health is required by law. Welding fumes can be caused by the heating of rods and fluxes or from the effect of the flame, arc, or radiation on the surrounding air or shielding gas or from coatings on the base metal. The present limit is 10 mg/cu m for iron oxide and for inert particles. It is possible from measurements of the rate of fume emission to estimate the volume of fresh air which must be introduced in order that the concentration of fume will not exceed 10 mg/cu m or any lower value required for a particular operation. Various types of welding can also produce ozone, nitric oxide, or nitrogen dioxide. Fume usually contains iron, manganese, oxides, and silicates, and may contain fluorides, chromium, and nickel. Paniculate fume from welding of copper base alloys contains typically 40 to 60% copper. Welding accessories for the removal of fumes or protection against their effects are discussed.

INVESTIGATION ON EMISSION GAS AND ATMOSPHERIC FLUORIDE IN NIIGATA PREFECTURE. (Niigata kenka ni okeru haigasuyobi taikichu no fukkabutsu chosa). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):235, 1975. (Presented at the National Air Pollution Research Conference, 16th, Niigata, Nov. 5-7, 1975.)

The fluoride and the waste gases from aluminum refineries and phosphatic fertilizer manufacturers was analyzed. The analysis was made for both gaseous fluorides and paniculate fluorides by trapping with an alkaline filter paper and millipore filter respectively. Detection was by the ion electrode method, after the dissolution of the trapped fluorides. The total fluoride emission ranged from 43 to 568 kg F/cu m, and the paniculate fluorides were represented more than the gaseous fluorides, ranging from 41 to 540 kg F/cu m. Fifty to 90% of the paniculate fluorides were less than 1 micron in diameter. The particle size distribution curve did not follow the logarithmic normal distribution curve.

82944

Itai, Kazuyoshi

ATMOSPHERIC CONCENTRATION OF FLUORIDE COMPOUNDS IN VARIOUS PLACES. (Honpo kakuchi no taikichu fukkabutsu nodo ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):233, 1975. (Presented at the National Air Pollution Research Conference, 16th, Niigata, Nov. 5-7, 1975.)

Atmospheric fluoride was analyzed at an active volcano and at various industries such as aluminum refining, ceramics, iron-steel manufacture, and phosphatic fertilizer manufacture. The air sample was collected both by Millipore AA filter and a filter paper with 1% sodium carbonate solution in order to have differentiated collection of fluoride particulates and gaseous fluorides. Of the residential areas without a specific fluoride pollution source, 84% showed less than 0.1 microgram F/cu m air. The fluoride level near the volcano was 1 microgram F/cu m, of which 72.2% was gaseous fluoride. Of the fluorides at areas with ceramics industries, 70% were gaseous, while 10% of the fluorides at an area with aluminum refining were gaseous.

Fukui Prefectural Government

SURVEY REPORT ON FLUORIDES IN THE NATURAL ENVIRONMENT OF FUKUI AND SAKAI REGIONS. (Fukui, Sakai chiku ni okeru shizen kankyo chu no fukkabutsu chosa hokokusho). Text in Japanese. 86p., March 1975. 49 refs. Fluoride concentrations in the environment of the Fukui and Sakai regions were surveyed from April 1972 to March 1975, prior to the establishment of an aluminum refinery in the Fukui Coastal Industrial Area in 1977. Fluoride (F) concentra-

tions in all cases were in the range of normal natural concentrations. Values were as follows - Farm produce: leaves below 20 ppm; rice, about 8 ppm. Soil: 110-530 ppm (average 313 ppm). Ocean water (not at a river mouth): 1.0-1.2 ppm. Marine produce: Sea urchins and marine algae showed higher concentrations in comparison to fish, shellfish, and crustaceans. Pines: 1-3 ppm, for both first-year and second-year needles; ponderosa pines, highly susceptible to fluoride pollution, were suggested as possible pollutant indicators. Weeds (primrose, clover, mugwort): about 10 ppm. Drinking water: 0.02-0.37 ppm (average 0.12 ppm). Atmosphere: average relative concentrations, 6.3 microgram F/sq dm/month (absolute concentrations, less than 0.018 microgram/cu m. Rain water: average soluble F concentration 0.013 ppm. Water-soluble F precipitants: 1.21 kg F/sq km/month. River water: average 0.10 mg/l. Environmental guidance standards for fluorides in Fukui prefecture were suggested as follows: continuous 24-hour value, below 1.0 microgram/cu m; continuous one-week value, below 0.5 microgram/cu m.

Huber, G. L.

IMPROVEMENT OF THE ENVIRONMENTAL SITUATION
IN THE CANTON VALAIS AND ITS SPECIFIC PROBLEMS.

(Etat de l'assainissement dans le canton du Valais et ses problemes specifiques). Text in French. Gas Wasser Abwasser, 55(11):725-727, 1975.

While the canton Valais has made significant progress over the past 10 years to control water pollution and treat waste water, tolerable emission concentrations have not been achieved for the most part. Fluorine remains the major air pollutant since the area encompasses all Swiss aluminum industry installations. These are equipped with scrubbers to treat waste gases from electrolytic processes. Although such measures are efficient, emission concentrations are still too high. In the Martigny region, a mathematical model has been established to determine concentration rates of pollutants emitted from specific sources. Chimney heights of a number of incinerator and refining installations have been adjusted on the basis of similar procedures. Natural phenomena such as irregular wind patterns and air currents from lateral valleys must also be contended with.

EFFECT OF SURFACTANTS ON THE DECOMPOSITION OF
PHOSPHATE ROCKS AND EVALUATION OF FLUORINE
GAS IN THE PRODUCTION OF SUPERPHOSPHATE. (Wplyw

Zwiazkow Powierzchniowo-Czynnych Na Rozklad Surowcow Fosforowych I Wydzielanie Gazow Fluorowych W Procesie Otrzymywania Superfosfatu). Text in Polish. Chem. Stoso. Ser. A, 14(1): 81-89, 1970. 7 refs.

The effect of surfactant compounds on the extent of phosphorus-containing ore decomposition and fluorine release during the latter was studied. The phosphorus-holding material under investigation was Marocco I, Marocco II, apatite and a mixture of 2 pt of apatite and 1 pt of Marocco II decomposed by sulfuric acid. The disintegration tests for any ore type were performed with and without surfactants at the same concentration and quantity of H₂SO₄, temperature, length of time and mixing speed. The amount of surfactant added was 0.02% of the total weight of the ground material used and H₂SO₄. The surfactants were of the non-ionic, anionic and cationic types.

<xref image="2000WVBZ.TIF|V3|2006:09:28:01:20:32.00|121830|0"> image: </xref>

Analysis for water-soluble P2O5 and total P2O5 was carried out 3 hr, 3 and 7 days after the reagents were mixed and the decomposition level was calculated by gravimetry. Simultaneously, the degree of defluorination was determined by the balance of the fluorine content in the ore and in the end product. Its superphosphate content was evaluated 7 days after the reagents were mixed. Cationic compounds of the fatty amine group did not affect the decomposition process. The greatest effect among the non-ionic surfactants was shown by stanol, a condensation product of ethylene oxide and saturated fatty acid. In the anionic group, the strongest effect was demonstrated by sodium tetradecylbenzene sulfonate. The surfactant activity was comparatively more intensive in the decomposition of apatite than that of phosphate rock. With regard to defluorination, an addition of 0.04% stanol was the most effective raising the level by 8%. The studies indicated approaches to achieve higher efficiency in superphosphate production.

ON THE RESULTS OF A SURVEY OF FLUORIDES IN THE
AIR OF THE WESTERN PART OF SHIMANE PREFECTURE
BY METHODS LTP AND DJ. (Shimaneken Seibu chiku ni
okeru LTP ho oyobi DJ ho niyoru taikichu fukkabutsu no kan-
kyochosa kekka ni (suite). Text in Japanese. Shimane Ken Eisei
Kenkyusho Nenpo (Annu. Rep. Shimane Prefect. Public Health
Inst.), no. 16:61-66, 1975.

In the western part of Shimane Prefecture, there are many glazed-roof tile manufacturing factories. Around them, damage to silkworms, agricultural crops, and plants sometimes occurs. The fluorine concentration of air was determined by the LTP and DJ methods. A high concentration was found (more than 100 microgram/sq dm/month (LTP)) near a single factory and in the area of tile manufacturers. There was a correlation between values obtained by the LTP and DJ methods.

B. CONTROL METHODS

02541

(SCIENTIFIC METHODS AND TECHNIQUES TO DECREASE THE POLLUTION OF THE ENVIRONMENT, THROUGH INHALATION OR INGESTION, AND OF ACOUSTICAL 'NUISANCES.')

Moyens scientifiques et techniques de diminuer la pollution des milieux inhales ou ingeres et des 'nuisances' acoustiques. (Chapter 3: Les pollutions et 'nuisances' d'origine industrielle et urbaine. Tome 1. Leur prevention et les problems scientifiques et techniques qu'elle pose en France.) Premier Ministre, Delegation generate a la recherche scientifique et technique. June 1966. pp. 47-59.

The functioning of chlorophyll in the course of photosynthesis in leaves of plants serves as a method of air purification of sufficient importance to consider its use in control. Vegetation, like men and animals, can sustain a considerable amount of damage to the point where the threshold limit of absorption of toxic substances is exceeded. The three gases causing the most damage to vegetation are carbon monoxide, the sulfur oxides, and those containing fluorine. Also to be considered are acid 'smog', toxic 'smog', ozone, and nitrogen oxides. Other industrial pollutants which have a toxic influence, but less severe and localized, are dusts, hydrogen sulfides, hydrochloric acid, etc. Ethylene and carbon monoxide cause great damage to the growth hormones, particularly auxin. The effects of SO₂, SO₃, and H₂SO₄ are related to the quantity of gas emitted, the degree of resistance of the species, their state of development, and the various environmental conditions. The sensitivity of vegetation to the action of sulfur gases varies essentially as a function of the speed of absorption of the gas by the leaves. Through experimentation it has been found that the plant species which are most sensitive to SO₂ are chickweed, alfalfa, barley, oats, wheat, rhubarb, lettuce, endive, spinach, cabbage, and tobacco. Apples, apricots, peaches, grapes, corn, and beans are less sensitive, whereas the floral species such as gladiolus, rose, and lilac offer considerable resistance. Aquatic vegetation is often used as purifying means for polluted streams. Subsoils purify themselves of pollutant materials in various ways, including uptake by vegetation and dispersion in the soil with rain water, etc. In a section on means of decreasing the inhaled pollutants the following are mentioned: dust collectors, normal methods of dispersion in the atmosphere, fumes from domestic fires, auto exhaust fumes, fuel additives, improvement of combustion in engines, recycling of crankcase gases, post-combustion appliances, and redesigning of motors. Also given in this section (Chapter 3) is some similar information on ingested pollutants and on problems of noise.

J. P. Jewell

CONTROL OF FLUORIDE EMISSIONS. Proc. Ann. Sanitary Water Resources Eng. Conf., Vanderbilt Univ., Nashville, Tenn., 1965. pp. 226-32.

The chemistry of fluorine and the fluoride problem encountered in certain industries, namely the phosphate industry, both elemental and fertilizer, part of the steel industry, aluminum reduction, and other industries engaged in processing ores containing fluoride are described. In detail, and more specifically, the control of fluoride emissions from an elemental phosphorus plant is discussed.

FURTHER DEVELOPMENTS OF THE FLUORINE PROBLEM IN THE ALUMINUM INDUSTRY. Weitere Entwicklungen zum Fluorproblem in der Aluminium-Industrie. Z. Erzbergbau Metallhuettenwesen 18, (3) 111-5, Mar. 1965. Ger. This paper reports on the state of the arts concerning control and scrubbing equipment for fluoride inside working premises

as well as directly from electrolytic furnaces. Far reaching research has improved the already very effective methods and installations. An optimal aerodynamic air ventilation is used very effectively. Control of dust and gaseous components, measurements of fluorine from the air inside of working premises and from the exhaust are done separately. Measurement and control is accomplished according to VDI-Richtlinien (guides) No. 2093 and 2452. The success of reduction in fluorine content with the installation of control equipment can be measured by the reduction of the fluoride content in grass, in the vicinity of the plant, which is used as cattle feed.

VENTURI AND RADIAL FLOW SCRUBBERS FOR COOLING AND CLEANING OF UTILITY AND WASTE GASES.

Venturi- und Radialstrom-wascher zur Kühlung und Reinigung von Nutz- und Abgasen. Stahl Eisen (Dusseldorf) 86, (8) 399-406, Apr. 8, 1966. Ger.

Two scrubbers are discussed in this paper: The venturi scrubber with central jet and the radial flow scrubber. Operating experiences and results of measurement are given. Venturi scrubbers are used in a variety of industries for gas cooling and dust cleaning. They are used for scrubbing of gaseous components, for instance fluorine washing. The versatile use of the venturi scrubber, it can be operated according to need without or with high pressure losses, has opened a wide field of application. The operation and application by low and high pressure losses are explained. The radial flow scrubber is an adjustable high performance scrubber, developed for cooling and cleaning of large gas masses, for example such from blast furnaces. Design and construction is explained and the effect discussed.

PLSTIC-COVERED GREENHOUSES SUPPLY CONTROLLED ATMOSPHERES TO CITRUS TREES. Trans.

ASAE (Am. Soc. Agr. Engrs.), 9(3):338-339, 342, 1966. 5 refs.

Details of a greenhouse for studies of air pollution (smog) on individual fruitbearing citrus trees are described. A structure was needed for this purpose that would endure for a minimum

<xref image="2000WVC1.TIF|V3|2006:09:28:01:20:38.00|101763|0"> image: </xref>

of five years, would admit the entire solar spectrum, and would not become excessively overheated when outside temperatures rose to 115 F. After three years of operation, the durability and convenience of the structures described are very satisfactory. No discoloration, crazing or cracking of the plastic glazing material is apparent. Paint on the aluminum is holding well. Repainting on some steel surfaces was necessary after two years. Activated carbon and limestone for removing photochemical smog and fluorides, respectively, from the air streams must be renewed about every 12 hours. Some minor damage was done by windstorms of 80 mph, which was easily taken care of.

HIGH TEMPERATURE GAS AND AEROSOL REMOVAL WITH FIBROUS FILTERS. Proc. Air Water Pollution Abatement Conf., 1957. pp. 10-23m.

The use of a slag wool fiber filter as an inexpensive cleaner of high temperature gases and fumes produced in open hearth steel furnaces was described and evaluated. These fibers are small (4 microns mean diameter) and are refractory, thus able to withstand temperatures of 1100 F. ;or high efficiency separation of fine aerosols, fine targets in large number are necessary which packed slag fiber layers can provide. Theoretical, laboratory and field studies show that slag wool filters show efficiencies ranging from 90 to 99%, depending upon fiber layer compositions, density, and thickness. The chief separating mechanisms appear to be diffusion and impaction. Results are presented of the air flow resistance characteristics of a rotary screw agglomerator, used to provide dynamic gas treatment to increase particle size of the efficiency of the screw as an inertia collector for iron oxide fume. The collection efficiency and resistance characteristics of slag wool fiber filters was extended to other aerosols and gases such as fly ash, sulfur dioxide, hydrofluoric acid and sulfuric acid mist. The filter (one inch thickness, five pounds per cubic foot density) at velocities used for collecting iron fume (50 to 150 feet per minute) showed efficiencies for SO₂ of approximately 30% when moist and zero when dry. For hydrogen fluoride (dry and wet), efficiencies range from 70 to 90%. For fly ash resuspended from Cottrell ash, efficiencies ranged from 60 to 90%, whereas when freshly formed fly ash was created by burning powdered fuel, efficiencies ranged from 93 to 99%. A revised pilot model slag wool filter was constructed for 750 to 1000 cfm gas flow based on results of the first field unit.

GASEOUS FLUORIDE EMISSIONS FROM STATIONARY SOURCES. Chem. Eng. Progr. 63, (5) 78-84, May 1967.

Methods of controlling the emission of fluorides from the brick and tile, steel, aluminum, and phosphate fertilizer industries are examined. The brick and tile industry receives brief treatment and a concluding statement mentions that a venturi type scrubber was used in bottle manufacture with 92% efficiency. In the steel industry, the emission of fluorides from sintering plants exceeds those from open hearth furnaces and different control measures are required. The addition of 6% weight of ground limestone to the sintering mix reduced fluoride emission by nearly one half. The final treatment consists of the means for supplying and injecting pulverized limestone and the final dust separation equipment. Reduction of fluorides is estimated at 96%. The basic difference between the treating systems of the sintering and open hearth processes is the pressure under which they operate and the material used as a reactant; CA (OH)₂ is used in the open hearth process. Among the methods discussed in regard to the aluminum industry are the wetting by sprays of the hot gases escaping through roof monitors, the use of a sieve-plate gas absorber

column, and a floating bed type of scrubber which overcomes the tar-fouling problem and is reported to remove 95% of fluorides. Fluoride control is achieved with cyclones and packed towers. The effects of fluorides on vegetation, cattle, and man are briefly discussed including the effects of inhalation of HF at various concentrations.

07190

R. C. Timberlake

FLUORINE SCRUBBER. Southern Eng. 85(6):62-64, June 1967.

The control of gaseous fluorides from the superphosphate curing area of the American Cyanamid's Brewster, Florida plant is described. The problem involved handling large volumes of air containing widely varying concentrations of fluorine. Four blowers, each with a capacity of 87,500 cfm, were used to deliver the exhausted air to rubber-lined scrubbers. The 9-ft impeller is made of stainless steel and the housing is rubber lined. The ducts are made of Cyanamid's Laminae polyester resin. Each of the four scrubbers has 50 spray nozzles and uses 500 gallons of water per minute to capture the fluorine as dilute fluosilicic acid. The scrubber project eliminates 98% of the total fluorides liberated by all sources of the operations.

N. Yamate

AIR POLLUTION BY TOXIC GAS AND ITS COUNTER

MEASURE. Text in Japanese. Kuki Seijo (Clean Air, J. Japan Air Cleaning Assoc., Tokyo) 3(2):19-25, 1965. 5 reis.

The present status of air pollution in Japan and its counter measures are described according to the chemical composition of the pollutants: sulfur oxides, nitrogen oxides, halogen compounds, organic compounds, and solid particles (dusts). The hourly variation of SO₂ concentration is graphed. In Tokyo, there is a peak around noon of about 15 pphm; NO₂ ranges from 1 to 1.5 pphm with little variation. Concentrations of SO₂, NO, NO₂, H₂S, and CO were measured in Yokkaichi, Osaka and Ube as well as in Tokyo. Graphs relating amount of traffic to CO concentration show almost the same pattern. Concentrations of HCl and HF in the air are quite small (0.35 ppm and 0.3-0.4 micrograms/cu m., respectively) near chemical plants producing these gases. Counter measures used against the various pollutant emissions are: the dry method, wet method, activated carbon method for sulfur oxides; alkali or oxidation method for nitrogen oxide; dry iron oxide and dry absorption methods for H₂S; and water washing method for HCl and HF. Afterburner methods by sparking and heat concentration are described for control of automobile exhausts. However, problems encountered with the afterburner methods are the high temperature required and nitrogen oxide increase. The equipment required is also rather large. Another method employing catalysts is described in which loam, molybdenum, white gold, nickel or vanadium are used effectively.

B. CONTROL METHODS

75

the 51st Annual Meeting, Air Pollution Control Assoc., Philadelphia, Pa., May 26-29, 1958.)

Investigations have indicated that two in. thick filters at four lb/cu. ft. packing density will remove up to 80% of acid mist and up to 99% of acid gases and fumes. Total filter life depends upon concentration of contaminant in the entering air. A summary of filter performance is given. Estimated operating life based upon one use of the filter material can be obtained from the data given. With particulates such as iron oxide and fly ash, it has been found possible to wash and reuse filters about ten times. When iron oxide was collected simultaneously with SO₂, filters were reused about eight times. Acid gas collection is significantly improved by the presence of moisture on slag wool filters. Mineral wool filters have several features such as, low cost (about 1 cents/lb.), small fiber diameter (4 micron and ability to withstand high temperatures (1000 deg F.). Slag wool will simultaneously remove sub-micron particulate materials with 90 to 99% efficiency. Resistance to flow through two in. slag wool filters (with an HF efficiency of 95%) is on the order of one or two in. of water, or if continuously moistened, at most 6 in. of water.

DIRECT FUME EXTRACTION FOR LARGE ARC FURN-

NACES. In: Fume Arrestment, Special Rept. 83, London, William Lea and Co., Ltd., 1964, p. 150-159. (Report of the Proceedings of the Autumn General Meeting, Iron and Steel Inst., London, England, Nov. 26-27, 1963.)

The development of a suitable fume extraction and cleaning system for large electrical arc furnaces using tonnage oxygen is taken in logical sequence through pilot plant trials to the final design stage. The choice of a wet cleaning plant is influenced by the ease of hot gas conditioning and fluorine removal, the economies due to reduced volumes at the outlet, and an improved effluent treatment and disposal system. The steps taken to ensure complete combustion of the gases evolved during the furnace cycle by the use of an adjustable sealed connection to the furnace, combined with a controlled combustion air and ignition source, are described in detail. Control of furnace pressure is achieved by control of speed of the fan and a water-cooled damper in the furnace offtake. Operational experience and plant reliability are discussed, together with reasons for modifications found to be necessary.

AIR POLLUTION CONTROL IN NON-FERROUS METAL-

LURGICAL INDUSTRY. (THE USE OF WET SCRUBBERS).

Ind. Heating, 34(10):1866, 1868, 1870, Oct. 1967.

Fumes emitted from the processes involved in the non-ferrous metallurgical industry consist of extremely fine particulate matter of submicron size. These fumes result from the heating operations, from the use of fluxes and from reduction processes, all of which produce highly corrosive emissions. Types of controls include wet-scrubbers and bag filters. A typical Airetron installation for capturing fluoride emissions during electrolysis of aluminum ore is described; it employs 20 cyclonic air scrubbers operating at a low pressure drop of 3 in. w.g. which neutralizes gaseous fluorides at the rate of 90,000 cfm at 200-250 deg F. for a total of 1.8 million cfm of gas purified. Recovery of the metal is accomplished, in this case, by permitting it to settle out of the resulting liquid and recharging it into the furnace. In this system all solids are recovered through the recycling. In the wet-scrubbers, the fumes become highly corrosive when wetted and linings such as rubber or polyester-fiberglass must be used in their construction. Bag filters provide high cleaning efficiency and operate at relatively low power costs. However, the replacement of the filter bags themselves is a high maintenance item. The non-ferrous industry thus requires some of the most sophisticated air pollution

control equipment for production of an essentially low-cost product.

Sheppard, Stanton V.

CONTROL OF NOXIOUS GASEOUS EMISSIONS. Proc.

MECAR Synip., New Developments in Air Pollution Control, Metropolitan Engineers Council on Air Resources, New York City, p. 21-28, Oct. 23, 1967. 3 refs.

Several new developments have taken place which have helped improve scrubber designs for controlling emission of noxious gases. Some major new technical developments have been: Greater use of the crossflow scrubber design principle, availability of light weight plastic tower packings, and wider acceptance of corrosion resistant glass reinforced polyester plastics. Some noxious gases commonly encountered are oxides of nitrogen, hydrogen chloride, hydrogen fluoride, silicon tetrafluoride, chlorine, chlorine dioxide, sulfur dioxide, hydrogen sulfide and mercaptans. In industrial applications, the removal of noxious gases from exhaust air streams is most often accomplished by bringing the air stream into contact with a liquid stream for a certain period of time. The amount of time required to transfer the noxious gas to the liquid is a function of several factors. These are: Gas rate, liquid rate, solubility of gas, mechanism of contact, and scrubber type. The packed scrubber is used most often today for controlling emission of noxious gases to the atmosphere. It is available in three basic operating designs: Counter current, cocurrent and crossflow. In the counter current packed design, the air stream containing the noxious gases is passed vertically upward in opposite direction to the flow of the down coming scrubbing liquid. The cocurrent packed scrubber allows the air stream and the scrubbing liquid stream to pass through the packed bed in the same direction. In the cross-flow scrubber the air stream moves horizontally through the packed bed while the scrubbing liquid moves vertically downward through the packed bed and perpendicular to the air streams. Three relatively new tower packing shapes are being used more frequently by engineers in designing scrubber equipment for removing gases. These packing materials are constructed of high density polyethylene or polypropylene. This gives them good resistance to corrosion and light weight compared to ceramic ring and saddle packing. Fiber reinforced plastics (commonly designated as FRP) are being used more and more to replace stainless steel, rubber and PVC lined steel and other metallic alloys for scrubber bodies. FRP is a material that uses a combination of polyester or epoxy thermosetting resins and glass fiber reinforcements to give a finished laminate that has excellent corrosion resistance, a high strength to weight ratio, and light weight.

SOME ECONOMIC ASPECTS OF AIR POLLUTION CONTROL WITH SPECIAL REFERENCE TO POLK COUNTY, FLORIDA. 337p., Jan. 1968. 178 refs.

A report is given which studies the economic analysis and modification of air pollution problems. By determining the pattern of apparent air pollution damage to the citrus and cat-

<xref image="2000WVC3.TIF|V3|2006:09:28:01:20:44.00|123064|0"> image: </xref>

tie industries of Polk County, Florida; and by drawing inferences from the pattern, an attempt is made to analyze what might be some of the more important impediments to efficient management of the atmospheric resources and to identify the conditions under which institutional innovations might have to be made to improve management of this resource. The following procedure is used to accomplish this: The economic nature of air pollution is discussed. Information is given on the economic backgrounds of Polk County's cattle, citrus, and phosphate fertilizer industries. A short description of the evolution of potentially toxic fluorides during the phosphate fertilizing process is given. A comprehensive discussion is given on the effects of airborne fluorides upon the citrus and cattle. The results of a study between the intensity of air pollution and Polk county land values are presented and interpreted. Proposals for control of air pollution are reviewed. Finally, an attempt is made to present the writer's views about implications of the results of the land value analysis for the control proposals and their applicability.

09773

FAN SCRUBBER HALTS CORROSION ENDING NEED FOR ROOF REPAIRS. Chem. Process., 31(4):67, April 1968. The manner in which escaping acid fumes were controlled at a particular plant is described. An existing system of water scrubbers was supplanted by a separator based on a centrifugal fan. Flow through the separator is 14,000 cfm of an exhaust containing 750 ppm of nitric acid and nitrogen oxides and 350 ppm of hydrofluoric acid. Most of the fumes are separated by centrifugal force in the fan, into which 6 gpm of water is sprayed. The partially cleaned exhaust then passes through a 48 x 80 x 6 in-thick polypropylene filter which removes nearly all of the remaining wetted fumes. Fumes leaving the separator were reduced to trace amounts. Scrubbing water requirements were reduced by 34 gpm. The complete system was installed at a cost of \$8100, less than \$0.70/cfm.

09902

Wett, Theodore W.
COMPETITORS COLLABORATE TO CHOKER OFF AIR POLLUTION. Chem. Process., 31 (1):27, 34-35, Jan. 1968. Some 289 air-pollution control devices have been installed by 13 phosphate-producing companies operating 18 plants and a dozen large curing sheds. This equipment includes electrostatic precipitators, cyclonic and venturi scrubbers, bag-type dust collectors and absorption towers. Although all companies do not disclose capital investment in air-pollution control, a rough 'rule of thumb' indicates that it will run \$3.25/cfm of effluent air treated. Yearly operating cost for pollution-control equipment averages 15 percent of installed cost, sometimes more, not including depreciation. Fluorine from the phosphate industry consists mostly of SiF₄ and insoluble particulate fluorapatites generated in clashing the phosphate rock. Presented sampling techniques, involving considerable agitation and very finely divided particulate matter, can indicate a higher concentration of soluble fluoride in ambient air than is actually in the case. In addition, there is no method of distinguishing between SiF₄ and HF. Since most of the work in fluoride pollution studies has been done with HF, much more toxic than SiF₄, the effect of phosphate industry fluoride emissions on plants, animals and man has not been adequately determined.

GAS CLEANING PRACTICES AT MOSJOEN ALUMINUM WORKS. ((Gassrensseanlegg ved Mosjoen Aluminiumverk.)) Text in Norwegian. Tek. Ukeblad (Oslo), 114(12):232-237, March 30, 1967. 3 refs. Mosjoen Aluminum Works' solution to cleaning the oven gases given off by the electrolytic aluminum production processes is outlined, with emphasis on the fluoride com-

pounds which have adverse effects on the environment. Mosjoen has developed the construction of a practical model (by Erga et. al.) which uses selective absorption of fluorine from the gases from aluminum reduction cells with vertical spike Soderberg anodes. Economic and efficiency statistics are given to justify the method in the Norwegian industrial environment. Diagrams showing the components of the equipment are given illustrating the fluoride recovery technique.

DETECTION AND REMOVAL OF FLUORINE IN THE
WASTE GASES OF A STEELWORKS AND MEASURING
AIR QUALITY IN ITS SURROUNDINGS. Staub (English
translation), 28(1):9-17, Jan. 1968. 5 refs. CFSTI: XT 68-50448/1

Air-quality measurements of fluorides were taken near a large steelworks for a period of three years. They revealed that the positioning of the measuring devices is of decisive importance. For example, gross errors are liable to occur if ore dust entrained near ground level is included. After eliminating such errors the total precipitation of fluoride in the course of 3 years was established as between 2 and 6 mg/sq.m./day. No free fluorine is emitted by steelworks, although gaseous fluoride compounds can occur. Downstream of metallurgical furnaces, particularly where 'brown smoke' is emitted, this fluorine is partially completely adsorbed on the dust. Consequently, even when using excessive quantities of fluorite, it is retained by the dust collectors just like the dust itself. It is irrelevant whether wet or dry collectors are used. Accordingly, there is no reason to avoid the use of fluorite in steel making, provided efficient collecting units are used. Emission of coal-fired boiler plants is less governed by the fluoride content of coal than by the more or less basic character of the ash. Emission of this origin can be largely prevented by dust collection. (Authors' conclusions, modified)

H.R. Hickey
CONTROLLING ALUMINUM EFFLUENT REDUCTION. Air
Eng., 10(10):20-22, Oct. 1968.
In the manufacture of aluminum from alumina by electrolytic reduction, fluorides and hydrocarbons are the principal effluents. Fluoride removal from collected gases poses no problem with conventional scrubbing equipment. However, the hydrocarbons condense as submicron tar particles which plug multiple cyclones and baghouses thereby limiting the options available in selecting control devices. Research to overcome the hydrocarbon problem is needed.

B. CONTROL METHODS

77

Chemical Engineers, New York, N. Y., 22p., 1964. 3 refs. (Presented at the Symposium on Nuclear Plant Experience with Fluidized Beds, Part I, American Institute of Chemical Engineers, 53rd National Meeting, Pittsburgh, Pa., May 17-20, 1964.)

Recovery of dilute fluorine at the Atomic Energy Commission's Gaseous Diffusion Plant at Paducah, Kentucky, is based on a fluidized bed process. The all Monel reactor is 27-in. in diameter and employs a bed of UF₄ at a depth of 4.5 ft. Operation of the reactor depends on the reaction of fluorine with UF₄ to produce gaseous UF₆ and several solid compounds with fluoride-to-uranium ratios between UF₄ and UF₆. The reactor operates at approximately 750 F. The process gas stream for the reactor is the primary UF₆ process vent gas stream containing 20-40% fluorine. Initial development of the fluidized bed recovery process was conducted in an existing plant reactor. Because of the similarity of operation, the facilities of the fluidized bed UF₆ absorber were temporarily modified for a pilot-plant investigation. A total of eight runs were made during the investigation with fluorine concentrations of 5-30% and at 600 to 900 F. Based on the results of this study, a prototype reactor was built and operated for one year. With the current unit, fluorine recovery efficiencies are greater than 95% while reactor-on-stream efficiencies average about 99%. Equipment maintenance is negligible.

Navratil, James D.
DISPOSAL OF FLUORINE. Dow Chemical Co., Golden, Colo., Rocky Flats Div., AEC. Contract AT(29-1)-1106, Aug. 29, 1968. 44 refs.

A literature review of fluorine disposal systems utilizing liquids, solids, and gases is given. The literature makes frequent mention of caustic solutions and water. Sodium hydroxide solution is the most desirable liquid agent, especially when CaO is added to regenerate NaOH. A review of media used for solid disposal includes charcoal, alumina, soda lime, and several other less efficient agents. Static beds of coconut charcoal and fluid beds of activated alumina were reported to be highly effective fluorine disposal systems. No explosions were encountered with the use of charcoal. Apart from the literature review, experiments were static-bed disposal traps to evaluate activated alumina, soda lime, and charcoal as fluorine disposal agents are described. Exhaust line plugging occurred when alumina was used as the disposal medium. Plugging problems were less severe with soda lime. Water evolved during the fluorine-soda lime reaction, but it presented no problem. The use of wood charcoal eliminated plugging problems, but pressure surges were noted during the reaction. A check valve upstream from the disposal trap prevented interference on the upstream system from the trap. Charcoal was selected as the most desirable disposal medium because of its high disposal capacity, gaseous reaction product (CF₄), and freedom from trap plugging.

Gully, A. J., R. M. Bethea, R. R. Graham, and M. C. Meador
REMOVAL OF ACID GASES AND OXIDES OF NITROGEN FROM SPACECABIN ATMOSPHERES. Texas Technical Univ., Lubbock, Contract NAS 1-7584, 139p., July 1969. 122 refs. CFSTI: NASA CR-1388

Investigations were made on methods of removal of oxides of nitrogen and of the acid gases sulfur dioxide, hydrogen chloride, hydrogen fluoride and chlorine in low concentrations from air as part of the effort to develop an effective atmospheric purification subsystem for long-term manned space missions. Methods investigated were: reaction with basic solid materials, adsorption, and for oxides of nitrogen, catalytic reduction of nontoxic to less toxic gases. Adsorption at ambient temperature of both chlorine and nitrogen dioxide on ac-

tivated carbon was found to be rapid with sulfur dioxide being adsorbed to a lesser extent. In exploratory work, nickel oxide and copper oxide were found to exhibit appreciable activity in the catalytic decomposition of nitrogen dioxide. Maximum decomposition of nitrogen dioxide observed (nickel oxide catalyst at 482 C) was 53%. Nitric oxide was the major decomposition product. Solid-gas reaction was found to be the most generally effective method of contaminant removal. The solid reactants tested included sodium carbonate, sodium bicarbonate, barium carbonate, calcium carbonate, lithium carbonate, and manganese dioxide. Of these, lithium carbonate and manganese dioxide were the most effective by a large margin for acid gas removal. Manganese dioxide reacts faster with sulfur dioxide and chlorine, and lithium carbonate faster with the hydrogen halides at the temperature of interest (340-380 C). Reaction rates increase rapidly with temperature. The reaction between nitrogen dioxide and any solid tested was too slow for effective removal. A mathematical model of the solid-gas reaction system, based on the shrinking core concept, was developed. This model served both as a basis for experimental data interpretation and as a design tool. The model, which requires only two experimentally determined constants for each gas-solid pair, adequately fits the breakthrough data on all solid-gas reaction systems investigated. On the basis of information developed in this study, it is confidently estimated that by using a 11 cm reaction bed containing both manganese dioxide and lithium carbonate, over 88% of the sulfur dioxide and over 99% of the chlorine and hydrogen halides in the entering stream can be removed on a once-through basis for up to 750 hours of operation. (Author summary)

Erga, Olav, Rare Ryan, and Adolf Syrdal

RECOVERY AND UTILIZATION OF FLUORINE PRODUCTS
FROM ALUMINUM ELECTROLYSIS WASTE GASES. In:

Abwasser, Abgas Schwebstofftechnik, Dechema-Monograph., 59(1045-1069), Frankfurt am Main, Deutsche Gesellschaft für chemisches Apparatewesen E.V., 1968, p. 191-198. 4 refs. Gases released during aluminum electrolysis contain HF, SO₂, and CO₂ which are all absorbed with the alkaline solution used in present recovery procedures. A method and apparatus are presented for the selective recovery of HF for hydrofluoric acid production. A sieve plate scrubber utilizing water as the absorption agent was developed by Elektrokemisk. The device features a tower consisting of sieve plates and funnels and a circulation pump for gas distribution. One unit is sufficient for HF recovery. Pilot plant tests showed more than 99% of the HF was absorbed, producing an acid of 3% HF by weight. The co-absorption of SO₂ was negligible. Use of the tower for cryolite production also results in an economically feasible by-product.

ACOUSTIC COAGULATION OF MIST CONTAINING
FLUORINE COMPOUNDS. J. Appl. Chem. USSR (English
Transl.), 41(12):2494-2499, Dec. 1968. 4 refs.

Investigations of the particle-number concentrations and size distributions in mist containing fluorine compounds were conducted with a flow ultramicroscope and photomicrography

<xref image="2000WVC5.TIF|V3|2006:09:28:01:20:50.00|126420|0"> image: </xref>

under laboratory and plant conditions before and after acoustic treatment. The results of these studies showed that the number of particles decreases by a factor of 100-1000 as a result of acoustic treatment for 3 to 5 sec. Examination of the experimental data obtained in studies of the particle-size distribution of aqueous mist showed that the minimum size of the drops was 0.9 micron and the greatest frequency was in the 5 to 6 micron range. In the case of industrial mist, the number of particles deposited per unit area is decreased by a factor of 125 after acoustic treatment for 1.5 sec, while the average diameter increases from 2.5 to 18.7 microns. Before treatment, 88% of the particles were in the 1 to 4 micron range. Acoustic treatment shifts the distribution to the right and increases the variance. (Author conclusions modified)

CONSTRUCTION OF DIFFERENTIAL PRESSURE GAGE
FOR FLUORINE AND ITS APPLICATION TO AUTOMATIC
DISPOSAL OF FLUORINE. J. Nucl. Sci. Tech., 5(1):30-34. Jan.
1968. 9 refs.

A differential pressure gage for fluorine, consisting of two metal bellows connected end to end was constructed. This device can be applied in measurement of pressure drop across fluid bed reactors, pack bed reactors, filters, orifices of flowmeters, and other similar uses. The gage has been shown to possess excellent stability against corrosion by fluorine. The output voltage obtained was 1.7 mV/mm H₂O, and drift was less than 0.5 mm H₂O. The gage can be used for control of fluorine disposal by absorption in a wide range of mean flow rates, and dispenses with the use of fluorine-resistant control valves.

Tuerkoelmez, S.
NEW METHOD FOR WASTE GAS CLEANING. ELIMINATION OF ODORS BY EXCHANGE ADSORPTION WITH ARTIFICIAL RESIN ION EXCHANGERS. PART I. (Neues Verfahren der Abgasreinigung. Beseitigung der Geruchbelaestigungen durch Austausch-Adsorption mittels Kunstharzlonenaustauschern. Teil I). Text in German. Wasser Luft Betrieb, no. 11:737-743, 1965.

For the removal of odors from industrial waste gases, the use of artificial ion exchanger resins is suggested. The reaction takes place in the gas phase in the case of inorganic waste gases and in the liquid phase for organic compounds. Four types of exchangers, IR-45(OH), IRA-410(OH), IRC-50(H), and IR-120(H), were successfully tested with phenols, mercaptans, bromides, fluorides, cyanides, nitriles, chlorides, SO₂, and a number of organic compounds. Fluorides, cyanides, chlorides, and SO₂ could be completely removed. Pre-adsorption with alkaline earth hydroxides in scrubbers was used only in the case of phenols.

Teske, Wolfgang
AIR POLLUTION CONTROL IN THE CHEMICAL INDUSTRY. (Luftreinhaltung in der chemischen Industrie). Text in German. Zentr. Arbeitsmed. Arbeitsschutz, 19(10):289-294, 1969. 11 refs.

Emissions developing from chemical production processes can be reduced either by modification of the process itself or by cleaning the stack gas. As an example of the first approach, the so-called double contact process is described. Sulfur dioxide from pyrite roasting is converted by catalytic oxidation with atmospheric oxygen to SO₃. By addition of water, the latter is converted into sulfuric acid. The reaction is not complete; in the first stage of the process, 90% of the SO₂ is converted to SO₃, which is removed from the reaction gas mixture by absorption. The remaining 10% SO₂ is converted to SO₃ in the second stage. The residual SO₂ concentration in

the cleaned gas lies between 0.5 and 0.7 g/std cu m. The emission of NO and NO₂ can be reduced by the use of higher pressures either during combustion or prior to absorption. The dust emissions from acetylene production can be reduced through the construction of a completely closed furnace from which no waste gas can escape without having first been cleaned. For cleaning of waste gases, there are several wet and dry methods. Hydrogen sulfide and carbon disulfide from the manufacture of synthetics are removed from the waste gas by adsorption on two layers of activated charcoal. Silicon tetrafluoride and hydrogen fluoride can be removed by venturi scrubbers, by Doyle scrubbers, where the gas is accelerated in an annular nozzle so that it hits the scrubbing liquid at high speed, by cyclone scrubbers, or by spray chambers.

MAINTENANCE OF AIR PURITY AND DETERMINATIONS
OF IMMISSION BY THE ALUMINUM INDUSTRY:
FLUORINE POLLUTION, ESPECIALLY HYDROGEN

FLUORIDE GAS, IN WASTE GASES CAUSES DAMAGE TO
VEGETATION. (Luftvard och immissionskontroll i aluminium-
niindustrin: fluorforeningarna, sarskilt det gasformiga fluor-
vatet, i avgaserna). Text in Swedish. Tek. Tidskr., 99(12):251-
253, May 27, 1969.

The Sundsvall aluminum plant, the only alumina-electrolysis plant in Sweden, operates 300 cells currently producing 65,000 tons of Al per year, representing a fivefold increase of production since 1962. To date the company has spent 20 million kroner (about \$4,000,000 in 1969) on air pollution control equipment, but there is still some damage to vegetation from hydrogen fluoride gas. Comfort of workers requires 20 to 30 changes of air per hour (12 million cu m/hr) in pot-line area, which complicates air pollution control. Most recent of several air-washing devices used in a 'spin bath' in which plastic balls are sprayed with water from jets. Exhaust gases escape through four 70-m concrete chimneys, 10-11 m in diameter and lined internally with plastic. The equipment removes 90% of water-soluble fluorides from exhaust. The company also maintains 160 inspection stations in the area, which by means of pollutant-sensitive plants record the immission of toxic material, which is the basis of a map of Sundsvall region with 'isofluoride' lines to indicate pollution zones.

Lunde, K. E.

PERFORMANCE OF EQUIPMENT FOR CONTROL OF
FLUORIDE EMISSIONS. Ind. Eng. Chem., 50(3):293-298,
March 1958. 12 refs. (Presented at American Chemical Society,
Division of Analytical Chemistry, Symposium on Air Pollution,
Joint with Division of Industrial and Engineering Chemistry and
American Chemical Society Committee on Air Pollution, 130th
Meeting, Atlantic City, N. J., 1956.)

Metallurgical, heavy chemical, fertilizer, and ceramic processes discharge fluorides to the atmosphere as hydrogen fluoride, silicon tetrafluoride, or solid fluorides of varying composition and particle size. The efficiency of various equipment for controlling these emissions is evaluated for purposes of minimizing capital investment and operating costs. Absorption data are reported in terms of the number of transfer units

<xref image="2000WVC6.TIF|V3|2006:09:28:01:20:54.00|116711|0"> image: </xref>

B. CONTROL METHODS

79

and related to liquid and gas flow rates, which are expressed in terms of theoretical power consumed per unit of gas flow rate. The absorption of gaseous fluorides is analogous to the absorption of sulfur dioxide and the relative performance of equipment should be similar. It is shown that the number of transfer units obtainable on grid towers is controlled principally by tower height and is only slightly affected by power expended on the liquid and gas phases. The performance of cyclone spray scrubbers is primarily a function of power expended in the liquid phase, while the performance of venturi scrubbers depends on the power expended in the gas phase. These factors dominate the performance of equipment used in the absorption of gaseous fluorides. Various spray towers exhibit significant differences in performance. Wet-cell washers require a higher power consumption than simple spray towers. In designing spray towers, the removal of silicon tetrafluoride by scrubbing with water should not be considered a case of simple gas absorption. In the case of silicon tetrafluoride, mists formed in the tower are collected primarily in entrainment separators just prior to emergence from the tower. The mist is presumably rather coarse because jet scrubbers do not exhibit substantially better performance than the low-power-consuming spray towers. To be efficiently collected by separation, the mist should be 10 microns or larger. Adequate data are not available to evaluate the performance of equipment for collecting paniculate fluorides. However, the performance is probably controlled largely by the total power consumption of the device and design of equipment is of relatively unimportant. (Author summary modified)

Fukui, Syozo

EXAMPLES OF GAS INJURY BY HYDROFLUOROIC ACID AND NITROGEN DIOXIDE, AND REMOVAL OF THE GASES FROM WASTE GAS. (Fukka suisso oyobi nisanka chisso ni yoru kogai to sono jogai jisshirei). Text in Japanese. Kogai to Taisaku, (J. Pollution Control), 2(7):481-486, Aug. 15, 1966. 3 refs.

Among the methods of nitrogen-dioxide removal, washing by water or alkaline solutions are only 50% effective. The author investigated a method based on ammonia gas. For the sake of comparison, an experiment using water alone was conducted. Nitrogen dioxide concentration was about 200 to 300 ppm; gas velocity, 0.6 l/min; and water volume, 20 ml. Removal efficiency was only 30 to 40%. Next, washing by a caustic soda solution was examined. The caustic soda concentration was 10% under identical experimental conditions. The rate of removal was 40 to 50%. The rate of nitrogen dioxide removal by ammonia was 85 to 95%. The drawback of this method, however, is that it generates white smoke of ammonium nitrite or nitrate. In the experiments conducted at a plant site, washing by water removed only 12 to 55% nitrogen dioxide while ammonia removed 70 to 93%. Hydrofluoric acid is harmful to silkworms. Mulberry leaves containing 1 mg of fluorine per 100 g of leaves completely killed silkworms. Elimination of hydrofluoric acid was comparatively easy. Satisfactory results were achieved by alkaline washing. The removal rate of this method was higher than 99% and the acid concentration of tail gas was lower than 1 ppm. The mortality rate of silkworms fed untreated mulberry leaves was 3.0 percent; that of controls was 2.0.

16962

Kielback, A. W.

THE DEVELOPMENT OF FLOATING-BED SCRUBBERS. Chem. Eng. Progr. Symp. Ser., 57(35):51-54, 1961. 6 refs. Aluminum is produced by the electrolysis of alumina dissolved in an electrolyte consisting of cryolite and other fluoride salts. The reduction process is carried out in cells called pots. During operation of the pots, fluoride-bearing fume, gaseous

hydrogen fluoride, carbon oxides, sulfur dioxide, and particulate matter such as alumina, carbon, and tar are released from the pots. Containment of these materials has been a problem in wet scrubbers with grids or other fixed packing and impingement surfaces because the surfaces requiring the most wash receive the least. Cleaning problems are severe when the gas contains either tar particles or tar-coated solids. Floating-bed scrubbers eliminate these problems by virtue of a self-cleaning device. Gas is passed upward through a bed of light spheres, increasing liquid hold-up and sphere buoyancy. As a result, the spheres are free for rotational movement and for movement in relation to each other. High gas turbulence is set up in the bed when the upward flowing gas contacts the descending liquor. The effect is intimate mixing of gas and liquor to promote a hard scrubbing action. About 95% removal of fluorides at pressure drops of 3 1/2 to 4 in. water gauge was obtained in pilot studies of scrubbers containing polyethylene spheres. Other proven application of the floating-bed scrubber are treatment of aluminum-fluoride converter tail gas to remove silicon tetrafluoride and treatment of magnesium chlorinator tail gas to remove silicon tetrachloride.

Hoeke, Bert and Horst Arnim Wittbold

WASH SOLUTION FOR PURIFYING FLUORINE-CONTAINING WASTE GASES IN ALUMINIUM INDUSTRY.

(Waschloesung zur Reinigung fluorhaltiger Abgase in der Aluminiumindustrie). Text in German. Wasser Luft Betrieb, 14(1):24-29, Jan. 1970. 7 refs.

The separation of fluorine compounds and dust from waste gases of aluminum plants was studied in the laboratory. A suitable scrubbing liquid was determined for the waste gas; the developing compounds had to be soluble to avoid crystallization in the dust collectors and on pipes. Four test series were carried out with a rotating wet collector. The fluorine compounds could be removed to a large extent with an alkaline scrubbing liquid. A slight dependence of the degree of efficiency on the pH value of the scrubbing liquid was observed. At pH 8 to 12, the gaseous fluorine compounds could be removed to a residual concentration of less than 0.5 mg/standard cu m. The salt content of the circulating scrubbing liquid increased in the course of the experiments to a maximum of 64 g salt/liter water. The fluoride content of the scrubbing water reached 7 g F/l. Maintenance of a pH of more than 10.5 and a salt content of less than 70 g/l helped to prevent any incrustations. This necessitated periodic replenishment of the spent scrubbing liquid by fresh water. The spent liquid was treated with aluminum salts to precipitate the fluoride in the form of kryolith. The dry precipitant contained between 48 and 51% F which could be reused. The sludge collecting in the circulating scrubbing liquid had a settling time of 2 hours. Flocculants did not reduce this settling time. The water content of the sludge was 98%.

Molyneux, F.

CRYOLITE FROM FERTILISER WASTE GASES. (PART 1).

Australian Chem. Process. Eng. (Sydney), 23(2):32-36, Feb. 1970. 23 refs.

Processes for recovering fluorine from the stack gases of plants making superphosphate fertilizers and phosphoric acid from rock phosphate are discussed. Rock phosphate is the

<xref image="2000WVC7.TIF|V3|2006:09:28:01:20:58.00|123881|0"> image: </xref>

only important alternative source of fluorine to scarce feldspar; the fluorine is required for the manufacture of cryolite, which occurs naturally and in limited quantities only in Greenland and which is required for the manufacture of aluminum from bauxite. The gases evolved in these fertilizer manufacturing processes present a serious air pollution hazard; since they are corrosive, their control without recovery of valuable fluorine compounds presents a difficult maintenance problem. One recovery process now in use at a demonstration scale plant consists in absorbing the fluorine which is present as hydrogen fluoride in a bed of lump limestone at temperatures above the dew-point of the stack gas. The Moritz process for cryolite from superphosphate plants utilizes the hydrofluorosilicic acid obtained from the scrubber gases in the superphosphate manufacture. A method of making aluminum fluoride, with which the industrial manufacture of synthetic cryolite is normally integrated, uses fluorine values from the waste gases from phosphate rock acidulation. A new and more general process recently developed for production of $(AlF_3)(3H_2O)$ and synthetic cryolite from phosphate waste gas depends on making treble superphosphate by the acidulation of phosphate rock with phosphoric instead of sulfuric acid; this is described in some detail. Fluorine recovery can be made to materially assist the economics of a phosphate or phosphoric acid plant. A general evaluation of all processes, including wet phosphoric acid manufacture, provides a figure of 0.15-0.2 lb fluorine per 1000 cu ft of gas, of which up to 50% could occur in the process effluent as H_2SiF_6 .

DUST CONTROL: SOLVING THE AIR POLLUTION PROBLEM. Agr. Chem., 24(6):15-17, June 1969. 7 refs. When an air quality control region has been designated, the state involved must set standards for that region. States are beginning to take action against factories suspected of contributing to air pollution. Suspected violations in Montana led to an abatement conference at which the emission of fluorides by phosphate plants was investigated following complaints from local residents concerning nose, throat, and respiratory irritation and property damage to metal and glass. It was noted that fluoride emissions are an adjunct to the process used but that they could be reduced with a high degree of efficiency. Land configurations and prevailing winds added to the problem at one plant. The TVA has developed methods for detecting, measuring, and recovering process materials. In one system, dust is recovered from dry cyclones and slurried in dilute process liquor for return to the process. Other suggested systems recovered carryover from a nitric phosphate pre-neutralizer and dust in a granular fertilizer plant.

Chem. Průmysl (Prague), 7(9):465-469, 1957. 20 refs.
The possibility of obtaining fluorine and rare earth elements from the production of citrate-soluble phosphate, and the dependence of the fluosilicate yield on the amount of sodium nitrate used in precipitation were studied. Results indicated that the best method of obtaining fluorine during production of citrate-soluble phosphate fertilizer is by the precipitation of sodium fluosilicate with sodium nitrate. Fluosilicate prepared in this way is as pure as the byproducts of superphosphate production. The addition of 12-20 parts of a solid precipitating agent per hundred parts of apatite yields 58 to 76% fluorine. However, the precipitation of fluosilicate during the produc-

tion of mixed fertilizers is not advisable. Evidence is presented for the possibility of obtaining a concentrate of fluorine and rare earth elements by the preliminary precipitation of a solution of decomposed phosphate rock, followed by partial acidification of the precipitate with diluted nitric acid.

SELECTIVE TRAPPING AND RECOVERY OF FLUORINE
FROM WASTE GASES. (Spusob selektivneho zachytavania a regeneracie fluoru z odpadnych plynov). Text in Slovak. (Assignee not given.) Czech. Pat. 121,428. 3p., Dec. 15, 1966. (Appl. May 17, 1965, 2 claims).

A method is described for the selective trapping and recovery of fluorine from waste gases emitted in the electrolytic process of the manufacture of aluminum. The waste gases are drawn off and washed in water to which aluminum hydroxide or metallic aluminum has been added, so that aluminum fluoride is gradually formed. When a concentration of 7-70 g fluorine per liter and 1-15 g aluminum per liter has been reached, cryolite is precipitated by the addition of sodium-aluminum solutions. In the example given, the waste gases are drawn off in such a way that the fluorine content is kept at a level above 200 mg/cu m. The gas flows through a pipe line where its temperature drops and then into absorption columns containing water to which an excess quantity of aluminum hydroxide or metallic aluminum scrap has been added. During absorption the concentration of the aluminum fluoride gradually rises. The untrapped sulfur dioxide can be retained in a second stage of washing, for instance, by washing in a lime solution. Cryolite is precipitated by the gradual addition of a sodium-aluminum solution to the absorbing acid, with intense stirring, until complete neutralization, i.e., a pH value of 6.5 to 7.0, is reached. The cryolite is then separated (by sedimentation), filtered, and annealed at 500-600 C.

SELECTIVE ABSORPTION OF FLUORINE FROM THE
GASES FROM ALUMINUM REDUCTION CELLS WITH
VERTICAL SPIKE SODERBERG ANODES. In: Extractive
Metallurgy of Aluminum. G. Gerard (ed.), Vol. 2, New York,
Wiley, 1962, p. 83-96. 13 refs.

The principle of selective absorption of hydrogen fluoride from the burned anode gases as a control method for aluminum plants is examined. The device uses pure water as an absorbent and produces HF solutions in concentrations higher than 20 g/l (0.17 lb/gal) combined with absorption efficiencies up to above 99% and negligible absorption of sulfur dioxide. The efficiency of the device, which also serves as a dust separator and is essentially a sieve plate column modified to be self-cleaning within a continuous process, was tested in full-scale operation. B. CONTROL METHODS

81

Control methods adapted to the plants are reviewed. Waste gases escaping from reduction cells contain fluorine as a gaseous compound, especially in the form of hydrofluoric acid, dusts, and aerosols. Based on tests of gases emitted from anodes, hydrocarbons emitted before the burner, i.e., methane, ethane, propane, and butane, were all combusted. Thus, there is no evidence of an emission of organic fluorine compounds either in the form of gases or condensates. Control equipment for an aluminum plant would consist of dust cyclones, an electrostatic precipitator, and scrubbers. Spray chambers to clean the air escaping from cell rooms are also considered. With this equipment, the absorption efficiency for fluorine in gas form amounts to 90%.

SULFURIC ACID PRODUCTION FROM ORE ROASTER

GASES. *J. Metals*, 19(11):45-50, Nov. 1967. 15 refs. (Presented at the American Institute of Mining, Metallurgical, and Petroleum Engineers, Annual Meeting, Los Angeles, Calif., 1967.)

Feed gas requirements for the contact acid process and available roaster gases and their purification for acid plant use are examined. The contact process using a vanadium catalyst is the accepted technique for making sulfuric acid from sulfur dioxide gases. Major features of this process are outlined. Optimum SO₂ concentration in a conventional metallurgical type contact plant is approximately 7.0-7.5% by volume. As SO₂ concentration decreases, smaller fractions of the reaction heat are available to preheat incoming cold gases. At approximately 3.5-4.0% SO₂, the acid plant is thermally balanced; any lower concentrations require the addition of external heat. At low SO₂ concentrations, the amount of water vapor brought in may exceed stoichiometric requirements for acid formation and consequently reduce product acid concentrations below desired limits. To minimize this problem, the gas stream is cooled to condense excess water. If all product is wanted as 25% oleum, refrigerated gas cooling will be needed at concentrations below 7%. At the other extreme, if product wanted is 93% acid, one can operate at SO₂ concentrations in the range of 3.5-4.0% without refrigeration. Maximum limits for objectionable impurities, such as chlorides, fluorides, arsenic, lead, mercury, selenium, dust, and sulfuric acid mist, at the acid plant are reviewed. The composition of gas coming from any roaster depends on the amount of excess air used and the roaster temperature. The magnitude of sulfur trioxide formation is largely determined by the roaster system, with excess oxygen, temperature, and presence of finely divided catalytic oxides as the critical variables. Gas cleaning and conditioning equipment, including the Peabody scrubber and a two-tower scrubbing system, are discussed.

FLUIDIZED BED DISPOSAL OF FLUORINE. *Ind. Eng. Chem.*

Process Design Develop., 6(4):408-413, Oct. 1967. 16 refs. (Presented at the American Chemical Society, National Meeting, 152nd, New York, Sept. 1966.)

A fluidized bed process developed for the disposal of fluorine, using activated alumina as the reactive solid and a potassium iodide scrubber, was over 99.9% effective in the removal of fluorine from a gas stream and utilized the activated alumina to near the theoretical conversion. It has capability for high fluorine disposal rates and produces a free-flowing solid product for waste disposal. A factorial experiment was used to determine that increasing temperature (300-400 C), increasing ratio of bed depth to diameter (3:6), and decreasing particle size (399-183 micron) significantly increased the capacity of activated alumina for fluorine removal. Changing the fluorine concentration from 5 to 75 volume % or the velocity from 1.25 to 1.65 times the minimum fluidizing velocity had no signifi-

cant effect. A higher velocity (3.0) decreased the capacity slightly. Other solids reactants, less expensive than activated alumina, were given preliminary evaluation. Soda ash was especially promising. (Author abstract modified)

Tripler, Arch B. Jr. and G. Ray Smithson, Jr.

A REVIEW OF AIR POLLUTION PROBLEMS AND CON-

TROL IN THE CERAMIC INDUSTRIES. Preprint, American

Ceramic Society, Columbus, Ohio, 25p., May 5, 1970. 19 refs.

(Presented at the American Ceramic Society Annual Meeting, 72nd, Philadelphia, Pa., May 5, 1970.)

Air pollution in the ceramic industry stems from the large amounts of dust and fumes which form at various processing stages. Five segments of the industry (glass, cement, mineral wool, asbestos, and brick) are considered. Prior to the analysis of the problems of each of these, eight basic control methods are listed along with comment on the application and approximate cost of each. The control methods listed are cyclones, scrubbers, fabric filters, electrostatic precipitators, adsorption, burning, stacks, and process modification. In the manufacture of glass three chief sources of air contaminants are batch drying of finely divided raw material prior to melting, gas or oil fired melting furnaces, and glass forming. The first of these presents only a dust problem. The furnaces, on the other hand, emit particulates and a gas combination representing both fuel products and the melt composition. Glass forming machines generate heavy smoke from vaporization of hydrocarbon lubricants. Both process modification and electrostatic precipitation are recommended. In the cement industry, dust is the major problem; dust reclamation is an economic necessity. In spite of highly efficient collection, some of the dust escapes. Dustfall rates of 35 tons per square mile were recorded in areas adjacent to efficiently controlled kilns. A secondary problem is the effluent from the kilns which contain gaseous pollutants from the fuel and from the heating of the components. In the mineral wood industry, stack emissions containing condensed fumes from the molten material, sulfur dioxide, and fluorides as well as blow chamber and curing oven emissions consisting of fumes, oil vapors, binding agent materials, and up to 90% wool fibers must be contended with. The asbestos industry is faced with the twin threats of asbestosis and lung cancer as a result of asbestos dust in which a fiber thickness of 0.01 micron is fairly common. The current threshold limit value of 5 million particles per cu ft of air for a daily 8-hr exposure, 40 hrs per week is thought by some to be too high. The importance of controlling dust in the manufacture of silica brick was pinpointed in a Pennsylvania Dept. of Health report in 1939 revealing that 51.9% of 1035 workers examined had silicosis. The threshold limit value of airborne dust as set by the American Conference of Governmental Industrial Hygienists is a function of the silica content. In a dust containing 5% free SiO₂, the TLV is 25 mppcf, but in a dust containing 45% free SiO₂, the TLV is only 5 mppcf. For amorphous silica, the TLV is 20 mppcf.

ABATEMENT OF AIR POLLUTION CAUSED BY

FLUORIDE. (Fukkasuiso oyobi kakushu fukkabutsu niyoru

taikiosen no taisaku). Text in Japanese. Kogai to Taisaku (J.

Pollution Control), 6(7):509-514, July 15, 1970.

<xref image="2000WVC9.TIF|V3|2006:09:28:01:21:04.00|127481|0"> image: </xref>

Sources of fluoride pollutants include aluminum refining and phosphate fertilizer, brick, glass, glass-fiber, steel, and cement manufacturing. Fluorides emissions from an aluminum refinery and a phosphate fertilizer plant, both subject to large numbers of damage claims, are shown in a block diagram. Examples of fluoride pollution by the Showa Denko plants in Fukushima and Chiba and Sumitomo Chemicals in Ehime are presented. Regulations applicable to pollutant sources in Osaka and Fukushima Prefectures are noted. A common method of processing fluorine compounds is the use of caustic soda. Fluorine becomes sodium fluoride, which is subsequently converted to calcium fluoride by lime. In aluminum refineries, the recovery rate of fluorine by the method is over 99%. Exhaust gas, however, shows a recovery rate of only 60-70%, even in factories equipped with a recovery device. If the density at the source is lowered to several ppm, the use of chimneys around 200-m high will reduce the ground concentration to .1 ppb. At present, the recovery of fluorides is accomplished by wet methods, which give rise to mists such as hydrofluoric acid. The efficient processing of the mist is a future problem. Since the demand for aluminum is predicted to be 2,000,000 tons in 1975, an increase in aluminum refineries is expected. In the process of construction, future refineries must be thoroughly evaluated for fluoride pollution.

AIR POLLUTION CONTROL EQUIPMENT FOR FLUORIDE

AND FLUORIDE PROPERTIES. (Fusso kagobutsu no seiyo to sono jogai shisetsu). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 6(7):S21-530, July 1970.

Guidelines issued by a local government recommend that processing plants choose economical and practical installations for purifying exhaust gas. A guideline for plants processing fluorides is described. A jet scrubber or a spray tower is recommended for cleaning by water. The standards for fluoride concentration in plants are 15 ppm at the maximum and 10 ppm on the average. After a detailed description of the general properties of fluorides including hydrogen fluoride, hydrofluoric acid, silicon fluoride, and hexafluoro silicic acid, their effects on health are reviewed, together with the maximum permissible concentration of threshold values. A 3-stage floating-bed type of wet scrubber, which is employed by a hydrogen fluoride manufacturing plant in Tokyo, is schematically illustrated. Also described are principles of removing or recovering fluorides, apparatus for absorbing fluorides, anti-corrosive materials for the apparatus, processing of the water used to remove fluorides, re-use of the cleaning water, and the use of alkaline solutions for cleaning. Unit operations in the plant, which give rise to fluoride pollution, are tabulated. In addition, various local government standards for harmful gases and particulates are noted.

TREATMENT OF GASES EVOLVED IN THE PRODUCTION

OF ALUMINUM. (Aluminum Co. of America, Pittsburgh, Pa.)

U. S. Pat. 3,503,184. 3p., March 3, 1970. 5 refs. (Appl. March 7, 1968, 5 claims).

A process for removing hydrogen fluoride and finely divided solids from gas evolved in the electrolytic production of aluminum entails passing the gas stream upward for 0.25 to 1.5 sec through a 2- to 12-in. bed of finely divided alumina particles. The hydrogen fluoride is sorbed by the alumina particles and the finely divided solids are entrapped in the fluidized bed, which contains 50 to 150 pounds of alumina per pound of hydrogen fluoride. The alumina particles containing hydrogen fluoride are removed from the bed and fed to the fluoride baths of electrolytic cells. The gas stream leaving the bed is passed through bag filters on the surfaces of which any remaining finely divided solids and alumina particles small

enough to be carried upward are deposited. The average residence time of alumina particles in the bed is 2 to 14 hrs.

ATMOSPHERIC POLLUTION INTERRELATION AND GREEN SPACES AS A PROTECTIVE PRINCIPLE OF INDUSTRIAL TOWNS.

(Interrelation pollution atmospherique et espaces verts en tant que principe protecteur des villes industrielles). Tribune CEBEDEAU (Centre Beige Etude Doc. Eaux), no. 301:143-153, July-Sept. 1969. 59 refs. Translated from French. Belov and Associates, Denver, Colorado.

The protection of residential areas from air pollution due to industrial sources, by means of green plantings, is discussed. Plants intended for such protective zones should be resistant species and they should act on the atmosphere. The pollutants known for their phytotoxic properties are presented in tabular form. The action of plants on air polluted by dusts consists of decreasing the wind speed, collecting the dust on the leaves, and acting on the local air movement. The plants found to be resistant to pollutants are also listed in tabular form. The retention of sulfurous gas, fluorine, hydrogen sulfide, and nitrogen oxides has been established. A correlation between the type and concentration of the pollutant and the degree of plant resistance is needed when managing green spaces for sanitary protection. For each situation, the degree of toxicity of the pollutants should be known in order to choose species with a specific resistance. Plantings with an aerated structure, obtained by grouping wind breaks or rows of trees, retain dusts and gaseous pollutants better than compact areas. Methods which are recommended for determining the form of future protective zones include zoning the values of pollutants obtained by ground studies, mathematical processes based on the laws of pollutant dispersion, and graphic processes.

THE BATTLE AGAINST AIR POLLUTION IN THE FERTILIZER INDUSTRY.

(La lutte contre la pollution atmospherique dans l'Industrie des engrais). Text in French. Inform. Chim. Numero Spec., 69(43): 63-66, 69, Dec. 1966. 10 refs.

Sulfuric acid is widely used in the production of ammonium sulfate, superphosphates, phosphoric acid, potassium sulfate, and other fertilizers. The oxidation reaction is never complete and sulfur dioxide and sulfur trioxide are present in concentrations of 0.1 to 0.2% in the waste gases. Dry methods of their purification are briefly described; the wet methods involve scrubbing with an alkaline aqueous solution and utilize different reactions to recover either pure S or definite S compounds, such as sulfates or mixtures of sulfites and bisulfites. A wet method for recovery of ammonium sulfate utilizes the overall reaction: $2\text{SO}_3\text{H}(\text{NH}_4) + \text{SO}_3(\text{NH}_4)_2 + 2\text{H}_2\text{SO}_4$ yields $2\text{SO}_4(\text{NH}_4)_2 + 3\text{SO}_2 + 3\text{H}_2\text{O}$. The nitrogen-bearing fertilizers are produced by neutralization of nitric acid by the corresponding base. This acid is obtained by oxidation of ammonia. The air-pollution is due to incomplete oxidation of the intermediately formed nitric oxide to nitrogen dioxide and to incomplete dissolution of NO_2 in water, so that the waste gas contains 0.2 or more % NO . Present day methods of their purification are not efficient and uneconomical. Natural phosphates used in the production of phosphor-bearing fertil-

PREVENTING HAZARDOUS POLLUTION DURING PLANT

CATASTROPHES. Chem. Eng., 77(10):97-102, May 4, 1970. 5

refs.

A plant handling toxic materials must plan to prevent hazardous pollution during sudden and unexpected occurrences such as equipment malfunction, power failure, failure of cooling water, fire, flooding, and thick fogs which can lead to high ground-level concentrations. The necessary provisions, which will vary from one plant to another, are illustrated by the example of a plant in which hydrocarbon liquids are reacted in the presence of anhydrous hydrogen fluoride. To prevent high ground concentrations in the absence of thermal lift, provisions were made to keep the flare stack ignited by installing flare tips and pilots suitable for operation in hurricane winds. A flare-ignition system remotely operated in conjunction with a flare-flame-monitoring system warns the operator of flame failure. Reliability of the watercooling system on the HF recovery column is insured by the presence of three water-cooling pumps with suitable automatic controls, and a device to cut off the flow of process heat to the reboiler whenever there is no cooling-water flow. An oversize fluoride scrubber handles larger than normal flows of HF through the vent line. Fire hazards are reduced by insulating all vessels containing HF. To protect against excess pressure in the storage tank, it is equipped with a pressure relief valve venting into the common HF manifold leading to the drenching towers and flare stack.

REDUCTION OF EMISSIONS IN METAL FOUNDRIES AND

REFINISHING PLANTS. (Emissionsverminderung in Metall-

huetten und Umschmelzwerken). Text in German. VDI (Ver.

Deut. Ingr.) Ber., no. 149:260-273, 1970. 12 refs.

Although the non-ferrous metal industry is not a primary polluter of our environment, it is nevertheless confronted with the problem of reducing the sulfur dioxide, fluorine and dust emissions. The SO_2 -containing gases are used for the production of sulfuric acid; the so-called Bayer Contact Process with intermediate absorption is used for this conversion. A large-scale plant has gone into operation and the price of the sulfuric acid obtained with this method is up 1 to 2%. Fluorine emissions are usually drawn off by an exhaust system at the point of origin and scrubbed out of the waste gases. Dust with a high salt content (two thirds NaCl and KCl) as well as extremely fine particles containing grease and soot, is produced in aluminum plants. It is separated by cooling the 550 C flue

gases in 4 cooling chambers to 150 C. A bag-type cloth filter consisting of 7 chambers and made of felt is used for dust collection. The filter is cleaned by a reverse air jet. Zinc alloy is increasingly processed by the imperial-smelting method plants which leaves a waste gas free of SO₂. In copper and lead smelting plants electrostatic precipitators or bag filters are primarily used for waste gas cleaning. They are usually preceded by cyclones. Emissions due to metal recovery from old cables have not yet been satisfactorily reduced. Of the 70 plants of this kind existing in England and Wales, 60 use after-burners, while 9 operate with wet scrubbers.

GAS SCRUBBER APPARATUS AND PROCESS. (Wellman-
Lord, Inc., Lakeland, Fla.) U. S. Pat. 3,505,788. 4p., April 14,
1970. 2 refs. (Appl. May 23, 1968, 9 claims).

A gas scrubbing apparatus for recovering foreign materials, particularly fluoride gas and particulates, from a carrier gas is described. The carrier gas and foreign material are introduced tangentially into a vertical cylindrical recovery zone into which a washing liquid is radially sprayed. The foreign material is captured in a slurry and discharged. The gas then passes into a packed bed and second washing liquid to further remove contaminants. The bed is packed with a material having a nonadhering surface and a high free volume. The carrier gas then passes through another packed bed to remove entrained liquid. The advantages of this system over previous ones include low cost, fewer pieces of equipment, and no deposition of solid buildup. (Author abstract modified)

Jewell, John P. and Burton B. Crocker
CONTROL OF FLUORIDE EMISSIONS. Vanderbilt Univ.,
Nashville, Tenn., School of Engineering, Tennessee Stream Pollution Control Board, and Tennessee Dept. of Public Health, Proc. Conf. Environ. Water Resources Eng., 8th Ann., Nashville, Tenn., 1969, p. 211- 228. 21 refs. (June 5-6.)
Fluoride compounds released to the atmosphere may be particulate, gaseous, or a mixture of the two. Solic particulate fluorides are usually released from handling operations which generate dust. Hoods or enclosures to contain or collect the particles and bag filters are desirable recovery devices. There are several methods for controlling gaseous fluorides including injection of ground limestone dust into the gas stream and wet scrubbing. Most installations for controlling gaseous fluoride emissions have involved absorption in water. Packed towers and spray towers are generally used for this purpose. One method of sizing water scrubbers is to obtain an idea of the number of transfer units needed to get from the maximum fluoride concentration in the inlet gas to the desired concentration in the outlet gas. Venturi scrubbers waste power when only gaseous fluorides are to be collected, but they may be the most economical multi-purpose scrubbers when a mixture of gaseous and particulate fluorides must be collected. It is recommended that the effluents be sampled and monitored to determine the operating efficiency of control equipment. Several sampling techniques are discussed.

Karbe, K.

FLUORIDE EMISSION FROM FERTILISER PRODUCTION.

Chem. Engr. (London) 46(7):CE268, Sept. 1968.

In general, the crude phosphates that are used as starting material for the production of fertilizers and phosphates contain 3-4% fluorine compounds. In the preparation of the fertilizers and phosphoric acid, the natural phosphates are decomposed by treatment with acids or by thermal decomposition processes. All methods of decomposition produce fluorine compounds as air contaminants, the thermal processes emitting the compounds as both gases and particulate aerosols. Dry and wet methods are available for purifying exhaust gases from fertilizer production. In the dry methods, hydrogen fluoride is absorbed by chalk or limestone with formation of calcium fluoride. Efficiency is 95%. In the wet methods, the gases are washed with water to convert hydrogen fluoride and silicon tetrafluoride to hydrofluoric and hydrofluosilicic acids, respectively. Removal efficiency of the wet methods is generally better than 90% and can be greater than 98%. Difficulties arise due to the conversion of silicon tetrafluoride to silicon dioxide, which can cause plant blockage. In Germany, exhaust gas emissions from new fertilizer plants cannot exceed 50 mg F1/cu m.

Cochran, C. N., W. C. Sleppy, and W. B. Frank

FUMES IN ALUMINUM SMELTING: CHEMISTRY OF

EVOLUTION AND RECOVERY. J. Metals, 22(9):S4-57, Sept.

1970. 7 refs. (Presented at the TMS-AIME Annual Meeting,

1970.)

Traces of gaseous and particulate fluoride must be removed from the effluent of aluminum smelting cells. Fluoride emission, both particulate and gaseous, increases with increase of temperature and decrease of bath ratio and aluminum oxide content. Hydrogen fluoride from reaction of moisture with aluminum fluoride-containing bath species increases with increasing partial pressure of H₂O. The water vapor originates from the atmosphere, from constitutional water or water adsorbed on the aluminum oxide or from burning of hydrogen or hydrocarbons from the anodes. The particulate is removed by electrostatic precipitators, mechanical precipitators, scrubbers or bag filters. Gas scrubbers or adsorption on aluminum oxide are used for removal of HF. Adsorbing HF on aluminum oxide as a chemisorbed monomolecular layer permits recovery of the sorbed fluoride and the direct return of the fluoride to the pot. The chemisorbed fluoride is initially amorphous but forms aluminum fluoride upon heating. Physically adsorbed HF (in contrast to the chemisorbed layer) is re-evolved as HF on adding the recovery product to the pot. Thus, the fume removal process should be limited to the chemisorption reaction. Efficiency of HF recovery with aluminum oxide increases as fume concentration increases and the ratio of recovery product to pot feed increases. (Author abstract)

ATMOSPHERIC EMISSIONS FROM WET-PROCESS

PHOSPHORIC ACID MANUFACTURE. NAPCA Pub. AP-S7,

86p., April 1970. 39 refs. CFSTI: PB 192222

In 1966, the production of wet-process phosphoric acid, expressed as P₂O₅, was approximately 3.5 million tons. Much of this was produced as 54% P₂O₅, and virtually all of it was used to produce various phosphate fertilizers. Fertilizers are produced by treating phosphate rock with wet-process phosphoric acid to form triple super-phosphate, TSP, or by reacting phosphoric acid with anhydrous ammonia to form ammonium phosphates, especially diammonium phosphate, DAP. The emissions of most concern are fluoride compounds

liberated from the phosphate rock by sulfuric acid: hydrogen fluoride, silicon tetrafluoride, and some products of reaction and decomposition of the latter. Vapor scrubbing is universally employed to control emissions, while specific devices used for control include venturi scrubbers, impingement scrubbers, and various kinds of spray towers. The major source of gaseous fluoride emissions in wet-process phosphoric acid plants is the digester. Emissions and methods of emission control are discussed in detail, and sampling and analytical techniques are summarized. Wet-process phosphoric acid manufacture is described, as well as growth of the industry.

VOLATILE FLUORIDE RECOVERY. (Standard Oil Co., Cleveland, Ohio) U. S. Pat. 2,440,542. 3p., April 27, 1948. 7 refs. (Appl. July 17, 1942, 18 claims).

Volatile fluorides, such as boron fluoride and hydrogen fluoride, used in catalytic operations are discharged in admixture with themselves or with hydrocarbons. While the fluorides can be separated by fractional distillation and condensation, this method is expensive and in many cases not profitable. In contrast, the fluorides can be conveniently recovered with relatively little expense by exposing gas containing them, in countercurrent flow in a tower, to dihydroxyfluoboric acid. Part of the fluoride is absorbed at about 27-55 C while the remainder is liberated by raising the temperature of the acid to 120 C or above. As an example, gas containing hydrogen fluoride at 1 atm was subjected to absorption at 35.2 C, and 91% by weight of HF was absorbed. By raising the temperature to 170 C, 95.7% by weight of HF was recovered. The acid is recycled to contact fresh incoming gas.

Hammond, Roll

ELIMINATING DUST IN CHEMICAL PLANT. Chem. Age, (New York), vol. 77:431-433, March 9, 1957.

Among new equipment for eliminating dust from chemical plant flue gases is a multi-wash collector that removes sub-micron particles with maximum efficiency. The collector comprises a cylindrical stainless steel tower with six and one-half vaned impingement stages. An entrainment separator placed above the units forms a seventh tier. Air enters the tower just below its conical base, which acts as a wet cyclone to collect the heavier particles upon entry. A water curtain descending from the top of the tower combines with spray and impingement to envelop the particles rising with the air, carrying them down into the cone and out of the collector. When most of the dust is above the submicron range, collectors with fewer stages are employed. These collectors are equally effective on both soluble and insoluble dusts and on soluble gases. For the removal of gaseous contaminants such as hydrogen sulfide, sulfur dioxide, hydrochloric or hydrofluoric acid vapors, alkaline solutions are added to the recirculated liquid. For the 0.1 to 5 micron particles found in pharmaceutical and bacteriological work, an esparto grass-based paper filter with asbestos fibers has an efficiency of 99.95%. This filter can be accommodated in a very small place. A reverse-jet type filter has proved very efficient for vaporized silica of 0.6 micron and less. Electrostatic precipitators are used to remove dust and

85

fumes from pyrite roasters, sulfuric acid mist from wet catalyst sulfuric acid plants, and sulfuric acid mist from coal roaster gases. Static rectifiers for the precipitators are available that dispense with the high-tension connections formerly required. Alternating current is rectified and used without high-frequency effect on the wave-form, as in the case of mechanical rectifiers.

Purvance, W. T.

ATMOSPHERIC POLLUTION CONTROL. Chem. Eng. Progr., 55(7):49-53, July 1959. (Presented at the American Institute of Chemical Engineers Meeting, Salt Lake City, Utah, Sept. 1958.) The development of measures to control fluoride emissions from a Utah steel plant which had caused damage to local animals is described in detail. The open hearth shop and sintering plant were the major sources of emission, while the locally-mined iron ore was the raw material responsible for the greatest quantity of fluorine. On the basis of extensive pilot plant testing, limestone was added to the sintering mix, and equipment for cleaning sintering waste gases were installed, including facilities for injecting pulverized limestone into the gas stream, a battery of mechanical cyclones, and an electrostatic precipitator. A reduction of 96% in fluoride emissions from this source was thus achieved, with important savings from recycling the waste gas. For the open hearth operations, it was decided to collect and blend the waste gas effluent from all the furnaces in a collector main flue, from where it is passed to individual precipitator units. Clean gases are discharged into existing stacks; hydrated lime is the reactant in the process. The major problems encountered were handling of the collected dust, control of gas moisture, and furnace pressure control. The \$9 million cost of the entire control program from research through operation is viewed as part of the cost of using Utah iron ore. The equipment is considered unique in that extremely large volumes of gas are continuously undergoing chemical treatment and final cleaning while the final collected product is disposed of.

ACOUSTIC COAGULATION OF MIST CONTAINING

FLUORINE COMPOUNDS. I. (Akusticheskaya koagulyatsiya tumana, soderzhashchego soyedineniya ftora. I). Text in Russian. Zh. Prikl. Khim., 34(1):78-84, 1961. 28 refs.

Removal of fluorine compounds from mist was increased from 42-69% to 80-95% by inducing acoustic coagulation through application of 16.5-kHz sound at 153-155 dB. Degree of removal was significantly affected by the concentration of the mist; increasing moisture content from 15 to 120 g/cu m upgraded removal from 73 to as high as 95%. With constant moisture content, the degree of removal increased with initial fluorine concentration and with the duration of the sonic treatment. Tests at a granulated superphosphate plant showed precipitation of 87% of the fluorine in exhaust gases after 3 seconds of sonic treatment; fluorine content was reduced from 0.18 to 0.025 g/cu m directly within the sonic-treatment tube without auxiliary mechanical precipitation.

Boehlen, B.

FLUORINE EMISSION AT ALUMINIUM WORKS. Chem.

Engr. (London), 46(7):266-268, Sept. 1968.

The electrolysis of fused alumina, with cryolite as the fluxing agent and electrolyte, gives rise to waste gases with a fluorine content. The method by which the electrolysis furnaces operate requires two separate waste-gas purification systems, one for interception and conveyance of waste furnace gases to a purification plant, and one for cleaning fluorine-con-

taminated air used for ventilation of furnace room premises. The purification processes for both systems are described briefly, and the problems are reviewed. Because of the large quantities of waste air involved, considerable costs are incurred to provide the power required for ventilation, the large quantities of scrubbing water, and the pumps to convey the water; the presence of corrosive hydrogen fluoride creates added difficulties. The possibility of replacing cryolite by electrolytes which do not contain fluorine is recommended for future research.

Damon, W. A.

THE CONTROL OF NOXIOUS GASES AND FUMES
DISCHARGED FROM INDUSTRIAL UNDERTAKINGS.

World Health Organization, Copenhagen (Denmark), Regional Office for Europe, Proc. Conf. Public Health Aspects Air Pollution Europe, Milan, Italy, 1957, p. 103-130. 26 refs. (Nov. 6-14.)

The greatest contribution to air pollution arises from the combustion of fuel for domestic and industrial purposes and from motor traffic. Its damaging effects include injury to plants, deterioration of property, and possible or proven hazards to the health of humans and animals. British air pollution legislation is embodied mainly in three Acts of Parliament: the Alkali etc. Works Regulation Acts, first enacted in 1863; the Public Health Acts, 1936; and the Clean Air Act, 1956. Evolution of the chemical industry has caused a variety of changed and new pollutants. Fluorine compounds can be washed in alkaline solutions, followed by electrical precipitation. The escape of SO₂ from the exits of sulfuric acid plants depend on the efficiency with which the the process is conducted. In four stage contact plants burning brimstone, recourse to scrubbing the exit gas with either soda or ammonia may be necessary. Power stations remove SO₂ from waste- fuel gases by scrubbing with slightly alkaline water. Sulfur dioxide arising from the roasting of copper as in the production of iron oxides is normally absorbed by passage through towers packed with limestone. Hydrogen chloride may be recovered at a useful strength by arranging a counter current series of absorbers. Hydrogen sulfide may be scrubbed with caustic soda to produce sodium sulfide; it may be absorbed by passage through hydrated iron oxide which can be regenerated to produce spent oxide containing up to 50% sulfur; or it can be stripped out by means of a solvent and regenerated in concentrated form for treatment in a Claus Kiln. Gases containing chlorine may be scrubbed with an alkaline solution or by contact with milk of lime; passage through a tower packed with scrap iron is also effective. Nitrogen peroxide may be recovered in the form of nitric acid by water washing; but for every three molecules of nitrogen peroxide thus absorbed there is evolution of one molecule of nitric oxide which must be reoxidized to nitrogen peroxide.

RECOVERY OF SOLUBLE GAS AND AEROSOLS FROM

AIR STREAMS. Ind. Eng. Chem., 46(9):1769-1777, Sept. 1954.

18 refs.

<xref image="2000WVCD.TIF|V3|2006:09:28:01:21:16.00|120210|0"> image: </xref>

High efficiency absorption of soluble or reactive gases was obtained with wetted fiber beds. Wetted fibers were five to 10 times more efficient than Raschig rings or Berl saddles, compared on the basis of equal volumes. When compared on the basis of weight of packing, 1 pound of 78-micron-diameter saran fibers was 75 times more effective for the absorption of hydrogen fluoride gas than 1 pound of 1/2 inch Berl saddles. In addition to hydrogen fluoride gas, cleaning efficiency for sulfuric acid and ammonium bifluoride mists, ammonium bifluoride and aluminum chloride fumes, and silica, tale, and atmospheric dusts was investigated. High efficiency collection (greater than 99.9%) generally required the addition of a droplet eliminator composed of a 1- to 2-inch depth of dry fibers less than 5 microns in diameter. Although absorption of the gas was complete, a significant quantity of fluorides passed the scrubber in the form of fine (less than 10 micron) mist droplets formed from condensation of hydrogen fluoride gas in the humid atmosphere of the scrubber or from fine droplets formed by the sprays. When gas streams containing inert particles were treated, the absorbing stages were protected from fouling and plugging by the use of an impingement device such as a Neva-Clog screen as a prefilter. Over-all resistance of the scrubber was proportional to the flow rate. For gas flows of 200 cu ft/min, sq ft of scrubber face area, high efficiency scrubbing of gas and submicron particulate matter was obtained with resistances not exceeding 6 inches of water gauge. For atmospheric pollution control of stack gas, emissions resistances less than half this may be adequate. (Author summary)

McCabe, Louis C.

ATMOSPHERIC POLLUTION. Ind. Eng. Chem., 47(8):95A-96A, Aug. 1955. 1 ref.

In the electrolytic reduction of alumina, oxygen liberated in the cryolite bath combines with the carbon of the node to produce carbon dioxide. As the CO₂ rises through the blanket of alumina covering the electrolytic cells, small amounts of alumina dust and fluorides are entrained. On striking the air the fluorides are hydrolyzed, in part, to hydrogen fluoride gas. Heat generated in the reduction process requires that effective ventilation be maintained to provide satisfactory working conditions in the potrooms, but the high velocities of an induced draft pack up some of the fine dust from the top of the pots. The collecting systems consist basically of a dry type dust separator, an induced draft fan, and a wet scrubber. A typical system of this type uses a dry dynamic precipitator exhaustor that is so designed that the dust is separated from the main gas stream within the fan by means of specially shaped blades and a separate outlet in the scroll. The main gas stream, containing some fine dust, is discharged directly to an open tower type scrubber of redwood construction with suitable spray headers. At one large plant, the basic system has been supplemented by an electrostatic precipitator. Fumes generally can be controlled by accurate regulation of the temperature of the bath, the rate of firing, and the amount, method, and type of flux used.

Tarbutton, Grady, Thad. D. Fair, Thomas M. Jones, and Harry T. Lewis, Jr.

RECOVERY OF BY-PRODUCT FLOURINE. Ind. Eng. Chem., 50(10): 1525-1528, Oct. 1958. 14 refs. (Presented at the American Chemical Society, 132nd Meeting, Symposium on Fluorine Chemistry, New York, Sept. 1957.)

Basic information was obtained for developing practical methods for recovering fluorine compounds from effluent gases from phosphate processes and converting this fluorine into useful end products. The study included experiments with gases discharged from kilns for nodulizing rock phosphate and from a demonstration furnace for the manufacture of calcium metaphosphate fertilizer. On the assumption that the fluorine

in nodulizing kiln gas was present only as hydrogen fluoride, initial work on recovery of fluorine from dilute gases was directed toward a solid-bed system for absorbing the fluorine. In a quantitative test, two absorption beds of porous sodium fluoride were connected in series -the first, in a copper tube at 300 C, for absorption of sulfur trioxide, and the second, in a silver tube at 100 C, for absorption of the hydrogen fluoride liberated from the first. Later it was found that much of the fluorine was present as silicon tetrafluoride, and emphasis was shifted to other methods of recovery. A method partially developed by TVA for preparing aluminum fluoride from ammonium fluoride solutions containing phosphoric acid involves precipitation of ammonium hexafluoroaluminate, which is then decomposed by heat to leave a residue of aluminum fluoride; the volatilized ammonia and ammonium bifluoride are recycled. An alkaline and an acid method for preparing cryolite were also evaluated. In the alkaline method, solutions of the reactants are heated to boiling and mixed, and the hot basic solution is acidified to the phenolphthalein end point by slowly adding carbon dioxide. In the acid method, a slightly acidic solution of ammonium fluoride is mixed with a solution of sodium and aluminum salts without heating.

McCabe, Louis C.

ATMOSPHERIC POLLUTION. Ind. Eng. Chem., 43(8):83A-84A, 86A, Aug. 1951. 2 refs.

At Trail, British Columbia, essentially 100% gas is recovered from 1% sulfur dioxide zinc roaster gas through the use of 30% ammonia as the absorbent. The sulfur shortage is causing more than one large consumer of coal to look into the possibility of recovering sulfur from stack gases. A process patented by Simon-Carves entails control of the composition of the liquor in the scrubber by an electrical vapor pressure recorder. In the first pilot plant, the concentration of SO₂ in the exit gas was found regularly to be as low as 0.0005% which corresponded to the removal of 99% of the SO₂ in the flue gas. The flue gas at the Battersea power station in London is washed with large volumes of river water to which chalk has been added, so that the calcium sulfate formed remains in solution and can be discharged into the river. Another paper to be presented at the XII International Congress of Pure and Applied Chemistry (September 1951) pertains to atmospheric pollution by fluorine compounds in Rotterdam and its environs.

Hignett, T. P. and M. R. Siegel

RECOVERY OF FLUORINE FROM STACK GASES. Ind. Eng. Chem., 41(11): 2493-2498, Nov. 1949. 5 refs.

More than 90% of the fluorine present in the stack gases from thermal processing of rock phosphate was recovered by absorption in a 4-ft bed of lump limestone. The calcium fluoride product contained 80-95% CaF₂, which is in the range of commercial grades of fluor spar. In the pilot plant studies, the fluorine absorption coefficient was dependent on the rate of removal of the reaction product from the bed of limestone by screening. Temperatures in the range of 200-900 F were suitable for the process. Increasing the gas velocity in the range of 0.6 to 1.5 ft per sec increased the absorption coefficient but did not appreciably affect the percentage of fluorine absorbed.

Substantially complete recovery can be obtained by increasing the depth of packing to about 9 feet. (Author conclusions)

24683

INITIATIVE FOR WATER AND AIR POLLUTION CONTROL. (Initiative fuer Wasser-und Luftreinhaltung). Text in German. Wasser Luft Betrieb, 14(9):375-378, Sept. 1970. The Nordrhein-Westfalen Program 1975 contains an outline of water conservation, air pollution, and refuse disposal perspectives for the next 5 years. Discussed are water conservation, river pollution control, natural water pollution 1970 and 1975, waste disposal, air pollution control, new sources of pollution, current control of air quality, and noise control. Drinking water supply will be increased by increasing the capacity of water clearing installations, the water quality of the Rhine river and of its tributaries will be controlled by a number of automatic measuring stations; about 300 new biological clearing installations will be built. Controlled refuse dumps will be established for each 20,000 inhabitants; composting of refuse and incineration will serve larger population units. New air pollution measures are planned for Thomas steel converters, ore sintering plants, coke ovens, foundries, and steam power plants. New sources of pollution to be dealt with include the increasing number of atomic power plants being built and the tremendous growth rate of the chemical industry. Supervision of air quality will extend to fluorine, hydrocarbons, offensive sulfur and nitrogen compounds, dust concentration, chlorinated hydrocarbons, and oxidants. Noise pollution control will be concerned with the design and building of silent machines, motors and equipment, with improving insulation against noise, with a registration of sources of noise, and with noise control research

24834

Barber, J. C. and T. D. Farr
FLUORIDE RECOVERY FROM PHOSPHORUS PRODUCTION. Chem. Eng. Progr., 66(11):56-62, Nov. 1970. 9 refs. When phosphate rock is processed to make various phosphate chemicals, fluorine in the rock is evolved as gaseous hydrogen fluoride, silicon tetrafluoride, or a mixture of these gases. Substantially all the fluorine must be removed to comply with Federal, state, and local pollution abatement regulations. TVA studies of fluorine recovery revealed that fluorine compounds can be readily removed by scrubbing the gases with slightly acidic aqueous ammonium fluoride. The hydrogen fluoride dissolves and reacts with ammonia in the aqueous solution to form ammonium fluoride. The silicon tetrafluoride dissolves in aqueous ammonium fluoride to form a solution of ammonium fluosilicate. Silicon and iron compounds are removed from the ammonium fluoride-ammonium fluosilicate scrubber liquors by adding ammonia to raise the pH to 8-9; the fluosilicate decomposes, and precipitates of hydrated silica and iron hydroxide are separated from the ammonium fluoride solution. The silicon and iron contents of the filtrate will correspond to weight ratios F:SiO₂ and F:Fe₂O₃ well above the minimum values specified by the aluminum industry for cryolite and aluminum fluoride.

Gartrell, Francis E. and James C. Barber
ENVIRONMENTAL PROTECTION-TVA EXPERIENCE. J. Sanit. Eng., Am. Soc. Civil Engrs. Div., 96(6): 1321-1334, Dec. 1970. 7 refs. (Presented at the American Society Civil Engineers, Water Resources Engineering Meeting, Memphis, Jan. 26-30, 1970.) Establishment of the Tennessee Valley Authority created a unified program that saw in the Tennessee Valley's water, land, minerals, and forests one interrelated set of opportunities for improving the living standards of the people in the region.

Research on soil-fertilizer relationships, fertilizers, and fertilizer processes is conducted at the National Fertilizer Development Center. One water resource study which was undertaken at the Center involved determination of the conditions that give rise to excessive growth of nuisance weeds in a TVA reservoir, while another project involved determination of the amount of plant nutrients lost from land into both surface and ground waters. Two approaches may be followed in the development of fertilizers for the control of nutrient losses in streams; slow-release chemical compounds may be used as fertilizers, or the highly soluble fertilizer granules may be coated to retard their solubility in the soil. Various fertilizers are produced at the Center, and environmental control during their production is discussed. Electric furnace phosphoric acid production presents some particularly difficult pollution abatement problems. Production of fluoride by-products may be economical in some large electric furnace phosphoric acid plants or in plants where large amounts of fluorine are driven off during the phosphate ore heat hardening step. A modern ammonia plant is being constructed. Two of the 11 coal-fired power plants in the TVA system have cyclone furnaces, eight have dry bottom pulverized fuel furnaces, and one has a wet bottom pulverized fuel furnace. They all have essentially the same system for ash disposal. Research is being conducted on the removal of sulfur dioxide from power plant stack gases, including an ammonia scrubbing process, sorption by dry limestone, and limestone wet scrubbing. Waste heat for disposal has required a study of the effects of cooling tower discharge. Also, composting research is being conducted adjacent to the city's sewage treatment plant.

Rossano, August T., Jr. and Michael J. Pilat
RECENT DEVELOPMENTS IN THE CONTROL OF AIR
POLLUTION FROM PRIMARY ALUMINUM SMELTERS IN
THE UNITED STATES. Preprint, International Union of Air
Pollution Prevention Associations, 19p., 1970. 9 refs. (Presented
at the International Clean Air Congress, 2nd, Washington, D.
C., Dec. 6-11, 1970, Paper EN-16F.)

The alternative processes and equipment employed in the production of aluminum are described. Details of the types and relative magnitudes of pollutants emitted from both the prebaked and continuous anode type of electrolytic refining processes are briefly reviewed and illustrated. Air pollution regulations recently adopted by the Department of Ecology of the State of Washington are presented. These regulations stipulate the maximum permissible concentrations of fluorides in the ambient air surrounding an aluminum smelter and the maximum fluoride content of forage, both expressed on a time average basis. In addition, the regulations restrict the amount of particulate matter emitted. A brief resume of current efforts by industries to meet these new regulations is given. Engineering control measures being developed and tested include wet scrubbers, wet electrostatic precipitators and a new chemisorption technique involving a fluidized bed followed by bag filters. It is concluded that rapidly growing emphasis on the maintenance and improvement of air quality throughout the United States will serve to stimulate new and better technology for the control of emissions from primary aluminum smelters. (Author abstract)

Teworte, W. M.

SPECIFIC AIR POLLUTION CONTROL ARRANGEMENTS

AT NON-FERROUS METAL WORKS. Preprint, International Union of Air Pollution Prevention Associations, 41p., 1970. 20 p. (Presented at the International Clean Air Congress, 2nd, Washington, D. C., Dec. 6-11, Paper EN-28B.)

Information on the cost problem and on the necessity for air pollution control technology in the field of non-ferrous metals production is presented. Their price, high in comparison with that of steel, is an incentive to developing any means of increasing the yield and, thus, to recovering the metals from flue dusts. Therefore, the center of air pollution control arrangements shifts to the side of extracting accompanying elements in the ores, auxiliary materials, and highly volatile compounds. The negative biological effects of a large number of metals require particularly effective arrangements for waste gas purification. More recent specific methods of air pollution control are illustrated by several examples. Fluorine emissions from the flux are fought in aluminum works by means of effective wet purification processes; dry absorption methods are also being tried. Fluorine levels of 0.5-1.5 ppb were detected even in industrial areas where there was no aluminum production at all. Waste gas purification at aluminum re-melting works presents a particularly difficult problem with regard to the extraction of very fine salt fumes. The utilization of the sulfur content in the non-ferrous metal ores is discussed in detail. Here, the solution to the economic problem of marketing a sulfuric acid, aptly called 'acide fatal' by Belgian smelting works, is as important as the solution to the process-technical problem. The latter was dealt with very successfully by means of the development of a double-contact process with intermediate absorption for roasting gases poor in sulfur dioxide. The final gases contain less than 0.5% of the SO₂ charge. More and more processes favorable to air hygiene are being used by zinc metallurgy. Methods of recovery that cannot be controlled by waste gas technology, will be discarded. General and particular information is given on the cost problem of air pollution control. Frequently, the wrong conclusions are drawn from the fact that only 0.2% of the value of industrial production are required for direct steps, with secondary injurious effects, amounting to 1-2%, being prevented in this manner. Production at some works is hard hit by specific costs of 1-5% of the proceeds from sales. (Author abstract)

Lindberg, Gosta

AIR POLLUTION CONTROL IN THE SWEDISH ALUMINIUM

INDUSTRY. Preprint, International Union of Air Pollution Prevention Associations, 18p., 1970. (Presented at the International Clean Air Congress, 2nd, Washington, D. C., Dec. 6-11, 1970, Paper SU-24C.)

Aluminum metal is produced from aluminum oxide through an electrolytic reduction process at an elevated temperature (950-970 C) thereby generating atmospheric impurities containing gaseous and particulate fluorides. The polytoxic effect of even small amounts of fluorides on vegetation is well known and emitted gases from the process have therefore been carefully collected and cleaned in efficient scrubbing equipment. The smelter plant of AB Svenska Aluminiumkompaniet is located close to the town of Sundsvall with 65,000 inhabitants. For the latest production stages it has been necessary, not only to clean the primary process gases, but also the huge volumes of ventilation air at present amounting to 10 million cu ft/hr (6 mill cfm). The collection and cleaning system applied has an overall cleaning efficiency of fluorides exceeding 90%. Damage caused partly by fluoride emission from the older smelter plant on vegetation in adjacent regions has necessitated further dilution of released fluoride impurities. As a result of a combined meteorological and topographical study, 70-m (210 ft) high discharge stacks have been erected. As an

instrument for vegetation control in the smelter environment, a botanical study is recommended. Fluorine content determination of pine needles from a number of stations in the surrounding area has proved to be a method of considerable value in this respect. Sampling and analyses are made toward the end of the growing season. Isopleths for fluorides are obtained by combining testing stations with the same amount of fluoride content. The position of the curves yield information about the actual emission situation and the cleaning system efficiency. The isopleth positions have, however, changed somewhat from year to year- even without changes being carried out at the plant installations. Meteorological conditions such as amount of rainfall, prevailing wind directions, and rate of inversion appear to be confusing factors when judging the effects of plant extensions or other changes affecting the fluoride emission. Amount of rainfall and wind direction has been measured for years. To study the rate of inversion a mast of 40 m (130 ft) has been erected and equipped with temperature recording instruments at different heights above the ground. Comprehensive meteorological and ecological investigations should be a significant part of the preparatory work when examining the possibilities for further extension of existing plants or the location of new plants. (Author abstract modified)

25433

GIANT FUME CATCHER STOPS FLUORIDE EMISSION.

Chem. Eng., 65(4):66, 68, Feb. 24, 1958.

Measures taken to control fluorine-fluoride emissions from a steel mill's stacks are described. The emissions had been contaminating nearby grazing lands, and through ingestion and subsequent concentration in the bones and teeth of grazing cattle, had threatened the health of the herds and milk production. Major emission sources in the plant, which processes a relatively high-fluorine iron ore, where the sintering plant and open hearth section. The control method, suggested by the affinity of fluorine for calcium in animal bones, is based on the rapid gas-solid reaction between fluorine and calcium compounds (carbonate and hydroxide), to give calcium fluoride. Fluorine-containing gases are collected, calcium hydroxide dust injected into ducts, and fluoride particles removed in a 1-million cfm capacity cyclone-precipitator section. Powdered limestone injections in the sinter charge and effluent gases, and in the effluent gases from the open hearth furnaces, assist the process. The method removes about 96% of fluorine and fluorides in effluent, and represents a \$9 million investment.

Crocker, Burton B.

MINIMIZING AIR POLLUTION CONTROL COSTS IN AN

OLD PLANT. Pollut. Eng., 1(1):30-31, Oct.-Nov. 1969.

One of the first steps in controlling air pollution is to determine the sources of contaminant emission, quantity, size, physical state and carrying medium of the pollutants. When contaminants are a by-product of a production operation, generation can be minimized by changes in operating conditions. Fluorine compounds released when some ores are heated frequently can be decreased if water vapor is eliminated from the atmosphere. If contaminant gases are handled by an exhaust fan, it may be possible to obtain some collection in the fan by adding a water spray to the inlet. In many

<xref image="2000WVCG.TIF|V3|2006:09:28:01:21:26.00|129466|0"> image: </xref>

direct drying processes where the product is dried by direct contact with hot combustion gases on a one-pass basis, effluent can be reduced by recycling some of the flue gas to temper the incoming combustion gases. Cooling by radiation panels, finned surfaces, waste heat boilers, forced convection heat interchange, and direct spray cooling with water are all possible solutions. Questions concerning whether to use dry or wet collection are also cited.

Larson, Gordon P.

A PROGRESS REPORT ON CONTROLLING ATMOSPHERIC POLLUTANTS. J. Air Pollution Control Assoc., 7(4):302-307, Feb. 1958. (Presented at the Air Pollution Control Association, 50th Annual Meeting, St. Louis, Mo., June 2-6, 1957.) A review of the air pollution control activities in 1957 shows an impressive record of 6 million dollars expended in research, over 200 governmental agencies assigned some measure of responsibility for clean air in their communities, and annual sales in control equipment and engineering services in excess of 100 million dollars. This article discusses the state of the art of controlling sulfur dioxide emissions from smelters and refineries; dust and fumes, particularly those produced by metallurgical processes; organic vapors and gases, including hydrocarbons; fluorides from aluminum and phosphate fertilizer plants; and the three basic engineering methods that can be applied to reduce aerosols, vapors, and gaseous contaminants. Tables are presented which classify various types of collectors and control devices in relation to the processes and emissions. They also show the great number of systems to be considered and some of the advantages and disadvantages of each device. To a large extent, most of these installations are custom engineered and built on the site. The costs cover a broad range. As indicated by recent health studies, there is need for maximum controls on all forms of pollution for which solutions are known. These studies also point up the need to develop control measures for hydrocarbon emissions from industry and motor vehicles.

25638

PROTECTION AGAINST IMMISSION. (Immissionsschutz). Text in German. Rheinisch-Westfaelischer Technischer Uberwach.-Verein E.V., Jahresbericht, 1969:38-41, 1969. The five principles promulgated in the framework of an intensified air pollution control campaign by the state of Nordrhein-Westfalen and adopted also by the other West German states postulate that all polluters be identified and included in the pollution control program, that the atmosphere be kept as clean as possible and not as dirty as just about tolerable; that the costs of the program be born equally by all polluters so that no competitive advantages arise; that the polluters bear the cost of their pollution control measures and public funds be used only in special situations; and that air pollution control as a community responsibility requires the cooperation of all concerned. Thus, all polluters are subject to certification and must meet all prescribed maximal emission regulations pertaining to dust emission, SO₂ emission, and other applicable regulations. Fluorine is emitted by brick factories in quantities between 30 and 300 mg/N cu m, by cupola furnaces in quantities between 4 and 280 mg N/cu m, by Siemens-Martin furnaces in quantities between 7 and 70 mg N/cu m, by fertilizer plants in quantities between 6 and 80 mg N/cu m and by plants manufacturing insulating wool in quantities between 0.4 to 3 mg N/cu m. Guidelines regarding the required height of smoke stacks, emissions by refuse incineration plants, supervision of pollutant concentration and emission of pollutants, control of emission by boiler plants, control of olfactory pollutants and of noise pollution are outlined.

METHOD FOR THE REMOVAL OF FLUORINE FROM INDUSTRIAL GASES. (Research Corp., New York, N. Y.) Brit. Pat. 752,803. 6p., July 18, 1956. 1 ref. (Appl. Feb. 8, 1954, 7 claims).

A method is described for the removal of fluorine from industrial gases, which comprises adding comminuted lime to a stream of gases, subjecting the lime-containing stream to vortical action, skimming off a portion of the gas containing an increased concentration of particulate matter, and returning this portion to the stream to be subjected to vortical action. The separation of solid matter from the remaining portion of the gases may be effected by electrostatic precipitation. In its particular application to the removal of fluorine from gases in a sintering machine, the method may comprise recirculating a portion of the gases from which coarser suspended particles have been separated through the sintering machine and subjecting the other portion of the gases to the vortical action.

Zabel, Herman W.
NEW PENNSALT HF PLANT. Chem. Ind., vol. 66:508-509, 1950.

Use of reduced pressure in process equipment and thorough scrubbing with water has resulted in the successful control of fumes at a plant where hydrogen fluoride is formed in rotary kilns by the reaction of fluorspar with sulfuric acid. As a first step in HF purification, gas from the kilns is passed to coke-packed towers. These catch spar dust, entrained sulfuric acid, and some moisture condensates. The gas then goes to a surface cooler, after which it is liquefied in a two-stage steel condenser, the first water cooled and the second brine cooled. The gas from this condenser is scrubbed with water to absorb the last traces of hydrofluoric and hydrofluosilic acids. Before the exit gas is vented to the atmosphere, additional scrubbing takes place in a water injector, which also serves to maintain a small negative pressure on the system. Thus all leakage is inward and no HF or hydrofluosilic fumes can escape to the atmosphere.

GAS SCRUBBING IN THE HYDRODYNAMIC DUST SEPARATOR DURING ELECTROLYSIS OF ALUMINUM.

Soviet J. Non Ferrous Metals (English translation from Russian of: Tsvetn. Metal.), 9(12):68-70, Dec. 1968. 3 refs.
Design and operating data are given for a pilot hydrodynamic dust separator for treating fluorine compounds, dust, and resinous matter produced during aluminum electrolysis. The dust separator is a vertical chamber 3.1 m high and provided with two symmetrically located air scrubbing channels. The hydraulic resistance of the separator is 115 mm H₂O with an optimum flow velocity of 19 m/sec. Gaseous fluorine is collected with 98% efficiency, dust with 73.2-77.7% efficiency, and resinous matter with 35-73% efficiency.

REMOVAL OF HYDROGEN FLUORIDE FROM GASEOUS
MIXTURES WITH THE AID OF FLUIDIZED BED SCRUB-
BERS WITH SPHERICAL PACKING. (Ochistka gazov ot
ftoristogo vodoroda v scrubberakh s psevdoozhizhennoy
sharovoy nasadkoy). Text in Russian. Khim. Prom. (Moscow),
no. 10:62-64, 1970. 4 refs.

A fluidized-bed scrubber designed to remove hydrogen fluoride from exhaust gases generated during electrolytic production of aluminum is described. A 40-50 g/l sodium carbonate solution was used at an irrigation density of 2.2-31 cu m/sq m/hr, a linear gas flow rate of 2.2-5.6 m/sec, and an initial HF concentrations of 15-150 mg/cu m. The static column packing height was variable from 35 to 175 mm. Operating characteristics in terms of the unit transfer number, defined as the logarithm of the ratio of HF concentrations before and after scrubbing, are presented.

Stris, John

CONTROL OF FLUORINE AND HF DISCHARGES. A.P.C.A.
News, 5(3): 3, April 1957. (Presented at the Semi-Annual
Technical Meeting of APCA, Houston, Tex., Dec. 3-5, 1956.)

A method to control atmospheric fluoride emissions, successfully used at a plant which manufactures hydrofluoric acid from fluorspar, is described. The emissions are liberated from equipment used to purify the final hydrofluoric acid product. Polyethylene spray tower chambers were built which permit cocurrent and countercurrent flow of gas to water spray; the bottom of each chamber is open but submerged in water to form a seal. The water also allows waste discharge in a liquid state and permits redissolving of the silica gel that forms in the tower which would fall by gravity into the liquid. The technique involves almost no maintenance, and analytical samples of vent gases indicate no fluorine lost to the atmosphere.

Rushton William E. and George Kleinman

METHOD AND APPARATUS FOR THE RECOVERY OF
FLUORINE. (Whiting Corp., 111.) U. S. Pat. 3,415,039. 6p., Dec.
10, 1968. 6 refs. (Appl. Nov. 3, 1965, 13 claims).

A method is described by which fluorine compounds evolved in equilibrium concentrations from an evaporator can be recovered by scrubbing the vapor product in a tower operated at a reduced pressure with respect to the pressure in the evaporator. In the manufacture of phosphoric acid by the wet process phosphoric acid technique, fluorine is evolved in varying amounts in the various stages of the process. In an evaporator for concentrating a dilute phosphoric acid feed wherein the evaporator is operated at an absolute pressure of about 8 1/2 inches Hg, the scrubbing tower could be operated at an absolute pressure of 2 inches Hg. These increased recovery efficiencies become particularly significant in those situations wherein the scrubbing solution has a fluosilicic acid concentration of 20% or more. Suitable pressure reducing devices include, for example, throttle valves and entrainment separators having high flow restriction properties. (Author abstract modified)

FIELD EVALUATION OF WET FIBER FILTERS FOR
TREATMENT OF AIR CONTAMINANTS. J. Air Pollution
Control Assoc., 6(1):32-34, May 1956. 5 refs. (Presented at the
Air Pollution Control Association, 48th Annual Meeting,
Detroit, Mich., May 23-26, 1955.)

Laboratory studies of the absorption efficiency of wet fiber cells and fiber droplet eliminators show recoveries of approximately 99.9% for hydrogen fluoride and greater than 90% recovery of submicron size chemical fumes and mists. Fibers

are superior to the more usual types of packings in relation to the amount of surface available for absorption per unit volume, while high porosity of the fiber beds favors low-resistance gas flow. The porosity and relative efficiency of several packing materials are presented tabularly. Plastic fibers have excellent resistance to erosion and breakage; because of their specific gravity; they provide a large surface area per pound of packing. A minimum number of stages are required when the scrubbing liquid rapidly neutralizes or reacts with the gas or vapor to be removed from the gas stream. A wetted impingement type collector called a Neva-clog screen is capable of removing up to 85% of mineral particles (such as silica or talc dusts), and has considerable value as a gas absorption stage. An illustration is provided of a typical arrangement of wet and dry elements. Satisfactory air and gas flow rates are mentioned, as well as collector resistance. Results of field tests and a description of industrial gas scrubbers which were installed to control the discharge to the atmosphere of hydrogen fluoride, hydrochloric acid, and acetic acid-acetic anhydride are summarized. Operating conditions, manufacturing processes, design criteria, and an analysis of test results are also discussed.

Benger, Michael

REDUCTION OF AIR POLLUTION ARISING FROM REFINERIES. In: Pollution Prevention. Inst. of Petroleum, London (England), Proc. Inst. Petroleum, Summer Meeting, Brighton (England), 1968, p. 28-38.

When a new refinery project is under consideration, consultations are held to ensure that the anti-pollution proposals are acceptable. Statutory limits which are laid down by act of Parliament are well-established ones in which the technical possibilities by way of controlling emissions are well known. With the great majority of emissions, presumptive standards are laid down at the discretion of the Chief Alkali Inspector, and these can be altered as circumstances change. Technical feasibility, the effect on human and animal health, damage to vegetation, and odor thresholds are all taken into account. Potential nuisances include sulfur dioxide, hydrogen sulfide and mercaptans, fluorine, smoke, fuel ash, acid smuts, and noise. A major breakthrough in petroleum processing has been the replacement of the old liquid refining processes by catalytic desulfurization. Various methods used to control these pollutants are discussed, including cost factors. The Reinluft process is mentioned, as well as the Monsanto/Penelec process. The former utilizes activated carbon while the latter employs vanadium pentoxide. A dry absorption process utilized by the U. S. Bureau of Mines employs alkalized alumina to control SO₂. The offensive odor of mercaptans may be controlled by stripping the condensate with steam or flue gas or both. Recently it has become common practice to use the sour condensates as wash water to crude oil desalters.

B. CONTROL METHODS

91

Agriculture and forestry both are affected by and contribute to air pollution. Project Clean Air will establish a centrally located information center to collect and disseminate technical information on air pollution and provide educational materials and services. Use of power has grown at an alarming rate, and Project Clean Air will participate in the development of both selection criteria and basic data needed to facilitate energy management in California. More accurate methods will be developed by which to assess the economic losses to agriculture and forestry resulting from air pollution. A comprehensive program of research will be developed to determine: the growth depression effects on plants due to long-term low-level exposure to ethylene, sulfur dioxide, fluoride, and oxides of nitrogen; the extent of synergistic effects of combined sublethal concentrations of air pollutants on plants; the effects of air pollutants on the biochemistry, metabolism, and anatomy of plants; and the quality of the forest air environment where new damage is suspected. Ways and means to alleviate or modify agricultural, forest, and wood processing residue burning so as to minimize its contribution to air pollution are also indicated. A major program of research will be developed to make the expected transition to primarily nuclear power generation a safe one. Research will be developed to reduce nitrogen oxide emissions by means of combustion control, and several parallel projects will be developed to determine the potential usefulness of post-combustion removal of nitrogen oxides. Other recommendations include a program relating animal health to pollutants transported by air, ways to reduce dust resulting from livestock and poultry operations, and means to eliminate objectionable odors. The hazard from pesticide drift needs to be reduced, as well as sulfur dioxide emissions; industrial hydrocarbon and carbon monoxide emissions also need to be controlled. Project Clean Air will support research in which process engineering, meteorology, and economics are brought together to develop methods and criteria to optimally site the industrial emission sources which are currently most costly and hazardous.

Ellison, William

WET SCRUBBERS POPULAR FOR AIR CLEANING. Power, 115(2):62-63, Feb. 1971.

While collection of gas-borne particles is the primary function of wet scrubbers, they also embody a number of additional process steps such as gas conditioning, liquid separation, and mist elimination. The principal mechanism involved in wet collection of particulate matter is impingement of individual particles upon scrubbing liquid droplets. Advantages of wet scrubbers include the following: compact equipment, a generally smaller capital expenditure than for fabric filters or electrostatic precipitators, ability to collect particles from 0.2 to over 10 micron, selection of collection efficiency by varying input, elimination of dust disposal, no limitation on temperature or humidity, and low maintenance costs. Requirements for minimizing emissions of sulfur dioxide, hydrogen chloride, and fluoride are mentioned. Operating costs, capital cost, dust collection efficiency, and gas pressure drop are compared for various types of wet scrubbers.

Tomson, N. M.

GASEOUS EMISSION OF SUPERPHOSPHATE PRODUCTION AND RECOVERY EFFICIENCY. (Gazoobraznyye vybrosy superfosfatnogo proizvodstva i effektivnost' ikh ulavlivaniya). Text in Russian. Eesti NSV Tead. Akad. Toim, 4(1):134-136, 1955.

Installation of an electrofilter, and an increase in stack height from 60 to 100 meters reduced sulfur dioxide concentration in the vicinity of a superphosphate plant as follows: 49.5-fold at 500 meters distance, 37.8-fold at 1000 meters, and 9.7-fold at

2000 meters (actual concentrations at these distances: 0.42, 0.14, and 0.45 mg/cu m, respectively, with an emission concentration of 5000 mg/cu m). Nitrogen oxides emitted at a concentration of 5500 mg/cu m were reduced to 0.860, 0.042, and 0.100 mg/cu m at these same distances; hydrogen fluoride emitted at 900 mg/cu m, 0.23, 0.30, and 0.18 mg/cu m, respectively.

THE RECOVERY OF FLUORIDE FROM SUPERPHOSPHATE MANUFACTURE. Chem. Ind. New Zealand, 4(11):10-11, 13, Nov. 1968. 11 refs.

In the manufacture of superphosphate, finely ground phosphate rock is mixed with sulfuric acid in a continuous manufacturing process. Much heat is generated and gases are evolved containing mainly silicon tetrafluoride, carbon dioxide, and steam. A small water scrubbing system is described that permits a substantial part of the evolved fluoride to be recovered as 15% strength hydrofluosilic acid. This by-product is used for the fluoridation of public water supplies.

28034

UNIQUE GAS CLEANING JOB TRAPS FLUORIDES AT TSP PLANT. Air Eng., 4(3):46-48, 59, March 1962.

At the same time that design of a 600-ton per day triple superphosphate fertilizer plant was begun in 1956, an extensive program of air and stream sampling was initiated by the chemical firm. The program continued for five years, both to establish area pollution levels before plant operation, and to evaluate effectiveness of abatement procedures during operation. Once the monitoring program was set up, an on-the-spot tour of the sampling stations was arranged. In addition to comprehensive news releases and photographs, company personnel openly discussed the problems and the steps taken to solve them. Control measures include scrubbing, filtering, and various reactions to recover by-products. After three years of research, a solution to the problem of gaseous fluoride emission from the curing building was found. Instead of taking the pre-cured material from the settling belt and conveying it directly to the curing building, the product now drops from the settling belt into a chain mill, which breaks up the particles to a size of 1/2-in. or less. Control techniques at the chain mill and curing building are indicated, as well as the installation of electrostatic precipitators in the vicinity of the rock dust dryers. Precipitator operation is described.

28320

FILTER PROGRAM. (Filterprogramm). Text in German.

Wasser Lutt Betrieb, 15(1):36-39, Jan. 1971.

Various types of filters for cleaning waste gases are described. Gases escaping from electrolytic cells used in the melting of aluminum are cleaned by passing them through an aluminum oxide layer where the gaseous fluorides are absorbed. Next the gases are passed through envelope-type cloth filters which retain the aluminum oxide particles. The aluminum oxide is returned to the reduction cells, the fluorides to the melting zone. The process is a dry one which has the advantage of not converting an air-pollution problem to a water pollution

<xref image="2000WVCJ.TIF|V3|2006:09:28:01:21:34.00|120336|0"> image: </xref>

problem. A new wet dust collector consists of a high-capacity precipitator, 1200 mm high and 3000 mm long packed with synthetic material. Collection efficiency is about 99.4%. Water consumption is to 0.1 to 0.2 liters/cu m waste air. A filter for radioactive, pathogenic, and toxic substances consists of a rim board with 0- grooves and a plastic sack that allows contamination-free replacement of the air filter. In a metallurgical plant, the dust-laden waste gases are conducted through water-cooled pipes to a scrubber, where the gases are washed with water. The scrubbing water circulates in a closed system to avoid water pollution.

SCIENTIFIC AND TECHNICAL MEANS OF DIMINISHING POLLUTION, INHALED OR ASSIMILATED FROM THE ENVIRONMENT-AND OF DIMINISHING ACOUSTICAL INTERFERENCE. (Moyens scientifiques et techniques de diminuer la pollution des milieux inhalés ou ingérés et des 'nuisances' acoustiques). In: Pollution and Acoustical Interference of Industrial and Urban Origin. (Les pollutions et 'nuisances' d'origine industrielle et urbaine). Vol. I, Paris, France, June 1966, Chapt. 3, p. 47-59. Translated from French. Belov and Associates, Denver, Colo., 49p., Oct. 13, 1970.

Aspects of natural and technological control methods for air, water, and noise pollution are discussed, with suggested topics of research given for each. Plants have an ability to function as air purifiers, within the limits of their toleration to various individual pollutants. The effects of such pollutants as ethylene, carbon monoxide, sulfur dioxide, and fluorides on plants are described. The purifying action of water plants and bacterial beds has application to water purification in treatment facilities as well as in natural fresh water bodies. Purification processes within the bed of a lake are also considered. Control methods for suspended particulates from industrial and domestic sources including separators, filters, and electrostatic precipitators, are briefly noted, while the various design, operational, and control device techniques now under study for control of motor vehicle emissions, particularly storage batteries for electric propulsion, design modifications and catalytic afterburners, are considered at length. Also discussed are pretreatment of industrially polluted waters, potential uses of water treatment sludge, and means for preventing and/or absorbing noise in residential, business, and industrial areas.

THE GRILLO-AGS-METHOD FOR DESULFURIZATION OF WASTE GASES. (Das Grillo-AGS-Verfahren zur Entschwefelung von Abgasen). Text in German. (Brennstoff-Waerme-Kraft, 23(3):85-91, March 1971.

The Grillo-AGS-method for desulfurizing waste gases is based on wet absorption of sulfur dioxide on an absorbent composed of magnesium and manganese oxides. This level combination of an alkaline component and a heavy metal has the advantage that the alkaline fraction acts as the absorbent and the heavy metals as the oxygen donor. A high activity is obtained by this interaction. More than 90% of the SO₂ and the SO₃ of the waste gases are bound by the absorbent in the form of sulfate and sulfite. The efficiency of this method was tested on an oil-fired boiler furnace. For intense contact between the flue gas and the absorbent, a ratio of 0.7 l/cu m suspension flue gas was needed. The contact time ranged from 0.46 to 1.4 sec. A desulfurization efficiency of 85 and 90%, sometimes 95%, was obtained. Experiments to determine the efficiency of the method for selective removal of SO₃ and fluorine yielded 100% removal of SO₃ and removal of fluorine 70%. The Grillo-AGS-method is one of the most economical desulfurization methods available. It creates no secondary problems, such as wastewater treatment or disposal of the absorbent.

Hayashi, Hideo, Masahiro Yoshida, Masaaki Takahashi, Toshio Hasegawa, and Yoshiaki Yamasaki
REMOVAL OF FLUORIDES BY PACKED TOWER. (Juten to ni yoru fukkabutsu no jokyo). Text in Japanese. (Proceedings of the Japan Society of Air Pollution, Annual Meeting, 11th, 1970.)

The emission of fluorides from a hydrofluoric acid and aluminum fluoride manufacturing plant was investigated. The measurement was based on JIS-K0105-67, according to which gas is passed through three glass filter plates and through two serially arranged absorption bottles containing 0.1 N sodium hydroxide solution. For the emission from the reaction tank in the aluminum fluoride process, which generates a large amount of water vapor, the gas was separated from the mist before going to the filters by means of a trap. The samples were analyzed by alizarin complexion method. The gas emission from the absorption tower for hydrofluoric acid was 6.6-32.8 F mg/N cu m; that for gas leak was 115.6 - 215.4 F mg/N cu m. Since the absorption tower recycles the used water, the amount of fluorides tended to increase with the increase in the hydrofluoric acid concentration. For aluminum fluoride, when the synthesis began, the temperature inside the reaction tank rose and the amount of water vapor increased. The concentration of F in the mist was as high as 27.4 mg/N cu m; in the gas it was 17.9 mg/N cu m. The treatment efficiency of the absorption tower was 78-99%.

28786

Hayashi, Hideo, H. Yoshikawa, Tamotsu Teratani, Toshio Hasegawa, Yasumasa Yamada, and Ko Narita
DUSTS TREATMENT IN NONFERROUS METAL MELTING FURNACES. (Hitetsu kinzoku yokoro no baijin shori). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 5(1):185, 1970. (Proceedings of the Japan Society of Air Pollution, Annual Meeting, 11th, 1970.)

So that control measures could be established for metallic fumes, such as copper, zinc, and aluminum, several small non-ferrous production plants were investigated. Emissions from a fused-zinc plating factory included ammonium chloride in addition to zinc chloride and zinc oxide. The particulates were very minute, and relatively little zinc was removed although scrubbers and absorption towers were provided. In an aluminum recycling plant, the treatment method was spray scrubbing. The waste gas whose temperature was quite high, consisted of fumes of salts containing fluorine and chlorine. About two percent of the dust was aluminum; one percent was removed by treatment. Chlorine removal efficiency was about 46% and fluorine was not traceable. In a copper-wire manufacturing plant, the white smoke produced at the time the raw material is fed to the electric furnace and when the bath is taken out was collected by a hood and treated by bag filters. Dust collection efficiency was about 99%. The amount of copper in the dust was 1 mg/N cu m while that of zinc was 200-300 mg/N cu m.

Allmendinger, D. F., V. L. Miller, and Folke Johnson
THE CONTROL OF FLUORINE SCORCH OF GLADIOLUS
WITH FOLIAR DUSTS AND SPRAYS. Proc. Am. Soc. Hort.
Sci., vol. 56:427-432, 1950. 6 refs.

Data are presented from experiments conducted to control the scorch of gladiolus with foliar dusts and sprays. In 1948 the treatments consisted of a weekly spray of lime, dusts of lime at one-, two-, and three-week intervals, lime dust at one-week intervals with re-application after rains, and an untreated check. In addition to an unsprayed control, the 1949 treatments included the following materials applied at two-week intervals: lime spray, sugar-lime spray, magnesium silicate spray and dust, calcium silicate spray and dust, and dusts of lime, talc, and soil. Lime and sugar-lime sprays were applied at four-week intervals. Of the materials used, lime was the most effective in controlling scorch. Sprays were more effective in controlling the scorch than were dusts. Chemical analyses showed that the lime absorbed considerable quantities of fluorine, and the amount of fluorine in the plant tissue was markedly less as the effectiveness of the sprays and dusts in controlling scorch increased. (Author summary modified)

Donaldson, Harry M.
PROBLEMS IN THE CONTROL OF OPERATIONS IN A
BERYLLIUM-PROCESSING PLANT. A.M.A. Arch. Ind.
Health, 19(2):221-224, Feb. 1959.

Problems of control of a beryllium processing plant are extensive and begin with the conception of the idea that the plant must be built. First of all, the plant must be located on a stream capable of carrying away any liquid wastes generated in the process and, like any chemical plant, it should preferably be built in a location where accidental contamination of the environment will not be a health hazard or cause property damage. Though many processes and many types of process equipment are available for the recovery of beryllium, the problem in choosing that process and that equipment which are capable of being controlled down to 2 micrograms per cubic meter is a major one. The next problem of importance after choosing the process and equipment that can be ventilated is to apply the principles of local exhaust ventilation to the equipment in such a way that contamination in the plant is limited to the stringent requirement of 2 micrograms Be/cu m. An extensive air cleaning system is necessary to keep out-plant air at less than 0.01 micrograms Be/cu m. All employees working in the plant are supplied with a complete change of clothing and are required to take a shower in order to keep beryllium from going home with the worker. Sometimes there are dermal problems which result from working with beryllium fluoride or ammonium beryllium fluoride. Other problems include the indoctrination of new employees as well as working with veteran employees. Both in-plant and out-plant sampling programs are never ending.

29114

Teller, Aaron J.
NEW CONCEPTS OF POLLUTION CONTROL. Trans. N. Y.
Acad. Sci., 32(7):837-842, Nov. 1970.

Pollution control has been looked on as a 'nonprofit necessity' rather than as a source of material for recycle or sale. Because of this, engineers have incorrectly applied the technology of product separation to highly concentrated streams. What is needed for engineering solutions to air pollution problems is acceptance of the fact that boundary conditions are distinctly different from product-oriented separations. These conditions are discussed and four successful approaches to abatement based on their consideration are presented. A cross-flow scrubber permits 99.7% recovery of hydrogen fluoride and silicon tetrafluoride. A Brownian separator is capable of remov-

ing submicron liquid particles at pressure drops of 5-30 in. wg, while a nucleation scrubber collects both liquid and solid submicron particulates at a pressure drop of 2 in. wg. A new cooling tower provides cooling of 25,000,000 BTU/hr in a ground space of 120 sq ft. The surface-renewal capability of the packing internals constantly creates new surface for rapid mass heat transfer. A 'looped system' recycles hydrogen fluoride and submicron boron oxides back to the process, while dissipating the thermal energy in the exhaust in a cooling tower.

Strauss, W.

THE REMOVAL OF A GASEOUS CONSTITUENT: ABSORPTION, ADSORPTION AND COMBUSTION. FLUID RESISTANCE TO PARTICLE MOTION. GRAVITY AND MOMENTUM SEPARATION EQUIPMENT. In: Industrial Gas Cleaning. The Principles and Practice of the Control of Gaseous and Particulate Emissions. New York, Pergamon Press, 1966, Chapt. 3, p. 62-121; Chapt. 4, p. 122-143; and Chapt. 5, p. 144-159. (For references, see 29405.)

The three methods of removing gaseous constituents from flue gases are absorption in a liquid, adsorption on a solid surface, or a chemical change into a harmless gas, usually by combustion. The molecular diffusivity is calculated, and a film theory of absorption and the design of absorption systems is presented. Gas absorption processes are described for sulfur dioxide, fluorine and fluorine compounds, chlorine and chlorides, hydrogen sulfide, and nitrogen compounds. The adsorption of gases on solids and the combustion process of flame combustion and catalytic combustion are explained. The calculation of the fluid resistance to the cross-stream movement of the particle is essential in determining the effectiveness of a particular mechanism in removing the particle from the gas stream. The calculation of the resistance of a fluid to the movement of particles when these are acted on by forces outside the fluid are discussed. The simplest method for removing particles from a moving gas stream is to allow them to settle out under the force of gravity. Momentum separators rely essentially on producing a sudden change of direction in the gas stream. The theory of settling chamber design and applications of simple settling chambers are described. Momentum separators are more complex but take up less room and are able to collect particle down to about 20 microns with reasonable efficiency.

Bender, Rene J.

AIR POLLUTION CONTROL: WHERE DO WE STAND?
WHERE MUST WE GO? ... AND HOW DO WE GET
THERE? Power, 115(6):S.4-S.11, June 1971.

While adequate monitoring equipment is available, research is underway to improve the instruments. Fuel oil burning produces carbon monoxide; by monitoring the oxygen with a Polarographic method, combustion can be held at an ideal fuel-oil firing condition. The atomic absorption spectrophotometer and thin-layer chromatography followed by a fluorescence analysis are other measurement methods. Some improvement in air quality has occurred. The Federal Clean Air Act of 1970 has established air quality standards for sulfur dioxide, particulates, nitrogen oxides, CO, hydrocarbons, and

<xref image="2000WVCL.TIF|V3|2006:09:28:01:21:42.00|122796|0"> image: </xref>

oxidants. A compact monitoring system for SO₂, NO_x, hydrogen sulfide, fluorides, aldehydes, and oxidants uses absorption columns and colorimetry. An electrochemical transducer can monitor nitrogen oxides and SO₂. Particulate mass can be measured with a beta-ray beam passing through a filter. Firing conditions can effect stack gas composition. Also, gas-cleaning equipment can include water sprays, mechanical dust collectors, separators, dry scrubbers, fabric filters, electrostatic precipitators, cyclone dust collectors, bag filters, venturi scrubbers, impingement trays, wet scrubbers, or afterburners. Sulfur dioxide can be eliminated by the use of low sulfur fuels or the treatment of flue gases. Many pilot plants are attempting to recover the sulfur product. The most promising and economical SO₂ removal method depends on the scrubbing of gases with soda ash followed by the conversion of the product to calcium sulfite under the action of lime. The Tennessee Valley Authority is trying out several SO₂ removal processes. Nitrogen oxides are found in automotive exhaust and flue gas; they can be reduced by control of the combustion process. Fuel additives may also help stop atmospheric pollution. Tall chimneys are not the final answer to air pollution, but are an excellent stopgap. Pollution controls in incinerators, and the metallurgical industry (ferrous, bronze, and brass) are also discussed. The amount of emissions for multiple and single chamber incinerators, blast furnaces, sintering machines open hearths, electric arc furnaces, basic oxygen furnaces, crucibles, reverberatory furnaces, and rotary furnaces are given before and after the use of control equipment.

Ussar, Max

TECHNOLOGY RENDERS ITS SERVICES TO AIR PURIFICATION AND NOISE SUPPRESSION AS PART OF ENVIRONMENTAL HYGIENE. (Die Technik im Dienste der Luftreinhaltung und Lärminderung als Teil der Umwelthygiene). Text in German. Gas Wasser Waerme, 25(4):62-65, April 1971. In order to successfully combat air pollution caused by dust and gases, it is necessary to know the chemical and physical properties of these substances, and the concentrations in which they occur in the free atmosphere and at the source from which they originate. Devices for air sampling as well as for analysis of the dust and gases have been developed, but more standardization of methods would be desirable on a national and international basis. In air pollution by dust particles and gases, one differentiates between emission from sources, such as industrial plant, and emission which is the actual content of pollutants in the surrounding air, derived from all origins, such as dust from emissions and dust which is whirled up from the soil by moving air. Principal methods and equipment respectively for large scale dust removal are sedimentation, filtering, cyclones, high capacity washers of venturi type, and electrostatic separators. With regard to gases, the main industrial problem is the removal of troublesome and toxic gases such as sulfur dioxide, chlorine, fluorine, and nitric oxides which can be damaging to forestry and agriculture, and a health hazard to the human organism. One of the most applied methods in industries which generate waste gases containing any of the aforementioned gaseous pollutants is washing. In more recent years noise has become a very damaging occurrence in our environment. Future planning of residential buildings and industrial installations will have to take into account the need for acoustic insulation and noise suppression.

RESULTS OF FIVE-YEAR EFFORTS FOR REDUCTION OF FLUORINE EMISSIONS. (Ueber Ergebnisse fuefnjaehriger Bemuehungen mi die Verminderung von Kluoremissionen). Text in German. Chem. Tech. (Berlin), 23(4/5):264-266, April/May 1971. 2 refs.

When various methods were investigated for the removal of hydrogen fluoride from waste gases, such as packed columns

and absorption on activated charcoal or limestone, it was found that absorption was not efficient. The use of packed towers requires that the flow rate not exceed one m/sec. Each packed tower must be operated with an alkaline solution; a five to 10% sodium or potassium lye solution can be employed. While packed columns are easy to maintain, some production processes have waste gases which carry dust that may form insoluble products with the scrubbing fluid. Dust collectors should precede the packed tower in such cases. It is also advantageous to force the gases through the tower, to avoid some of the problems which its moveable parts may present.

Ball, D. F. and P. R. Dawson

AIR POLLUTION FROM ALUMINIUM SMELTERS. Chem

Process Eng., 52(6): 49-54, June 1971. 16 refs.

Control methods for a number of the pollutants emitted during aluminum production are discussed. The production process is briefly described. The main pollutants which arise in electrolysis are alumina, tar-pitch distillation products, inorganic fluorine, compounds including hydrogen fluoride, sulfur dioxide, hydrogen sulfide, carbonyl sulfide, carbon disulfide, silicon tetrafluoride, and water vapor. The gases from the furnace contain fluorine compounds, carbon monoxide, carbon dust and tar, and hydrocarbons. These gases are sent to an afterburner, a cyclone, and an electrostatic precipitator. The gases may still contain HF and SO₂, which can be removed by scrubbing with an alkaline solution. Ventilation is important in the potrooms to keep temperatures low and to remove fluorine compounds and dust from the room air. The large volumes of air withdrawn through the roof are usually cleaned with sprays or wet scrubbers. One new development is to clean the gases by absorption of fluoride on alumina followed by the removal of solid from the gas stream using bag filters. The costs and operating charges associated with the gas cleaning will vary with the design and location of the installation. The effects of fluorides on man and air quality standards are briefly discussed.

AIR POLLUTION AROUND THE ROOF-TILE-KILN. (Yuga

kojo shuhen no taiki osen chosa). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 5(1): 162, 1970.

(Proceedings of the Japan Society of Air Pollution, Annual Meeting, 11th, Tokyo, Japan, 1970.)

Many roof-tile kilns in northern Saitama Prefecture changed into manufacturing glazed tiles in recent years and caused considerable fluoride damage in the mulberry fields in the area for the last three years. Approximately a 400 m radius of these factories, especially the leeward areas, were completely unsuitable for sericulture; damage to rice, corn, and cucumber was also noted. The Saitama Prefecture Institute of Public Health ordered an installation of detoxification devices to the twelve glazed tile factories in 1970. The device is designed to

<xref image="2000WVCM.TIF|V3|2006:09:28:01:21:46.00|122985|0"> image: </xref>

B. CONTROL METHODS

95

clean fluoride and other fumes from the tunnel kiln by a 10% solution of sodium hydroxide and to turn the waste liquid into calcium fluoride and sodium sulfite. A cooling tower prevents the rise of the absorbent and white smoke. The fluoride content in the air permitted by the Saitama prefecture law is 3 ppm. As a result of the detoxification device, sulfur oxides in the smoke decreased from 29.1 to less than 1.0 ppm; hydrogen fluoride, from 6.4 to 1.2 ppm; and dusts, from 18.8 to 1.5 mg/cu m. The fluoride content in mulberry leaves decreased from 6.4 to 2.0 mg/100 g in 80 m west of the factory; from 1.5 to 1.4 in 140 m east of the factory; and from 3.1 to 1.6 in 200 m north of the factory.

OPERATING EXPERIENCE WITH THE ALCOA 398
PROCESS FOR FLUORIDE RECOVERY. Air Pollution Control Assoc. J., 21(8):479-483, Aug. 1971. 1 ref.

Following the application of water scrubbers, cyclones, and electrostatic precipitators, Alcoa Research Laboratories at New Kensington, Pennsylvania, discovered that small quantities of hydrogen fluoride would react at low temperature with alumina. The Alcoa 398 Process was developed, incorporating a fluidized bed reactor to contact pot gases with incoming feed alumina. Bag filters are used to separate entrained solid materials from pot gases. Ninety-five percent interception of pot gases is reported with 99% recovery of fluorides from gases treated. Installation costs are in the range of \$18-37 per annual ton for new installations and about 50% more for conversion of old plants. Direct operating costs range from \$2.90 to \$4.70/ton of aluminum and recover eight dollars worth of fluorine, giving a net credit. A general description of the Alcoa 398 Process is included, and applicability and limitations are discussed. Performance efficiency, effect on metal purity, and maintenance are mentioned.

(Heat Management: Energy and Pollution Control), 23(7): 12-20, July 1971.

Turbulent Contact Absorber (TCA) equipment has been popular for its performance, easy handling, and no need for maintenance. The equipment comprises two grids in the lower and upper part of a tower and, in between the grids, a small quantity of light, plastic balls which are filled and act as a catalyst between the gas and liquid. By allowing the gas and liquid to flow at high speed, the balls are given a turbulent motion, so that the gas and liquid are brought into intimate contact. There is no clogging of the equipment due to dust, while a considerable volume of gas can be handled with stable operation even if there is a change in gas volume. TCA equipment has been used for processing sulfur dioxide, chlorine, hydrogen fluoride, hydrogen sulfide, and other sulfur-containing gases. Alkaline calcium salt compounds may be used as the absorbent.

Faith, W. L.

GASES. In: Air Pollution Control. New York, John Wiley, 1959, Chapt. 5, p. 142-178. 84 refs.

Gaseous contaminants in the atmosphere arise from two general sources: combustion of fuels and the handling and processing of chemicals. The latter category includes not only chemical manufacture but related activities, such as petroleum refining, smelting of ores, and various solvent-handling activities. Almost every gaseous material known escapes to the air at one time or another, but the most common by far are sulfur dioxide, carbon monoxide, hydrogen sulfide, hydrogen fluoride, chlorine and its compounds, nitrogen oxides, and hydrocarbons. These gases are reviewed with respect to their specific sources, analysis, and abatement.

PROCESS FOR RECOVERY OF HF AND H₂SIF₆ FROM GASES CONTAINING HF AND SD74. (Assignee not given.) U. S. Pat. 3,574,542. 5p., April 13, 1971. 9 refs. (Appl. March 5, 1969, 2 claims).

Waste gases from phosphoric acid plants usually contain silicon fluoride. When absorbed in water, the SiF₄ reacts with hydrogen fluoride to form H₂SiF₆, which in turn reacts with sodium fluoride to form Na₂SiF₆. This material contaminates the NaF and also the ultimately produced HF with SiF₄. The invention provides for the removal of SiF₄ prior to HF recovery, and thus for recovery of HF of high purity. Gases leaving an electrostatic precipitator are contacted with an aqueous suspension of NaF and NaHF₂ or KF and KHF₂, the suspensions being maintained in excess to suppress absorption of HF. The contact with the aqueous suspension causes the SiF₄ to precipitate from the gas as a fluosilicate salt, which is heated and decomposed to evolve SiF₄. The evolved SiF₄ is then absorbed in water to form an aqueous solution of H₂SiF₆ from which silicon dioxide is separated. Hydrogen fluoride is then separately recovered from the SiF₄-free gas obtained early by contacting the waste gases with the aqueous suspension.

Yamaguchi, Fumihiko

DESULFURIZATION OF STACK GAS BY TCA METHOD. (TCA ho ni yoru haien datsuryu). Text in Japanese. Netsu Kami AIR POLLUTION CONTROL, NATIONAL FERTILIZER DEVELOPMENT CENTER, WILSON DAM, ALABAMA. Tenn. Ind. Hyg. News., 22(1):1-5, Winter 1965.

In the fertilizer development center, dusts are evolved from the agitation of solid dry materials. The phosphatic dusts are relatively easy to collect, being noncorrosive and fairly heavy. Coke and coal dusts are non-corrosive but less dense. Simple dry cyclones with collecting efficiencies of 80-90% are useful as precleaners. These must be followed by a wet scrubber. At the noduh'zing kilns, an electrostatic precipitator is employed for dust removal, and a scrubber is used for fluorine removal. Resolution of industrial hygiene-air pollution problems is based primarily on exhaust ventilation, modernization of air-cleaning equipment, and confinement of process materials to the process. Pollution control activities between 1950 and 1968 are described. During 1960 to 1968, a new stainless steel phosphoric acid unit was added where fluorine and phosphoric anhydride losses are reduced to a negligible amount. A phosphorus centrifuge for treating phosphorus sludge was also added. Improved oxides of nitrogen removal was accomplished with small pressure nitric acid units. Wet, dynamic scrubbers were installed. A 165 ton/day high-efficiency nitric acid unit was also added. Ammonia, dusts, fluorine, nitrogen oxides, P₂O₅, and sulfur dioxide have been reduced since the initiation of the control system.

POLLUTION CONTROL INTERRELATIONSHIPS. Chem. Eng. Prog., 62(10):44-47, Oct. 1966. 3 refs.

<xref image="2000WVCN.TIF|V3|2006:09:28:01:21:50.00|117228|0"> image: </xref>

Air pollution and water pollution control in industrial applications are closely related. Waste products are discharged for dilution and transport from their source into the atmosphere or a watercourse. They are discharged to open waste lagoons, storage areas, or, as in the case of high level, long-lived radioactive fission products, to permanent storage in closed containers. Devices for air pollution control which reduce the amount of waste material discharged to the atmosphere usually increase the quantities of such materials that must be disposed of by other means. Waste gas control in an ammonia plant, fluorine control in a phosphate plant, and fly ash control in coal-fired power plants were discussed. A scrubbing system was developed for the removal of ammonia from the gases given off when the copper solution was regenerated. Ammonium carbonate, the liquid waste, replaced about 36% of the ammonia previously supplied as ammonium hydroxide. Fluorine is controlled by a jet-venturi fume scrubber. Accumulated fly ash is pulled from collector hoppers by an induced vacuum. The vacuum is produced by a vertical venturi ringed internally with downward directed water nozzles. The water and ash are discharged into an air-separator tank which removes air from the mixture. The ash sluice water then flows by gravity or is pumped to the ash ponds. The ash settles in the pond; the overflow is discharged to the nearest watercourse.

METHODS OF PURIFICATION AND FURTHER
PROCESSING OF FLUORINE CONTAINING GASES IN THE
PRODUCTION OF PHOSPHATE FERTILIZERS. (Melody
ochistki i pererabotki ftorcoderzhashchikh gazov ot proizvodstv
fosfornykh udobreniy). Text in Russian. Zh. Vses. Khim.
Obshchestva im. D. I, Mendeleeva, vol. 14:415-420, 1969. 70
refs.

The choice of the gas purification method for fluorine-containing stack gases produced during phosphate fertilizer production depends on the character of the purified gases (the fluorine and dust content). In gases free of dust, silicon tetrafluoride can be recovered by absorption in water or ammonia solution. Dust containing gases have to be dedusted in cyclones and then SiF_4 can be obtained by absorption in sulfuric acid. Gases of low fluorine content containing dust can be purified directly by wet methods. Some industrial designs of the above methods are discussed. Further processing of absorbed fluorine leads, according to the method used, to one of the following products: sodium fluorosilicate, sodium fluoride, aluminium fluoride, sodium aluminium fluoride, potassium fluoride, hydrogen fluoride. If both technologic and economic aspects of the problem are considered, only a limited number of the above methods is suitable for practical realization.

Kangas, J., E. Nyholm, and J. Rastas
SMELTER GASES YIELD MERCURY. Chem. Eng., 78(20):55-
57, Sept. 6, 1971.

A technique was developed which scrubs the sulfur dioxide-rich gases from smelter or roasting operations of mercury before the gas is processed for sulfuric acid production. At the Kokkola plant of Outokumpu Oy (Finland), zinc concentrates are roasted in a fluidized-bed furnace at a temperature of 950 C. Mercury sulfide contained in the concentrate decomposes completely and mercury vaporizes. The heat contained in the gases is recovered in a waste heat boiler, and dust is separated from the gas by means of cyclones and electrostatic precipitators. Mercury-containing gases coming from the electrostatic precipitators at a temperature of 350 C go to the sulfatizing unit. The mercury sulfatizer is a brick-lined tower containing ceramic packing, in which mercury-bearing gases contact a countercurrent flow of strong sulfuric acid. Mercury and selenium are scrubbed from the gas by the acid. Sulfuric acid flows from the bottom of the tower to an intermediate storage

tank, it is then pumped through a heat exchanger and recycled to the tower. Zinc and iron salts, as well as chlorides and fluorides, can also be removed in this process. Washing the precipitate, and the production of metallic mercury are mentioned.

Dagan, B. N.

CLEANING OF OPEN HEARTH WASTE GASES BY KAISER STEEL CORPORATION, CALIFORNIA. Proc. Nat. Open Hearth Basic Oxygen Steel Conf., vol. 37:72-78, 1954. 2 refs. A precipitator installed on an open hearth furnace and dust and gas problems inherent to the open hearth process are described. The precipitator was directly connected between the induced-draft fan outlet and the stack. The precipitator was energized by two 25-kva full-wave mechanical rectifiers with a stand-by rectifier and an integrated high-voltage switch gear, so that the spare rectifier could be used with either transformer. Automatically controlled impulse-type rappers were used for cleaning the collecting electrodes. The collected dust, averaging approximately 3000 lb/day, was intermittently removed from the hoppers. The precipitator consistently performed at an efficiency between 90 and 96% with a loss of approximately 0.03 grain/standard cu ft. The precipitator collected between 105 and 140 lb of open hearth dust/hr. About 90% of the particulate matter was under five micron in size. Chemical analysis and x-ray diffraction indicate that the dust was composed primarily of iron oxides and is wholly magnetic. The two major problem areas were sulfur trioxide and fluorine. Thermodynamic data are discussed.

COMPARED TECHNOLOGIES FOR THE COLLECTION OF GASES AND FUMES AND THE VENTILATION OF ALUMINUM POTLINES. Metallurgical Society of AIME, New York, Design Metal Prod. Processes Conf. Proc., Chicago, 111., 1967, p. 158-171. (Dec. 11-13.)

Aluminum producers are increasingly concerned about problems raised by the collection of gas and solids and the ventilation of the lines of aluminum cells. Engineering solutions to these problems have been achieved at two plants employing Soderberg cells, one having a lengthwise arrangement of raised shells and the other a crosswise arrangement of cells with bedded shells and prebaked anodes. Since the cells alone were insufficient to prevent air pollution, the first plant now aspirates gases collected in the cells to the roof where they are first cleaned in electrofilters, then washed with sodic solution and water in two-stage spray scrubbers. Subsequent precipitation with sodium aluminate yields a substantial amount of fluorine in the form of cryolite. Total cleaning efficiency for both roof and floor installations is close to 93%. At the other plant, there is one scrubber for every four cells, which insures almost continuous aspiration and washing. Washing is carried out with pure water. Gases are almost completely trapped, and washing efficiency reaches 90-92%.

B. CONTROL METHODS

97

Residues from aluminum plants were investigated to determine if carbon could be removed by flotation while recovering fluorine and aluminum compounds for recycling to the reduction process. Samples of flue dust, pot skimmings, and pot linings all responded to a simple turpentine flotation scheme to reject 90-97% of the carbon. Aluminum compound recoveries were 42-94% on the flue dust, about 95% on the pot skimmings, and 75-89% on the pot linings. Fluorine recoveries from the same samples were 35-63, 92-95, and 77-86%, respectively. The pot linings contained soluble aluminum and fluorine salts that were recovered by precipitation with sodium aluminate and carbon dioxide gas. Composites of residues responded to flotation much the same as the individual samples. (Author summary modified)

Ruch, J. B.

VPP-DESIGN CRITERIA FOR AN INSTALLATION TO REMOVE HYDROGEN FLUORIDE AND FLUORINE FROM THE CELLS 1 AND 2 VENTILATION GASES PRIOR TO FILTRATION. Preprint, Oak Ridge National Lab., Tenn., 19p., April 11, 1960. 18 refs.

Criteria are presented for a horizontal spray nozzle scrubbing system designed to remove fluorine and hydrogen fluoride from the 3000 cfm of ventilation air passing through the Volatility Pilot Plant, built for uranium recovery studies of irradiated zirconium-uranium nuclear submarine fuels. A reduction of fluorine concentrations from 1520 to less than 2 ppm during a total release of 68 lbs, and a reduction of hydrogen fluoride concentrations from 4090 to less than 1 ppm during a total release of 200 lbs, will adequately protect the ventilation system fiberglass filters. Six scrubbing stages each containing four nozzle-throat spray units are needed with a 5-10% aqueous caustic potash recycle system pumping at a maximum rate of approximately 180 gal/min, with a range per nozzle from 3-7 gal/min. The scrubber will be 4 ft by 4 ft by approximately 25 ft, containing a deentrainment section of baffles and a demister. The associated ventilation system hardware, services, and instrumentation requirements are given. (Author abstract modified)

McCann, C. R., J. J. Demeter, A. A. Orning, and D. Bienstock

NOX EMISSIONS AT LOW EXCESS-AIR LEVELS IN PULVERIZED-COAL COMBUSTION. Preprint, American Society of Mechanical Engineers, New York, Air Pollution Controls Div., 8p., 1970. 21 refs. (Presented at the American Society of Mechanical Engineers, Winter Annual Meeting, New York, Nov. 29-Dec. 3, 1970, Paper 70-WA/APC-3.)

Emissions of air pollutants are reported in the combustion of 500 lb/hr of pulverized coal at various excess air levels in a dry-bottom furnace with water-cooled walls. Nitrogen oxides decreased 70% (from 575 ppm to 175 ppm) as excess air was lowered from 25 to 1.4%. Retention of coal sulfur by the ash was 2.4%, the balance appearing as sulfur oxides in the furnace gas. Sulfur dioxide ranged from 1415 at 21.4% excess air to 1785 ppm at 3.8%. Sulfur trioxide values were one to seven ppm. Retention of coal chlorine by the ash was 4.6%, the balance appearing as 8.0 to 14 ppm hydrogen chloride in the combustion gas. Retention of coal fluorine by the ash was 11.2%, the balance emitted as 8.0 to 14 ppm hydrogen fluoride in the gas. At lower excess air levels, carbon combustion efficiencies could be maintained at 99% by increasing the air preheat from 600-650 F to 700 F and maintaining a stable air-fuel ratio. (Author conclusions modified)

Teworte, W.

ENVIRONMENTAL PROTECTION FROM THE VIEWPOINT OF THE NON-FERROUS METAL INDUSTRY. (Umweltschutz

aus der Sicht der NE-Metallindustrie). Text in German. Z. Erzbergbau Metallhuettenwesen, 24(10):505-506, Oct. 1971. (Presented at the Gemeinsotnen analytikertagung, Duesseldorf, Germany, June 3, 1971.)

The non-ferrous metallurgical industry has solved the problem of sulfur dioxide emission: no sulfide-containing ore is processed without the subsequent production of sulfuric acid. In 1970, the equivalent of 550,000 tons of SO₂ went into the sulfuric acid production process. Dust collectors are employed at pyrometallurgical processes. In one method, furnace gases are drawn off to be cleaned and, in another method, the entire air in the workshop is cleaned. Fluorine emissions still present problems, and more research is required here.

Okumura, Eijiro and Hiroyasu Matsumoto
DESIGN OF FLOATING SCRUBBER AND TURBULENT ABSORBER. (Shisshiki sbujin oyobi gasu kyushu sochi no Sfkkei - Furotingu sukurabba, taburento abusoba ni (.suite). Text in Japanese. Kagaku Sochi (Plant and Process), 9(10):11-22, Oct. 1967. 4 refs.

The Floating Scrubber (FBWS), wet type dust collection device, and the Turbulent Absorber (TCA), a gas absorption device, were discussed including their basic mechanisms, construction, and design theories. Practical applications include dust removal in iron manufacturing plants; dust removal, sulfur dioxide recovery, and gas absorption in pulp factories; dust removal in steel manufacturing dust removal in sulfuric acid manufacturing plants; absorption of SO₂ from waste gas in H₂SO₄ manufacturing plants; recovery of fluoride compounds from waste gas phosphoric acid manufacturing industry and from waste gas in aluminum manufacturing industry. Both the FBWS and TCA are scrubber columns filled with lightweight plastic balls between two grids. The washing liquid is sprayed through a nozzle from above and the gas to be treated is fed in from below; the gas causes a violent turbulent motion as it ascends to contact the wash liquid. Since the gas-liquid contact system occurs in the space between the two grids, the balls contact the media, float with the gas and liquid. Since the gas-liquid contact system occurs in the space between the two grids, the balls contact the media, float with the gas and liquid, revolve, and hit each other, thus causing stirring. This keeps the surface of the balls clean so that a new liquid film can form. Also, the area of contact between the gas and the liquid is enlarged for effective dust collection and gas absorption. The constant stirring keeps the grid meshes free from viscous or other substances formed by the absorption reaction. This is known as self-cleaning. Both FBWS and TAC are patented to UPO of the U.S.A. and feature no clogging, even with viscous substances; low pressure loss compared with its high gas velocity; higher contact effect resulting in higher efficiency; and stable and long-life performance.

Mashita, Takashi
WET-TYPE DUST COLLECTOR UTILIZING CONDENSATION. (Gyoshuku o riyo shita shisshiki shujinki soriboru). Text in Japanese. Sangyo Kogai (Ind. Public Nuisance), 7(10):573-574, Oct. 1971.

A new, wet-type dust collector consists of a casing, and many venturi pipes arranged in parallel in the casing, and water jet nozzles at the both ends of the pipe bundle. Dust-containing

<xref image="2000WVCP.TIF|V3|2006:09:28:01:21:56.00|124325|0"> image: </xref>

gas flows into the casing and into the narrow part of the venturi pipes where the speed and pressure drop. Vapor condensation occurs and dust particles are covered by a thin liquid film. The turbulent air current created at the narrow throat and the difference in sizes and weight of the particles cause collision of dust particles and water drops, enlarging each particle. As they leave the venturi pipes, they are sprayed by the water jet and large dust particles drop down as sludge. Clean gas goes through a vapor separation apparatus and is discharged. This apparatus is particularly effective for collection of large quantities of small particles (down to 0.04 micron). The contact of the gas and jet liquid is great and uniform, and toxic gases such as sulfur dioxide and fluoride can be absorbed easily. The decrease in flow speed or quantity has no effect on the collection efficiency. The circulation of the jet water is easy, and the maintenance of the spray nozzle is easy because of the large opening. Wearing from friction is limited because of the slow speed of the gas.

Ministry of Commerce and Industry (Japan), Dept. of Environmental Pollution
AIR POLLUTION. (Taiki osen). Text in Japanese. In: A Survey of Industrial Pollutant Disposal Machines - 1971. p. 68-122, Dec. 1970.

A general discussion of control techniques methods of selecting a dust collector, calculation of collection rate, power requirement for a dust collector, and principles of various collectors such as settling chambers, inertial collectors, centrifugal separators, scrubbers, filters and electrostatic precipitators, are explained with illustrations. Methods of toxic gas treatment by absorption and adsorption are explained with illustrations. Representative toxic gases such as hydrogen sulfide, nitrogen oxides, hydrogen chloride, chlorine, fluorides, and ammonia are discussed. For sulfur dioxide, importation of low sulfur oils and desulfurization methods are discussed. Hydrogenation of heavy oil, wet absorption, and active carbon adsorption of stack gases are discussed with flow sheets. Cleansing of automobile exhaust gas, combustion improvement, smoke dispersion, and coal and oil additives are discussed. Various types of dust collectors and desulfurization systems available on the market are listed with illustrations and photographs.

Givaudon, Jean
ACTION IN THE CHEMICAL INDUSTRY. (Action dans l'industrie chimiques). Text in French. Pollut. Atmos. (Paris), vol. 13:44-47, Oct. 1971.

One of the plants of the Solvay Society installed dust arresters on top of furnaces and cyclones to control fine dust emanating from polyvinyl chloride manufacture, converted some boilers from coal to natural gas, eliminated all leaks of chlorine in its electrolytic installations, and disposed of several liquid chlorinated pollutants by combustion. In general the French chemical industry disposes of pollutants by absorption (recovery of fluorine in aluminum plants, control of effluents from sulfuric acid plants where residual gases containing 0.20 to 0.25% sulfur dioxide are purified by washing with a diluted ammonia solution down to 0.02%, absorption of maleic and citraconic anhydride from effluents of the phthalic anhydride manufacture) by combustion and catalytic oxidation (a special incinerator completely disposes of most undesirable liquid waste), or by other processes (pilot plant desulfurization of waste gases from coal-fired power plants catalytic afterburners for internal combustion engines).

REMOVAL OF SOLUBLE GASES AND PARTICULATES
FROM AIR STREAMS WITH SPECIAL REFERENCE TO
FLUORIDES. Atomic Energy Commission, Washington, D. C.,

Contract AT(30-1)-841, Rept. NYO-1585, 49p., April 18, 1952.

16 refs.

High efficiency absorption of soluble or reactive gases can be obtained with available equipment using wetted fiber beds. Wetted fibers are many times more efficient than Raschig rings or Berl Saddles when compared on the basis of equal volumes. When compared on the basis of weight of packing, one pound of 78-micron diameter Saran fibers are about 150 times more efficient for the absorption of hydrogen fluoride gas than one pound of 1/2-inch Raschig rings. This reduction in weight and bulk can be utilized to realize important savings in construction and maintenance of gas absorbing systems. A five-stage system of concurrently-wetted fiber beds and counter-current stages can produce 75% hydrofluoric acid from 19.8% HF gas and give a gaseous effluent which is hygienically safe. High efficiency collection generally requires the addition of a droplet eliminator composed of a 1-inch to 2-inch depth of dry fibers less than 5 microns in diameter. For particulate collection, best results are obtained when particles and the surfaces on which they are to be deposited are of the same size. When treating gas streams containing inert particles, the absorbing stages can be protected from fouling and plugging by the use of an impingement device as a prefilter. (Author summary modified)

Nelson, L. B. and J. C. Barber

WILL EAGERNESS FOR POLLUTION CONTROL AFFECT FERTILIZER MARKET? *Croplife*, 1970:25-28, Jan. 1970.

Depending on the kind of plant or complex, atmospheric emissions from fertilizer plants and ancillary facilities include fluorides (essentially as silicon fluoride), sulfur dioxide, nitrogen oxides, free ammonia, ammonium chloride, and various dusts. Such emissions can be controlled adequately by using electrical precipitators, condensers, mechanical dust collectors, and scrubbers. Recovery and reuse of plant nutrients and salable by-products from emissions and liquid wastes add measurably toward improving efficiency and reducing the cost of pollution abatement. Fluoride can be economically recovered as fluosilicic acid or fluosilicate salts at many locations.

B. CONTROL METHODS

99

6(1): 181, 1971. (Presented at the National Council Meeting of Air Pollution Studies, 12th, Nagoya, Japan, Oct. 27-29, 1971.) Among pollutants identified in the exhaust (ammonia, sulfur dioxide, chlorides, fluorides, sulfates, and phosphates), NH₃ showed extremely high concentration. The source of such high ammonia concentration was traced to a small amount of by-product, ammonium orthophosphate which readily decomposes at 100 C, giving ammonia. A substantial reduction in ammonia concentration was achieved by lowering the pH value of scrubber liquid. By this treatment, the ammonia concentration was reduced from 660 ppm to 6.60 ppm; however, the concentration of other oxidative gases was slightly increased.

Paulus, Harold J. and Cort Platt

AIR POLLUTION CONTROLS IN THE SMALL ELECTROPLATING SHOP. *Plating*, 59(1):12-14, Jan. 1972. 5 refs.

Methods of controlling solvent losses, acid gases, acid aerosols, and alkaline aerosols from electroplating are outlined. The simplest solvent control method is to substitute alkaline or emulsion cleaning for vapor degreasing with trichloroethylene and perchloroethylene solvents. Where the solvents are used, losses are reduced by proper design, location, and operation of the vapor degreaser and by an activated carbon adsorption system. The acid gases are produced during the pickling or descaling of metal before plating, they include nitrogen dioxide, nitrous oxide, hydrogen chloride, hydrogen fluoride, and hydrogen sulfide. For the small plating shop, the best control method is the packed tower. Chromic acid and sulfuric acid mists and alkaline aerosols are controlled at the tank surface by foam blankets of floating plastic shapes, while mist and aerosols are removed from the ventilation system by spray scrubbers. If the acid and alkaline ventilation systems are combined, one scrubber can remove both materials.

Smith, Peter V.

ADVANCEMENT IN THE CONTROL OF PARTICULATES.

Tennessee Univ., Knoxville, Proc. Ind. Air Pollut. Control Conf., A mm., 1st, Knoxville, Tenn., 1971, p. 56-71. 6 refs. (April 22-23.)

In addition to particulate control, the familiar collectors such as the precipitator, scrubber, mechanical collector, and fabric filterhouse can also remove gaseous emissions such as sulfur oxides, nitrogen oxides, chlorine, and fluorine. The precipitator can remove enough particulate matter to enable the gas removal device to operate effectively, independently of the entrained particulate matter which could be detrimental to its operation. In many instances where upgrading fly ash removal of an existing boiler is necessary to meet new regulations, the use of scrubbers is preferred because their compact size is compatible with the amount of available land area. The most recent innovation in the use of electrostatic precipitators is the application of the hot precipitator to utility boilers firing low sulfur coal. In the aluminum industry, electrostatic precipitators have been used on prebake pots. Packaged, low energy, venturi-slotted type scrubbers have been successfully applied to remove particulate emissions from apartment house incinerators.

Sherwin, K. A.

EFFLUENTS FROM THE MANUFACTURE OF SULFURPHOSPHATE AND COMPOUND FERTILIZERS. *Chem.*

Ind. (London), vol. 41:1274-1281, Oct. 8, 1955. 6 refs.

(Presented at the Society of Chemical Industry, Symposium on the Prevention of Atmospheric and Water Pollution in the Chemical Industry, London, England, April 4-5, 1955.)

Current control practices for treating waste gases, solids, and liquids from processes involved in manufacturing su-

perphosphate fertilizers are described and evaluated. In sulfuric acid production by the chamber process, correct loading of nitric oxides in the initial stages is the most effective control against excess sulfur oxides or nitrogen oxides in tail gases. Scrubbers are used to control exit gas acidity in acid production by the contact process. Gaseous fluorine effluents from superphosphate production are also controlled by various scrubbing systems. Most dust from the exit gases of granular fertilizer manufacture, particularly from drying and cooling operations, is removed by high-duty cyclones, sometimes supplemented by scrubbers. Emissions from phosphoric acid and triple superphosphate production are adequately controlled by methods similar to those used in ordinary superphosphate plants, allowing for a greater dilution of the gases. Disposal of solid gypsum is of increasing concern.

EVOLUTION OF FLUORIDE RECOVERY PROCESSES.

ALCOA SMELTERS. Tennessee Univ., Knoxville, Dept. of Civil Engineering, Proc. Ind. Air Pollut. Control Conf., Annu., 1st, Knoxville, Tenn., 1971, p. 145-157. (April 22-23.)

Fluoride recovery processes developed by Alcoa and various techniques of pollution control instituted in their aluminum plants are reviewed with respect to early history, development of gas cell technique and treatment facilities, dry process development, and the Alcoa-398 process. Wet scrubbers to capture gaseous fluorides, fume collection equipment, electrostatic precipitators, and filter bags comprise most of the control systems. The Alcoa-398 process consists of a fluidized bed of alumina, dust collector, conveyors for alumina transport, and storage space. Typical investment and operating costs are discussed.

Tomany, James P.

VALUABLE BY-PRODUCTS RECLAIMED THROUGH AIR

POLLUTION CONTROL. Aerotec Ind. Rev., 5(4):9-12, 1965.

A serious difficulty in preventing fertilizer industry emissions of hydrogen fluoride, silicon tetrafluoride, particulate matter, and ammonia with a conventional-type wet scrubber is the formation of gelatinous material during operation, causing plugging of the scrubber. Types of apparatus used in this industry include a turbulent-contact absorber and an aeromix scrubber. The absorber consists of a tower containing one or more stages of low-density spheres. When gas and liquids are introduced, the spheres are thrown into random, turbulent motion through the reaction zone, and this buffeting action promotes intimate contact between the gas and liquor phase. The scrubber is an improved version of the standard venturi-type wet scrubber. Design features of the absorber and aeromix scrubber are discussed with particular reference to the production of phosphoric acid, triple-superphosphate, and ammonium phosphate.

TEST OF FAN ATOMIZER FOR ABSORPTION OF

FLUORINE-CONTAINING GASES IN THE PRODUCTION

OF SUPERPHOSPHATE. Sov. Chem. Ind. (English translation

<xref image="2000WVCR.TIF|V3|2006:09:28:01:22:04.00|118471|0"> image: </xref>

from Russian of: Khun. Prom.), no. 4:286-287, April 1971. 13 refs.

Fine-dispersion atomization of the liquid is one of the most powerful means of intensifying mass-transfer processes between a liquid and gas. The intensity of the absorption process with fine atomization can be increased by using rotating perforated cans, particularly with outflow openings of relatively large diameter. This makes it possible to create a reliable, highly productive, and economic design for a fan liquid atomizer which then can be used to absorb fluorine-containing gases in the production of superphosphate.

EXHAUST FLUORIDES FROM GYPSUM PLANTS. (Sekko
kojo no haishutsu fukkabutsu ni tsuite). Text in Japanese. Taiki
Osen Kenkyu (J. Japan Soc. Air Pollution), 6(1):187, 1971.
(Presented at the National Council Meeting of Air Pollution Studies, 12th, Nagoya, Japan, Oct. 27-29, 1971.)

The hydrogen fluoride emission from a rotary kiln used in the manufacture of plaster of Paris was greatly reduced by a simple modification of the procedure. The colorimetric measurements indicated the variation in HF concentration during the processing, and that HF concentration was greatly reduced by the addition of neutralizing agents. By the addition of up to 0.50% of neutralizing agent, the HF concentration was markedly reduced from 81.8 ppm to 0.95 ppm. The relationship between HF concentration and pH was also investigated, so that the effect of pH on the product could be controlled.

THE INAUGURATION OF THE NEW ALUMINUM PLANT
PECHINEY IN VLISSINGEN BY PRINCE BERNHARD OF
THE NETHERLANDS. (Einweihung der neuen Pechiney Huette
Vlissingen durch Prinz Bernhard der Niederlande). Text in Ger-
man. Aluminium, 47(12):782-784, Dec. 1971.

The new aluminum plant with 256 furnaces in Vlissingen (The Netherlands) has not been equipped with a central waste air cleaning system. After extensive experiments in the wind tunnel, it was decided to install individual groups of ventilators and gas scrubbers. The 34 ventilators with which the plant has been equipped have a throughput of 30 million cu m/hr, each ventilator has a throughput of 63 cu m/sec. In the gas scrubbers, 30,000 cu m water are atomized/hr for binding the fluorine gases. The fluorine is precipitated and recovered and returned to the production process. Air monitoring stations both of the stationary and mobile type are in operation to a distance of 18 km from the plant. The costs for installation of this system amounted to 1.68 million dollars, the power consumption amounts to 90 million kWh/yr.

Hachmann, H.

THE MERITS OF SYNTHETICS. (Die Verdienste der Kunst-
stoffe). Text in German. Technica, 21(4):247-248, Feb. 1972.

In order to obtain the lowest possible quantity of harmful exhaust gases, modern vehicles preheat the combustion air. Synthetics such as glass fiber reinforced Ultramid are used as the material for the casings. Another example of the use of synthetics in the field of environmental protection is the scrubbing towers for the purification of waste gases from an aluminum plant. The walls and interior installations of the scrubbers are of glass fiber reinforced Palatal. The 38 m high towers have a gas throughput of 200,000 cu m/hr. The gas entrance temperature lies between 90 C and 120 C. In each scrubbing tower 300 kg fluorine and 600 kg sulfur dioxide are retained each day. The fluorine content causes the scrubbing fluid to become 2% hydrofluoric acid. The dust concentration in the gas causes the solid concentration in the scrubbing

water to rise to 5%. The synthetic material is able to resist the aggressiveness of the scrubbing water. Experiments are presently under way to test the protective influence of Lupolen foils spread out over vegetable crops to shield them from the emissions by airplanes.

Predikant, Hans H., Hermann Betz, and Johann Schaeffer
METHOD AND DEVICE FOR CLEANING INDUSTRIAL
WASTE GASES. (Verfahren und Vorrichtung zur Reinigung
von Industrieabgasen). Text in German. (UOP-Kavag,
Gesellschaft fuer Luftreinhaltung m.b.H., Gondsroth bei Frank-
furt am Main (West German)) W. Ger. Pat. 1,905,080. 15p.,
Aug. 13, 1970. (Appl. Feb. 1, 1969, 7 claims).
A new method and equipment for cleaning industrial waste
gases containing fluorine and/or hydrofluoric acid are
described. The waste gases are scrubbed with aqueous
hydrofluoric acid in a first scrubbing zone and with sodium lye
in a second scrubbing zone. The run-off from the first
scrubbing zone is recirculated to the first scrubbing zone until
the hydrogen fluoride concentration has risen to between 3
and 5% by weight. The run off from the second scrubbing
zone is recirculated to the second zone for enrichment of the
sodium fluoride. The two run-offs from both scrubbing zones
are combined in a neutralization zone; the precipitated sodium
fluoride is separated, and the base lye is returned from the
neutralization zone to the first scrubbing zone. The two
scrubbing zones are arranged above each other in a column.
Water is injected into the first scrubbing zone in proportion to
the volume reduction of the scrubbing fluid. Each scrubbing
zone has its own entrance and exit. The run-off from the two
zones is collected in containers with return connections to the
respective scrubbing zones.

37536

LOW COST REMOVAL OF ORGANIC VAPOUR POLLU-
TANTS. Chem. Process. (London), 17(12):9, 11, Dec. 1971.
An economical control system for low concentrations of or-
ganic vapors combines adsorption on one of two activated car-
bon beds with air incineration (thermal or catalytic). The car-
bon beds operate on alternate adsorption/regeneration cycles:
when one bed becomes saturated, it is removed and
regenerated with heat provided by the incinerated gases. Since
steam is not required for regeneration, the corrosive conden-
sate is absent from the system. The estimated annual average
cost of the system is \$27,900 versus \$46,100 for carbon ad-
sorption with steam regeneration, and \$77,400 for air incinera-
tion alone (with heat exchange). A modification of the process,
using cascade adsorption, allows the solvent vapors to be
recovered rather than incinerated. This alternative may also be
preferred if combustion products from the process contain
hydrogen fluoride, hydrogen chloride, and sulfur dioxide.

B. CONTROL METHODS

101

A pilot gas purifier consisting of an electric separator and a hollow scrubber with spray nozzles was tested for its ability to remove gaseous and solid fluoride compounds from exhaust gases at an aluminum plant. The efficiency of gas purification in the scrubber was determined at gas linear velocities of 3-7 m/sec, gas inlet temperatures of 40-50 C, and spraying densities of 20 and 30 cu m/sq m/hr. Spray density had a greater influence on the degree of hydrogen fluoride entrainment than a change in gas velocity. The degree of purification remained constant within the gas-velocity range tested, but increased with an increase in spraying density. An equation is given that predicts the performance of the hollow, high-speed scrubber under various operating conditions.

HOW IMPORTANT ARE THE PROBLEMS OF ENVIRONMENTAL PROTECTION FOR THE BRICK AND EARTH ENGINEER. (Welche Bedeutung haben Probleme des Umweltschutzes fuer Steine und Erden-Ingenieure). Text in German. *Tonind. Ztg*, 96(1):21-23, Jan. 1972.

The environmental problems with which brick and earth engineers are confronted include the cleaning of waste gases and the reduction of dust emissions. The removal of sulfur dioxide closely followed by that of fluorine from the industrial waste gases have top priority. Applicable waste gas desulfurization methods seem to be available now after several setbacks. They are mostly based on the binding of the gaseous SO₂ on fine-grained bases such as magnesium oxide, dolomite, caustic lime, lime hydrate or limestone present in suspended form or in the fluid-bed. No method for the removal of fluorine from the waste gases of fertilizer plants is available yet. The elimination of the fluorine emissions by aluminum plants has not been entirely solved yet either. The dust collection methods have reached a high level of achievement, so that dust elimination nowadays is mainly a problem of costs and of the disposal of the collected dust.

PRODUCTION OF BIFLUORIDE-AMMONIUM FLUORIDE

AND WHITE SOOT FROM OUTGOING FLUORINE-CONTAINING GASES IN THE PRODUCTION OF SUPERPHOSPHATES. (Polucheniye biftorida-ftorida anunoniya i beloy sazhy iz ftorsoderzhashchikh gazov superfosfatnykh proizvodstv). Text in Russian. *Khim. Prom.* (Moscow), no 12:22-24, 1971. 5 refs.

Laboratory and pilot-plant experiments were carried out to elaborate methods for the complex utilization of waste gases containing fluorine. Waste gases were absorbed by recycled ammonium fluoride solution containing 6-10% NH₄F and 1-2% NH₃. The solution thus obtained contained 15-20% ammonium silicon fluoride and 0.5-2% of H₂SiF₆. Excess ammonium hydroxide was used for neutralization which produced ammonium fluoride and SiO₂. The pulp contained ammonium fluoride in concentrations of 15-20%. After agitation and cooling to 40 C, the liquid and solid phases were separated in four filters. The filtrate obtained on one of these filters was recycled to the absorption process. Three subsequent washing cycles were applied for SiO₂, followed by the drying of the sprayed powder using high-temperature waste gases. The SiO₂ thus obtained was used as additive to rubber products. The filtrate from the first filter, containing 15-20% ammonium fluoride, was subjected to two-stage condensation. A concentration of 60% was reached in the first stage, using atmospheric pressure, while the condensation was increased to 90% in the second stage, in applying a pressure of 380-420 Hg mm. After cooling and centrifugation to a residual humidity of 1.5-

1.8%, a standard quality product was obtained.

EQUIPMENT FOR COOLING AND SCRUBBING CORRO-
SIVE HOT GASES. (Einrichtung /urn Kuehlen und Waschen
korrodierender heisser Gase). Text in German. (Sumitomo Metal
mining Co., Ltd., Tokyo (Japan)) W. Ger. Pat. 1,671,404. 4p.,
Oct. 14, 1971. 2 refs. (Appi. May 31, 1967, 3 claims).

The equipment includes a cylinder with outlets for gas and
liquid in the lower part, and a top cover lined with an organic
acid-proof material, which contains the gas inlet and the
sprayers for the cooling and washing liquid. The cylindrical part
made of glass fiber reinforced thermoset is lined on the inside
with a tissue resistant to solutions containing fluorine, and has
a circular channel on its top edge for the cooling liquid. The
top cover is separated from the cylindrical part by a corrosion-
resistant flexible foil to prevent stresses. The admission tem-
peratures range from 100 to 300 C, and the gas to be cleaned
may contain sulfur dioxide, fluorine, and chlorine.

PURIFICATION OF ELECTROLYSIS-FURNACE FLUE GAS
FROM ALUMINUM FOUNDRIES. (Abgasreueigung der Elek-
trolyseofen-Abgase von Aluminum-Huetten). Text in German.
Luftverreinigung, 1969:17-20, Oct. 1969.

A technique for the purification of waste gases emitted from
the electrolytic cells of aluminum manufacturing plants is
presented. The problems of withdrawing the gases from each
cell individually or from the building housing the cells are
reviewed. The best method of removing the gases from each
cell is individual encapsulation. The exhauster must be
designed to leave sufficient access to the cells but simultane-
ously prevent any emission of the waste gases into the work
shop. A negative pressure must be maintained in the exhauster
spanning the surface of the cell; removable sheet steel plates
are installed on the sides. In cases where individual withdrawal
is not feasible, centralized cleaning, using ventilators and
scrubbers, is possible. Due to the great volumes of air to be
drawn off in centralized cleaning, the cleaning efficiency of
the diluted gases withdrawn centrally is much lower than that
of the concentrated gases withdrawn individually. The process
for individual withdrawal is reviewed. The control equipment
consists of an exhaust system for waste gas drawing, cyclones
for dust removal, scrubbers for removal of gaseous fluorine,
and high stack discharge.

DUST COLLECTION OF HIGH TEMPERATURE GASES BY

WET-TYPE AND BAG FILTER COLLECTORS. (Shisshiki

oyobi baggu firuta ni yoru koon gasu no shujin). Text in

Japanese. Nenryo Oyobi Nensho (Fuel and Combustion),

39(1):40-46, Jan. 1972.

The collection of dusts from high temperature exhaust gases is problematical due to the corrosive nature of gases, high temperature, and the high cost of operation and maintenance of the systems. The previously, widely used wet dust collectors had only 70 to 80% collection efficiency, and damages to fans, caused by accumulation of dust, were quite frequent. More recently, the wet dust collector has been exclusively used for high temperature gas fume collection in foundry cupolas. The principle, mechanism, and effect of the venturi scrubber are explained. A venturi rod hydrofilter is discussed with illustrations. This is a relatively simple structure consisting of a number of wet pipes over which the high temperature gas fume is passed. Vapor is created on the surface of the pipes and mingles with the high speed gas current, colliding into dust particles and collecting them. Bag filters are most frequently used for dust collection of high temperature gases. Different filters are used according to the type of gas; problem gases are steam, sulfur dioxide, carbon monoxide, chlorine gas, and fluoride gas. Various types of corrosion and cooling methods are discussed. One type of dust tube collector is discussed with illustrations. The gas enters from the hopper and coarse dusts collide into a baffling board and settles. The gas current enters the filter bag and the cleaned air goes out from the top. The dust accumulation on the filter fabric is periodically shaken off by the horizontal movement of shaker pipes and the vertical movement of the bags. Excellent results are achieved. Various types of bag filters are compared in a table.

USE OF FLOCCULANTS FOR PRECIPITATING PARTICLES

IN GAS PURIFICATION SOLUTIONS. (Primeneniye floku-

lyantov diva osazdeniya chastuts v rastvorakh gazoochistki).

Text in Russian. Tsvetny. Metal., 8(44):36-37, 1971. 3 refs.

The effect of flocculants on the settling of suspended solids from sodium bicarbonate scrubber solutions used after the electrostatic precipitation of noxious gases from aluminum cells was examined. The solution contained approximately 25 g/l sodium fluoride, 53 g/l sodium carbonate and sodium bicarbonate, 47 g/l sodium sulfate, and 30 g/l suspended solids consisting of about 80% cryolite, aluminum fluoride, magnesium fluoride, and calcium fluoride and about 15% of calcination loss products, i.e., unburned coke and pitch. Decreasing the solution sodium sulfate concentration from 52 to 32 g/l and increasing the temperature from 20 to 50 deg increased the settling rate by 50 and 100%, respectively. Soap chips, sodium oleate, oleic acid, tall oil and its hydrolysis products, and hydrolyzed polyacrylamide accelerated the settling; of these, 30 mg/l of the hydrolyzed polyacrylamide was the best additive.

DESULFURIZATION PROCESS EMPLOYING UPFLOW OIL

AND HYDROGEN. (Chevron Research Co., San Francisco,

Calif.) U. S. Pat. 3,620,968. 4p., Nov. 16, 1971. 6 rets. (Appl. Oct. 31, 1968, 1 claim).

A process for the catalytic hydrodesulfurization of hydrocarbon oils, particularly those containing a substantial proportion of material boiling above 500 F and containing 0.5-10% by weight of organic sulfur, is presented. The major advantages of the process over prior hydrodesulfurization processes lie in improvements of the activity and stability of the catalyst and of flow arrangements. The hydrocarbon feedstock, a major

portion of which is in liquid phase during contact with the catalyst, is desulfurized by passing the oil and hydrogen upward in a cocurrent flow through at least one fixed bed of catalyst contained in a desulfurization reactor. The catalyst comprises pellets or other particles of alumina cogelled with a group VI hydrogenating component, a group VII hydrogenating component, group IV metal phosphate particles dispersed in the catalyst, and fluorine. The upflow oil and hydrogen operation with a cogel catalyst provide for higher activities and low initial fouling rates. (Author abstract modified)

EQUIPMENT FOR REDUCING THE QUANTITY OF HARMFUL GASEOUS, LIQUID AND SOLID EXHALATIONS.
Czech. Heavy Ind. (Prague), no. 11:2-10, 1971.
Performance data are given for several types of apparatus for removing harmful gases, liquids, and solids from industrial waste gases. Included are a foam-type separator for noncorrosive gases with a dust content up to 400 g/cu m; a current-type separator for highly dispersed liquid or solid aerosols; a separator for relatively coarse fibrous particles in a mixture with particles about 1 micron; and a two-stage Triton separator for solid or liquid aerosols with a particle size less than 1 micron. Also described are foam-type absorbers for soluble gaseous compounds such as hydrogen chloride and hydrogen fluoride or for aerosols of sulfuric acid, nitric acid, and sodium hydroxide; an overflow-type absorber for more demanding absorption processes; a fibrous filter for oil mists; a separator and retainer of minute liquid aerosols; and a combustion device that totally oxidizes combustible substances in waste gases to carbon dioxide and water. The rated gas capacities of different models of each item are given together with the application possibilities of some of the equipment.

Kraft, Guenther and Heinz Beck
PROCEDURE FOR THE REMOVAL OF FLUORINE FROM WASTE GASES OCCURRING IN ALUMINUM FUSION ELECTROLYSIS SHOPS. (Verfahren zur Entfernung von Fluor aus Abgasen, insbesondere solchen der Schmelzflusselektrolyse des Aluminiums) Text in German. (Metallgesellschaft A. G., Frankfurt, (West Germany)) W. Ger. Pat. 1,567,660. 3p., Dec. 23, 1971. (Appl. March 29, 1963, 2 claims).
Removal of fluorine from gases developed in the process of fusion electrolysis in aluminum plants is achieved by treatment with lithium containing washing solutions. The washing solutions should include lithium (hydroxide), sodium, and aluminum in proportions so that the fluorine will be precipitated as an insoluble Li-Na-Al-F-complex. Optimum pH of the washing solution for this reaction is 3, but satisfactory results are achieved as long as the pH is kept below 6.

B. CONTROL METHODS

103

Sulfur dioxide contained in the atmosphere has a toxic affect on man, plants, and materials. Pines die in the Ruhr Valley because of the sulfur dioxide; its effect on these trees was probably enhanced by fluorine also present in the atmosphere. Plants begin to show signs of injuries at an annual average concentration of 85 micrograms SO₂/cu m air. Materials begin to show serious signs of deterioration at an average annual SO₂ concentration of 345 micrograms/cu m. Considerable physical effects on man have been observed at SO₂ concentrations of more than 300 micrograms/cu m lasting for 3 or 4 days and of more than 115 micrograms/cu m air over the year. The existing maximum allowable emission concentration for SO₂ (0.4 mg SO₂/cu m air) in the Federal Republic of Germany is too high. Considerable plant injury at this concentration is not impossible. Unfortunately, the SO₂ emission will continue to rise in future - at least in the state of North Rhine Westphalia. Measures for reduction of the SO₂ emission include the use of low-sulfur fuel oil (1% sulfur) and the desulfurization of the waste gases. Of the various desulfurization methods the Grillo-process is ready for practical use. It is estimated that this process used in oil-fired power plants will raise the power costs by 0.1 cents/kWh.

PROCEDURE AND EQUIPMENT FOR THE REMOVAL OF
NOXIOUS CONTAMINANTS FROM GASES. (Verfahren und
Vorrichtung zum Entfernen von in einem Gas enthaltenen
schaedlichen Verunreinigungssubstanzen). Text in German.
(Showa Denko K. K., Tokyo (Japan)) W. Ger. Pat. Appl.
2,116,996. 29p., April 7, 1971. (9 claims).
The procedure and equipment for removing contaminants, e.g.,
fluorine, chlorine, sulfur dioxide, and hydrogen cyanide, from
waste gases by passing them over a packed bed sprayed with
an absorbing solution of sodium carbonate or sodium hydrox-
ide are described. Thin plastic plates were arranged in a
horizontal line across an absorption tower and sprayed with
the Na₂CO₃ solution to an average deposition thickness of
0.015 mm. The waste gas was cooled and scrubbed, and the
gas, containing 0.01% sulfur, 2-3% oxygen, 5-10% carbon diox-
ide, 0.005% nitric oxide, 20-25% moisture, and nitrogen, was
passed through the tower with an entrance temperature of 20-
25 C. The cleaned gas left with an SO_x concentration of
0.0005%. After 20 hr of continuous operation, SO_x concentra-
tion increased to 0.001%; the waste gases were then passed
through another tower, while the first tower was regenerated
by cleaning the packed bed with water or a solution of the ab-
sorbing agent. Waste gases containing 40 mg/cu m of chlorine
gas were passed through the tower at 200 cu m/min and were
cleaned to a residual hydrogen chloride concentration of 3
mg/cu m.

Wolfram, Walter
DEVELOPMENT OF A NEW FLUORINE ABSORPTION
PROCEDURE FOR THE REMOVAL OF SILICON
TETRAFLUORIDE FROM SUPERPHOSPHATE PLANT
WASTE GASES. (Die Entwicklung einer neuartigen Fluorab-
sorption fuer di" Abscheidung des Siliziumtetrafluorids aus den
Abgasen von Superphosphatanlagen). Text in German. In:
Technik und Uruweltschut/ Luft-Wasser-Boden-Laerm. Kanuner
der Technik, Brennstofftechnische Gesellschaft in der Deutschen
Demokratischen Republik (ed.), Leipzig, VEB Deutscher Verlag
fuer Grundstoffindustrie, 1972, p. 75-89. 18 refs.
Maximum separation of silicon tetrafluoride from the waste
gases of superphosphate plants is required. The actually used
fluorine absorption equipment such as spray towers, spray
chambers, or combinations fail to comply with the require-
ments of modern air hygiene. To obtain commercially utiliza-
ble waste products with efficiencies above 99.5%, a fully con-

tinuous and automatic fluorine absorber with a modified lattice bottom was developed and tested at the Coswig plant of VEB Stickstoffwerk Piesteritz (East Germany). Here, silica and silicofluoric acid are discharged continuously, and large phase contact area is provided. Thermodynamic and kinetic problems of silicon tetrafluoride absorption were studied, and single-stage absorption was sufficient for a silicofluoric acid concentration of 17%. The absorber consists of a round, rubber-lined steel tower with bottom inlet for the waste gases with fluorine concentrations of 8-12 g/cu m. The gas passes through four consecutive lattice bottoms made of brass, at a rate of 25,000 cu m/hr. The silicofluoric acid formed drops down through the bottoms at a rate of 800 l/min and sq m of tower cross-section area. A stable dynamic layer of 120 mm thickness is formed upon the bottoms, providing a large contact area. The water consumption is 1-1.5 cu m/hr. The silicofluoric acid is obtained in a concentration of 15.17% hydrogen while the purified gas contains fluorine in a concentration of 20-30 mg/cu m. The pressure drop within the absorber lies at 70-80 mm of water column. An automatic concentration control is planned. The pilot equipment has been operating successfully for 2 yrs.

STATE OF THE ART AND DEVELOPMENT OF INDUSTRIAL FLUORINE CHEMISTRY. (Stand und Entwicklung der industriellen Fluorochemie). Text in German. Chemiker Z. (Heidelberg), 96(2):65-75, Feb. 1972. 79 refs. Electrolytic aluminum production is by far the largest consumer of inorganic fluorine compounds. In 1970, the Federal Republic of Germany produced 309,000 t of aluminum for which 9000 t of AlF_3 and 8000 t of Na_3AlF_6 were used. Despite the present stagnation of aluminum consumption, considerable capacity increases are expected for Europe and Japan. For reducing fluorine emissions by these plants, expensive waste cleaning facilities are installed. An aluminum plant producing 100,000 tons of aluminum/annum, 5 to 6 t of HF are emitted daily in addition to considerable quantities of dust; at the Soederberg anodes, tar vapors, soot particles, and sulfur dioxide are emitted. In the so-called open furnaces (e.g., Al-suisse), type the waste gases are passed through rooftop scrubbers prior to discharge; 50% of the dust and 90% of the F are removed. The uncleaned gas usually arrives at the scrubber with 5 mg F/cu m. In furnaces with Soederberg anodes, the waste gases are collected and burned to eliminate tar vapors. They are then passed to cyclones or electrostatic precipitators for dust separation and to the scrubber for washing out the gaseous fluorine compounds. A dry method for cleaning such gases has recently been introduced wherein the waste gas is treated with Al_2O_3 . Dust and HF are retained. The HF and dust-laden clay then goes to an electrolytic bath. The method is disadvantageous in that the solid residues must be dumped.

EFFECT OF THE METHOD OF STOPPING THE ANODE EFFECT ON THE POLLUTION OF THE ATMOSPHERE WITH FLUORINE. (Vliyanie sposoba grsheniya anodnogo effekta na stepen zagryazneniya atmosferj ftorom). Text in Russian. Tsvetn. Metal., 44(8):26-28, Dec. 27, 1971. 6 refs. Fluorine salt losses and abatement of air pollution with fluorine from aluminum producing plants can be achieved by

<xref image="2000WVCV.TIF|V3|2006:09:28:01:22:20.00|127132|0"> image: </xref>

substituting the use of wood pulp or other hydrogen containing compounds with compressed air in the extinguishing of the anodic effects. However, the wide use of this procedure was prevented because of the explosion hazards involved, if the air included humidity drops. An air drying device should be applied before its use for this purpose. Since each hydrogen atom introduced into the electrolyte system produces an emission of one fluorine atom, and the carbon constituent of the wood pulp produces contamination of the electrolyte and thus increases its electrical resistance, the advantage of the compressed air use is emphasized.

INDUSTRIAL HIGH-SPEED HOLLOW SCRUBBER FOR ALUMINUM MANUFACTURING-GENERATED GAS

CLEANING. (Promyshlennyy polyv skorostnoy skrubber dlya ochitski gazov alyuminiyevogo proizvodstva). Text in Russian. Tsvetn. Metall., no. 12:28-31, Dec. 1971. 4 refs.

Scrubbers with diameters exceeding 5 m used in electrolysis shops were investigated. Before scrubber treatment the gas to be cleaned contained, per N cu m, 10-30 mg hydrogen fluoride, 30-100 mg dust, and 10-60 mg tar. The scrubber was sprayed with soda solution as an absorbing agent. Hydrogen fluoride absorption was dependent on the linear gas velocity and the spray density. The efficiency could be influenced by the site and direction of the spray. Spraying from the topside gave the best result up to a gas speed of 5 m/sec. The effects of the spray density were studied under various spraying conditions. Efficiencies of 97.5-98.0% were reached with a density of 37 cu m/sq m.hour. Single-stage dust separation and scrubbing were applied in the hollow scrubber. Increased gas speed and spray density resulted in increased efficiency, while the nozzle placement had only a slight influence. The residual dust concentration was 30-60 mg/N cu m. Efficiency for total dust was 73% with a gas speed of 3.3 m/sec and a spray of 30 cu m/sq m.hour. Efficiencies above 90% can be reached with appropriate gas velocities and spray density. The drop separator had a hydraulic resistance of 15-20 kg/sq m.

CLEANUP PAYS OFF FERTILIZER PLANT. Environ. Sci. Technol., 6(5):400-401, May 1972.

Farmland Industries of Bartow, Florida, spent nearly a million dollars a couple of years ago to install a fluorine recovery system in its 22 million dollar phosphate fertilizer plant. During the first full year of the systems operation, Farmland recovered more than 5000 tons of fluosilicic acid—a by-product it had previously been wasting—and sold every ounce of it. The fluorine recovery equipment is not complicated and works well. The tops of the evaporators were simply unbolted at a flange and a water recirculation system was installed in the exit gas stream. As the phosphoric acid is successively concentrated in the evaporator units, fluorine-containing off-gases are concentrated in an aqueous solution. With the recirculation system, a fluosilicic acid concentration of about 20% is obtained.

METHODS FOR PREVENTION OF SURFACE WATER CONTAMINATION AND AIR POLLUTION BY FLUORINE COMPOUNDS FROM PHOSPHATE PLANTS. (Assignee not given.)

U. S. Pat. 3,642,438. 12p., Feb. 15, 1972. 9 refs. (Appl. April 15, 1969, 5 claims).

A process is described for the elimination of the fluorine contamination of surface waters and other pollution by fluorine compounds from phosphate plants, and for recovery of fluorine as hydrofluosilicic acid. The processes involve the

separation of fluorine compounds from waste gases by absorption-desorption with sodium fluoride, barium difluoride, or potassium fluoride, and absorption of silicon tetrafluoride in water. Hydrofluoric acid may also be recovered in the process. A principle object of the invention is the control of fluorine content of gypsum pond waters. Scrubbers, filters, and settling tanks are part of the process.

Haenig, Gernot and Klaus Husmann
THE GRILLO-AGS PROCESS FOR DESULFURIZATION OF WASTE GASES. (Das Grillo-AGS-Verfahren zur Entschwefelung von Abgasen). Text in German. Z. Erzbergbau Metallhuettenwesen, 25(4): 175-181, April 1972. 13 refs. The Grillo-AGS desulfurization method, which is in its eighth year of development, is based on wet absorption using mixtures or compounds of magnesia and manganese oxides as absorbents. The efficiency of the method was tested under the operating conditions of an oil-fired steam boiler. At the same plant (8000 cu m/hr capacity), tests were conducted to determine whether, apart from sulfur dioxide a selective removal of sulfur trioxide at temperatures between 300 and 500 C is feasible. While in earlier experiments the absorption was carried out in spacious containers with diameters of 3 to 4 m and with gas residence times of several seconds in two stages, it later became feasible to desulfurize a waste gas flow of 27,500 cu m/hr in a single absorption tube 5 m long 0.8 m in diameter with an efficiency of more than 90%. At a pressure loss of only 50 mm water the gas residence times were below 0.5 sec. This is due to the extraordinary effectiveness of the magnesia-manganese oxide mixture which requires much shorter residence times than a pure magnesia oxide suspension. The coke filter of earlier experiments was replaced by a lamellar droplet separator. The original throughput of fresh absorption mass of 1.6 to 1.8 g/g SO₂ could be reduced to less than 1.5 g mass/g SO₂. The absorption of SO₃ at temperatures of about 350 C is almost total and that of fluorine is 70%.

Gelperin, N. I. and V. M. Tarasov
EQUIPMENT FOR CLEANING OF ALUMINUM ELECTROLYSIS SHOP-EMITTED GASES: EFFICIENCY AND INTENSITY OF OPERATION. (Ob intensivnosti i ettektivnosti apparatov dlya ochistki otkhodyashchikh gazov alyuminiyevykh elektrolizerov). Text in Russian. Zh. Prikl. Khim., 45(1):70-75, 1972. 9 refs.

Results of a comparative study of equipment for the removal of gaseous hydrofluoric acid, dust, and tar from aluminum electrolysis shop gases are described. Soda solution was used as absorbent in all cases. The relative characteristics of the different equipment were determined on the basis of efficiency, mass transfer, and energetic parameters, separately for electrolysis shops with lateral and top power supply. The efficiency for gaseous hydrofluoric acid was fairly high (90-98%), while the gas flow rates varied within a wide range of 0.9-6 m/sec. The rate of mass transfer, determining both the relative productivity and the efficiency, was highest in fluidized-bed scrubbers (18-23.4 m/sec), and lowest in scrubbing chambers (1.2 m/sec). The energetic parameters were lowest for

<xref image="2000WVCW.TIF|V3|2006:09:28:01:22:24.00|121772|0"> image: </xref>

fluidized-bed and high-speed scrubbers, and highest for cyclones. The rate of mass transfer for dust was best in fluidized-bed scrubbers and worse in foaming equipment (0.36 m/sec, energetic parameter 500 kg/sq m) which were hardly suitable for highly dispersed dust. The rate of mass transfer for tar products was best in fluidized-bed scrubbers and hydrodynamic dust collectors. Fluidized-bed scrubbers, satisfying sanitary standards in single-stage operation, were best regarding both intensity and efficiency for gases from electrolysis shops with lateral power supply, while none of the designs investigated was capable of meeting such standards in single-stage operation for electrolysis shops with top power supply.

Haenig, Gernot and Klaus Husmann

THE GRILLO-AGS PROCEDURE APPLIED FOR WASTE GAS DESULFURIZATION. (Das Grillo-AGS-Verfahren zur Entschwefelung von Abgasen). Text in German. Erzmetall, 25(4):175-181, 1972. 13 refs.

The Grillo-AGS wet absorption procedure, developed for the removal of sulfur oxides from waste gases in 1969, as well as related pilot plant experiments, realized equipments, and possible uses are described. The absorbent, formed by mixtures or compounds of magnesium and manganese oxides, is sprayed into the path of the waste gas flow in a reactor, and after being recirculated several times, the spent suspension is removed for drying. The dried matter, containing 17 to 21% of sulfur in the form of magnesium sulfate or sulfite, is then subjected to thermal regeneration in a separate, central roasting furnace, by adding a reducing agent such as oil, natural gas, sulfur, or coal. The roasting gas formed contains 5-7% of the sulfur dioxide by volume, and can be reprocessed to sulfuric acid in conventional equipment. A pilot plant, designed for an oil-fired steam boiler, was composed of a 5 m long tube of 0.8 m diameter. It had an efficiency of above 90% at a capacity of 27,500 cu m/hr, while the sulfur dioxide and sulfur trioxide concentrations in the waste gas were 1.3-2.5 g/cu m and 50-300 mg/cu m, respectively. The separation of the suspension from the waste gas was made in a tower, followed by a lamellar droplet separator with an over-all efficiency of 99.5%. The contact time was less than 0.5 sec, and the specific expenditure lay at 1.5 g/g of SO₂. Rapid hydration of the absorbent below pH 7 was observed. The SO₃ removal at 350 C was nearly quantitative, and the efficiency for fluorine was 70%. Full-size industrial equipment have efficiencies of 30-95%, and several units are preferably connected to a central, separate regenerator. The total costs of the SO₂ absorption at an oil-fired power plant lie in a range of .04-.07 cents/kWh (1.9 million cu m/hr, 3.5 g of SO₂ per cu m). The Grillo-AGS procedure can be applied to thermal power plants, remote heating plants, and metallurgic plants. Large regenerator plants with a capacity of 200,000 tons of sulfuric acid should be designed.

ENVIRONMENTAL PROTECTION AND STEEL INDUSTRY - PROBLEMS AND SUCCESSES. (Umweltschutz und Stahlindustrie - Probleme und Erfolge). Text in German. Stahl Eisen (Duesseldorf), 92(6):232-237, March 16, 1972. 13 refs.

Problems and achievements within the field of environmental pollution controls in the steel industry are reviewed. New technologies for steel production are viewed no longer solely from a point of economy but also from a point of how harmful they are to the environment. The share of the total emission of gaseous and particulate matter from steelmaking processes is 14% as compared with that of traffic at 42%. At the first stage of steel production, the preparation of the raw material, dusts are emitted. The waste gases from sintering plants contain sul-

fur dioxide and fluorine compounds. The blast furnace waste gases no longer pose problems since they can be cleaned to residual dust concentrations of 3-5 mg/cu m. Emission from steel plants have decreased to 10% in 1969-1970. Despite enormous production increases, the dust sedimentation decreased from 313,000 to about 245,000 tons. The SO₂ emission concentration has also decreased between 1963 and 1969 from 0.24 to 0.15 mg/cum. The major cause of pollution reductions is process and design modifications of furnaces.

Klimecek, Rostislav

THE PROBLEM OF REMOVAL OF INDUSTRIAL EXHALA-

TIONS. (Problem odstranovani prumyslovych exhalaci). Text in Czech. Chem. Prumysl (Prague), 21(12):615-618, 1971. 6 refs. Current concentrations of gaseous effluents emitted by the Czechoslovak chemical industry, control methods used, and desulfurization processes of gaseous effluents from thermal power plants were investigated. Total emission from chemical factories was 20,000 tons of sulfur dioxide and 3500 tons of sulfur trioxide; thermal power plants contributed approximately two million tons, with an additional 220,000 tons from the transportation industry, 150,000 tons from metallurgical plants and 400,000 tons SO₂ from home heating installations. Control measures instituted by plants of the chemical industry included washing of end gases variously with sodium hydroxide solutions, ammoniacal solutions, sodium Decarbonate, and by catalytic oxidation to SO₃ and its subsequent absorption. While these various technologies have been satisfactory for the chemical industry, they are not adequate for the thermal power plants due to the nature of the end gases and because of the problem of final disposition of the desulfurization by-products. Washing towers which could process several million cu m waste gases/hour containing fly-ash and having a temperature of 180 C and which could purify them so that they are hot enough to disperse fast enough in the atmosphere have not yet been developed. Foreign technologies cannot be applied because combustion gases in Czechoslovakia are of different composition. Under generally prevailing conditions, recovery of sulfur is more economical than desulfurization with gas purification as an end. Other pollutants emitted amount to 9500 tons carbon disulfide, 13,500 tons hydrogen sulfide, 10,500 tons nitrogen oxides, 2500 tons chlorine, 500 tons hydrochloric acid, and 500 tons fluorine. In the case of some large plants, recovery of pollutants and their recycling is more advantageous than liquidation (catalytic reduction of nitrogen oxides in nitric acid plants).

CONTROL OF ACID FUME FROM DROSS REPROCESSING.

Australian Chem. Process. Eng. (Sydney), 2S(2):13-16, Feb. 1972. 6 refs. (Presented at the Royal Australian Chemical Institute and Institution of Engineers, Joint Symposium on Chemical Process Waste Disposal, Sydney, Australia, Oct. 12, 1971.)

The process of aluminum melting for casting into billets or castings usually involves the use of fluxes to aid in the removal of gases, oxides, or other impurities. The dross formed during this operation is continually removed by skimming from the surface of the melt. Since the dross so formed may contain appreciable quantities of entrained aluminum metal, it is the usual practice to further process the

<xref image="2000WVCX.TIF|V3|2006:09:28:01:22:28.00|126935|0"> image: </xref>

dross to recover the metal. The performance of a venturi type scrubber in controlling acidic fume from dross reprocessing operations was examined by determining the collection efficiency for various compounds in the vapor and solid phase. Acid gases were completely removed provided the scrubbing liquor was maintained with an alkalinity above pH 10. Reduction in total chlorides ranging from 67-70% was achieved and a corresponding reduction in fluoride emissions was obtained; the collection efficiency was 70-87%. It was not practicable to sample the inlet gases isokinetically and only the emissions rate for total solids was determined. The unit has been in operation for almost two years and severe corrosion has occurred which no doubt has contributed to reduced overall efficiency. Construction materials evidently play an important part in the design of liquid scrubbers to control this type of fume. (Author conclusions modified)

Ussar, Max B.

PROTECTION OF THE ENVIRONMENT: PROBLEMS AND TENTATIVE SOLUTIONS. (Umweltschutz-Probleme und Loesungsversuche). Text in German. Glueckauf (Essen), 1971-1972: 4-6.

General problems of environmental protection in Austria are outlined with special regard to air and water pollution. Traffic and industry account for 40% and 35% of the total emissions, respectively. The separation techniques developed for solid as well as toxic and irritant pollutants such as sulfur dioxide, chlorine, fluorine and their compounds, as well as nitrogen oxides require further improvements technically and economically. The complex nature of ecologic problems calls for the cooperation of experts and institutions in many areas. Environmental aspects of industrial processes should be made part of the curriculum of institutions of higher education. Industry should be allowed time to adopt air pollution standards.

DISPOSAL OF FLUORINE AT LOW CONCENTRATIONS.

Union Carbide Corp., Paducah, Ky., Paducah Gaseous Diffusion plant, Atomic Energy Commission contract W-7405-eng-26, Rept. KY-638, 12p., April 15, 1972. 3 refs. NTIS: KY-638

Experimental work has been conducted to verify the safety of fluorine disposal by means of reaction with carbon and to investigate the efficiency of the process at low fluorine concentrations. The explosive reaction occasionally observed by other workers could be eliminated by the use of low surface area amorphous charcoal. Fluorine concentrations from 0.1 to 10% could be readily reduced to less than 50 ppm by reaction with heated charcoal to produce primarily gaseous nontoxic fluorocarbons. The process appears to provide a safe, efficient, and economical method for the disposal of waste fluorine.

HYDROGEN FLUORIDE EXTRACTION BY MEANS OF AN

ALPHA-NAPHTHYLAMINE BENZENE SOLUTION. (Ekstrakt-siya fluoristogo vodoroda benzolnym rastvorom alpha-naf-tilamina). Text in Russian. Zh. Prikl. Khim., 45(4):854-857, 1972. 14 refs.

In search for new means of hydrogen fluoride emission control, interactions between concentrated or diluted HF water solutions and alpha-naphthylamine benzene solutions as affected by the concentration of the amine were studied. Included are HF partition data between water and the organic phase utilizing 0.1 and 0.5 mole/l alpha-naphthylamine in benzene. Increasing HF concentrations in water enhanced its extraction by the organic phase. Higher concentrations of the amine increased the extraction power of the organic phase with the formation of an alpha-naphthylamine

monofluorohydrate. Utilization of 0.5 mole alpha-naphthylamine/1 benzene solutions led to the formation of a solid difluorohydrate derivative reaching 93.4% HF extraction yields for a 36.3% HF water solution concentration. Recovery of the extracted HF was made by treatment of the fluorohydrate with saturated sodium fluoride solutions. Utilization of alpha-naphthylamine for the extraction of HF from water solutions was feasible for the above purpose.

Fischer, Friedrich and Karl-Heinz Pfefferle
WASTE GAS CLEANING PROCEDURES. (Verfahren zur Abluftreinigung). Text in German. Chem. Tech. (Berlin), 1(5):215-219, 1972. 6 refs.

Pollutants from industrial gaseous effluents can be removed by adsorption, thermal combustion, catalytic combustion, absorption, or by a combination of two of these methods. Adsorption with activated carbon is applied when the recovery of organic vapors is desired which would otherwise create a malodorous and harmful work environment. The contaminated effluents are drawn by suction produced by blowers through a layer of the adsorbent which is, after saturation, regenerated by steam. The recovered solvent-steam mix is condensed and distilled. Fully automatic equipment in a number of modifications is now available. Per ton of recovered solvent, 0.5 kg activated carbon, 100 kWh energy, 2.5 tons steam, and 30-50 cu m cooling water is required. Where recovery is not feasible because of low concentration or a multicomponent mix, thermal or catalytic combustion is more economical. Combustion of halogen, sulfur, or nitrogen compounds, which would make catalytic combustion impossible, is accomplished between 650 and 850 C. The heat required is supplied by combustion of consumer gas; the cost of operation of such an installation is approximately \$18/hr. Catalytic combustion can be applied when nothing but carbon dioxide and water result. The process works with temperatures between 250 and 500 C, depending on the catalyst used; the hourly operational cost of such an installation is approximately \$8.00. In the case of water-soluble solvents, recovery can be achieved by absorption such as in the recovery of acetone and dimethylformamide which are scrubbed with water and subsequently distilled, or in the recovery of hydrogen fluoride which is scrubbed by a solution of potassium hydroxide and converted to calcium fluoride. Sometimes, two or more processes must be combined, such as in the recovery of carbon disulfide and the simultaneous elimination of hydrogen sulfide from gaseous effluents in the manufacture of viscose, where the first step is accomplished by adsorption, the second by scrubbing with an alkaline solution, and subsequent oxidation to elementary sulfur.

B. CONTROL METHODS

107

The development of a new air-purification device (Air Clean) is described together with the results of experimental field tests. Preliminary experiment was carried out using unwoven cloth, 10 mm thick and treated with alkali, for the adsorption of eight JIS test particulates at concentrations of 20 ppm and at surface wind velocity of 0.2 m/s. Conductivity measurements showed that sulfur dioxide collection efficiency was almost constant at gas concentrations from near zero to 100 ppm. At higher wind velocity, the efficiency decreased. At 45% relative humidity (RH) or higher, the efficiency remained constant; it decreased significantly at RH 30%. The filtering material had a germicidal effect on bacillus coli and staphylococcus. Device Air Clean P was tested for adsorption of SO₂ and other harmful gases. The SO₂ collection efficiency was plotted against the filter life and the curve was used to estimate the life of the filter. The collection efficiency reached 99% over a certain period of time, then started to decline. Collection efficiencies for other gases were 56% for nitrogen dioxide at wind velocity 0.3 m/s and RH 80%; 52% for carbon dioxide at wind velocity 0.5 m/s; 40% for carbon monoxide at wind velocity 0.2 m/s; and 85% for hydrogen fluoride at 0.5 m/s. Particulate collection efficiency was 45 to 67%. Extended field tests in Nagasaki confirmed the efficiency of the filter. Air Clean models A and F are graphically illustrated.

Schmid, Otto

A NEW TYPE OF SCRUBBER AND WET DUST COLLECTOR DESIGNED FOR THE CHEMICAL INDUSTRY. (Bin neuartiger Gaswaescher und Nassentstauber fuer die chemische Industrie). Text in German. Chem. Technik. (Berlin), 1(5):227-229, 1972.

The high efficiency scrubber and wet dust collector designed for the separation of solid and liquid particles and of noxious gases and vapors atomizes the washing liquid without the use of jets so that water and viscous liquids can be used for scrubbing. The equipment consists of a compact cylinder enclosing a preliminary filter for coarse particles, a washing zone for fine dust, a drip catcher for dust-laden droplets, and an exhaust fan; a detached settling tank is advantageous. The gas enters the cylinder tangentially above the conical bottom where coarse particles are separated by centrifugal force on the inside wall which is washed continuously by the washing liquid. Atomization of the washing liquid is accomplished by an electrically propelled, rotating, vertical atomizing wheel. The special construction of the wheel disperses the fog formed all the way to the cylinder walls, leaving no gaps. The gas passes through the fog zone at a moderate speed to achieve intimate contact with the washing liquid. The dust-laden droplets are thrust by centrifugal force against the cylinder wall, flow down, and leave the cylinder through a discharge neck in its conical bottom. The purified gas is drawn through a suction tube by suction produced by a fan situated in the upper part of the cylinder and discharged. A pump provides for the circulation of the washing liquid between the settling tank and the scrubber. The contact-time between gas and washing liquid is 20 times longer than in the venturi scrubber and hydrochloric acid, hydrofluoric acid, sulfur dioxide, and odors can, therefore, be removed simultaneously from waste gases. To increase the effectiveness of the scrubber, several atomizing wheels can be installed coaxially within the cylinder without substantial loss of gas pressure due to its flow velocity. The danger of dust explosion within the open scrubber is lessened in comparison with closed system scrubbers, but a safety valve is provided. Pressure loss is 85 to 100 mm H₂O.

Eickelpasch, Dieter, Helmut Kahnwald, and Herbert Tichy

EFFECT OF THE OPERATION PRACTICE ON THE EMISSION OF POLLUTING AGENTS AND CONCLUSIONS FOR

THE REDUCTION. (Der Einfluss des Prozessgeschehens auf Emissionen und Folgerungen zu deren Verminderung). Text in German. Stahl Eisen (Duesseldorf), 92(12):575-S81, June 1972. 8 refs. (Presented at the Eisenhuettentag, Duesseldorf, West Germany, Nov. 4, 1971.)

The close relationship between the raw material, the process conduction, and emission problems is shown by means of three examples. The gaseous fluorine compounds liberated at the sintering process can be converted to harmless calcium fluoride by the calcium oxide present in the sinter burden or that which is added to the process gas. A collection of the gaseous fluorine compounds emitted by the sintering stations with high quantities of waste gas is not yet technically feasible. The method of conversion of gaseous fluorine compounds with calcium oxide will not work if acid sinter must be produced. The quantity of brown smoke produced by steel production depends on the type of oxygen supply and on the decarbonization speed. It can be influenced to some extent at bottom-blown converters by division of the oxygen flow. The major part of brown smoke, however, can only be removed by high-efficiency dust collectors with a collection efficiency of more than 98.5% at arc furnaces and of more than 99.8% at converters. The development of nitric oxide in industrial furnaces depends on the amount of nitrogen chemically bound in the fuel, on the heating and cooling speed of the flue gases, the absolute height of the temperature, and the amount of excess air at the combustion. A reduction of the air surplus reduces the NO development. However, the combustion is not complete, which leads to the emission of carbon monoxide, smoke, and unburned matter. Through a return of 20% of the flue gas to the combustion chamber, a 60% reduction of the NO development was achieved. Injection of water or water vapor also reduces NO formation, but the capacity may be impaired and corrosive processes triggered. The NO formation can be entirely avoided by a two-step combustion or by the arrangement of several burners in the combustion chamber.

REMOVAL OF FLUORINE FROM WASTE GASES. (Entfernen von Fluor aus Abgasen). Text in German. Umwelt (Duesseldorf), 2(3):62-64, June-July 1972. 4 refs.

Aluminum plants emit waste gases containing at times 150/mg/cu m elemental fluorine or fluorine compounds. For each ton of crude aluminum produced, the plants emit 4 kg or more of fluorine. The waste gases of superphosphate plants contain volumetric concentrations between 0.5 and 1.0% silicon tetrafluoride according to some sources even up to 3% gaseous fluorine components. The design and operation of a waste air cleaning plant for a test stand for rocket engines is described. The waste air enters the cleaning system below the packed layer of a scrubber and passes countercurrent to the scrubbing fluid, an aqueous solution of potassium hydroxide. For removal of the droplets of scrubbing fluid which are carried along by the air another packed layer is arranged ahead of the exit to the stack. The scrubbing fluid enriched with fluorine is recovered, the sludge which accumulates at the recovery is subjected to special treatment for conversion of the fluorine compounds into harmless calcium fluoride. After this treatment it can be dumped.

REACTIVITY OF ALUMINA TOWARDS HYDROGEN

FLUORIDE. Preprint, American Inst. of Mining, Metallurgical, and Petroleum Engineers (AIME), New York, N. Y., 10p., 1971.

2 refs. (Presented at the American Inst. of Mining, Metallurgical and Petroleum Engineers, Annual Meeting, New York, Feb. 26-March 4, 1971.)

A simple method was developed to measure reactivity of alumina toward hydrogen fluoride. The apparatus consisted of a heated alumina desiccator. A platinum dish containing a known volume of HF solution was placed in the lower compartment and the desiccator was allowed to heat to a desired temperature. Weighed samples of the alumina in 40 ml platinum crucibles were then placed in the upper compartment. After a known length of time the samples were removed, put in an ordinary desiccator and after cooling analyzed for fluoride. Alpha-type alumina was about 10 times less reactive than the gamma-type. In plant tests using various dry scrubbing systems for pot gases, the gamma-type alumina absorbed over 2% fluorine in a fraction of a second. Other relationships between absorption of fluorine and alumina properties such as degree of calcination and reactivity towards water were investigated. Preliminary operation of a two-stage cell gas scrubbing system with a cyclone incorporated demonstrated flexibility and a number of other benefits, including segregation of impurities such as iron and phosphorus and economic tar fume handling.

EVALUATION AND CONTROL OF SELECTED AIR POLLU-

TANTS -- A LITERATURE SURVEY. Goodyear Atomic Corp.,

Piketon, Ohio, Chemistry Dept., Atomic Energy Commission

Contract AT-(33-2)-1, 13p., Dec. 30, 1971. 102 refs. NTIS: GAT-672

The current literature pertaining to the evaluation and control of fluorine and fluorides, sulfur dioxide, nitrogen oxides, and particulates is surveyed. The majority of the 102 references cited have been published in the last 5 years. Recovery, removal, sampling, and analytical techniques for the various air pollutants are pertinent topics discussed in the cited references. (Author abstract modified)

AIR POLLUTION CONTROL IN IRON METALLURGY - FU-

TURE TRENDS. (Kontrolle der Luftverschmutzung in der

Eisen- und Stahlindustrie - Entwicklungstendenzen). Text in

German. Int. Air Pollut. Control Noise Abatement Exhib. Conf.

(Proc.), Jonkoping, Sweden, 1971, p. 6:1-6:11. 6 refs. (Sept. 1-6.)

Air pollution control and related future trends in the iron metallurgy of West Germany are described. Emissions (dust, sulfur dioxide, fluorine, and other pollutants) from metallurgical plants cause nuisances of a temporary and local nature. Fine dust, SO₂, and fluorine are emitted by agglomerating plants, very fine dust of 0.01-0.1 micron (brown smoke) by steel mills, and SO₂ by rolling mills. The heavy fuel oil used contains 1.6% sulfur and a maximum of 10 ppm fluorine. Dust emissions from blast furnaces are controlled by electrostatic filters or wet dust separators, securing a maximum dust concentration of 3-5 mg/N cu m. Electrostatic filters and wet-type separators provide satisfactory dust separation for brown smoke. Electrostatic filters, wet processes, and particularly tissue filters are used for electric-arc and ultra-high-power furnaces. The SO₂ emissions from open-hearth furnaces have decreased considerably due to the increased use of low-sulfur fuel oil or natural gas. As a result of the insta'Jation of modern pollution control devices, the shutdown of obsolete plants, and other control measures, the 1969-1970 pollution level was one

tenth the 1956-level. The volume of dust sedimented over the Ruhr area decreased from 312,000 tons in 1963-1964 to 250,000 tons in 1967-1968, while the SO₂ concentration decreased by 40% from 1963-1969. Authorization is required for the alteration of existing plants and the construction on new ones. While both the Thomas and Siemens-Martin processes show a downward trend, the proportion of converter steel increases. A three-stage steel manufacturing process, including agglomeration, direct reduction with sulfur-free gas, and electric melting without overheating, is being developed.

Iversen, Reid E.

AIR POLLUTION CONTROL: ENGINEERING AND COST
STUDY OF THE PRIMARY ALUMINUM INDUSTRY.

Preprint, American Inst. of Mining, Metallurgical and Petroleum Engineers, New York, Metallurgical Society, 22p., 1972. 3 refs. (Presented at the American Institute of Mining, Metallurgical and Petroleum Engineers, Metallurgical Society, San Francisco, Calif., Feb. 22, 1972.)

Gaseous and particulate Fluorides are the most serious pollutants emitted from aluminum reduction plants. Other pollutants such as cryolite, aluminum fluoride, calcium fluoride, chiolite, hydrocarbons, and carbon have been identified. The gaseous emissions, in addition to the fluorides, have been identified as carbon monoxide, carbon dioxide, sulfur dioxide, nitrogen oxides, hydrogen sulfide, carbonyl sulfide, carbon disulfide, silicon tetrafluoride, and hydrogen fluoride. The greatest source of pollutants of all types is normally at the individual electric cells or pot lines. The anode bake plant is potentially the second greatest source. Emissions from an uncontrolled pre-bake potline have been measured at 92 Ib/t Al, total solids, 60 Ib/t SO₂, and 46 Ib/t total F as well as volatilized hydrocarbons. Primary controls collect emissions at the pot head; secondary controls are located in the roof monitor area. About 75% of the plants in the U. S. have primary controls only, 7% have primary and secondary, 15% have secondary controls only, and 3% have no controls. The industry as a whole showed an emission control factor for total F of 73%. This amounts to 12 Ib gaseous/t of Al and 19 Ib/t for solids. A well designed pre-bake plant with primary and secondary controls could reduce emissions to 1.6 Ib/t gaseous and 5 Ib/t solids. Annual costs to the industry for control devices are now \$58/T for capital and \$16/T for operating expenses. Control systems include baffles, spray towers, wet cyclones, packed towers, bubbler towers, venturi scrubbers, mechanical collectors, multicyclones, electrostatic precipitators, bag filters, absorption, and fluidized beds.

B. CONTROL METHODS

109

fluoride-bearing compounds emitted from the stack. Because fluoride was present in the stack emissions, a wet control system was necessitated. Letters were sent to 21 companies requesting a firm quote on venturi-type scrubbers, each system to consist of five separate gas-cleaning systems. Only one gas-scrubbing device consisting of a quench unit, a venturi scrubber, and a separator unit is to be initially installed in order to determine the following: the need for debugging of the air pollution control equipment; the effect on visible plume; the effect on particulate emissions; the effect on lead, fluoride, and nitrogen oxide emission; the effect on water pollution; the effect on water economics; the proper sizing of the pressure drop in the venturi throat; and possible methods of increasing the number of smelters per system. A synopsis of a computer model study of the plant pollution run by the Baltimore Systems Department is presented.

Pettit, A. B.

CONTROLLING FLUORIDE EMISSIONS FROM ACIDULATION OF PHOSPHATE ROCK. Air pollution and Smoke Prevention Assoc. of America, Proc. Air Pollution Smoke Prevention Assoc., Annu. Conv., 44th, Roanoke, Va., 1951, p. 98-104.

Superphosphate, used to fertilize soils which are deficient in phosphorus, is produced from phosphate rock treated with sulfuric acid in an operation known as acidulation. Analysis of 72.0-72.5% B.P.L. Florida pebble phosphate rock shows a fluoride content of 3.6%. When the rock is acidulated, in normal practice, approximately 32% of the fluorine is released. Construction specifications, operating and maintenance problems, water requirements, and apparent efficiency are described for three emission control techniques: water-spray scrubbing towers, the Schutte and Koerting fume scrubber, and a water-spray horizontal scrubber. The apparent efficiencies are 95%, 98%, and 99%, respectively. The efficiency data were obtained by analyzing the rock going to the mixer and the superphosphate as it left the elevator and then calculating the fluorine evolved. Stack exit gases were sampled and analyzed for fluorides, and the total emissions to the atmosphere were calculated. The efficiency was based upon the relative amounts evolved and emitted.

Hemming, Charles

WHAT INDUSTRY IS DOING ABOUT POLLUTION CONTROL. Civil Eng. (N. Y.), 41(9):59-62, Sept. 1971.

Developments in air and water pollution control by five major industries are reviewed. Hercules, Inc. is constructing an advanced solid-waste reclamation plant in Delaware that will convert 500 tons of refuse and 70 tons of sewage sludge/day into marketable products. Dow Chemical Company has a number of projects underway at its Midland, Michigan, Division, including brine purification, the installation of detection devices on sewers, and environmental monitoring in the form of a specially designed van which tours potential trouble areas around the plant. Alcoa has perfected a system for recycling fluoride effluents in smelting operations. The fumes given off in an aluminum smelting, heavy with particulate and gaseous fluorides, are ducted through a bed of alumina which chemisorbs the gaseous fluoride. Particulate fluoride is captured in filter bags. Recovered fluorides are recycled to potline cells where they contribute to the continuous smelting process. The Alcoa 398 Process is more than 99% efficient in recovering potential pollutants. General Motors is active in planning abandoned-car cleanup campaigns. Allied Chemical Corporation has developed a pipeline-charging system that controls air pollution resulting from coke ovens by reducing smoke and gases from by-products by as much as 70%.

Jackson, Jesse, Jr.

TOTAL UTILIZATION OF FLY ASH. Bureau of Mines, Washington, D. C. and IIT Research Inst., Chicago, Ill., Proc. Mineral Waste Utilization Symp., 3rd, Chicago, Ill., 1972, p. 85-93. 9 refs. (March 14-16.)

Progress was made in demonstrating the feasibility of a proposed flowsheet for the total utilization of a powerplant-generated fly ash. The flowsheet takes advantage of the existing commercial Enercon-Stirling process for production of low-cost iron oxide, carbon, pozzolan, and lightweight aggregate, and expands it by diverting beneficiated nonmagnetic fly ash or pozzolan streams into alumina, regulated-set, and Portland cement production. Greater than 90% alumina was recovered from fly ash by either the lime-soda-sinter-leach technique or the lime-sinter-leach technique. Good quality regulated-set and portland cements were made by clinkering a mixture of recovered alumina, limestone, beneficiated fly ash, and the calcium silicate residues from the lime-sinter alumina recovery process. Preliminary results are also presented from studies directed toward expanding the proposed flowsheet to encompass waste silico-fluorides from superphosphate fertilizer production. Recommendations for future research are made. (Author conclusions modified)

Blake, Henry E. and W. A. Stickney

UTILIZATION OF BY-PRODUCT FLUOSILICIC ACID. Bureau of Mines, Washington, D. C., and HT Research Inst., Chicago, Ill., Proc. Miner. Waste Util Symp., 3rd, Chicago, Ill., 1972, p. 179-183. (March 14-16.)

Two processes are described for utilizing the waste fluosilicic acid (H_2SiF_6) generated by the processing of phosphate-rock into fertilizers. The first process involves conversion of fluosilicic acid to a synthetic acid-grade fluorspar (CaF_2) by first precipitating the silica with ammonia and filtering, and then reacting the ammonium fluoride (NH_4F) filtrate with hydrated lime ($\text{Ca}(\text{OH})_2$). By this method over 95% of the fluoride is converted to calcium fluoride (CaF_2). The second process involves neutralizing the H_2SiF_6 with $\text{Ca}(\text{OH})_2$ and silica and filtering and then volatilizing hydrofluoric acid (HF) from the dry precipitate by pyrohydrolysis at 1050 C. The HF - H_2O vapors are condensed and the fluoride precipitated as sodium bifluoride (NaHF_2) by addition of sodium fluoride (NaF) to saturation. Anhydrous HF is recovered from the dried NaHF_2 by pyrolysis at 400 C. By this method, over 80% of the fluoride in H_2SiF_6 is recovered as anhydrous HF . (Author abstract)

Schmidt, Ernst

REDUCTION OF AIR-POLLUTANT FLUORIDE EMISSIONS BY MEANS OF PULVERIZED HYDRATE OF LIME. (Verminderung luftverunreinigender Fluor-Emissionen durch Kalkhydrat-Pulver). Text in German. Ziegelind. (Weisbaden), 25(3): 1-16, 1972. 16 refs.

A study was conducted with the aim of reducing the emission of gaseous air pollutants, mainly fluoride compounds, from the raw material in the course of brick firing. The method tested is based on the dry injection of pulverized lime hydrate. The primary objective was to reduce the sulfur oxides concentration, <xref image="2000WVD1.TIF|V3|2006:09:28:01:22:42.00|120784|0"> image: </xref>

since this had been shown to influence the fluoride emission during firing. The pulverized lime hydrate was injected directly into the kiln. It was found that with a suitable feed, proportioning, and distribution a considerable linkage of the sulfur components may be achieved and also an indirect reduction of the fluoride emissions. The disadvantage of direct feeding into the kiln is that the powder comes in contact with the brick setting. Therefore, the process cannot be used for sintering goods. Considerable drawbacks also arise where large quantities of powder are required. The injection of powder into the smoke flue was tested. Observations of performance showed that, in addition to almost complete chemical linkage of sulfuric acid, favorable results were obtained with fluoride under certain specific conditions. The essential preconditions for this were reaction areas of adequate size, i.e., smoke flues of sufficient length and correct proportions. In the first plant installation with powder feed of one-third into the kiln and two-thirds into the smoke flue, a fluoride emission was down from about 70 mg/cu m to 2.3 mg/cu m. With feed into the smoke flue alone, a reduction of 90% was obtained. These results indicate that the process may be applicable to many brickworks as a means of avoiding damage or of enabling lower chimney stacks to be used.

Waki, Koichi

ALUMINUM REFINERIES. (Aruminyumu seirenjo). Text in Japanese. (Kinzoku Zairyo (Metals in Engineering), 12(5):45-51, May 1972. 19 refs.

Pollution at aluminum refineries and its control is discussed. The major material for the production of aluminum by the electrolytic method is cryolite to which aluminum trifluoride is usually added to increase the current efficiency, decrease the melting point, and protect the electrolyzer. The addition results in the formation of sodium aluminum tetrafluoride, which is volatile and reacts readily with water vapor to form hydrogen fluoride. The amount of fluoride discharged depends largely on the residue hydrocarbon on the anode, the alumina in electrolyzer, and the temperature and bath ratio. A combination of dust collector, such as a cyclone or an electrostatic precipitator, for the removal of particulates, and a washing tower for the removal of HF gas is used for the purification of flue gas from Al refineries.

Francis, Fred J.

SECONDARY ALUMINUM SMELTER AIR POLLUTION CONTROL USING A CHROMATOGRAPHIC COATED BAGHOUSE -- A TECHNICALLY NEW AND ECONOMIC SOLUTION. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 25p., 1972. (Presented at the Air Pollution Control Association, Annual Meeting, 65th, Miami, Fla., June 18-22, 1972, Paper 72-79.)

The sources of air pollution for secondary aluminum smelters and chromatographic coated baghouses to control that pollution are described. The secondary aluminum smelting industry consumes aluminum scrap generated by wastage from new factory production or from obsolescence and scrapping of old products. This industry represents approximately 25% of total production of aluminum in the United States. The raw material is scrap, and it comes with pollutants, such as: oil, paint, and plastics, and because of its volume it has to be melted under a flux cover containing salt, potash, cryolite, or fluorspar, which gives off fumes containing chlorides and fluorides. In addition, most of the scrap intake into a smelter consists of wrought alloys containing magnesium (e.g., beer cans). The pollutants in aluminum industry are: carbonaceous particles both combustible and noncombustible, oil particulates, magnesium and aluminum chlorides, chlorine, hydrogen chloride, and hydrogen fluoride. Control methods attempted throughout the world, namely scrubbers, afterburners, and baghouses are reviewed

briefly. The reasons for choosing the novel chromatographic coated baghouses are explained. Results of tests from a total of four runs completed utilizing chromatographic coated baghouses are discussed. Samples taken for dust analysis reveal that in all four runs, the amount of emitted dust was down to the minimum (an average of 0.0005 grain). The results of runs show it is possible to reduce particulate emission and noxious emissions to virtually zero by means of chromatographic coated baghouses. An analysis is made of operating costs, which are 1/3 to 1/2 of other potential systems, such as scrubbers and afterburners. (Author abstract modified)

Kauffmann, Heinz and Dieter Kreuch
WASTE INCINERATOR AT THE HEIDENHEIM COMPOST-
ING PLANT. (Die Resteverbrennungsanlage des Kompostwerkes
Heidenheim). Text in German. Muell Abfall, 2(3):76-83, 1970.
The waste incinerator of the composting plant at Heidenheim,
West Germany is described. The incinerator, designed to han-
dle a total of 12,000 tons of domestic and industrial wastes
yearly, has a throughput of 500-2000 kg/hr at an average
calorific value of 3000 kcal/kg. The wastes contain relatively
large proportions of polystyrol and polyurethane with
hydrochloric and hydrofluoric acids in the waste gas as a
result. A high combustion chamber was built to provide op-
timum thermodynamic conditions. The waste gases, discharged
at a rate of 25,000 N cu m/hr at 140 C, are purified after
passing through a two-stage heat exchanger in a venturi
scrubber using water with a lime milk additive. Effective dust
separation is reached, and some 44% of the sulfur dioxide and
HCl and HF are absorbed. The pressure loss lies at 260 mm
water column. The purified gases are heated before discharge
to avoid fog formation. Oil residues are burnt by means of
gasification burners, and an auxiliary combustion chamber,
equipped with oil burners, is provided for the incineration of
slaughterhouse wastes.

O Connor, G. V.
THE CHEMICAL INDUSTRY S ASSISTANCE TO ANOTHER
INDUSTRY IN ABATING POLLUTION. Air Pollution Control
Assoc., Pittsburgh, Pa., Proc. Air Pollution Control Assoc.,
Annu. Meet., 49th, Buffalo, N. Y., 1956, p. 32/1-32/6. (May 20-
24.)
A number of successful air pollution abatement programs
established by the chemical industry are discussed. One of
these is the recovery of sulfur dioxide from the waste gases of
sulfide ore refineries. Sulfuric acid is manufactured from this
by-product SO₂ and is used in the manufacture of fertilizer
from low grade phosphate rock. Thus, the threat of SO₂ as a
hazard to vegetation, animals, and humans is removed and at
the same time a useful and economically profitable product is
made. The chemical industry has also developed a process for
converting the hydrogen sulfide in natural gas to elemental sul-
fur. The problem of carbon black waste has been solved by in-
stalling triplicate and quadruplicate collection systems, which
insure 100% carbon black recovery. Fluorine is one of the pol-
lutants emitted by the fertilizer industry. A process was
devised where additional silica is added to the phosphate rock
digestion system, producing hydrofluosilicic acid. This is
scrubbed with a dilute caustic soda solution forming soldium
<xref image="2000WVD2.TIF|V3|2006:09:28:01:22:46.00|124270|0"> image: </xref>

B. CONTROL METHODS

111

fluosilicate, which is used for the fluoridation of municipal water supplies. In the coking of coal, the gas produced has traditionally been scrubbed with H₂SO₄ to remove ammonia and produce ammonium sulfate. However, the value of ammonium sulfate has fallen so that it is no longer economical to recover it. If ammonia is not removed from coke oven gases, it will be released to the atmosphere. A process in which phosphoric acid is substituted for H₂SO₄ is described in detail. The economic advantages of this process are also discussed.

Rush, Dumont, John C. Russell, and Reid E. Iversen
EFFECTIVENESS AND COST OF AIR POLLUTION ABATE-
MENT ON PRIMARY ALUMINUM POTLINES. Preprint, Air
Pollution Control Assoc., Pittsburgh, Pa., 23p., 1972. (Presented
at the Air Pollution Control Association, Annual Meeting, 65th,
Miami, Fla., June 18-22, 1972, Paper 72-78.)

Effluent data from aluminum potlines permits the construction of models of smelter effluents, representative of present practice in the United States, which may be acted upon in accordance with various demonstrated collection and removal efficiencies of control systems and their costs in order to evaluate the cost-effectiveness of various control schemes and to estimate the costs involved in upgrading pollution abatement in the industry. Representative capital and operating costs and removal efficiencies for a number of kinds of applicable control equipment have been developed and organized in a way which permits approximate evaluations among alternative approaches to pollution abatement. The application of the best demonstrated pollution abatement technology to the collected primary effluents from aluminum potlines would result in representative total fluoride emissions of from 1.2 to 4.7 lbs/1000 lbs of aluminum produced depending on the type of potline. The addition of scrubbing equipment on the secondary or building ventilation streams would reduce total fluoride emissions to the range of 0.8 to 2 lbs/1000 lbs aluminum, at considerably increased costs. A systems analysis was applied to the entire United States aluminum production industry showing the expected costs and performance parameters associated with upgrading the industry control from the present 74% to four higher levels of control. This analysis indicates that the application of best demonstrated control technology to the entire industry would raise overall control efficiency from 74 to 92%; it would increase invested industry capital for pollution control from \$51 to \$175/ton capacity, and would raise the industry operating cost of pollution abatement from \$13 to \$43/ton of aluminum produced at capacity. Pollutants from aluminum smelters include fluoride, hydrogen fluoride, alumina, particulates, and sulfur oxides. Control equipment includes scrubbers, electrostatic precipitators, cyclones, venturi scrubbers, and lime desulfurization.

Brandt, Alleu D. and David M. Anderson
THE CONTROL OF INDUSTRIAL AIR POLLUTION
SOURCES. Dept. of Commerce, Washington, D. C., Bureau of
International Commerce, Environ. Control Sem. Proc., Rotter-
dam, Warsaw, Bucharest, 1971, p. 199-212. 26 refs. (May 25-
June 4.) NTIS: PB COM-72-50078; GPO
Efforts to control air pollution have increased in the past 2 years, a period during which profits have fallen. The total investment required to control air pollution from the major process industries between 1970 and 1976 is approximately \$3,900,000. Particulate matter is the major pollutant released from most industrial processes, and includes fumes, mists, and smoke. Gaseous pollutants, such as sulfur dioxide, hydrocarbons, fluorides, and carbon monoxide are problems for a few specific industries. Controlling a point source is purely a problem in gas or air treatment, while control of a mobile source is much more evasive because technology is frequently

not available. Control of particulate emissions may be achieved through process changes and operational changes, or through particulate removal equipment. Treatment facilities include centrifugal separators, fabric filters, scrubbers, and electrostatic precipitators. It is expected that by 1980 the emission rate from industrial air pollution sources in the United States will be reduced by at least 90% from 1967 levels. Industrial sources include mineral processing, kraft pulping petroleum refineries, metallurgy, fertilizer manufacturing, and rubber manufacturing. Other sources are transportation, electric generation, forest fires, and solid waste disposal.

45004

Richter, Frank

POLLUTION CONTROL EQUIPMENT PAYS OFF IN TWO

YEARS. Air Eng., vol. 2:27-29, 53, July 1960.

New pollution control equipment installed at the Virginia-Carolina Chemical Corporation plant, Memphis, Tennessee, is described. Two plant processes caused air pollution: the acidulation of ground phosphate rock dust with sulfuric acid, and the chemical mixing of dry phosphates and potash with liquid nitrogen. To solve the first problem, an injector-type gas scrubber (80% efficiency), which allowed the discharge of noxious substances to the atmosphere, was replaced with a low-velocity cell-type wet scrubber designed to absorb the fluorine and precipitate the solid silica fluoride flakes with 99% efficiency. The unit consists of five stove tubes in series, with two 12-in. baffles in each tube, and with a 6000 cu ft/m induced draft paddle impeller fan at the discharge end, 30-ft stack, and a 15-ft by 21-ft by 12-in. deep concrete pan, lined with acid-proof brick. There are 13 sprays in the five tubes using 190 g/hr each. Fluorine in the discharged gas stream is reduced to 8 ppm. Silica fluoride as a solid is precipitated 100% to condenser pan. The installation will not pay for itself, but it is a necessity to continue operating in Memphis. The second problem was solved by installing multiple tube collectors on the exhaust side of the fans. A 177 tube collector on the dryer has a 18,000 cu ft/m capacity at 5.1 in. water-gage pressure drop and 125 F. A 120 tube collector has a 12,000 cu ft/m in capacity at 5.1 in water-gage pressure drop and 125 F. The breeching, flues, cyclone and collectors were insulated. The 25 hp fan motors were replaced by 40 hp motors, and the speeds of fans were increased. The installed collectors collect 100% of all 14-micron dust and larger. It is estimated that this installation will repay the capital cost in 2 years from the value of materials recovered. Total cost of the air pollution control equipment was \$62,000. Intangible savings were improved formulation; greater production efficiency; improved working conditions; and better public relations due to elimination of annoying dust in the neighborhood.

ENGINEERING AND COST EFFECTIVENESS STUDY OF

FLUORIDE EMISSIONS CONTROL. (FINAL REPORT).

VOLUME II. Resources Research, Inc., McLean, Va. and TRW

Systems Group, McLean, Va., Office of Air Programs Contract

EHSD 71-14, APTD 0944, 171p., Jan. 1972. 1026 refs. NTIS: PB

209647

The appendix and bibliography of a report on the costs of fluoride emissions control are presented. Two general types of pollution control equipment are currently used for fluoride

<xref image="2000WVD3.TIF|V3|2006:09:28:01:22:50.00|126447|0"> image: </xref>

emissions, wet collection equipment and dry collection equipment. The majority of capture devices used for fluoride removal are of the wet type. Wet collection systems simultaneously remove gaseous and particulate pollutants. The types of wet collection equipment described include: spray towers, packed bed scrubbers, wet cyclones, self-induced spray scrubbers, orifice plate bubblers, venturi scrubbers, jet scrubbers, and dynamic wet scrubbers. Under certain conditions, dry collection systems have been applied to fluoride emissions control. Three main classes are available: mechanical collection equipment, such as settling chambers, baffle chambers, skimming chambers, louver type collectors, dry cyclones, impingement collectors, and dry dynamic collectors; electrostatic precipitation; and fabric filtration. Inventories of industrial plant locations and capacities were prepared for the industries which are known or potential sources for fluoride emissions. The industries covered include: phosphate rock processing, iron and steel production, primary aluminum smelting, coal burning, steam electric power generation, hydrogen fluoride production; clay products, glass products, enamel frits, and non-ferrous metal smelters. A bibliography containing more than 1000 references is included.

45254

WASTE GAS CLEANING SYSTEM FOR FERTILIZER PLANT. (Abgasbeseitigung bei einer Vollduengeranlage). Text in German. *Wasser Luft Betrieb*, 16(8):274, 1972. Results obtained with a wet-type electrostatic separator at a fertilizer plant are described. After particulate pollutants have been separated by a preliminary stage scrubber, the waste gases, discharged at a rate of 8000 N cu m/hr at 60 C, contain 4320 mg/N cu m of ammonium nitrate, 5000 mg/N cu m of ammonia, 140 mg/N cu m of silicon tetrafluoride, and 270 mg/N cu m of nitric oxide and nitrogen dioxide (maximum values). The wet-type electrostatic filter has efficiencies of 94.2-98.9% for ammonium nitrate, 80-100% for nitric acid, and practically 100% for ammonia; and the purified waste gas is invisible. The matter separated by the electrostatic separator is recovered from the circulated water.

ON THE DETERMINATION OF SANITARY PROTECTION ZONES AROUND NONFERROUS METALLURGICAL PLANTS. (K voprosu ob opredelenii sanitarno-sashchitnykh zon vokrug predpriyatiy tsvetnoy metallurgii). Text in Russian. *Gigiena i Sanit.*, 37(16):94-96, 1972.

Emissions from an electrolyte copper and an aluminum alloy manufacturing plant were measured. The three-stage process at the electrolyte copper manufacturing plant includes a shaft furnace, a converter, and an anode furnace. The shaft furnace and converter processes, at temperatures up to 1400 C, emit zinc, lead, tin, and other nonferrous oxides; carbon monoxide; and sulfur dioxide. The maximum zinc and lead contents in dust samples were 70 to 10%, respectively. Two-stage dust separation using a cyclone-bag filter combination with an overall efficiency of 99.8% was used as a control. The aluminum alloy manufacturing plant releases generally small amounts of such pollutants as chlorine and fluorine compounds, CO, and SO₂. Two-stage gas cleaning using scrubbers and venturi tubes effected an over-all efficiency of 98%. Replacing the shaft furnace with an electric-arc furnace and abandoning fluorine-base fluxes also considerably reduced the pollution.

45468

Bernatzky, Aloys
GREEN AREAS AND URBAN CLIMATE. (Gruenflaechen und Stadtklima). Text in German. *Staedtehygiene (Uelzen/Hamburg)*, 21(6):131-135, June 1970. Facts showing the major changes in urban climate due to air

pollution and the positive effects of green areas and trees are reviewed. Dust, sulfur dioxide, hydrofluoric acid, and carbon monoxide are the most dangerous air pollutants in urban atmospheres. Some 10-20% of the total solar radiation and almost the total ultraviolet radiation are absorbed by the polluted atmosphere over cities. Increased carbon dioxide levels, causing the well-known greenhouse effect, result in elevated temperatures in cities compared to their suburbs. The temperature differences may be 0.5-1.5 C on a yearly average, and more than 10 C in absolute values. Green areas and trees, though unable to eliminate the effects of pollution, have many advantages. Dust, including radioactive substances, are filtered out by trees in considerable proportions, and decreased wind speeds, by a minimum of 10%, can be observed. Radioactivity, measured on the lee side of trees, accounted for only 25% of that measured on the weather side. Trees absorb very high amounts of CO₂ and produce oxygen. Decreased temperatures in green areas are a fact. Temperatures up to 3.5 C lower over green areas, compared to adjacent areas, were measured. In addition, green areas are of great value from a psychic point of view.

Descolas, Jean

THE ACTION TAKEN BY DUST SEPARATORS MANUFACTURERS.

(Action des constructeurs de separateurs et epurateurs). Text in French. Pollut. Atmos. (Paris), vol. 13:48-49, May 1971.

Developments in dust separating techniques and dust separator production in France are reviewed. Economic and reliability factors should be considered when choosing between optional dust separating techniques. Dry dust collectors, venturi scrubbers for blast furnaces, bag filters, electrostatic precipitators, and gas scrubbers underwent spectacular development during the past years. Glass-fiber bag filters are able to treat gases with a maximum temperature of 315 C, with dust removal from bag filters by knocking and air counter-flow. Discharge electrodes with increased strength, electronic controls, and silicon rectifiers have been developed for electrostatic precipitators. Scrubbers are used for the removal of sulfur dioxide, fluorine, and odorous gases in the aluminum, pulp, and chemical industries. The market of dust separators projects a yearly growth of 15-20% in the near future. Exports accounted for some 20% of the total sales. The respective shares of dry cyclones, wet type dust separators, electrostatic precipitators, and bag filters are 15, 20, 35, and 25%, respectively.

CONTROL OF EMISSIONS FROM GLASS MANUFACTURE.

Ceram. Bull., 51(8):637-640, Aug. 1972. 5 refs. (Presented at the American Ceramic Society, Ceramic-Metal Systems Division, Fall Meeting, St Louis, Mo., Sept. 13, 1971, Paper 3-C-71F.)

Emissions from glass furnaces, ranging from noxious gases to submicron particulates, are unique in that they consist to a high degree of raw materials or degraded raw materials. Typical emissions from glass furnaces include particulates containing sodium fluoride, calcium fluoride, silica, calcium oxides, lead oxides, sodium sulfate, and boron oxides and gases of fluorides, nitrogen oxides, and sulfur oxides. Two systems were tested as prototypes for the control of emissions and to establish the potential for the recycle of the recovered contaminants. The wet system comprises a quench section, nucleation scrubber, and a water system consisting of a reactor-precipitator, solids separator, and cooling tower. The dry recovery system is based on simultaneous filtration and chromatographic absorption with pipeline solids injection and baghouse recovery. Both systems are characterized by low energy consumption and control emissions of particulates to the range of 0.01-0.03 grain/scf and noxious gases to the range of 1 ppm. System design, operation, efficiency, operating variables, and capital and operating costs are examined.

ACTION IN THE CHEMICAL INDUSTRY. (Action dans Industrie chimique). Text in French. Pollut. Alums. (Paris), vol. 13:44-47, May 1971.

The efforts by the French chemical industry in the field of pollution control are outlined. Pollution control is very often combined with, or motivated by, the recovery of certain products. Scrubbing, absorption, adsorption, and oxidation are the basic means of controlling air pollution in the chemical industry. Scrubbers are used for the removal of fluorine compounds. Sulfur dioxide formed during sulfuric acid production is recovered at 90% efficiency by diluted ammonia solution. Nitrous vapors can be reduced by means of hydrocarbon in the presence of a high-temperature catalyst or by increasing the nitric acid absorption rate to 99.5-99.7%. Maleic and citraconic anhydrides formed during phthalic anhydride production are removed by means of catalyst and scrubbers, and maleic anhydride is recovered. Waste gases from the purification of natural gas, containing small amounts of SO₂ and hydrogen sulfide, but high concentration, of water vapor, are burned to form sulfur trioxide which is then converted into sulfuric acid at a rate of 90-95%. The desulfurization of waste gases from oil-fired power plants and catalysts for the after-burning of automotive exhaust are also considered.

Konopka, A. P. and N. W. Frisch

THE CONTROL OF AIR POLLUTION FROM GLASS

PRODUCTION - A STATE OF THE ART REVIEW. Preprint, American Ceramics Society, Columbus, Ohio, 58p., 1971. 24 refs. (Presented at the American Ceramics Society, Annual Meeting, 73rd, Chicago, 111., April 27, 1971.)

Techniques for the control of emissions from glass production are not well developed. On a weight basis, uncontrolled emissions from glass production are lower than uncontrolled emissions from typical major sources. Nevertheless, the trend in emissions code requirements and plume opacity criteria is to continue to heighten restrictions. Increasing concern over fine particles and hazardous pollutants also concerns the glass industry. Major sources of atmospheric emissions from glass production are glass melting and fiberglass forming. During glass melting, gases are liberated via decomposition and by the volatility phenomena. The potential gaseous emissions from soda lime glass melting include sulfur dioxide, nitric oxides, carbon monoxide, and fluorides. Particulates and opacity are considered. U.S. air pollution laws, particulate codes, and opacity and odor regulations are discussed. The impact on glass production is discussed. The uncontrolled glass furnace emissions are generally within code compliance. Except for marginal violation situations, the process modification route does not offer much promise for compliance. The nature of the submicron particulates requires sophisticated control techniques. A first-approximation estimate of 80% minimum collection efficiency, or an 0.01 gr/std cu ft stack discharge, appears reasonable to satisfy opacity criteria. In addition, fluorides and sulfur trioxide will need to be controlled or eliminated in the near future. Techniques such as high-energy scrubbing, fabric filtration, and electrostatic precipitation are far from immediate solutions to the problems. A great deal of additional study is required, and much of this is already underway.

REMOVAL OF SILICON TETRAFLUORIDE IN
PERPHOSPHATE MANUFACTURING PLANTS. (Depura/jone
da SiF₄ in impianti per perfosfata). Text in Italian. Atti Ist.
Veneto Sci. Lett. Arti Cl. Sci. Mat. Natur., vol. 128:1-14, 1969-
1970. 8 refs.

The control and removal of silicon tetrafluoride from gases evolved in the manufacture of superphosphate when ground phosphate rock reacts with sulfuric acid are examined. Physico-chemical aspects of SiF₄ absorption in water, the effect of silicon hydroxide on the superficial properties of the water drops, and the mist formation are considered. Silicon tetrafluoride is evolved from calcium fluoride impurities of the phosphate mineral in the presence of silicon dioxide. The formation of Si(OH)₄ by absorption and reaction of SiF₄ in water produces fog through change of the surface properties of water droplets. The scrubbing efficiency of industrial plants are compared. The rotating disk tower appears to be the most convenient SiF₄ scrubber.

THE MOHAVE/NAVAJO PILOT FACILITY FOR SULFUR

DIOXIDE REMOVAL. Preprint, Office of Air Programs, Research Triangle Park, N. C., Div. of Control Systems, p. 507-526, 1971. (Presented at the International Lime/Limestone Wet Scrubbing Symposium, 2nd, New Orleans, La., Nov. 8-12, 1971.)

The Mohave/Navajo Sulfur Dioxide Removal Research Program is a project for testing alkali absorption processes on a pilot-size basis. The major thrust of the work is to determine the characteristics of these processes as applied to boilers fired with low-sulfur coal. The pilot plant facility is described, including the four types of absorbers to be tested, the analysis procedures, and the test plan. Turbulent contact, venturi, polygrid packed, and Lurgi impingement absorbers are indicated. Sulfur dioxide, oxides of nitrogen, dust loading, trace metals, sulfur trioxide, and fluorine concentrations are to be tested, as well as pH, density, and liquor stream concentrations.

THE INDUSTRIAL USE OF THE FLUORINE CONCENTRA-

TION OF THE RAW PHOSPHATE. (Die industrielle Nutzung des Fluor-Gehaltes der Rohphosphate). Text in German. Chem.

Ing.-Tech., 44(19):1093-1099, Oct. 1972. 10 refs.

The rapidly increasing demand of fluorine as a raw material has made the utilization of a hexafluoro-silicic acid, which is obtained at the production of phosphate fertilizer, necessary. The recovery of the hexafluoro-silicic acid from the waste gases or vapors is simple. The waste gas, cleaned by various types of scrubbers, must contain silicium tetrafluoride which liberates part of the silicic acid upon absorption in water. The separated silicic acid tends to incrustate the scrubber. For best results therefore centrifugal or venturi scrubbers are used. The recovery of the fluorine from the vapors of the phosphoric acid concentration is somewhat more difficult, since the evaporators operate with a vacuum. In this case empty scrubbers are used into which the scrubbing fluid is injected by several nozzles. In both cases a 20 to 25% hexafluoro-silicic acid solution can be obtained. The methods of production of calcium fluoride, aluminum fluoride, and cryolite, as well as hydrogen fluoride, from hexafluoro-silicic acid are described.

FOUNDRY OF CAST IRON, SAYAMA FACTORY, HONDA

MOTOR CO. - REMARKABLE FEATURE REGARDING TO

THE COUNTERMEASURES FOR PUBLIC NUISANCE. (Hon-

da giken kogyo (kabu) sayama seisaku-sho chuzo kojo - kogai taisaku ni tokushoku). Text in Japanese. I mono (Foundry), 44(7):593-597, July 1972.

A new melting process at a cast iron foundry uses a cupola of the heating-water-cooling type with a 5 ton/hr capacity. The entire exhaust gas is treated in a recombustion furnace, then

the exhaust gas goes through a heat exchanger, and is cooled again by a gas cooler to 400 C. Microparticle dusts go through a wet chamber and then are sent to an electrostatic precipitator. The final gas emission contains less than 0.05 g/cu cm of dust. The radical operation system previously used fluorite and created the problem of fluoride gas. It was replaced by an alumina base solvent specially developed by this plant. Good results are obtained.

ARH-2343

Caustic or aluminum scrubber solutions were tested to remove hydrogen fluoride vapors from waste off-gas streams. The efficiency of the tested solutions was greater than 99%. Two potential problem areas were observed: rapid HF addition rates could increase the temperature of potassium hydroxide to near boiling; and solids appeared in aluminum scrubber solutions when the fluoride: aluminum molar ratio exceeded 1.6. When the aluminum scrubber solutions were heated, a fluoride:aluminum molar ratio of 5.8 could be achieved with no solids formation. (Author summary modified)

TOXIC GAS TREATMENT IN ALUMINUM INDUSTRIES.
(Aluniiniurnu sangyo ni okeru yugai gasu no shori gijutsu). Text
in Japanese. Kankyo Sozo (Environ. Creation), 2(10):33-37, Oct.
1972.

A hydrogen fluoride elimination system for aluminum refining industries and treatment of toxic matter in the exhausts from the primary and secondary aluminum processing are discussed. Exhaust gas from these processes contains hydrogen chloride, chlorine, aluminum chloride, and sometimes sulfur oxides. The AlCl₃ is contained in an extremely minute fume form, and the quantity depends on the temperature and force of chlorine gas blown into the aluminum solution. The exhaust gas from the chlorine treatment is sucked by a fan and is sent to the cleansing system, where, the gas is first cooled in a heat exchanger. The temperature is dropped to the degree where the use of bag filters becomes possible. The wall temperature of the heat exchanger must be kept above the dew point. The air used for cooling the gas will be used for warming the stack gas to eliminate white smoke. The flue gas is then sent to bag filters, which eliminate solid particles of AlCl₃ and magnesium chloride at a temperature above dew point. The gas then is sent to a scrubber, where it is washed in 10% caustic soda.

B. CONTROL METHODS

115

bines static electricity, a mat filter, and a scrubber. Since cupola flue gas contains minute particles of fume, static electricity helps form larger particles instantly and adsorbs particles onto electrodes. The dusts are washed down by sprays. There are two layers of mat filters above the electrode sprays. The mat filters are packages of mesh filters, through which the already cleaned gas is sucked. Clogging of mesh is prevented by two more levels of sprays. Sulfur dioxide, chlorine, ammonia, and fluorine are also absorbed, and caustic soda solution in the spray water helps desulfurization action. The mist created by these sprays is eliminated by a demister layer above the mat filters. Clean air goes out from the stack at the top. A pilot plant was tested for 6 months; the first plant was constructed in August. The gas containing 0.2 g/N cu m of dusts at the exit of the cupola is cleaned to 0.08 - 0.12 g/N cu m. The construction and operation costs are also extremely favorable compared to other types of dust collectors for cupola.

In a bubble-cap column or an other cascade arrangement, a mixture containing hydrogen fluoride, hydrogen chloride, and perhaps organic compounds, can be scrubbed at minus 20 to 50 C with 2-30 g water or aqueous HCl solution for each mole HF to be absorbed. A polyethylene column having 30 bubble-cap trays was filled with approximately 4 l of concentrated HCl. A gas mixture consisting of 2 cu m/hr HCl, 1.2 cu m/hr nitrogen, and 80 g/hr HF was introduced at the bottom. At the top of the column, 160 ml of concentrated HCl was introduced. The lowest two trays were maintained at minus 3 C by circulating the scrubbing liquid contained therein through an outside cooler. The gaseous mixture leaving the top of the column contained 0.0007 wt% HF based on HCl.

POLLUTION CONTROL IN THE STEEL INDUSTRY. In: Industrial Pollution Control Handbook. Herbert F. Lund (ed.),

New York, McGraw-Hill, 1971, Chapt. 10, p. 10-3 to 10-20.

Water requirements and typical contaminants, air requirements and contaminants, and solids handling are discussed for the steel industry. Particulates, sulfur compounds, carbon monoxide, cyanides, fluorides, and benzene compounds are the most frequently encountered air contaminants. Waste water problems are considered for blast furnaces, casting operations, foundries, open hearth furnaces, basic oxygen furnaces, electric furnaces, rolling mills, sinter plants, heat treatment, acid pickling, vacuum degassing, coke plants, slag plants, utilities, and maintenance shops. The basic cleaning devices for waste

gases are simple gravity separators, wet scrubbers, electrostatic precipitators, and baghouse filters. Control device selection is considered.

Spencer, Emmet F., Jr.

POLLUTION CONTROL IN THE CHEMICAL INDUSTRY.

In: Industrial Pollution Control Handbook. Herbert F. Lund (ed.), New York, McGraw-Hill, 1971, Chapt. 14, p. 14-1 to 14-31.

The air pollution control measures applied in chemical manufacturing are for the most part the everyday application of chemical engineering unit operations using mechanical collectors, bag filters, electrostatic precipitators, wet collectors, absorption, catalytic oxidation, reduction, direct flame incinerators, or adsorbers, alone or in combination. The selection of the control device for the particular process is a function of the degree of control necessary, the nature of the effluent, the capital and operating costs of the control equipment, the effect of the control system on the process itself, reliability, and the ultimate disposal of the collected waste material. In addition, process or equipment modifications may be specifically incorporated to eliminate or minimize the emission of air pollutants. Emission and control methods are discussed for the manufacture of sulfuric acid, nitric acid, phosphoric acid, hydrochloric acid, sulfur dioxide, hydrogen sulfide, oxides of nitrogen, gaseous fluorides, and chlorine. Problems associated with particulate matter, solids and tars, liquids, gases and vapors, odors, and water pollution are also considered. Odor threshold values for a number of compounds are presented.

Planning Committee

A PROGRESS REPORT ON A LONG-TERM VIEW OF ENVIRONMENTAL PROTECTION. (DRAFT). (Kankyo hozen choki bijon chukan hokoku (an)). Text in Japanese. 94p., 1972 (?).

The direction of environmental science technology in the future is examined. All the technical aspects of pollution control should be almost completely developed (excepting the areas of life sciences) by 1985. Treatment technology for air and water pollution is expected to be developed relatively early. But those pollutions that offend sensitivity more or less, such as noise, vibration, and bad odor, may not be controlled until later. An effective carbon monoxide elimination device is expected to be developed by 1977, and so is an economical elimination system for hydrogen fluoride; an economical catalyst for nitrogen oxides from fixed sources is expected to be realized by 1978; and pollutionless community cars (small and safe individual transportation means) will be developed by 1978. The development of process conversion methods and recycling systems will be relatively slow. Protection technology for the natural environment and analyses of pollutant influences on human bodies will be even slower. Selecting sulfur dioxide and paper pulp BOD pollution as study cases, the futures of control techniques and economic feasibility were examined. It was concluded that these problems will be solved by 1985.

WATER SUPPLY FOR ELECTRIC STEEL MELTING FURNACE-EMITTED GAS SCRUBBERS. (Vodosnabzheniye gazoochistok elektrostaleplavilnykh pechey). Text in Russian. Stal, no. 9:866-868, Sept. 1972. 3 refs.

Problems of the water treatment for electric-arc steel smelting furnace scrubbers are described. Such scrubbers retain 90-92% of the fine dust, 84-98% of the hydrofluoric acid, and up to 94% of the sulfur dioxide present in the furnace gas, which along with the retention of other components results in increased mineral salt and suspended matter content in the scrubber water. Various treatments and neutralization of the waste water are required for the recycling of the water within the scrubbing process. The water to be recycled should not contain more than 100-200 mg/l of suspended matter. Analyses of the recycled water revealed sharp decline in the rate of increase of the salt content in the water by the sixth day of recycling, which is due mainly to the precipitation of calcium silicate and fluoride. It is possible to increase the specific load of the cyclone to 3 cu m/sq m/hr by combined magnetic and chemical coagulation by means of 1 mg/l of polyacrylamide.

48143

Wondraezek, W.

PLANT FOR THE ABSORPTION OF FLUORINE-CONTAINING GASES. (Anlage zur Absorption fluorhaltiger Gase). Text in German. Chem. Tech. (Berlin), 24(8):522-S23, Aug. 1972. A slotted bottom absorber was developed for the absorption of fluorine-containing gases from the fertilizer industry. For satisfactory silicon tetra-fluoride absorption, the slotted bottom has a relatively large slot area with very specific flow velocities in the slots. At a certain spray density, the deposition of fluosilicic acid is avoided. A stable dynamic bubble zone of 1200 mm height is produced which provides the required contact areas for the phases. Single-stage absorbers are used for maximum fluosilicic acid concentration of 15 to 17 mass % and for fluorine concentrations in the scrubbed waste gas of 30 to 50 mg F/cu m; for higher H₂SiF₆ concentrations two-stage systems are used. The absorbers presently available are designed for gas throughputs of up to 50,000 cu m gas/hr. Absorbers with waste gas quantities of up to 150,000 cu m are being developed. The operation and construction of a two-stage absorber is described. The waste gas is drawn off from the reactor by a ventilator and passed into the lower section of the first absorber where the fluorine-laden gas rises countercurrent to the washing fluid. After passage of a droplet precipitator, the preliminarily cleaned gas enters the second absorber and passes through it countercurrently to the washing fluid. A cyclone is used as second droplet precipitator where the cleaned gas is pressed into the waste gas duct.

Naoi, Yasukazu

PERFORMANCE AND PROBLEMS OF AIR FILTERS IMPREGNATED WITH ALKALI. (Arakari tenchaku firuta no seino to mondaiten). Text in Japanese. Kuki Seijo (Clean Air-.I. Japan Air Cleaning Assoc., Tokyo, 10(6):53-58, Dec. 1972. 3 refs.

An air filter impregnated with alkali can remove harmful gases by a chemical reaction such as neutralization of acidic gases. Sodium hydroxide and sodium carbonate are often used as alkaline agents. The alkali-impregnated filter gives a higher removal efficiency for chlorine, hydrogen fluoride, and hydrogen sulfide than normal filters. The efficiency is poor for nitrogen dioxide. Carbon monoxide and carbon dioxide can be removed in the early stages of use, but the removal efficiency drops so rapidly that it is not practical. Humidity, temperature, sulfur dioxide concentration, filter thickness, and flow rates affect SO₂ removal efficiency. The filters are greatly affected

by humidity, so they should be used at low humidities. Dispersal of the absorbent or substances formed as a result of the reaction should be avoided by using a flow rate of 0.5 m/sec or lower and an adhesive agent. Maintenance and disposal of used filters can also be a problem.

48805

Schwartz, Werner and Werner Eisert
EXAMPLES AND LIMITS OF COMBATING AIR POLLUTION IN COPPER PLANTS. (Beispiele und Grenzen der Reinhaltung von Luft in Kupferhuetten). Text in German. Z. Erzbau Metallhuettenwesen, 25(10):505-511, 1972. 6 refs. (Presented at the Gesellschaft Deutscher Metallnetten- und Bergleute Hauptversammlung, Stuttgart, West Germany, April 28, 1972.)

Any dust and metal recovery in copper plants, as well as the reduction of emissions depends on the special type of raw copper processing plant. In preroasting plants, the waste gas quantity amounts to only 43% of that from a greenfeed plant. In the flash plant, the waste gas quantity is only 33% of that of the greenfeed plant. The large waste gas quantity of the greenfeed plant, however, contains only small sulfur dioxide and trioxide concentrations for which no economic recovery process is available. Nearly the entire amount of sulfur is discharged into the atmosphere. In the case of the preroasting plant, only 12% of the sulfur is directly emitted. Prior to any sulfur recovery, the waste gases must be thoroughly cleaned of dust and interfering components. The waste gases usually carry various pollutants along which require different collection methods. Dust and fumes are retained in hot gas electrostatic precipitators which operate at temperatures between 300 and 400 C. Volatile substances (mercury) and gaseous substances (hydrogen chloride and hydrogen fluoride) can be removed in high-capacity scrubbers. Knowledge of the developmental process of the system is necessary for an optimum solution of the gas cleaning problem. The costs depend primarily on the gas quantity to be treated. Costs rise progressively with the desired collection efficiency.

48811

Schackmann, H.
ENVIRONMENTAL PROTECTION IN METALLURGICAL PLANTS. (Umweltschutz in Huettenbetrieben). Text in German. Metall (Berlin), 27(1): 41-47, Jan. 1973.

The non-ferrous metal industry has to cope with four environmental problems, the pollution of water and air, noise, and solid waste disposal. For the production of copper, tin, and lead, as well as other non-ferrous metals, sulfur-containing ores are used. The sulfides are roasted and the developing sulfur dioxide is usually so concentrated that it can be converted to sulfuric acid. All newer plants are equipped with Bayer double catalyst plants which operate with an efficiency of 99.5%. While the entire SO₂ emission in the Federal Republic of Germany amounts to between 3.5 and 4 million tons, the total emission of SO₂ from sulfuric acid production is only 25,000 tons, i.e., 0.6% of the total quantity. There is no metallurgical industry today in West Germany which is not re-using the SO₂. The dust emission causes greater problems in this industrial branch than does the SO₂ emission. Most of the dust cleaning problems can be solved, with the exception of the

<xref image="2000WVD8.TIF|V3|2006:09:28:01:23:08.00|123325|0"> image: </xref>

B. CONTROL METHODS

117

aerosols developing at the production of ferro-alloys. The most expensive problem is the removal of fluorine. Expensive cleaning plants had to be installed in new aluminum electrolysis plants whose costs amounted to 20 and 25% the total investment costs. All air pollution problems in industry can be solved, it is just a matter of costs.

48814

REMOVAL OF FLUORINE FROM THE WASTE GASES OF THE ALUMINUM FUSION ELECTROLYSIS IN A HEAVILY EXPANDED ALUMINUM OXIDE FLUIDIZED BED.

(Fluorentfernung aus den Abgasen der Aluminium-Schmelzflusselektrolyse in stark expandierten Aluminiumoxid-Wirbelschichten). Text in German. *Aluminium*, 48(11):738-740, 1972. 8 refs. (Presented at the Gesellschaft Deutscher Metallhuetten- und Bergleute, Stuttgart, West Germany, April 1972.) A method is described for the binding of fluorine from waste gases of aluminum fusion electrolysis in a heavily expanded alumina fluidized bed. The method was first tested on a laboratory set-up. The fluorine polluted gas was drawn on by a fan and passed to the fluidized bed reactor. A constant quantity of oxide was also entered continuously. With gas velocities of 1-5 m/sec, a greatly expanded fluidized bed was formed which was maintained by returning the oxide carried off in the cleaned gas and retained in two cyclones and a subsequent bag filter. For an oxide throughput of 300 g/hr, a gas throughput of 108 cu m/hr, and a pressure loss of the fluidized bed of 150 mm water, the average gaseous fluorine concentration was reduced from 23.2 mg/cu m to 0.57 mg/cu m. The good collection efficiency of more than 97.5% was due to the long contact time between gas and solid phase and the intense mixing of the two phases. The satisfactory laboratory results lead to the erection of a scaled down experimental plant and eventually to a large scale plant for an aluminum manufacturing plant with an annual production capacity of 60,000 tons of aluminum and an hourly waste gas volume of one million cu m/hr. The waste gases are drawn off from the enclosed electrolysis furnaces and passed to two fluidized bed adsorbers. The cleaned gases are passed through a bag filter for recovery of the oxide and discharged through a 40 m high stack. The oxide throughput will amount to 750 kg/hr, and the pressure loss is expected to remain below 700 mm water over the entire facility from electrolysis furnace to stack exit. The gaseous fluorine concentration in the cleaned gas is below 1 mg/cu m.

48879

THE REMOVAL OF FLUORIDES BY PACKED TOWER. (Jutento ni yoru fusso kagobutsu no jokyo ni tsuite).

Text in Japanese. *Japan Society of Air Pollution, Proc. Symp. Japan Soc. Air Pollut.*, 13th, 1972, p. 149. (Nov. 7-9, Paper 104.) Recently the number of tile manufacturing factories have increased in northern Saitama Prefecture where mulberry trees are grown for the silkworm industry. Damages to mulberry leaves by fluoride emissions from these factories have been noticed, so fluoride control systems were installed in many of these plants. The system generally utilizes caustic soda alkaline scrubbers for the flue gas; due to the lack of an ideal waste water drainage, water is recirculated. Sodium fluoride is recovered and lime is added, producing calcium fluoride. The two kinds of systems used in this area both employ packed towers. System A employs terralette packing and two-stage net shelves in the upper part of the scrubber. The gas is cooled before entering the scrubber, which is made of plastic. System B utilizes slate tile waste as the packing material in the tower to lower cost, and the tower is made of mortar cement. It has an automatic pH adjuster in order to save manpower. These systems have eliminated most hydrogen fluoride from the flue gases of the plants. Now the concentration is less than 1 ppm

at the exit. Sulfur dioxide in the emission gas is also almost completely eliminated. The damages to mulberry leaves have been successfully controlled.

FUME AND EFFLUENT TREATMENT PLANT IN THE NON-FERROUS METALS INDUSTRY IN BRITAIN. Int. Met. Rev., vol. 17:227-239, Dec. 1972. 116 refs.

Control technology for gaseous and liquid effluents from the non-ferrous metals industry in England is reviewed with respect to pollution legislation, emission sources within the industry, control equipment design and operation, overall costs, comparative efficiency, and liquid effluent treatment. Gaseous effluents include dark smokes, sulfur dioxide, carbon, metal oxides, sulfates, chlorides, dust, and grit generated from smelting operations or furnaces; nitrogen oxides, hydrochloric acid, cyanogens, hydrocyanic acid, solvents, fluorides, and chlorides from welding and fluxes; and fumes from grinding operations. The basic mechanisms for dust and fume control include inertial collectors (cyclones, baffles, and settling chambers), electrostatic precipitators, scrubbers (jet-impingement, spray towers, and venturi), and filters (bag and fabric).

Ross, W. K.

DESIGNING A CANADIAN REFINERY'S EXPANSION TO COMPLY WITH PRESENT AND IMMEDIATELY FORESEEABLE ENVIRONMENTAL REQUIREMENTS. Preprint, lip., 1972. (Presented at the International Pollution Engineering Congress, Cleveland, Ohio, Dec. 4-6, 1972, Paper 21.)

Plans for new pollution control measures at a refinery which will be expanded are discussed. Air pollutant emission standards for sulfur dioxide, hydrogen sulfide, carbon monoxide, particulate matter, hydrogen fluoride, and smoke are listed. Planned control measures include scrubbing raw fuel gas with amine to remove H₂S and converting 92% of the H₂S to elemental sulfur for sale. The rest, as sulfur dioxide, plus the flue gas from oil burning will go to a 300-foot stack. Crude oil storage tanks will be fitted with roofs to prevent the loss of hydrocarbon and H₂S vapors. All H₂S-bearing waters will be stored in a closed system and disposed of in a disposal well. Hydrofluoric acid transfer lines will be purged to clear them of HF vapors. The purged gas will flow to the flare through a gas scrubber to remove remaining HF vapors. After use as a catalyst, the HF will be recovered by distillation. The catalytic cracking unit is the major source of carbon monoxide and particulates. The CO will be directed to a boiler, where it will be burned to carbon dioxide. The regenerator will also be equipped with primary and secondary cyclones to remove 99.99% of the circulated catalyst particulates. Three possibilities were considered to reduce smoke when burning flared gases and oil sludges, including the installation of spare steam-driven river water and circulating water pumps, the provision of duplicate incoming electrical power lines, and the provision of a compressor on crude gas. The flares will be equipped with automatic steam injection to minimize smoke. Oily sludges will be centrifuged to remove the bulk of oil and water; and the centrifuge cake will go to a multi-hearth furnace, where it will be reduced to dry ash. The gases will pass through a chamber in which burners actuated by a smoke detector will burn the carbon in the smoke. Processes to minimize the loss of

<xref image="2000WVD9.TIF|V3|2006:09:28:01:23:12.00|129877|0"> image: </xref>

hydrocarbons are also described. Continuous monitoring is discussed, and environmental monitors of air pollutants are listed.

DESIGN OF GAS RECOVERY EQUIPMENT (I). (Yugai gasu kaishu sochi no sekkei (I)). Text in Japanese. Kagaku Sochi (Plant and Process), 15(2):32-41, Feb. 1973.

A method of recovering high purity hydrogen fluoride from flue gases containing a lot of HF uses a combination of ordinary gas absorption and dispersion. The waste gas from the absorption tower is led to a cleaning tower where it is washed with water. By going through the lime layer at the top of the tower, the HF in the waste gas from the recovery system is kept at less than 1 ppm. The gas led into the absorption tower is 36 mol%, the temperature at the tower inlet is 23 C. The composition of waste gases from the absorption tower is to be 1.0 vol% HF, 11.11 vol% water, and 87.89 vol% air. The waste gas volume is 3.112 kmol/hr; its composition is 0.031 kmol/hr HF, 0.346 kmol/hr water, and 2.735 kmol/hr air. Almost 99.8% of the HF is recovered. Absorption of HF in the absorption tower is 15.469 kmol/hr and absorption in the packed tower is 15.305 kmol/hr.

Wesenberg, H.

GAS COLLECTION AND CLEANING IN CLOSED PREBAKED SYSTEMS. Preprint, Norwegian Society of Professional Engineers, Oslo, lip., 1972. 2 rets. (Presented at the International Symposium on the Fluoride Problem in the Aluminum Industry, May 24-26, 1972.)

A combination of wet scrubbing with dry cleaning (bag filters) as adopted at an aluminum smelting plant in Norway for the removal of fluorides and sulfur dioxide from potline emissions is described. Neither wet scrubbing nor electrostatic precipitation proved to be sufficient to meet the requirement for a maximum external emission of 1 kg of fluorine per ton of metal in new potlines. A minimum collecting efficiency was achieved by introducing a forced inlet of the necessary ventilation air through the basement with the aid of fans so that the amount of air could be maintained at a predetermined level instead of using roof ventilation. The potroom vents are thus working with the collecting system from the pots instead of against it. The results from the first year of operation indicate that under normal conditions the cleaning efficiency will be well over 98%. The dry cleaning system seems to be relatively unaffected by variations in the fluorine content in the raw gases. The combined system of dry scrubbing and wet washing made it possible to remove at least 80% of the sulfur emission in addition to the fluorides. Maintenance of the bag filtering system is mentioned.

Ross, Richard D.

INCINERATION OF PROCESS WASTES. Air Pollution Control Assoc., Pittsburgh, Pa., Proc. Air Pollut. Control Assoc. Mid-Atlantic States Sect., Semi-Ann. Tech. Conl., Edison, N. J., 1972, p. 79-85. (May 12.)

Incineration of liquid process wastes is discussed. Combustible liquid wastes generally have caloric values of 8000 Btu/lb to 10,000 Btu/lb or higher; partially combustible wastes have a heating value below 8000 Btu/lb. The characteristics of each are described and the incinerating procedure used for each is reviewed. Incinerator design criteria for each combustion process is presented. Pollutants produced in the process, including metal oxides, chlorine, fluorine, hydrogen chloride, and sulfur dioxide are reviewed. Control methods used to reduce emissions include the use of venturi and packed scrubbers and by-product recovery. New incinerating processes, their development and operation are discussed. A number of

processes have been developed for the incineration of chlorinated hydrocarbons and recovery of HCl.

Kantner, A. and W. Kersting
INCINERATION, A CONTRIBUTION TO ENVIRONMENTAL PROTECTION. (Muellverbrennung, ein Beitrag zum Umweltschutz). Text in German. VGB Kraftwerkstechnik, 53(1):62-68, Jan. 1973.

Great progress has been made in modern incinerators with respect to flue gas cleaning. High-capacity filters with a collection efficiency of 99% and more have been developed. They permit a reduction of the dust concentration to 150 mg/cu m flue gas. Apart from dust the waste gases from incinerators contain carbon dioxide, sulfur dioxide, hydrogen chloride, and hydrogen fluoride. Depending on the type of waste material, the emitted concentrations of HCl fluctuate between 0.2 and 0.8 g/cu m, of SO₂ between 0.2 and 1.2 g/cu m, HF up to 3 mg/cu m, and 7% CO₂. The most efficient means of reducing local, as well as temporal, peaks of toxic flue gas components, is the construction of high stacks. The Frankfurt and Kassel incinerators have a stack height of 110 m, the Munich incinerators of 80, 130 and 145 m, the Mannheim incinerator of 146 m, the Nuremberg incinerator of 100 m, the Stuttgart incinerator of 180 m and the Berlin-Ruhleben incinerator of 76 m. Flue gas scrubbing is technically feasible, but has the disadvantage of creating a water pollution problem. Moreover, the cooled waste gases lack thermal buoyancy. The costs for flue gas cleaning systems, extra high stacks, and other measures necessary for the operation of an incinerator without annoying the environment are estimated to amount to 12% of the investment costs of a large incinerator.

INCINERATION: AN AIR POLLUTION PROBLEM? WAYS OF REDUCING HYDROGEN CHLORIDE EMISSIONS.

(Muellverbrennung: Ein Luftreinhalteproblem? Wege zur Minderung der Chlorwasserstoff-Emissionen). Text in German. Luftverunreinigung, 1972:43-51, Dec. 1972. 11 refs.

In incinerators of West Germany, no measures are generally taken against the gaseous emissions. The incinerators are equipped with electrostatic precipitators which remove the dust from the off-gases. Measurements of the gaseous emissions from incinerators yielded a hydrogen chloride concentration of 1 g/cu m, sulfur dioxide 0.6 g/cu m, and hydrogen fluoride 10 mg/cu m. The concentration of HCl is so high that a stack incrementation is necessary. In order to give an idea of the required stack incrementation at an increase of the presently valid maximum allowable average emission value from 2 g to 2.5 g/cu m, diagrams are given in which the stack height isohypses are plotted in dependence of the waste gas volume flow, temperature, and maximum emission concentration. The needed stack height is 177 m with a waste gas flow of 300,000 cu m/hr, a maximum hourly average concentration of 2 g HCl/cu m, and a waste gas temperature of 200 C. Independent of increasing the stack height of incinerators, other measures must be taken to reduce the gaseous pollutants. They comprise the actual reduction of the pollutant, the processing of the obtained reaction products, and the disposal

<xref image="2000WVDA.TIF|V3|2006:09:28:01:23:14.00|119437|0"> image: </xref>

B. CONTROL METHODS

119

of the obtained waste product by dumping, discharge into the sewer, or chemical-technical recycling. A cost calculation for the installation of an electrostatic precipitator for dust removal with HCl absorption and neutralization and evaporation of the scrubbing water yielded operating costs of \$.54/ton of waste. Scrubbers are very suitable for the removal of the gaseous pollutants in incinerator off-gases.

Miyazaki, Yoshitaka

PUBLIC NUISANCE PREVENTION EQUIPMENT AND RE-LATED WELDING TECHNOLOGY. (Kogaiboshikiki to yosetsu kanren gijutsu). Text in Japanese. Preprint, Japan Welding Assoc., Tokyo, 14p., 1973. 8 refs. (Presented at the Seminar on Plastics Used in Public Nuisance Prevention Devices and Their Processing Techniques, Osaka, Japan, Feb. 19-20, 1973.) The construction of pollution control equipment and factors such as corrosion resistance, and mechanical strength are discussed. Corrosion resistance of plastics are generally superior to other construction materials such as stainless steel. Polyvinyl chloride (PVC), fiber glass reinforced plastic (FRP) and PVC/FRP, are used as anti-corrosion materials. Industrial sources of sulfur dioxide, hydrogen fluoride, chlorine, hydrogen chloride, and other harmful gases are listed with their disposal devices and processes. Plastic welding technology is discussed, and a non-plasticizing welding rod is recommended over an ordinary welding rod.

Netzer, W. D.

FLUORINE DISPOSAL METHODS. Atomic Energy Commission, Div. of Operational Safety, Proc. AEC Pollut. Contr. Conf., Oak Ridge, Tenn., 1972, CONF-721030, p. 62-86. 27 refs. (Oct. 25-27.) Safe and economical methods of disposing fluorine presently vented from a uranium oxide conversion facility were investigated. The facility produces uranium hexafluoride by reacting high assay uranium oxides with fluorine. The disposal processes under consideration included caustic scrubbing, fixed bed reactors, and a fluidized bed reactor. A 5 in. countercurrent spray tower was built which can absorb 90% of a standard 3 cu ft/min fluorine flow using a 3 gal/min flow of 5 wt% potassium hydroxide. But the toxic gases oxygen difluoride and nitroxy fluoride are also produced in the scrubber. Fixed bed charcoal and iron reactors were operated, but the charcoal reaction produced large quantities of carbon monoxide, carbonyl fluoride, and silicon tetrafluoride; and the iron reaction produced molten iron which plugged the reactor. Fixed bed reactor systems are hampered by high maintenance costs, and studies utilizing fluidized bed reactors are now being considered. (Author abstract modified)

CONTROL TECHNIQUES OF SPECIFIC TOXICANTS RELATED TO AIR POLLUTION. (Taiki osen kankei yugai busshitsu shori gijutsu). Text in Japanese. PPM (Japan), 4(4):58-79, April 1973. Control techniques for cadmium, cadmium compounds, chlorine, hydrogen chloride, fluorine, hydrogen fluoride, silicon tetrafluoride, lead, and lead compounds are outlined. Sources and characteristics of these compounds are mentioned. Particulates containing cadmium, lead, and their compounds can be easily removed by dust collectors. Efficiency, application, and selection of dust collectors are discussed. Gaseous toxicants are usually removed by liquid scrubbing or gas-solid adsorption. Characteristics of packed columns, spray towers, cyclone scrubbers, venturi scrubbers, jet scrubbers, and other scrubbers are summarized. Maintenance of control equipment and safety practices are described.

Davids, P. and W. Brocke

TECHNICAL POSSIBILITIES FOR REDUCTION OF THE
POLLUTANT EMISSION FROM INCINERATORS.

(Technische Moeglichkeiten zur Verminderung der Schadstoff-
emission aus Muellverbrennungsanlagen). Text in German.
Muell Abfall, 5(3):72-75, 1973. 10 refs. (Presented at the Muell-
technische Kolloquium, Stuttgart, West Germany, March 8,
1973.)

Incinerators emit hydrogen chloride, hydrogen fluoride, sulfur
dioxide, and oxides of nitrogen. Since hydrogen chloride is
water soluble its separation is relatively easy compared to
SO₂. Through scrubbing with water, cleaned gas concentra-
tions of less than 10 mg HCl/cu m can be reached. Hydrogen
fluoride, too, is water soluble. In aluminum plants, scrubbers
for HF for several million cu m/hr are in operation. The
cleaned gas concentrations are around 1 mg HF/cu m. For sul-
fur dioxide, alkaline absorbents must be used. For desulfuriza-
tion, a number of processes exist, some are in operation be-
hind steam generators. In incinerators of the Federal Republic
of Germany, scrubbers for waste gas cleaning are hardly used.
Extensive measurements were carried out with a scrubber in
an incinerator with a throughput of 2.5 tons/hr and an off-gas
quantity of 18,000 cu m/hr. The off-gas was first cooled to 70
C. In several parallel venturi nozzles the dust was separated
and the water soluble gaseous components absorbed. After
passage of a droplet separator, the off-gas was heated again
and blown out through the stack. An average collection effi-
ciency for HCl of 95% and for HF of 96% was obtained. The
average concentrations in the cleaned gas were 27 mg HCl/cu
m and 0.3 mg HF/cu m. The collection efficiency for SO₂ was
7% and for NO_x was 12%. Thermogravimetric and laboratory
experiments concerning the sorption properties of comminuted
slag from incinerators for HCl and SO₂ under simulated condi-
tions revealed that at between 500 and 700 C the slag has a
large binding potential for these substances.

PRODUCTION OF FLUOSILICATES FROM WASTE GASES
OF EGYPTIAN SUPERPHOSPHATE INDUSTRY. Indian
Ceram., 16(6): 111-114, Sept. 1972. 4 refs.

<xref image="2000WVDB.TIF|V3|2006:09:28:01:23:20.00|115758|0"> image: </xref>

The chemical analysis of Egyptian phosphate rock shows the fluorine content to be 3.3%. About 30% of the fluorine present in the rock is evolved during acidulation with 70% sulfuric acid. Silicon tetrafluoride is evolved as a gas during acidulation of phosphate rock with H_2SO_4 , which reacts with water to produce an aqueous solution of fluosilicic acid. This solution is the starting material for preparation of the different metal fluosilicates. Experiments were made on the preparation of sodium and calcium fluosilicate by neutralizing fluosilicic acid with various sodium and calcium salts. Sodium and calcium chlorides are the preferred salt solutions. (Author abstract modified)

Koethe, Klaus and Ludwig Mueller
DETERMINATION OF THE HYDROGEN FLUORIDE PARTIAL PRESSURES. (Beitrag zur Ermittlung von Fluorwasserstoff-Partialdruecken). Text in German. Neue Huette, '8(6):332-336, June 1973. 9 refs.

The thermal treatment of zinc concentrates by a blasting process is connected with a volatilization of fluorine and arsenic. These pollutants can be removed from the waste gases by absorption in an aqueous solution. For calculation of the absorber, the vapor pressure equilibria of fluorine-containing systems and the interference by sulfur and arsenic-containing components must be known. A literature survey on the fluoride partial vapor pressures of aqueous fluorine containing systems turned out data for the systems hydrogen fluoride water, HF-fluosilicic acid-sulfuric acid, and $H_2SiF_6-H_2$. No data concerning the partial pressures for concentrations below 10 g F/l and temperatures between 20 and 60 C, whose knowledge is essential for the absorber calculation, were found. Therefore, the HF partial pressures of binary and ternary systems for concentrations between 0.1 and 10g F/l and temperatures between 20 and 60 C were determined. For the system HF- H_2O , a vapor pressure equation is given. The fluorine concentration in the absorption solution depends solely on the HF partial pressure of the system HF- H_2O . The influence of the compounds H_2SiF_6 , H_2SO_4 , sulfur dioxide, arsenic trioxide, and arsenic pentoxide is negligible. The fluoride concentrations in the gas cleaned by a wet process are determined by the HF concentration in the absorption solution and by the temperature on the last absorption stage.

Behrens, D.
ENVIRONMENTAL PROTECTION: A CHALLENGE FOR CHEMICAL ENGINEERING. Chem. Engr. (London), 9(271): 143-150, March 1973. 4 refs. (Presented at Europe - The Differences, Symposium of the Midlands Branch, Birmingham, England, April 18-19, 1972.)

The amounts of major air and water pollutants and solid waste generated by the main sectors of West German Industry in 1969/1970 are shown. Specific tasks for the chemical engineer in the field of air pollution include large-scale testing of flue gas and fuel oil desulfurization problems and the development of processes, such as sorption, ozonization, and ultraviolet irradiation for control of malodorous substances. Other effluent gas problems are thermal catalytic combustion of large effluent gas flows, purification of gases containing hydrogen fluoride from aluminum smelters and ceramic works, as well as the disposal of nitrogen oxides from combustion engine exhausts. Effective effluent control will require removal of traces of heavy metals and treatment of substances resistant to biological degradation. The chemical engineer can contribute to treatment of municipal rubbish by systems analysis of alternative processing systems and by rendering plastics subject to complete combustion or biological degradation. Protection of the environment must also be considered in the stage of process development. There is yet no feasible method of producing detergents without triphosphates, but alternatives to

insecticides are under study, including the use of sterilants, the sexual attraction mechanism, and juvenile hormones. Blending of grafting of more readily macromolecular compounds in synthetic polymers and plasticizers may speed up the biological degradation of plastics.

FLUORINE CONSUMPTION TRENDS OF THE ALUMINUM
INDUSTRY. Preprint, American Inst of Mining, Metallurgical,
and Petroleum Engineers, New York, Society of Mining En-
gineers, 21p., 1973. 10 refs. (Presented at the American Institute
of Mining, Metallurgical, and Petroleum Engineers, Annual
Meeting, Chicago, 111., Feb. 25- March 1, 1973, Paper 73-H-50.)

The factors and trends of fluorine consumption in the alu-
minum industry during the next decades are discussed. Vir-
tually all fluorine consumed by the aluminum industry is as the
electrolyte of the Hall-Heroult process for producing primary
aluminum. A small amount of fluorspar is used, but most
fluorine is consumed as either aluminum or cryolite. Some
fluorine-containing materials are used in secondary aluminum
production. Increasingly stringent restrictions on the emission
of pollutants and the continuing cost-price squeeze factors are
taken into consideration in the analysis of the future of the
primary aluminum industry. In the future, much more fluorine
will be recycled, thereby reducing the demand for new
fluorine. Hydrogen fluoride fume scrubbing and fluoride
recovery are discussed in detail. Fluoride recovery is also
economically evaluated.

Muhlrad, W. and A. Chauvineau
PECHINEY/PRAT DANIEL DRY PROCESS FOR CONTROL
OF FLUORINE COMPOUNDS RELEASED BY ALUMINUM
REDUCTION POTS. Preprint, American Inst. of Mining,
Metallurgical, and Petroleum Engineers, New York, Metallurigi-
cal Society, p. 209-222, 1973. 8 refs. (Presented at the American
Institute of Mining, Metallurgical, and Petroleum Engineers,
Metallurgical Society, 1973, Paper A73-16.)

A process for controlling fluorine emissions from aluminum
reduction pots is based on adsorption of fume by alumina. The
pot fume is brought into contact with alumina injected into a
venturi tube installed at the bottom of a vertical duct which
conveys the alumina/fume mixture to a bag filter unit. The
fluorinated alumina is collected and recycled to the venturi
tube or the reduction pots. The process configuration operates
on a small pressure drop, so energy expenditure is minimal.
Process efficiency is directly related to alumina surface area
and is 99.5% when the area is more than 20 sq m/g. Operating
experience with a commercial unit used to treat fume from 20
pots operating at 130,000 A is discussed.

B. CONTROL METHODS

121

Metallurgical, and Petroleum Engineers, Metallurgical Society, 1973, Paper A73-24.)

External and internal control of total fluorine and fluorides in aluminum pot rooms is discussed. Fume collection efficiencies of VS Soderberg pots, open pots with prebaked anodes, and hooded pots with prebaked anodes are, respectively 70, 0, and 90-95%. Medium-pressure fluidized bed scrubbers are frequently used to clean the primary gases from Soderberg and hood prebaked pots. Cleaning efficiencies on total fluorine are 97% on Soderberg gas and 85% on gas from hooded prebaked pots. High-pressure scrubbing of hooded pot gas is necessary to obtain 95% total fluorine cleaning efficiency. Fine particulate fluorides are collected with 97% efficiency by bag filters. For smelters that have based their fluorine economy on wet systems with cryolite recovery, a bag filter installation followed by a low-energy wet scrubber may be the optimal solution. Water tank model studies of air flow patterns are necessary to optimize pot room ventilation with a minimum of air. Such studies are particularly important for rooms with open pots and VS Soderberg pots, where 100 and 30%, respectively, of the fumes are emitted on the pot room.

Kozima, Yaichi and Yoshisuke Nakamura
DEFLUORIDIZATION AND DESULFURIZATION FROM
FLUE GAS IN A TUNNEL KILN IN FIREPROOF BRICK
FACTORY. (Taikarenga kojo ni okeru haien daffutsu datsuryu ni tsuite). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 9(6):621-624, June 1973. 3 refs.

The cause of withering of grape leaves in Okayama Prefecture was fluoride-containing flue gas emitted by a fireproof brick factory. Several defluoridization/desulfurization processes were tested to find one that could give 99.5% or higher defluoridization efficiency, low water consumption, low fluorine content in the waste water, less sludge, and cheaper running costs. The most suitable process involved absorption of the sulfur oxides and fluorides with sodium hydroxide. Absorbent was recirculated and fluorine and particulates were removed from the absorbent. The process gives 99.6-99.9% defluoridization efficiency and 94-98% desulfurization.

52838

Iversen, R. E.

AIR POLLUTION IN THE ALUMINUM INDUSTRY. J.
Metals, 25(1): 19-23, Jan. 1973. 3 refs.

Gaseous and particulate fluorides are the most serious pollutants from aluminum electrolytic reduction plants. The greatest source of pollutants of all types is normally at the individual cells or potlines, followed by the anode bake plant. In 1970 controlled emission prebaked potlines released 51% of the industry's total fluoride emissions. The greater portion of these prebake potlines employed only primary control systems (i.e., floating beds, spray towers, impingement baffles, cyclonic towers, packed towers, bubble towers, and venturi scrubbers preceded by mechanical collectors, multicyclones, or dry electrostatic precipitators for particulate removal). Control efficiency was 78% of cell emissions. Control efficiency of 85% was obtained for prebake lines employing both primary and secondary (i.e., spray screens and packed beds) systems. For vertical stud Soderberg cell production, overall fluoride collection efficiency was 78% for lines using primary collection only and 95% for lines using both primary and secondary control. All horizontal stud Soderberg production occurred on lines with primary collection only; overall collection efficiency was 70%. The use of primary and secondary control systems can reduce prebake plant emissions to 1.60 lb fluorides and 5.0 lb particulates/ton of aluminum; vertical stud Soderberg emissions to 2.8 lb fluorides and 9.1 lb particulates; and horizontal stud Soderberg emissions to 3.60 lb fluorides and 12.30 lb particulates. The estimated capital investment for installed con-

trols on potlines is \$240 million; operating costs are about \$65 million/yr.

52852

Ishiyama, Koichi

WASHING TOWER FOR EXHAUST EMISSIONS USING FRP

- ITS OPERATION AND MAINTENANCE. (FRP o tsukatta haigasu senjo sochi - sono unten to hoshu). Text in Japanese. Kagaku Kojo (Chem. Factory), 17(7):82-86, July 1973, 7 refs. A gas washing tower was designed to remove sulfuric acid, hydrocyanic acid, hydrochloric acid, chromic acid, and fluorine emitted in the surface finishing process. The tower is made from fiber glass reinforced bisphenol type polyester (FRP), a strong, corrosion-resistant material. The tower is a liquid packed type. Inspection and maintenance are relatively simple, since the corrosion-resistant FRP requires no protective coating and since the packing material is made from rolled polyvinyl chloride film. The costs are less than normal. Cost of a washing tower for H₂SO₄ and H₂CrO₄ removal is a function of the flow rate. The absorption efficiency of H₂CrO₄ mist is a function of the liquid/gas ratio at the constant gas space velocity of 1.2-1.5 m/sec. An absorption efficiency of more than 95% occurred at 1.0 and 2.0 liquid/gas ratio. The washing tower is very effective in reducing chromic acid emission to less than the emission standard of 1 mg/N cu m.

53603

Teller, Aaron J.

PROCESS FOR RECOVERY OF ACID GASES. (Teller Environmental Systems, Inc., New York) U. S. Pat. 3,721,066. 4p., March 20, 1973. 4 refs. (Appl. Dec. 29, 1970, 10 claims).

A process for the removal and recovery of acid gas components such as hydrogen fluoride, silicon tetrafluoride, and sulfur dioxide from waste gases produced in the manufacture of glass, fertilizer, or aluminum during electrolysis is accomplished by passing the gases over a finely divided natural ore known as nepheline syenite. The nepheline syenite is desirably in the form of particles ranging in size from 4 to 500 mesh. Particles are preferably 200 to 325 mesh for bag filters, 6 to 14 mesh for fixed or moving bed applications, and 200 to 500 mesh for pipeline reactions. The sorbant properties of the nepheline syenite can be substantially improved by treating the syenite with 10 to 50 Ibs of water per 100 Ibs of syenite at ambient conditions. The finely divided nepheline syenite may be employed in the form of a fixed or a moving or a fluidized bed through which a stream of gas containing the acid components is passed. The gases desirably pass through the bed at a temperature of 100 to 400 F and preferably from 100 to 200 F. The space velocity of the gas should range from 100 to 10,000,000/hr and preferably from 10,000 to 1,000,000/hr. The preferred process temperatures and space velocities depend upon the concentration of the acid gases, the thickness of the bed of sorbing medium, the average particle size of the sorbing medium, and the amount of acid gases already sorbed.

PROCESS FOR PURIFYING INDUSTRIAL WASTE GASES

CONTAINING HYDROGEN FLUORIDE. (Universal Oil

Products Co., Des Plaines, III.) U. S. Pat. 3,709,978. 4p., Jan. 9, 1973. 7 refs. (Appl. Nov. 9, 1970, 6 claims).

<xref image="2000WVDD.TIF|V3|2006:09:28:01:23:26.00|124296|0"> image: </xref>

A multi-stage, continuous process for scrubbing a waste gas stream containing such components as hydrogen fluoride, fluorine, sulfur dioxide, and aluminum dust generated during the production of aluminum from alumina has been developed for obtaining improved purities of the treated waste gases. The present method is capable of purification to a maximum content of hydrogen fluoride not exceeding 1 mg/N cu m. The waste gases are subjected to a first washing zone by means of a recycled aqueous hydrogen fluoride-containing solution and to a second washing zone by means of a recycled aqueous solution. Aqueous HF is transferred from the first washing zone to a neutralization zone where it is neutralized by means of aqueous sodium hydroxide or sodium carbonate. The sodium fluoride formed is separated, and the mother liquor is recycled as the first washing liquid. The aqueous HF for the first washing zone is enriched by recycling to a content of from 1.0 to 2.9% by weight, while the aqueous solution of the second washing zone is adjusted to maintain a content of from 0.01 to 0.5% by weight of free HF. The purpose of controlling the wash streams is to prevent too much HF from reaching the second stage where sodium fluoride would precipitate and block valves and piping. Treatment of the combined effluent from each wash stage in a neutralization zone accomplishes precipitation of sodium fluoride, sodium sulfate, and entrained dust or aluminum particulates.

REMOVAL AND RECOVERY OF FLUORINE COMPOUNDS.

(Fusso kagobutsu no jogai to kaisyu ni tsuite). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 9(4):395-402, April 1973. 7 refs.

The emission, removal, and recovery of fluorine compounds such as hydrogen fluoride and silicon tetrafluoride from glass fiber industries are discussed. The emission standards of fluorine and HF are tabulated. The dry and wet removal systems can be used to remove fluorides. Emitted HF concentrations are 540 ppm without a control system and 1.4 ppm after the stack gas goes through a dry removal system. The latter is less than the 11.2 ppm emission standard.

Kawase, Zenichi

REMOVAL OF FLUORIDES IN ROOF-TILE-KILN. (Kawara

seizokojo ni okeru fussokagobutsu no jogairei). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 9(4):389-393, April 1973.

On roof-tile-kiln company uses a washing tower and settling tanks to remove fluorides from waste gases. The temperature of the gas is lowered to 80 C near the inlet of the washing tower by a long cooling path. The pH of the absorbing solution is controlled to more than 8 by adding sodium hydroxide. Thus, the concentration of hydrogen fluoride in the gas can be decreased from 5.8-11.2 ppm to 0.3-0.9 ppm, and 100 ppm of sulfur dioxide can be removed. Another company uses a washing tower, two circulating tanks, and a settling tank to remove HF. The gas temperature is lowered to 100 C by a shower, and the pH of the absorbing solution is controlled to higher than 7 with HaOH. When a solution of sodium fluoride occurs in the circulating tanks, one tank is stopped, and the solution is transferred to the settling tank where fluoride is settled in the form of calcium fluoride by adding slaked lime. The concentration of emitted fluoride can be decreased from 6.8 ppm M 0.8 ppm, and SO₂ is decreased to less than 1 ppm.

ABATEMENT OF AIR POLLUTION CAUSED BY FLUORIDE

AND PROBLEMS. (Fussokagobutsu no jokyo to sono mon-daiten). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 9(4):367-373, April 1973.

Emission standards, removal and recovery methods, and mea-

surement methods for fluorides emitted from an aluminum smelter are discussed. In Japan there are two emission standards for fluorides: the weight concentration standard (mg/cu m) and the total amount standard. Since the weight concentration can be easily lowered by diluting the air, the total amount is a more elective standard. A dust collector and a scrubber are usually used for collection of particulate and gaseous fluoride, respectively. A combination of these methods gives more effectiveness. Corrosion of collection equipment must be avoided during removal of hydrogen fluoride. Calcium hydroxide, sodium hydroxide, sodium sulfate, and limestone can be used to absorb HF.

PROCESS FOR PURIFYING INDUSTRIAL WASTE GASES
CONTAINING FLUORINE VALUES. (Universal Oil Products
Co., Des Plaines, 111.) U. S. Pat. 3,660,019. Sp., May 2, 1972. 6
refs. (Appl. Jan. 29, 1970, 6 claims).

A continuous process for removing fluorine and hydrogen fluoride from industrial waste gases evolved in the manufacture of aluminum through electrolysis of alumina in the presence of cryolite has been developed to avoid precipitation of sodium fluoride within the washing zone by the neutralization of the main amount of hydrogen fluoride in a separate neutralization zone. The waste gases are scrubbed within a first washing zone with aqueous hydrogen fluoride and within a second washing zone with aqueous sodium hydroxide. The effluent of the first washing zone is then recycled to the first washing zone until the concentration of hydrogen fluoride is at least about 3% by weight, while the effluent of the second washing zone is recycled to the second washing zone to enrich sodium fluoride as long as the concentration of sodium fluoride within the aqueous sodium hydroxide is still below the solubility product. The concentrated effluents from both washing zones are then combined within a neutralization zone, and the precipitated sodium fluoride is separated from the mother liquor which is recycled to the first washing zone.

Connor, J. M., G. J. Dell, and D. J. Newman
POLLUTION CONTROL IN ACID PLANTS. Chem. Age India,
23(2): 103- 116, Feb. 1972.

Pollution control problems and processes are reviewed for plants engaged in the production of sulfuric acid, phosphoric acid, and nitric acid. Incomplete conversion of sulfur dioxide to sulfur trioxide is the fundamental difficulty for sulfuric acid-producing plants. The most successful approach to this problem on a commercial scale has thus far proven to be the Double Absorption process in which an intermediate absorption stage is incorporated between two of the catalyst stages. Fluorides released during rock digestion and acid concentration are the main problems in phosphoric acid production. These emissions can be minimized by use of properly designed scrubbers, and recovery can provide a valuable by-product. Most nitric acid plants discharge tail gas containing 1500 to 3000 ppm by volume of nitrogen oxides if no treatment is provided. Catalytic combustion is the only abatement method now

FILTER FABRIC-THE HEART OF THE SYSTEM. Air Pollution Control Assoc., Pittsburgh, Pa., Proc. Spec. Conf. Des. Oper. Maint. High Effic. Contr. Equip., St. Louis, Mo., 1973, p. 103-117. (March 29-30.)

The development, application, and problems of filter fabrics are described. The growth in the use of fabric filters, and the evolution of various equipment types (cleaning methods) can be tied directly to the development of new fibers and their conversion to various fabrics, woven and felted, suitable for use in fabric filters. Prior to 1946 there were two basic fibers used in dust collectors. Both fibers were natural fibers, cotton and wool, both had low recommended operating temperatures. Polyamides were introduced prior to the war, but began to have filter fabric significance with their availability after World War II. In 1955 polyester fibers became commercially available. This fiber type is today the most widely used of all synthetic types available. In 1964 Teflon and Nomex came into existence and initial filtration usage began. Tables are presented to rate the various fibers relative to each other based on heat, abrasion, and chemistry. Temperature capability ranges from 180 F for polypropylene to 525 F for fiberglass. The real problem most often experienced is acid attack. Nomex is attacked by sulfur trioxide in a high oxygen content atmosphere even when moisture is low. Sulfuric acid is detrimental to most of the high temperature fibers, as polyester and Nomex, but not to fiberglass. Hydrofluoric acid is detrimental to polyester, Nomex, and glass. Periodic precoating with lime will absorb sulfur dioxide and SO₃ providing some protection to the filter fabric. Proper construction and selection of the filter fabric assures quality performance. The type and size of the pollutant determines the type of fabric. The wrong fabric can severely reduce effectiveness.

CHEMICAL DEVELOPMENT WORK IN SUPPORT OF FLUIDIZED-BED CALCINATION OF RADIOACTIVE WASTES AT THE IDAHO CHEMICAL PROCESSING PLANT. Allied Chemical Corp., Idaho Falls, Idaho, National Reactor Testing Station, Atomic Energy Commission Contract AT (10-1)-1375 S-72-1, 23p., Aug. 1973. 23 refs. NTIS: ICP-102S

Chemical development work in support of fluidized bed calcination of radioactive wastes at the Idaho chemical processing plant is reported. Aqueous radioactive wastes are routinely converted to granular solids by calcining in a fluidized bed calciner at 400-500 C. Wastes calcined to date include acid aluminum nitrate, acid zirconium fluoride, acid deficient ammonium nitrate, and acid stainless steel sulfate. Significant chemistry development work was performed to make possible the calcination of these wastes. The formation of alpha instead of amorphous alumina is possible by the addition of boric acid to the feed solution. Volatilization of fluoride, sulfate, and ruthenium was prevented by adding calcium nitrate to the waste prior to calcination. Complete decomposition of ammonium nitrate was obtained by blending it with acid aluminum nitrate waste. Potential volatilization of mercury was removed in the wet scrubbing system. Acid sulfate waste was blended with aluminum nitrate solution to form aluminum sulfate which is stable during calcination. If the sulfate volatilized, it could concentrate in the scrubbing solution and corrode the stainless steel equipment. Other problems associated with the calcination process that currently are being

studied include agglomeration in the bed during calcination of sodium nitrate containing wastes, and possible volatility and concentration of chloride in the scrubbing solution during calcination of wastes containing low concentration (greater than 2 g/l) of chloride. (Author abstract modified)

EXPERIENCES WITH MEASURES TAKEN TO ABATE AIR

POLLUTANT EMISSIONS. (Erfahrungen mit Massnahmen zur

Verminderung der Emission luftverunreinigender Stoffe). Text in German. Ziegelind. (Weisbaden), no. 9:325-334, Sept. 1973. 11 refs.

Effectiveness and cost of various devices and installations used to abate air pollutant emissions at brick factories are discussed in detail. The differentiation is made between emission and immission, illustrated by showing the diffusion of flue gases using a long time exposure. Sulfur dioxide, fluorine, and aluminum emissions are described. The sulfur content found in emissions varied between 0.1 and 2 g/cu m in the form of SO₂. The legal aspects of standards, rules, and regulations concerning the maximum allowable pollutant emissions are discussed. The maximum emission standards in Germany are 0.750 mg/cu m SO₂ for short emissions and 0.4 mg/cu m for long ones, they are 0.005 mg/cu m and 0.002 mg/cu m for fluorine respectively. The normal allowed pollutant concentration limit is 0.350 mg/cu m SO₂ and 0.003 mg/cu m fluorine. Decomposition of lime leads to generation of calcium oxide and carbon dioxide. Lime disintegration depends on the temperature. The mean values of fluoride and SO₂ at kilns fired with coal, heavy oil, light oil, and gas are 48 mg/N cu m fluoride, and 0.49 g/N cu m SO₂. Various types of dry absorption and wet scrubber installations are described.

NONFERROUS METALS MANUFACTURING POINT

SOURCE CATEGORY. PROPOSED EFFLUENT LIMITA-

TIONS GUIDELINES. Federal Register, 38(230):33170- 33183, part 2, Nov. 30, 1973.

The control of pollutants which develop during the manufacture of nonferrous metals are discussed in a notice on effluent limitation guidelines. Most of the waste waters from primary aluminum smelting result from air pollution control devices which employ wet scrubbers to control air emissions. The sig-

<xref image="2000WVDF.TIF|V3|2006:09:28:01:23:34.00|119930|0"> image: </xref>

nificant pollutants are fluorides, suspended solids, oil and grease, cyanide, and pH. The significant pollutants in the waste water from bauxite refining include alkalinity, pH, total dissolved solids, and suspended solids. Secondary aluminum smelting pollutants include suspended solids, lead, manganese, and oil and grease. In the primary aluminum industry the most significant reduction in discharge volume is obtained by converting wet fume scrubbers to dry fume scrubbers or by treating and recycling the water from wet scrubbers. The dry scrubbing of pot gas is effective for removal of pollutants from the gases evolved from the electrolytic cell by contacting the gases with dry alumina to effect the adsorption of pollutants and subsequent collecting particulates by fabric filtration. The fumes formed during chemical magnesium removal can be controlled by either wet or dry methods. Three most popular methods which use little water are the Derham process, Alcoa process, and Teller process.

DETERMINATION OF GASEOUS FLUORINE IN AIR. Am.

Ind. Hyg. Assoc. J., 34(9):418-420, Sept. 1973. 2 refs.

The efficiency of a caustic scrubbing technique for determining trace quantities of elemental fluorine in air was investigated. A recovery of 98% was obtained with a single scrubber for concentrations studied in the range of 3-4480 ppb. Depletion of the sodium hydroxide in the scrubber by other acid gases in the air was not a factor as long as excess caustic was present. Conversion of the sodium hydroxide to sodium carbonate through reaction with atmospheric carbon dioxide reduced the efficiency only slightly. (Author abstract modified)

FLUE GAS SCRUBBING AFTER INCINERATORS.

(Rauchgaswaesche nach Muellverbrennungsanlagen). Text in German. VGB Kraftwerkstechnik, 53(11):735-742, Nov. 1973. 6 refs.

The extent and effect of the major pollutants emitted by incinerators are reviewed. A reduction of the pollutant emission particularly with regard to hydrogen chloride and hydrogen fluoride is important. Design and operation of some scrubbers, e.g., radial flow, countercurrent flow with and without installations, Stroeder scrubbers, and venturi scrubbers, are discussed. As a consequence of the high solubility of HCl in water, no major problems are encountered with scrubbers. With reaction times of less than one second, most familiar scrubbers are capable of reducing the HCl concentration to the demanded 100 mg/cu m (new version of the VDI guideline 2114). The calculatory design of the scrubber poses difficulties. Countercurrent scrubbers with water atomization are most suitable with regard to investment and operating costs. Venturi scrubbers and packed towers don't seem to be necessary, at least not for HCl absorption. Since the scrubbing process takes place at temperatures below 100 C, a cooling of the gases is necessary. Heat utilization is advisable for reasons of economy and environmental protection. Design and testing program of a flue gas scrubbing facility in the incinerator Hamburg I are described. First results of measurements of the plant which has been in operation since May 1972 are given. Apart from the physical absorption of HCl by water, the chemical adsorption by dust (dolomite, quicklime, and magnesium oxide) was studied. The results permit the conclusion that considerable amounts of HCl can be bound this way. The investment costs for scrubbers are proportional to the entering flue gas volume. They increase relatively little with increasing capacity so that there is little impetus for a combined treatment of the flue gases from several units. It seems to be better not to exceed the capacity of one scrubber of 50,000 cu m in major proportions. For larger volumes, several scrubbers should be operated in parallel, this increases the availability of each unit. The operating costs cannot yet be given in exact

terms, estimates run over \$1/ton of refuse.

STUDY OF THE VOLATILIZATION OF ACCOMPANYING
ELEMENTS AT ALUMINUM FUSION ELECTROLYSIS.

(Beitrag zur Verfluechtigung der Begleitelemente bei der Alu-
minium-Schmelzflusselektrolyse). Text in German. *Erzmetall*,
26(11):529-533, Nov. 1973. 12 refs.

Total encapsulation of the furnaces for experimental fusion
analysis by a pilot plant for adsorption of fluorine compounds
on aluminum oxide permitted the study of the volatilization of
important elements such as silicon, iron, titanium, phosphorus,
vanadium, zinc, and gallium. The adsorption process for
fluorine has been extensively described earlier. It is based on
the formation of a fluidized bed between aluminum oxide and
waste gas. The process reduces the gaseous fluorine to a
residual concentration of 1 mg/cu m. The major disadvantage
of the method is that together with the retained fluorine
volatile fractions of the above elements are returned to the
furnace where they reduce the quality of the metal by 0.05 to
0.06%. The dry waste gas cleaning method developed by Lurgi
requires only 10% of the oxide consumed by the furnaces for
the fluorine adsorption. This has the advantage that the
volatile pollutants are concentrated in a relatively small oxide
quantity which limits the reduction of the metal quality to only
part of the production.

WET TYPE NITROGEN OXIDES REMOVAL METHOD.

(Chissosankabutsu no shisshiki jokyoho). Text in Japanese.
Preprint, Japan Petroleum Inst., Tokyo, 14p., 1973. 1 ref.
(Presented at the Japan Petroleum Institute, Meeting on NOx
Reduction, Tokyo, Japan, Aug. 29-30, 1973.)

The NE wet denitration process uses a solution of perman-
ganate as an oxidation/absorption agent for removal of
nitrogen oxides in waste gas. It removes both nitrogen dioxide
and nitric oxide, as well as hydrogen chloride and hydrogen
fluoride. A waste gas of 2000 cu m/hr with an NOx concentra-
tion of 4000 ppm or less gives only 100 ppm or less NOx after
denitration. It is not difficult to reduce the NOx content
further to only 20 ppm. No secondary pollution occurs.

IS A SOLUTION OF THE FLUORINE EMISSION PROBLEM

IN THE BRICK INDUSTRY IN SIGHT? (Ist eine Loesung des
Fluor-Immissionsproblems in der Ziegelindustrie in Sicht)? Text
in German. *Luftverunreinigung*, 1973:38-46, 1973. 6 refs.

The dry injection of calcium hydrate (calcium hydroxide) in
brick kilns was tested. The method aims at the reduction of
the oxides of sulfur and particularly of the aggressive fluorine
compounds. First the injection of the pulverized substance
directly into the kiln was tested to see whether a reduction of
the SOx present in high concentrations in the flue gas in-
directly also reduces the fluorine emission. Earlier studies had
shown that the driving off of fluorine compounds from brick

<xref image="2000WVDG.TIF|V3|2006:09:28:01:23:38.00|119035|0"> image: </xref>

B. CONTROL METHODS

125

parts was greatly influenced by the concentration of sulfur dioxide. The fluorine emission could be considerably reduced. The direct contact of the brick material with the pulverized calcium hydrate permitted the application of this method only for products which require no pure color. Very favorable results were achieved with the injection of only 1/3 of the calcium hydrate into the furnace and 2/3 (of a total of 5 kg/hr) into the smoke collector leading to the stack. The fluorine emission could be reduced from the long-term average of 70 mg/cu m waste gas to less than 3.5 mg/cu m, which is a reduction of more than 95%. Similar favorable results were achieved with the sole injection of the calcium hydrate into smoke flue outside the furnace provided the reaction path was sufficiently long. Through this the dust emission may be increased to beyond the existing limit concentrations. The problem of a suitable dust collector in this case remains to be solved.

Cochran, C. Norman

RECOVERY OF HYDROGEN FLUORIDE FUMES ON ALUMINA IN ALUMINUM SMELTING. Environ. Sci. Technol., 8(1):63-66, Jan. 1974. 17 refs.

The adsorption of hydrogen fluoride fumes from aluminum smelting on alumina was studied. Calcined aluminas with widely ranging surface areas rapidly chemisorbed a monolayer of HF at partial pressures of a few microns in Al smelting fumes at 120 C. The chemisorbed layer contained two HF molecules/surface Al₂O₃ molecule and converted aluminum fluoride to a crystal above 300 C. Additional HF physisorbed at higher partial pressures was mostly desorbed on heating above 120 C. Adsorption isotherms were derived from data for processes in which the fumes were contacted with calcined Al₂O₃ for recovery of fluorides. The fluoride-containing Al₂O₃ was fed to the Al smelting cell for electrolysis to close the fluoride fume generation and recovery loop. This lowered the AlF₃ requirements of Al smelting to essentially that for converting the sodium oxide impurity (introduced with the Al₂O₃) to a fluoride bath of the desired composition. The HF was generated near the 975 C smelting temperature by reaction of AlF₃-containing species with moisture. The reverse reaction favored at lower temperatures was the basis for the recovery process. (Author abstract modified)

ON FLUORIDES IN EXHAUST GAS (2). (Fusso kagobutsu hasseigen chosa ni tsuite -sono 2-tekko kanren kojo hasseigen chosa). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 8(3):362, 1973. (Presented at the Japan. Society of Air Pollution, Annual Meeting, 14th, Fukushima, Japan, Nov. 6-8, 1973, Paper 106.)

Six iron and steel factories were investigated for fluoride emissions. Four factories had traceable amount of F in stack gases; one factory with a 25-ton electric furnace utilizing 1-2 kg/ton of steel, had 1.6 mg/N cu m of F, and another factory with one furnace of 40 ton utilizing 10 kg/ton of steel and another furnace of 10 ton capacity utilizing 8 kg/t produced stack gas containing 41.9 mg/N cu m of F. In both factories, the flue gases are treated by bag filters. The highest amount of F was emitted immediately after fluorite is thrown into the furnace, and that reduction of the amount of CaF₂ and eliminating gas at the initial stage of CaF₂ melting together with slug will decrease F emission considerably. When the treatment was adopted the CaF₂ consumption was decreased from 18 kg/ton to 1.4 kg; F emission decreased from 41.9 to 1.3 mg/N cu m.

Gopalachari, A. S.

RECOVERY OF FLUORINE FROM THE WASTE GASES OF PHOSPHATIC FERTILIZER PLANTS. Chem. Age India,

22(10):677-683, Oct. 1973. 4 refs.

When raw rock phosphate is treated for fertilizer production, fluorine escapes in the form of waste gases. Since this is normally the loss of a valuable by-product, particularly in the context of ever increasing demand for cryolite, aluminum fluoride, and a wide range of fluorine chemicals, a process was developed to recover the fluorine from the above source. The by-product recovery of fluorine also improves the environment by reducing fluorine pollution. The availability, consumption, and demand for fluoride compounds, the composition of commercial raw phosphates, the distribution of phosphate fertilizer plants in India according to rock phosphate consumption, the principal phosphatic fertilizer/phosphoric acid plants in India during 1972, the process for recovering fluorine from waste gases, and licensed and installed capacity for synthetic cryolite production and for sodium silico fluoride based on fluorine gases from phosphatic fertilizer plants are described.

Zaytsev, V. A., V. I. Rodin, B. V. Gromov, L. N. Arkhipova, V. N. Senin, A. A. Novikov, and T. G. Repenkova
WASTE PRODUCTS FROM THE PRODUCTION OF
PHOSPHATE FERTILIZERS AS POSSIBLE RAW MATERIAL FOR FLUORINE PRODUCTION. Soviet Chem. Ind. (English translation from Russian of: Khim. Prom.), no. 547-550, Aug. 1971. 22 refs.

The main mineral from which fluorine compounds are obtained is fluorspar. Fluorspar ores are categorized as chemical, metallurgical, and ceramic. The ever-increasing demand for fluorine compounds has increased the mining of fluorspar and decreased the fluorspar reserves. Thus new sources of fluorine are being studied, including apatite, a raw material for producing phosphate fertilizers. The fluorine content of apatite varies from 1.3-3.9%. If only 50% of the fluorine released during production of phosphate fertilizers were recovered, it would equal 700 thousand tons/yr. Reserves of fluorine contained in phosphorites and apatites in different countries are listed; they equal 25,867,000 and 776,000 tons of phosphorite and fluorine, respectively. The waste gases of simple superphosphate production contain 15-30 g/cu m silicon tetrafluoride on the basis of fluorine. The parameters of the technological system of wet-process phosphoric acid production by the dihydrate method and the amount of alkaline metals in the initial stock have a considerable effect on the distribution of fluorine in the production of superphosphate. The various phosphate and superphosphate producing processes are reviewed with respect to their production of fluorine. Possible means of increasing the degree of isolation of fluorine in the production of phosphate fertilizers include decreasing the losses in the production of fluorine salts from fluorine-containing solutions; development of effective methods of isolating fluorine from wet-process phosphoric acid; and intensifying the processes of absorption of fluorine-containing gases.

Opie, W. R.
PROBLEMS IN SMELTING COPPER SCRAP. National Assoc. of Secondary Material Industries, Inc., New York, and Bureau of Mines, Washington, D. C., Eff. Technol. Res. Scrap Met. Recycling, Proc. Workshop, Washington, D. C., 1971, p. 52-54. (Jan. 7.)

<xref image="2000WVDH.TIF|V3|2006:09:28:01:23:40.00|122955|0"> image: </xref>

In copper reclamation there are two grades of consumer-generated secondaries that are real metallurgical challenges--insulated wire and iron bearing material. With the first, the basic problem is how to handle the organic insulation. Burning it off is the preferred solution but this creates pollution problems. A universal solution is to design and operate a smelting unit which will use as much of the heat of combustion as possible to melt the copper, slag off some impurities, burn the resulting gases to completion in an afterburner, and scrub the products of combustion with a basic solution to neutralize the hydrochloric and hydrofluoric acids. A feasible approach to handling iron-bearing secondaries is to smelt them in a unit with suitable fume collection afterburning and gas scrubbing equipment. The fumes which come off blast furnaces and converters treating the smelter-grade copper scraps are essentially zinc oxides contaminated with large quantities of lead, tin, iron, chlorides, and fluorides. These products are caught in baghouses which are essentially for operating without polluting the atmosphere.

Nix, Thomas B.

REMOVAL OF FLUORIDES FROM GASES. (Fuller Co., Catasauqua, Pa.) U. S. Pat. 3,790,143. 5p., Feb. 5, 1974. 1 ref. (Appl. July 31, 1972, 4 claims).

Methods and apparatus for removing gaseous fluorides from gases evolved from an aluminum smelting furnace are described. Basically, the fluorides are removed by achieving intimate contact between finely divided particles of alumina and the fluoride-containing gases. This is achieved by feeding the particles of alumina into a stream of gases collected from the aluminum smelting furnaces countercurrent to the flow of gases. The particles of alumina adsorb the fluorides. The particles of alumina and adsorbed fluorides are then separated in a gas-solids separator, such as a cyclone, and the alumina may then be fed to the smelting furnaces. Preferably, two stages are used. The gases supplied to the second or last cyclone in the direction of gas flow are supplied with new alumina countercurrent to the flow of gases. The alumina particles removed in this second cyclone are conveyed to the gas stream supplied to the first cyclone in the direction of gas flow. In a two-stage apparatus, these gases will be those evolved from the smelting furnace or recirculated or a portion may be recirculated and a portion conveyed to the smelting furnace. The gases separated in the first cyclone are conveyed to the second cyclone. This method eliminates the necessity to cool the effluents as with a baghouse.

Frasca, Ralph L.

HANDLING OF INSULATED COPPER WIRE SCRAP. National Assoc. of Secondary Material Industries, Inc., New York, Air Pollut. Control Technol., Proc. Workshop, Chicago, 111., 1970, p. 107-116. (Oct. 22.)

Some of the basic problems encountered in the removal of insulation during the recovery of the conducting materials and the type of auxiliary equipment necessary to operate within air pollution control regulations are discussed. The most frequently used method is burning off. The insulations considered are polyethylene, polypropylene, polyvinyl chloride, teflon, nylon, neoprene, rubber and paper. Once ignited, polyethylene generates hydrocarbon gases which burn intensely. Burning under controlled conditions, only carbon dioxide and water vapor will be emitted. The necessary controls consist of a primary combustion chamber in which the burning rate is limited, and a secondary combustion chamber which is fired by auxiliary fuel and provided with overtired air. A high temperature secondary combustion chamber with sufficient air supply will completely burn the volatilized hydrocarbons giving a clean or steamy plume. The removal of polypropylene is like that of polyethylene. Facilities to handle polyvinyl

chloride insulated wire should include a primary distillation chamber provided with a means of supplying the heat and temperatures necessary to start and continue at a reasonable rate the combustion of this flame retarding material, a secondary combustion chamber with an auxiliary fuel fire plus overtired air to complete the combustion of the carbonaceous materials, and a scrubbing unit to remove the hydrogen chloride fumes and metallic salts. Paper insulation on burns with too many problems of an air pollution nature. Fly ash is the biggest problem and this can be removed by a cyclone, electrostatic precipitator, or a wet scrubber. Processing of nylon insulation with primary and secondary combustion chambers will emit a gas containing mostly carbon dioxide and water. Since hydrogen chloride will be generated by burning neoprene, the gases must be passed through a scrubber. The burning of teflon releases hydrogen fluoride, and great care should be exercised.

DISPOSAL METHOD OF WASTE GAS CONTAINING HYDROFLUORIC ACID. (HF ganyu haigasu no shoriho). Text in Japanese. (Otomi Sangyo Co., Ltd., Osaka (Japan)) Japan. Pat. Sho 48-37662. 3p., Nov. 13, 1973. 4 refs. (Appl. June 3, 1966, 1 claim).

A method for the disposal of waste gas containing hydrofluoric acid produced during the manufacture of phosphate fertilizer and electrolytic manufacture of aluminum is presented. The waste gas containing HF is treated with an acidic solution containing alkaline salt to recover HF as acidic fluorides of alkali, which is neutralized by ammonia to produce both ammonium fluoride and alkali fluoride. The alkali fluoride so obtained is used for neutralizing the free acid formed in the process. The neutralization reproduces the alkaline salt which is recirculated for repeated use in the disposal process.

B. CONTROL METHODS

127

ide and 1.3 kg nitrogen oxides per ton of trash are emitted on the average. The contribution of incinerators to the total pollution is relatively low. Incinerators pose mainly a local pollution problem which can be rather easily solved because of the relatively high concentration of the pollutants in the waste gas. High collection efficiencies can be achieved with simple technical facilities. The removal of HCl and HF from waste gases is successfully applied in a number of processes. Even behind incinerators, scrubbers have been successfully used. Although these scrubbers have been primarily used for dust collection, every expert knows that simultaneously a high collection efficiency for HO and HF is achieved. Calculations of the investment and operating costs of scrubbers are given.

REMOVAL OF HF FROM AN HF-CONTAINING GAS. (du Pont de Nemours (E. I.) and Co., Wilmington, Del.) U. S. Pat. 3,743,704. 2p., July 3, 1973. 4 rets. (Appl. May 12, 1971, 4 claims).

A process for removing hydrogen fluoride from an HF-containing gas by scrubbing is described. The gas is scrubbed with water so that the HF enters the aqueous phase to form hydrofluoric acid, and the gas phase is vented as virtually HF-free gas. Precipitation of the fluoride ion in the aqueous solution as calcium fluoride is carried out by adding calcium hydroxide, calcium carbonate, or a mixture to the solution. Settling of the precipitate is improved by adding calcium sulfate to the aqueous solution during the reaction forming the precipitate. The precipitate is readily filterable. The aqueous phase which remains is virtually free of HF and can be used for scrubbing the HF-containing gas. The neutralization reaction which accompanies addition of Ca(OH)₂ or CaCO₃ to the aqueous solution can be carried out in two steps, first to partially neutralize the solution, e.g., pH up to six so that the solution is still able to be pumped to a settling tank, and second to complete neutralization in the settling tank. The CaSO₄ addition can be postponed until the addition of Ca(OH)₂, CaCO₃, or their mixture to the settling tank. (Author abstract modified)

THE TECHNIQUES OF TREATING THE AIR POLLUTING POISONOUS SUBSTANCES. (Taiki osen kankei yugai busshitsu shori gijutsu). Text in Japanese. Seikatsu Eisei (J. Urban Living Health Assoc.), 17(4):133-143, April 1973. 5 refs.

Poisonous gases are eliminated by a wet gas absorption process. The main role of the equipment used for this is to increase the contact area between the gas and liquid as much as possible by dispersing the gas through the liquid. This can be done by a packed tower (PT), spray tower (ST), cyclone scrubber (CS), venturi scrubber (VS), jet scrubber (JS), wetted wall tower (WWT), and gas bubble column. Hydrogen fluoride and silicon fluoride can be eliminated by dissolving them in water using ST, PT, VS, or JT. The HF is collected by treating the solution with calcium hydroxide or sodium nitrate, or by absorption on calcium oxide. Fluorine should be dissolved in 5 to 10% sodium hydroxide. Chlorine can be eliminated by washing with water or alkaline solution, or by adsorption. The WWT is used when the concentration of poisonous gas is high, and PT or ST when it is low.

Fish, William M.

ANTI-POLLUTION METHOD. (Aluminum Co. of America, Pittsburgh, Pa.) U. S. Pat. 3,760,565. 4p., Sept. 25, 1973. 4 refs. (Appl. July 19, 1971, 7 claims).

Removal of fluoride from a stream of gas contaminated with fluoride is described. Fluoride is adsorbed on alumina moving in the same direction and in contact therewith for not exceed-

ing 20 sec. This method can be used to remove fluorides such as hydrogen fluoride from various off gases such as off gas from electrolytic cells used in production of aluminum by electrolysis of alumina. This invention is less costly and more efficient than previous methods using static and fluidized beds of alumina, since it requires a shorter contact time between alumina and fluoride. Alumina used in removal of fluoride from off gas from electrolytic production of aluminum can be used as alumina to be electrolyzed in one or more cells, resulting in a highly economical use of alumina. FLUE GAS DESULFURIZATION FACILITIES FOR SMALL BOILERS AND A GAS WASHING EQUIPMENT. (Kogata boirayo haien datsuryu sochi to mezarato gasu senjo sochi). Text in Japanese. Boira Gishi (Boilermen), 29(1):10-15, Jan. 1974. The stack gas desulfurization facilities for small boilers, developed by Ebara Manufacturing Co., are described. Sulfur dioxide produced by the burning of heavy oil is dissolved in caustic soda to form sodium sulfite, which is, in turn, converted into sodium sulfate by special oxidation equipment and the caustic soda absorption liquid recycled. The facilities are characterized by high efficiency, low pressure loss, low power consumption, simplicity and compactness of design, easy maintenance, good adaptability to variation in gas volume, and the prevention of white smoke by a white smoke remover. Also described is the Ebara mesh plate tower gas washing facility designed to remove fluorine gas and dust from aluminum electrolysis factories.

POLLUTION AND ITS ABATEMENT IN FERTILISER INDUSTRY. Indian J. Environ. Health, 15(4):289-303, Oct. 1973. 42 refs.
Control methods for major air pollutants generated by fertilizer manufacturing operations are reviewed. Pollutants of significant concern include: dust, sulfur oxides, nitrogen oxides, fluorides, and ammonia. Abatement methods outlined include: collectors, wet scrubbing methods, electrostatic precipitation, various filter devices, dry absorption and adsorption processes, chemical and catalytic reduction, catalytic oxidation, combustion techniques, and by-product recovery. Major effects on the environment and human health are also tabulated for are also tabulated for each pollutant considered.

Ministry of Labor, Health, and Welfare of North Rhine-Westphalia (West Germany)
ENERGY GENERATION. (Energieerzeugung). Text in German. In: Reine Luft fuer morgen. Utopie oder Wirklichkeit? Ein Konzept fuer das Nordrhein-Westfalen bis 1980. p. 40-51, 1972. The state of the art and the evolution expected until 1985 in particulate matter, sulfur dioxide, nitrogen oxides, and gaseous
<xref image="2000WVDJ.TIF|V3|2006:09:28:01:23:46.00|112101|0"> image: </xref>

fluoride emissions from energy generation processes in power plants and in industries in North Rhine-Westphalia are outlined. Reduction of coal consumption, and increase in both fuel oil and natural gas consumption in both power plants and industrial power plants are expected during the period ending 1985. Accordingly, increases in the particulate matter, SO₂, NO_x, and F emissions would be unavoidable without further emission control measures. The installation of automatic recording instruments for the control of the combustion equipment alone would result in a decrease of about 50% in the dust emissions. Limitation of the dust emissions to 150 mg/N cu m in pit coal firings, to 100 mg/N cu m in brown coal firings, and to 0.6 kg/ton of heavy fuel oil by means of centrifugal dust separators would result in a decrease by 76% in the particulate matter emissions. Further decrease would be possible by increasing the efficiency of the dust separators in coal-firing equipment, and thereby limiting the dust emissions from pit coal firings and brown coal firings to 100 mg/N cu m and to 50 mg/N cu m, respectively. The flue gas desulfurization and coal desulfurization efficiencies are expected to reach 80% and 30%, respectively, and desulfurization of heavy fuel oil to 1% is anticipated. Heavy fuel oil with over 1% sulfur should be used in power plants with flue gas desulfurization, and industrial power plants should use fuel oils with less than 1% S. The SO₂ emissions could be decreased by 54% by the use of fuel oil with a maximum S content of 1%, and of desulfurized coal in power plants equipped with flue gas desulfurization facilities. Flue gas desulfurization would also result in a decrease in the fluoride emissions by about 48%.

CHEMICAL INDUSTRY. (Chimie). Text in German. In: Reine Luft fuer morgen. Utopie oder Wirklichkeit? Ein Konzept fuer das Nordrhein-Westfalen bis 1980. p. 14-26, 1972.

The state of the art and the expected evolution of air pollutant emissions in different branches of the chemical industry in North Rhine-Westphalia are outlined. The output of the chemical industry is predicted to rise by 320% by 1985, and new products will also cause new emission problems. The increase in the output will be highest in the most emission-intensive branches, e.g., plastic materials, synthetic fibers, and other organic materials. Organic gases and vapors, such as aldehydes, ketones, carbonic acids, organic sulfur and nitrogen compounds, hydrogen sulfide, sulfur dioxide, hydrochloric acid, fluorine compounds, carbides, arsenic, asbestos, and dusts of ferroalloys are the basic pollutants emitted by chemical plants. Since the emissions from synthetic fiber manufacturing plants would increase by 420% by 1985, all new plants to be put into operation in 1973 or later will have to be equipped with adequate emission control equipment for an emission abatement of 80%, and a similar reduction will be required for old plants from 1978. The same degree of emission abatement will be required for all new and old production plants in the pesticide manufacturing area from 1973. The SO₂ emissions from sulfuric acid production can be lowered by 85% by the introduction of the Bayer double-contact process. The nitrous gas emissions from nitric acid production can be abated by 88% by catalytic reduction by means of natural gas or hydrogen. Abandonment of open-air operations, leakage control, automatic control of chemical processes, total, multi-stage or combined purification of malodorous and toxic emissions, and the use of recording analytical instruments are the basic possibilities of emission abatement in the chemical industry as a whole.

THE PRESENT AND FUTURE AIR POLLUTION BY INCINERATORS - EMISSION AND REDUCTION OF EMISSIONS. (Die derzeitige und zukuenftige Luftverunreinigung

durch Muellverbrennungsanlagen - Emission und Emissionsverminderung). Text in German. Staub, Reinhaltung Luft, 33(12): 483-489, 1973. 43 refs.

Measurements carried out in many refuse incineration plants have shown that, by using high-quality dust separators (electrostatic precipitators) or by optimum firing, it is possible to reduce the emission of dust and of unburned organic gases to relatively satisfactory values. However, the emissions of inorganic gases such as hydrogen chloride, hydrogen fluoride, sulfur dioxide, and nitrogen oxides present problems. About one half of the present HCl emission is due to the burning of chlorinated plastics (PVC). A forecast made for 1980 shows that this emission will increase. At present, wet separation is used to remove HCl and HF from waste gas. Operating experience and possibilities of optimizing the method are discussed.

Teller, Aaron J.

PROCESS FOR RECOVERING GASEOUS HF FROM GASEOUS EFFLUENTS. (Wellman-Lord, Inc., Lakeland, Fla.) U. S. Pat. 3,773,633. 7p., Nov. 20, 1973. 5 refs. (Appl. March 13, 1970, 23 claims).

A process is described for recovering hydrogen fluoride from gases by contacting the gases with alumina pretreated with sodium hydroxide, potassium hydroxide, or their mixture. This process can be used to recover gaseous HF from the waste gases produced in the manufacture of aluminum by the electrolytic process. The recovered HF can be reused in the electrolytic process. In a modification of this invention, the gases can be scrubbed by inertial impaction to remove particulates before they are placed in contact with the pretreated alumina for HF removal. METHOD AND APPARATUS FOR CLEANING WASTE FLUE GASES. (Hitachi Co., Ltd., Tokyo (Japan)) Brit. Pat. 1,333,635. 6p., Oct. 10, 1973. (Appl. Nov. 16, 1971, 6 claims).

A method and apparatus for cleaning waste flue gases by removing such toxic gases as sulfur dioxide, nitrogen dioxide, nitric oxide, hydrogen sulfide, hydrogen fluoride, and fluorine is described. The method consists of spraying a reactant solution in the form of a fine mist into a hot waste flue gas, causing the toxic components contained in the waste flue gas to be absorbed by and react with the reactant solution. The water present in the droplets of the reactant solution is dried by the sensible heat of the waste flue gas and the reaction products are collected in the form of solid particles. The entire operation is carried out within a single spray drying tower in a short period of time in a manner to prevent a temperature lowering and humidity increase of the waste flue gas caused by the vaporization of the water contained in the sprayed reactant solution. The humidity of the flue gas released into the atmosphere is constantly maintained above the dew point to prevent the atmospheric pollution otherwise caused by the flue gas.

AIR POLLUTION CONTROL IN GLASS INDUSTRY. (Garasu kogyo ni okeru taikiosen boshi taisaku). Text in Japanese. Seramikkusu (Ceramics), 9(1):49-55, Jan. 1974.

In the processes of glass production pollutants like sulfur oxides, nitrogen oxides, poisonous compounds, and dust are emitted. The allowable amounts of these products are regulated by laws issued by the central government or by contracts made between the local governments and the manufacturers. Sulfur oxides produced by combustion of heavy oil and pyrolysis of mirabilite are removed by wet desulfurization (Evergreen method) or dry desulfurization methods. In either case sulfur oxides are absorbed by sodium hydroxide solutions and oxidized by air, and then recovered as mirabilite. The desulfurization rate is better than 97% in the wet method and 80-90% in the dry method. In factories of the Asahi Co., Ltd., installations handling 370, 70, and 280 kcu m/hr of SO_x-containing gas are operated. Fluorine compounds exhausted during glass production are handled by two methods. In the dry method fluorine reacts with lime or alumina and 99.5% of the fluorides are removed by a bag filter lowering the contents in exhaust gas to below 1 mg/Ncu m. In the wet method fluorides are absorbed by sodium hydroxide solutions to give a removal rate of better than 97% and a fluoride content of below 1 mg/Ncu m. No effective process has yet been obtained to remove nitrogen oxides, although concentrations in the exhaust gas from the melting furnace are from 310-1400 ppm. An electric melting method is now being investigated to solve pollution problems in the industry.

Fuller, William Robert, Barrie Hill Bieler, and David Cecil Morgan

METHOD OF REDUCING HALIDE EMISSIONS FROM THE INCINERATION OF HALOGEN-CONTAINING PLASTICS. (Dow Chemical Co., Midland, Mich.) Brit. Pat. 1,325,460. 4p., Aug. 1, 1973. (Appl. Oct. 2, 1970, 10 claims).

A method of reducing halide emissions from the incineration of halogen containing plastics is described. The emissions can be substantially reduced by adding to the polymer a mineral alkali or alkali precursor before it is incinerated. It can be added to the waste in the form of an aqueous dispersion or of a particulate solid or powder. The suitable alkalis include hydroxides, oxides, carbonates, carboxylates, xanthates, sulfites, and hydrosulfites of the alkali and alkaline earth metals. Particularly good results can be obtained if a cellulosic waste (as paper) is also added and mixed with the halogen containing organic polymer waste before it is incinerated. The waste is preferably reduced to shredded or particulate form before it is incinerated. Advantageously the alkali or alkali-precursor is added to the shredded or particulate waste in an amount to provide 0.4 to 1 mole of alkali for each mole of halogen emission generated by the burning of the waste.

TECHNIQUE OF DISPOSAL OF DISCHARGED GASES. (Haigasu shori gijutsu. 1.). Text in Japanese. Seifuti Daijesuto (Safety Dig.), 19(9):351-363, Sept. 1973.

Waste gas treatment and characteristics of poisonous gases and steams are discussed. For the treatment of stack gases, physical properties (such as boiling point, melting point, specific gravity, and vapor pressure), chemical properties (such as inflammability and explosiveness), and biological properties (such as toxicity) are important. Absorption, adsorption, combustion, and catalytic oxidation are used as control methods. Water and solutions of alkali in water are often used for the absorption of waste gases. Hydrogen chloride, hydrogen sulfide, and various acidic gases are effectively

eliminated by this method. Active carbon is effective for the adsorption of nonpolar solvent vapors. Regeneration of active carbon is done with water vapor. Combustion is effective for organic gases, but this method cannot be used for waste gases containing sulfur compounds, sulfides, halogens, amines, and various nitrogen compounds because these appear as hazardous gases after combustion. Various data are given for chlorine, hydrocyanic acid, mercury, hydrofluoric acid, hydrogen sulfide, ammonia, carbon monoxide, hydrochloric acid, sulfur dioxide, ethylene cyanide, phenol, carbonyl chloride, formaldehyde, CH₂CHCH, and toluene diisocyanate and other lesser compounds.

62786

(Inventor not given.)

REMOVAL OF HF FROM AN HF-CONTAINING GAS. (Du Pont (E.I.) de Nemours, Wilmington, Del.) Brit. Pat. 1,342,703. 3p., Jan. 3, 1974. (Appl. May 12, 1972, 10 claims).

A process for the removal of hydrogen fluoride from an HF-containing gas is described. The HF-containing gas is contacted with water to form an aqueous HF solution. The solution is neutralized with calcium hydroxide, calcium carbonate, or mixtures of them in the presence of calcium sulfate. The presence of CaSO₄ is an improvement over other systems using Ca(OH)₂ because the sulfate alters the gelatinous nature of the precipitate to a form which settles more rapidly and which is more readily filterable from the aqueous solution.

Mohanrao, C. J.

POLLUTION IN FERTILISER INDUSTRY. Fertiliser News., 18(11): 7-13,16, Nov. 1973. 10 refs.

The control of air pollutants from the fertilizer industry in India is discussed. The Indian Standards Institution is in the process of setting up air quality standards. The major pollutants are dust, sulfur and nitrogen oxides, fluorides, hydrogen sulfide, and ammonia. Commonly used dust control units include cyclone separator, wet scrubbers, bag filters, and electrostatic precipitators. The reduction of SO_x in stack gas is accomplished by dry processes, wet processes, catalytic oxidation, and reduction. The NO_x from the nitric acid and nitrophosphate plants are treated by absorption, adsorption, and catalytic reduction through the double combustion process or selective reaction process. The fluorine compounds are normally removed by wet scrubbing.

STATEMENT ON CURRENT PRACTICE FOR THE REDUC-
TION OF FLUORIDE EMISSION IN THE BRICK AND TILE
INDUSTRIES BY SCRUBBING OF THE FLUE GASES. (Fest-
stellung des Standcs der Technik zur Verminderung der
Fluoremission in der Ziegelindustrie durch Reinigung der Ab-
gase). Text in German. Ziegelind. (Weisbaden), no. 4:155-162,
1974.

A state-of-the-art report on the separation of fluorine and sul-
fur oxides in the brick and tile industry is presented. The sul-
fur oxides and fluorides generated in firing processes in the
ceramic industry are due to the inherent sulfur and fluorine
contents of the fuels and raw materials, respectively, which
make neutralization and separation of the pollutants the only
possible solution. Sulfur dioxide, sulfur trioxide, and gaseous
fluorides present in the flue gases in firing processes can be
adsorbed and neutralized to form solid particles by dry and
wet methods, especially by the injection of lime with sub-
sequent dust separation by means of bag filters or electrostatic
precipitators. While the dry processes have increasingly
replaced the wet ones, scrubbing with lye solution is especially
suitable for the joint removal of sulfur oxides and fluorine.

ADSORPTION OF FLUORINE AND FLUORINE COM-
POUNDS ON ALUMINA. (Air Industrie, Courbevoie (France))
U. S. Pat. 3,780,497. 7p., Dec. 25, 1973. 3 refs. (Appl. Aug. 20,
1971, 10 claims).

A method is provided for adsorbing fluorine on particles of
alumina, the fluorine being in the elemental state or in the
form of gaseous fluorine compounds, and for collecting any
ultra-fine dust resulting for example from sublimation. The
fumes charge with fluorine compounds are one of the most un-
pleasant sources of atmospheric pollution, and their removal
upon leaving electrolytic baths is necessary. The adsorption of
the fluorine compounds on powdered alumina mitigates at-
mospheric pollution. The alumina particles are introduced at
the base of an adsorption column through which the stream of
gas to be scrubbed flows, the column terminating in a separa-
tor where the particles charged with fluorine are recovered.
The path of the exhaust gas is cyclone separator to cloth-filter
separator to scrubber. The method is particularly suitable for
scrubbing of gas from electrolytic baths in an aluminum-
producing plant.

FILTER AND METHOD FOR LOWERING ACIDIC GAS
DISCHARGE IN EXHAUST PROCESS GAS. (Verfahren und
Filtervorrichtung zum Senken von Saeuregasausstroemungen in
einem ausstroemenden Prozessgas). Text in German. (Teller En-
vironmental Systems, Inc., New York) W. Ger. Pat. Appl.
2,251,031. 15p., May 10, 1973. (30 claims).
Hydrogen fluoride, hydrogen chloride, and chloride are
removed from industrial spent gases from glass making and
aluminum producing processes by passage through sieves of
finely divided nephelite syenite ore or alumina activated with
sodium hydroxide or sodium carbonate. The adsorbents are
blown as a finely dispersed powder or sprayed in aqueous
suspension onto a sacking cloth filter 11.15 sq m to a depth of
1.27 mm. The acidic gases may be passed through a similar
bed of adsorbent. The process may be continuous or carried
out batch-wise.

64092

Walthall, J. H.

COMPACT SCRUBBER LESSENS DUCTWORK. Chem.
Process. (Chicago), vol. 28:93, Aug. 1965.
A fume control system was designed to draw air from a su-
perphosphate-curing den and to scrub out varying amounts of

fluoride which would minimize costly ductwork use in controlling the corrosive fluorides. The fluoride concentration ranged from 0 to 0.001 lbs/cu ft during a 24-hour cycle of operation. The volume handled was 12,500 cu ft/min of gas. A jet-venturi flame scrubber operating on a principle similar to a steam-jet ejector was selected as the control method. It used a water or aqueous solution and a spray nozzle. With a concentration of 0.001 lbs/cu ft fluoride, when the fluorine content of the scrubber liquor is limited to about 3000 ppm, removal efficiency was approximately 98%.

Graetz, Reinhard

FLUORIDE IN CERAMIC MATERIALS AND FUELS -
PROVISION OF MATERIALS FOR THE PREVENTION OF
FLUORIDE EMISSION. PART I. (Fluor in keramischen
Materialien und in Brennstoffen. Stoffliche Massnahmen zur
Vermeidung von Fluor-Emissionen (Teil I)). Text in German.
Ziegelind. (Wiesbaden), no. 4:164-168, 1974. 27 refs. BSTRACT
The general problem of fluoride emissions, and the possibility
of reduction of fluoride emissions in the stone and earth indus-
try by the use of clays and fuels with low fluorine contents,
and by stabilizing fluorine during the burning process, are
described. Flue gas scrubbing for fluorine removal is not prac-
tical in the stone and earth industry due to the prohibitively
high costs involved. During the burning process, gaseous
fluorine emission should be prevented. Clays contain 0.01-0.1
weight percent fluorine, of which less than 20% are emitted in
the flue gases

PROCESS FOR REMOVING HYDROGEN FLUORIDE FROM
GASES CONTAINING IT. (Metallgesellschaft Aktien-
gesellschaft, Reuterweg (Germany) and Vereinigte Aluminium-
werke Aktien-Gesellschaft, Gerichtsweg (Germany)) Brit. Pat.
1,341,313. 8p., Dec. 19, 1973. (Appl. Nov. 12, 1971, 7 claims).
An adsorption process for removing hydrogen fluoride from
gases in electrolytic aluminum recovery plants is described
which allows good absorption at relatively high gas
throughputs as compared to prior art adsorption processes.
The gases which contain HF are injected as a fluidizing gas
into a fluidized bed reactor containing a solid adsorbent for
the HF at such velocity that they cause the solids to form an
expanded fluidized bed in which the solids concentration
decreases upwardly and from which solids containing adsorbed
HF are discharged in an upward direction due to the velocity
of the gases. The solids are thereafter separated from the
gases. A preferred embodiment of the process involves supply-
ing fresh solid adsorbent continuously to the fluidized bed,
with HF-containing solid adsorbent being continuously
removed from the bed.

B. CONTROL METHODS

131

(Emissionsbegrenzung an Abfallverbrennungsanlagen - Er-fahrungen mit einer Pilotanlage fuer die Schadgasbeseitigung). Text in German. Aufbereitungs Technik, 15(5):229-233, 1974. A gas scrubber pilot plant was installed in the incinerator operated by the city of Duesseldorf. The plant should help to determine the efficiency of the scrubbing method concerning elimination of hydrogen chloride, hydrogen fluoride and sulfur dioxide. Of these pollutants, the following weight fractions per cubic meter are measured in the flue gases from incinerators. up to 2000 mg hydrochloric acid, up to 1000 mg sulfur dioxide, 20 mg hydrogen fluoride and 400 to 500 mg nitrogen oxides. The flue gases which come from the electrostatic precipitator with a temperature of 280 C are cooled to 75 to 80 C and passed through a venturi scrubber and a droplet separator. The results indicate an increase of the HCl collection efficiency with increasing water quantity. At a stepwise artificial increase of the HCl concentration in the uncleaned gas to 5 g/cu m the HCl concentration in the cleaned gas rose as anticipated but the collection efficiency improved too. The collection efficiency for SO2 too depended on the water quantity and on the pH value of the scrubbing water. The residence time in the scrubber was too short to obtain any higher collection efficiency than 60 percent. Through installation of a second scrubbing stage an essential improvement of the SO2 collection efficiency was achieved. Experiments are still in progress so that no final results can be given.

EXHAUST GAS CLEANSING METHOD AND DEVICE. (Haigasu joka hobo oyobi shochi). Text in Japanese. (Hitachi Co. (Japan)) Japan. Pat. Sho 49-24342. 5p., June 21, 1974. (Appl. Dec. 4, 1970, 2 claims).

A cleansing method and device for exhaust gas containing sulfur dioxide, nitrogen dioxide, nitric oxide, hydrogen sulfide, sulfur, hydrogen fluoride, and fluorine based on the chemical reaction with substances such as sodium hydroxide are described. In the vaporization tower, the exhaust gas is mixed with a spray mist of reaction solution, the toxic gases absorbed into the reaction solution undergo reactions, and the reaction products are solidified by the evaporation of water with heat retained in exhaust gas and recovered as solid particles. In the device of this invention, the vaporization tower with exhaust gas inlet located at the top and outlet located on the lower side wall is equipped with spray nozzles for supplying reaction solution mist located at the upper part of the tower. The detector device for measuring the toxic gas concentrations at the inlet of the tower and the supply system of reaction solution, in which the ratio of water and reactant is adjusted depending on the toxic gas concentration by means of the electrical signal from the detector, are connected to the vaporization tower. The supply of reaction solution is regulated so that the temperature in the vaporization tower would be maintained above the dew point by monitoring the temperature and humidity at the exhaust gas outlet of the tower. The exhaust gas containing solidified reaction products is led into a cyclone, separated, and recovered. A part of the solidified reaction product is led out of the tower through the outlet pipe with rotary valve or double air lock damper located at the bottom of the tower.

RECOVERY OF FLUORIDES AND THEIR REUSE IN THE ALUMINUM REFINING INDUSTRY-CONSTRUCTION OF AN ALCOA DRY SCRUBBER. (Aruminium seiren kogyo ni okeru fukkabutsu no kaishu to sono sairiyo? Arukoashiki dorai sukuraba no keiIset.su). Text in Japanese. Kagaku Kojo (Cheni. Factory), 18(8):81-84, Aug. 1974. A dry scrubber for hydrogen fluoride recovery was discussed.

Gases containing fluorides from an electrolytic furnace are introduced to the reactor where a flow bed is formed and HF is absorbed on alumina. Particles and dusts in the gas are collected with a bag filter above the flow bed and removed periodically. Clean gas which passes through the bag filter is released from the top of the reactor. Distribution of gas in the reactor is homogeneous and the area efficiencies which determine the reactor efficiency are high. The depth of the flow bed can be adjusted between 50 and 300 mm. The bag chamber above the flow bed comprises a row of bag filters and shaking rods. The total height of the bag chamber is 8 ft. Flue gases to the reactor were introduced from the main duct through a number of branch ducts designed to give an optimum operation cost.

Droscha, Hellmut

HEAT AND ELECTRIC POWER FROM PRESSURE

GASIFIED COAL. (Waerme und Strom aus druckvergaseter Kohle). Text in German. Technica, 23(17):1403-1404, 1974.

An integrated coal pressure gasification and power generating pilot plant with a capacity of about 170 MW has been erected in Luenen, Westphalia, Federal Republic of Germany. A full-size plant is already under development. The main operating materials are coal, water, and air. The hot gas produced from coal first passes a scrubbing cooler and then drives with a pressure of 20 atm an auxiliary turbine which is succeeded by a compressor where preliminarily compressed air is further compressed to the pressure required for coal gasification. The gas, which now leaves the auxiliary turbine with a lower pressure, enters the combustion chamber of the steam boiler where it is burned together with compressed air at which process a high amount of heat is liberated. This is used for generation of high-pressure steam. At the same time the combustion gases drive the main gas turbine. The steam with a pressure of 130 atm and a temperature of 525 C drives the steam turbine of the system whose generator produces the main quantity of electric energy. The plant works with an efficiency of 43%. The pollutant emission is down to 1/4 of the emission of conventional plants. The dust and fluorine emission has been eliminated almost entirely, the emission of oxides of sulfur has been reduced by 90% and that of the oxides of nitrogen has been cut to 1/2.

COUNTERMEASURES FOR PREVENTING AIR POLLUTION

CAUSED BY GLASS INDUSTRY. (Garasu kogyo ni okeru taiki osen boshi taiseaku). Text in Japanese. Seramikkusu (Ceramics), 9(1):15-21, 1974.

Emission standards for general glass industries are: 1.0 mg/N cu m for cadmium and its compounds, 10 mg/N cu m for fluorides, and 20 mg/N cu m for lead and its compounds. The standards are much more stringent in Kaganaga prefecture, and are 0.5, 2.5 and 10, respectively. Emission standards for soot and dusts for glass industries are also stricter in Kanagawa prefecture than in other prefectures. Various control measures for air pollutants emitted by glass industries are discussed. For controlling sulfur oxides, the use of low sulfur fuels, high stacks, stack gas desulfurization systems are successfully employed. For dusts and soot, electrostatic precipita-

<xref image="2000WVDN.TIF|V3|2006:09:28:01:24:00.00|123372|0"> image: </xref>

tors and filters can keep the emission concentrations to less than 0.05 g/N cu m. For toxic substances, more than 98% of lead and cadmium compounds can be eliminated by specially designed electrostatic precipitators. Fluorine, hydrogen fluoride, and silica fluoride are absorbed by powder absorbents such as slake lime and alumina, and filtered by glass fiber bag filter. The elimination rate exceeds 99.5%. The wet method of absorption utilizes caustic soda solution as absorbent. The process includes gas cooling, gas scrubbing and liquid waste treatment. The efficiency is more than 97% and the rate of dust collection is more than 75%. Fluorides in the stack gas are less than 1 mg/N cu m and soot is less than 0.05 g/N cu m. The emission standards for nitrogen oxides are expected to be set in 1974. Denitrization in glass industries is problematical. Glass melting furnaces cannot adopt systems such as flue gas recirculation or two-stage combustion. The only method presently being studied is an improvement in combustion methods. Unanswered questions include the acceleration of denitrization reaction speed, elimination of interfering substances in the gas, and the use and treatment method for by-products.

FLUORINE RECOVERY BY THE PHOSPHATE FERTILIZER
INDUSTRY PART II COMMERCIALY AVAILABLE
PROCESSES FOR RECOVERING FLUORIDES ETC.
Phosphorus Potassium, no. 15:21-24, 28-29, July/Aug. 1971 4
refs.

Commercially available processes for the emission control of fluorine compounds in phosphate processing are discussed. In the past fluorine chemicals from phosphate plant off gases were scrubbed and disposed of, usually as fluosilicic acid. Today fluosilicic acid is the starting material for the production of a large range of fluorine compounds. The almost inexhaustible source of supply offered by recovery from phosphate processing has provided incentive for the development of a number of commercially feasible systems for the manufacture of materials as fluosilicates, fluorides, synthetic cryolite, and hydrofluoric acid from the fluorine effluent from phosphatic fertilizer production.

Reither, K.
CLEAN AIR MAINTENANCE IN THE METAL WORKING INDUSTRY. (Luftreinhaltung in der metallverarbeitenden Industrie). Text in German. Galvanotechnik, 65(7):628-630, 1974. The principle and uses in the metalworking industry of KT model gas scrubbers are described. The gas scrubbers, of vertical or horizontal cylindrical design, have spray nozzles parallel with and opposite to the waste gas flow. They are available for throughputs of 36,000 and 280,000 cu m/hr. Higher capacity can be achieved by parallel connection of several units. The scrubbers are characterized by small pressure losses comprised between 15 and 70 mm water column for single-stage, and between 30 and 40 mm water column for two-stage designs. The hydrochloric acid-containing waste gases from a continuous wire pickling unit are scrubbed with water, and the dilute hydrochloric acid solution obtained is recycled within the pickling process. In two-stage operation, the HCl concentration is reduced from 3000 mg/cu m to 0.5 mg/cu m. In an electroplating shop, the vent air loaded with droplets and vapors of chromic acid from a chromium-plating bath is treated with KT model scrubbers, and the chromic acid recovered is recycled within the process. The chromic acid concentration in the air is reduced from 0.21 mg/cu m to 0.003 mg/cu m. The hydrofluoric acid-containing air in an etching shop is purified by KT scrubbers, using dilute sodium hydroxide solution as absorbent. Water is used for absorption of cyanides from the air in a hardening shop.

ABSORBER FOR NEUTRALIZING ACID VAPORS
GENERATED IN CHEMICAL POLISHING OF GLASS. (Absorber dlya neytralizatsii kislotnykh isparenii pri khimicheskoy polirovke stekla). Text in Russian. Steklo Keram. (Glass Ceram.), no. 7:37-38, 1974.

A two-stage foam type absorber for the absorption and neutralization of hydrofluoric acid vapors from the air in chemical glass polishing shops is described. The air with the acid vapors is admitted at the bottom of a vertical plate column where a foam layer is formed over the plates for intensified contact between the wash liquid (water) and the air to be cleaned. The absorption efficiency amounts to 70-80%. If the residual HF output in the cleaned air exceeds 0.3 kg/hr further purification is done in a second stage at an efficiency of 91-96%.

THE PRESENT STATE AND FUTURE PROBLEMS FOR
MAINTENANCE AND MANAGEMENT OF HIGH TEMPERATURE BAG FILTERS. (Koonyo baggu firuta no hoshu kauri no genjo to kongo no mondai). Text in Japanese. Preprint, Japanese Society for Chemical Engineering, p. 18-25, 1974. (Presented at the Symposium on Practical Problems in Factory Dust Collection Systems, Tokyo, Japan, July 5, 1974.)

A dry type bag filter for treatment of high temperature exhaust gas from a fiber glass plant is described. The exhaust gas contains fluorides, sulfur trioxide, soot, and other components. Exhaust gas is cooled from higher than 750 to 250 deg and powder absorbent is added. The resulting gas is then introduced to a bag house and dust is reduced to 0.001 gr/N cu m and fluoride to less than 2 ppm. Exhaust gas must be cooled to a temperature below the limit applicable to the filter cloth. An individual bag ranges from 130 mm in diameter, 3 m long, to 300 mm by 10 m. A reverse-pressure dumper is used to remove dusts on the filter bag. The suitable tensile strength of the bag is 15 kg for the small size and 35 kg for the large size. The future problems include improvement of mounting method of the bag, development of new bag cloths using special treating agents, and increasing velocity of filtering air. By increasing air velocity the scale can be reduced, thus the cost is minimized.

Winkler, H. D.

MEASURES FOR REDUCING EMISSIONS FROM BRICK
KILNS. (Massnahmen zur Emissionsminderung bei Ziegeleien). Text in German. Gesundh.-Ingr., 95(9):267-271, 1974. 8 refs. (Presented at the Second Symposium on Branch-Specific Emissions, Fluorine Emissions by Brick Kilns, Munich, Feb. 1, 1974.)

For the reduction of fluorine emissions from brick kilns in principle two different methods are applicable, chemisorption and absorption. The dry chemisorption process is in general preferred over of the wet absorption process because it avoids the waste water problem. With the injection of pulverized calcium hydroxide into the flue gas flow a direct reduction of the gaseous fluorine compounds as well as of the oxides of sulfur

<xref image="2000WVDO.TIF|V3|2006:09:28:01:24:04.00|117996|0"> image: </xref>

B. CONTROL METHODS

133

can be achieved. A schematic diagram of the process is given. With this method clean gas concentrations of around 5 mg F/cu m could be achieved. Essential for a sufficient binding of the pollutants is a long residence time. Therefore the method is applicable only if the flue gas ducts are longer than 10 m. The particulate emission rises through the injection of pulverized calcium hydrate. A dust collector is therefore indispensable. The costs are lowest if a cyclone is installed for this purpose. Better results are achieved with a cloth filter, however. In the latter case the operating costs are as high as that of acid scrubbing. The dry system is in some plants presently in operation, however without dust collectors. Two plants in West Germany have been equipped with wet absorbers. For the collection of gaseous fluorine compounds, acid absorption with water and subsequent neutralization with lime-milk was found most suitable. Clean gas concentrations of less than 5 mg F/cu m were achieved with this method.

FLUORINE RECOVERY FROM PHOSPHATIC FERTILIZER

MANUFACTURE. Chem. Process Eng., vol. 48:43-47, Dec.

1967. 12 refs.

The present demand for fluorine is expanding so rapidly that the traditional sources ~ natural cryolite and fluorspar ? may soon be exhausted. An alternative source is fluorapatite, containing 3.5% fluorine, used principally for the production of superphosphate and phosphoric acid for fertilizers by the wet process. A process is described for using the by-product from the process, fluorosilicic acid, which is generally discarded, in the commercial production of fluorosilicates, cryolites, and fluorides. The fluorosilicic acid is produced during production of superphosphate and phosphoric acid when fluorine compounds in the stack gas are absorbed in a countercurrent scrubber. (Author abstract modified)

67137

ALUMINUM FLUORIDE FROM WET PROCESS

PHOSPHORIC ACID WASTES. Brit. Chem. Eng. Proc. Tech.,

17(7/8):609-610, July/Aug. 1972. 1 ref.

The wet phosphoric acid process evolves large quantities of fluorine compounds; upwards of 40-45 fluosilic acid kg/ton phosphoric anhydride emitted is recoverable. The present capacity of the fertilizer industry is enough to supply virtually the entire aluminum industry with the fluorine compounds it requires, particularly aluminum fluoride. A process capable of producing AlF_3 from H_2SiF_6 solution arising from the scrubbing of the waste gases evolved in the production of phosphoric acid is described. Variable costs for this process are cited. An approximate estimate of the investment for a plant to produce 100 tons/day of AlF_3 is \$752,000. An analysis is presented of investment distribution by different sections of the process and by function.

Morns, George O.

RECOVERY OF HYDROGEN FLUORIDE. (Imperial Chemical

Industries, Ltd., London (England)) U. S. Pat. 3,798,875. 4p.,

March 26, 1974. 2 refs. (Appl. Feb. 22, 1972, 16 claims).

A process for the recovery of hydrogen fluoride from gaseous mixtures is presented which overcomes prior art problems associated with heat transfer and breakdown of solid absorbents by using the absorbing solid in an inert liquid. The gaseous mixture is passed through a suspension of an alkali-metal fluoride, preferably sodium fluoride, in an inert liquid having a boiling point of at least 250 C. The suspension is maintained at a temperature below 180 C and at a temperature at which the hydrogen fluoride is absorbed by the suspension. The suspen-

sion is heated to a temperature of greater than 180 C for liberation of the hydrogen fluoride, with the suspension then being regenerated. The process may be applied to the recovery of hydrogen fluoride from mixtures in which the hydrogen fluoride content varies as much as from 2-98% by weight.

POWER PLANTS WITH COAL PRESSURE GASIFICATION.

(Kraftwerke mit Kohledruckvergasung). Text in German. VGB Kraftwerkstechnik, 54(8):S32-536, Aug. 1974.

For the first time in the Federal Republic of Germany the combined gas steam turbine process with preceding coal pressure gasification has been realized in the power plant Luenen. The gas from coal pressure gasification is burned in a steam generator at high overpressure. A gas turbine is installed in the flue gas path where the temperature is between 800 and 1000 C. The steam produced is used in a conventional steam turbine set. The compressor of the gas turbine set supplies the gasification and combustion air. The gas from coal gasification is cleaned in a scrubber system to remove dust and tar residues. Subsequently the sulfur content is reduced by 90%. The power plant produces 170 MW, 74 MW coming from the gas turbine and 96 MW from the steam turbine. The entire power plant has been in operation for 3000 hr. The operating experiences to date are described in detail. The gas cleaning system failed to reach the guaranteed efficiency. The tar separator is presently being modified and enlarged. The hydrogen sulfide from the desulfurization plant is processed in a Claus plant to obtain elemental sulfur. Despite the present shortcomings, the dust emission is far lower than that of fossil fuel-fired power plants, the oxides of nitrogen emission is also far lower, and the desulfurization plant not only removes the sulfur dioxide content but also the fluorine content of flue gases.

Statens Naturvardsverk, Stockholm (Sweden)

AIR AND WATER POLLUTION PROBLEM IN FERTILIZER

PRODUCTION. (Vatten- och luftvardsproblem vid tillverkning av godsmedel). Text in Swedish. Kept. 1971:6, 120p., 1971. 8 refs.

The emissions and control of air pollutants from the fertilizer industry in Sweden are discussed. Atmospheric emissions for 1969-1970 in Landskrova totaled 100 kg/hr nitrogen compounds, 12 kg/hr fluorine compounds, 100 kg/hr sulfur dioxide, and 30 kg/hr of dust. In Koping the N₂ emissions were 170 kg/hr, phosphorus 0.2 kg/hr, F₂ 410 kg/hr, and dust 70 kg/hr. Pollution control measures are practiced: ammonia and F₂ are adsorbed, dust is removed with cyclones and filters, and residual gases containing F₂, nitrous gases, and dust are removed by scrubbing. Fluorine can also be controlled by using evaporated phosphoric acid which has a low F₂ content. Some by-products are recovered as NH₃ from a urea plant.

ENVIRONMENTAL PROTECTION IN ALUMINA

PROCESSING UNITS AND ALUMINUM PLANTS. (Kor-nyezetvedelem a timfoldgyarakban es aluminiumkohaszati uzemekben). Text in Hungarian. Musz. Tud., 46(3-4):363-378, 1973. 33 refs.

Environmental problems in alumina processing and aluminum melting plants are described. It is now possible to prevent dust emission by wet milling of bauxite in ball mills. The sulfur dioxide and alumina dust emissions generated during alumina calcination can be abated by the use of low-sulfur fuel, especially natural gas. Fluorine emissions, found to cause damage to forests and cattle around aluminum melting plants, can be abated by modern processes, such as the activated alumina process, filtration with alumina-coated bag filters, or flue gas scrubbing. The environmental nuisances due to red mud dumps, releasing alkaline dust steadily into the atmosphere can be best prevented by the complex utilization of this material for iron recovery, brick manufacture, or other purposes.

DISPOSAL OF FLUORINE BY REACTION WITH CHAR-

COAL. Du Pont (E. I.) de Nemours and Co., Aiken, S. C., Savannah River Lab., Atomic Energy Commission Contract AT(07-2)-1, 15p., Aug. 1974. 7 refs. NTIS: DP-1359

Tests were made to determine the type of charcoal and operating parameters best suited for fluorine disposal. Nonactivated wood charcoal was safe in operation, and heating of the charcoal to approximately 300 C was necessary for efficient reaction of fluorine. At low fluorine concentrations (less than 25% fluorine in the gas stream), the principal reaction product is a white fluorocarbon smoke. Carbon tetrafluoride is the principal product with 100% fluorine. A small amount of condensable fluorocarbons is formed by the fluorine-charcoal reaction. (Author abstract)

REMOVAL OF ACID COMPONENTS FROM REFUSE IN-

CINERATOR. (Verfahren zur Reinigung von Abgasen aus Muellverbrennungsanlagen). Text in German. (BAMAG Verfahrenstechnik GmbH, Butzbach (Germany)) W. Ger. Pat. Appl. 2,139,678. 2p., Feb. 15, 1973. 2 refs. (1 claim).

A method for the removal of acid gases such as sulfur dioxide, sulfur trioxide, hydrogen chloride, hydrogen fluoride, and

nitrogen dioxide from waste incinerator flue gases is described. The gas to be purified is passed through a loose layer of active carbon at a temperature that lies 30 C, and preferably 15 C, above the water-vapor dew point. In one example, when flue gas with 3000 ppm HCl, 1000 ppm SO₂, 300 ppm SO₃, 20 ppm H₂F₂, and 35 ppm NO₂ was passed through a 1.5 m thick active carbon layer at a rate of 0.45 m/sec and at 85 C, the purified gas contained 3 ppm HCl, 10 ppm SO₃, 1 ppm H₂F₂, and 5 ppm NO₂. The activated carbon is regenerated by washing first with water, and then with dilute ammonia solution.

Connor, J. M., G. J. Dell, and D. J. Newman
POLLUTION CONTROL IN ACID PLANTS. Chem. Age India,
23(2):103-117, 1972. (Presented at the UNIDO 2nd International
Fertilizer Symposium, Viev, USSR and New Delhi, India, 1971.)

Pollution problems and emission control measures are reviewed for plants involved in the production of sulfuric acid, phosphoric acid, and nitric acid. Incomplete conversion of sulfur dioxide to the trioxide is the fundamental difficulty encountered in H₂SO₄ plants. The double absorption process appears to be the most successful on a commercial scale for minimizing sulfur dioxide emissions. Fluorides released during rock digestion and acid concentration are the main problems of phosphoric acid production. These emissions can be minimized by use of properly designed scrubbers and by product recovery techniques. Nitric acid plants discharge unabsorbed nitrogen oxides in the absence of control measures. These can be most economically eliminated by reaction with fuel in a catalytic combustor. Adsorption of NO_x on silica gel or on molecular sieves is also feasible, though not economically competitive at present with catalytic combustion.

HYDROGEN FLUORIDE ABSORPTION TREATMENT

METHOD. (Fukka suiso no kyushu shoriho). Text in Japanese.

(Asada Chemical Industry Co., Himeji (Japan)) Japan. Pat. Sho
49-38440. 3p., Oct. 17, 1974. (Appl. Oct. 27, 1969, 1 claim).

When aluminum is electrolyzed a large quantity of fluoride gas is emitted, and this gas is usually treated by aluminum sulfate solution absorbent. But the absorption process is slow and the high temperature tends to create hydrogen fluoride from the by-product sulfuric acid when the aluminum fluoride settles. This invention prevents the secondary emission of HF and also improves the absorption rate of HF by using a solution of basic aluminum (30-60% of basicity). The HF is reacted while boiling to 30-60% base aluminum and is precipitated in the form of aluminum fluoride or its hydrate. The method of calculating basicity from the concentration of aluminum oxide and chlorine ion is described along with several examples.

PROCESS FOR THE ABSORPTION OF SiF₄-CONTAINING
OFF GASES IN WATER OR AQUEOUS HEXAFLUOSILICIC
ACID. (Verfahren zur Absorption von SiF₄-haltigen Abgasen in
Wasser oder waessriger Hexafluorkieselsaeure). Text in German.
(Assignee not given.) E. Ger. Pat. 88,078. 2p., Feb. 20, 1972.
(Appl. Jan. 13, 1971, 2 claims).

A method for the absorption of silicon tetrafluoride-containing waste gases in water or aqueous hexafluosilicic acid to obtain commercial hexafluosilicic acid of at least 20% concentration is described. The silicon tetrafluoride is absorbed in two successive, slotted-bottom absorbers with a maximum temperature of the absorbing suspension on the first absorption stage of 50 to 60 C, corresponding to a desired hexafluosilicic acid concentration of 20-30% to prevent incrustation of the absorber bottom. Cooling of the SiF₄-containing waste gas is achieved by dilution with cold air.

DOUBLE CATALYSIS SULFURIC ACID PLANTS FOR
COPPER CONVERTER GAS. Preprint, American Inst. of
Chemical Engineers, New York, 1974. (Presented at the
American Institute of Chemical Engineers, National Meeting,
78th, Salt Lake City, Utah, Aug. 18-21, 1974.)

A double catalysis sulfuric acid plant for the conversion of sulfur dioxide in copper converter gas to H₂SO₄ is described which achieves SO₂ emissions well below the 500 ppm level. As opposed to the conventional plant where the conversion of SO₂ to sulfur trioxide is carried out in three or four catalyst beds in series with cooling between the beds to remove the heat of reaction, the double contact catalysis plant removes a major portion of the SO₃ in an intermediate absorption tower after the second stage of conversion. The balance of the gas, which is returned to the converter for the final two stages of conversion, is a very weak SO₂ gas with a high oxygen/SO₂ ratio. The equilibrium conditions for this gas leaving the converter are very close to 100% conversion of the total SO₂ entering the converter. With steady state operation, which is not realized in practice, the overall conversion of SO₂ to SO₃ is greater than 99.8%. The presence of appreciable fluorine in the gas may require two scrubbing towers in series to achieve complete removal of the fluorine, this is primarily to protect the catalyst in the contact section of the acid plant. Sulfuric acid mist is removed in a purification section of the plant consisting of electrostatic mist precipitators

Mantle, E. C
PREVENTION OF AIR POLLUTION IN THE NON-FERROUS
METALS INDUSTRIES. BNF Metals Technology Center, Oxon
(England), 207p., 1974. 132 refs.

Methods for the assessment, prevention, and control of air pollution from the non-ferrous metals industries (primary smelting of copper, lead, zinc, and aluminum; melting and casting of non-ferrous metals and their alloys; and secondary metallurgical operations) are reviewed. Pollutants associated with such operations include: sulfur dioxide and sulfur trioxide, fluorides, dusts containing metals, metal oxide fumes, and solvent vapors. Prevention and control measures include: pretreatment of materials, fume containment and ducting, reduction of pollution by dispersal (stacks), and various collection methods. Principles of collection are discussed in terms of settling chambers, cyclone collectors, wet scrubbers, filters, and electrostatic precipitators. Sampling and monitoring requirements are reviewed in terms of techniques applicable to measurements in ducts or stacks, indoor atmospheric measurements, and outdoor ambient measurements. Threshold limit values for substances in workroom air (American Conference

of Governmental Industrial Hygienists, 1972) are also reviewed in an appendix.

Radke, D.

DRY CLEANING PROCESSES FOR WASTE GASES FOR SEPARATION OF DUSTS AND HYDROGEN FLUORIDE.

(Trockenreinigungsverfahren fuer Abgase zur Abscheidung von Staeben). Text in German. Tech. Mitt., 67(11):484-489, 1974. 6 refs. (Presented at the Seminar on Dust Collection in Industrial and Commercial Plants, Hans der Technik, Essen, West Germany, May 15, 1974.)

A dry method for the separation of hydrogen fluoride is described. Quicklime is agitated as separating agent in funnel-shaped reactors, reducing the hydrogen fluoride concentration to less than 1 mg/cu m waste gas. With the same method, hydrogen chloride could be separated on laboratory scale if quicklime dust was added to an oxygen lancing plant. The equipment comprises a radial ventilator, two reactors, one cyclone, one bag filter, and accessories such as armatures, pipes, lime storage and a feeder. The waste gas is pressed by the ventilator through two successive reactors where reaction of the fluorine with the agitated quicklime takes place and calcium fluoride is formed. The solid matter carried off with the waste gas from the second reactor is separated first in a cyclone and then in a cloth filter.

TREATMENT OF DUST FROM METAL MELTING FURNACE (NONFERROUS METAL).

(Kinzoku yokairo (hitetsu kinzoku) no baijin shori ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 9(2):429, Nov. 1974. (Presented at the National Air Pollution Research Conference, 15th, Chiba, Japan, Nov. 6-8, 1974, Paper 280.)

Results of an investigation on 217 facilities for metal processing in Osaka Prefecture (excluding Osaka city) are given. The facilities included 50 reverberatory furnaces, 148 crucible furnaces, and 19 low-frequency induction furnaces. Furnaces used to regenerate Al emitted Al metal fumes, chlorine, and fluorine, whereas those used for alloy manufacturing emitted metal fumes and sulfur dioxide. For the removal of metal fumes, bag filters were employed, and for the removal of metal fume accompanied with gaseous substances, a bag filter together with a scrubber was used. Results of measurement at a manufacturing plant showed that the combination of a bag filter and a scrubber reduced particulates from 0.11 g/N cu m to 0.04 g/N cu m, Cl₂ from 1896 ppm to 15 ppm, and HCl from 2000 ppm to 50 ppm.

CRITERIA FOR DESIGN AND SELECTION OF AIR POLLUTION CONTROL SYSTEMS. Central Labour Inst., Bombay (India), Proc. Semin. Air Pollut. Control Tech., India, 1973, p. 111-118. (Sept. 11-12.)

Guidelines are given for the control and dispersion of gaseous and particulate air pollutants commonly emitted by the fertilizer industry. Pollutants most frequently associated with chemical operations in fertilizer manufacturing include: sulfur oxides, carbon monoxide and dioxide, nitrogen oxides, ammonia, fluorides, and particulates. Gaseous pollutants can be removed from air streams by condensation, scrubbing, adsorption, or incineration. Vapors present in high concentration and at dew-point temperatures greater than 90 F can be removed by condensation (direct cooling or compression). Scrubbing can be used to remove pollutants at concentrations greater than 1% and soluble in water. Pollutants with molecular weights greater than the normal components of air can be removed by adsorption. Combustible vapors can be burnt in direct or catalytic units. Mists less than 10 micron and at low concentrations can be removed with electrostatic precipitators, scrubbers, high-density fibrous filters, or packed beds; while sprays greater than 10 micron in size and in concentrations greater than 1 grain/cu ft can be removed with inertia separators, coarse fibrous filters, or packed beds. Submicron particles (fumes can be cleaned from exhausts with high-energy wet collectors, electrostatic precipitators, or bag filters. Dusts between 1-10 micron can be removed with wet collectors and mechanical or inertia separators, whereas dusts greater than 10 micron can be cleaned from exhausts with settling chambers or cyclones. Effective dispersion of the final exhaust requires a stack height of at least two times the height of any surrounding obstacle. The stack should be designed to ensure that gases will escape the turbulent wake of the stack.

METHOD OF RECOVERING FLUORINE FROM WASTE GASES. (Elkem- Spigerverket A.S., Oslo (Norway)) U. S. Pat. 3,812,852. 3p., June 4, 1974. 3 refs. (Appl. March 19, 1973, 8 claims).

A method for the economical adsorptive recovery of fluorine components from high temperature (500 C) gas streams is described that utilizes steam to increase the amount of fluorine chemically bound to an aluminum oxide adsorbent. The amount of steam added to the dry gas stream must be at least 0.5% by volume of the waste gases and is generally not more than 25% by volume. The steam can be added directly to the waste gases as a separate stream or it can be added to the waste gases in a fluidized bed reactor. Alternatively, the dry fluorine-containing gases can be mixed with gases having moist fluorine. The contact between the gas stream and the aluminum oxide adsorbent occurs at temperatures above the boiling point of the water in the particular contacting environment and below temperatures at which fluorine adsorbed by the aluminum oxide is liberated during the contact period.

TURRET?ACIDIC GAS ABSORPTION BY WATER. (Teraretto?Mi/.u ni yoru sansei gasu no kyushu). Text in

Japanese. Kagaku Kojo (Chem. Factory), 18(11):49-55, Nov. 1974. 16 refs.

The of acidic gas by water is one of the most basic forms of gas absorption, and can be handled by physical absorption theory. Some calculation examples made to obtain data for designing a packed tower using S and L type turrets for the absorption of sulfur dioxide, hydrogen chloride, hydrogen cyanide, and hydrogen fluoride by water are shown. In an SO₂-air-H₂O system, the Whitney's equation constant, liquid-gas equilibrium and turret pressure loss under a given set of conditions were calculated. In the case of HCl-air-H₂O system, the calculations for tower diameter, packed tower height, and pressure loss to attain certain absorption rates are shown. In the case of phosphorus ore treatment as an example of the HF-air-H₂O system, the silicon tetrafluoride partial pressure over hydrofluosilicic acid solution, H₂F₂-SiF₄-H₂O phase composition and HF-H₂O equilibrium were calculated. Similar calculations were also made for an HCN-air-H₂O system. The effects of fume on absorption, particularly in the case of acidic gases such as sulfur trioxide, HCl, and chloric acid are discussed.

TREATMENT METHOD OF GASES CONTAINING HYDROGEN FLUORIDE AND SULFUR DIOXIDE. (Fukka suiso to nisanka iou konyu gasu no short hoho). Text in Japanese. (Denki Kagaku Kogyo Co. Ltd., Tokyo (Japan)) Japan. Pat. Sho 49-47629. 4p., Dec. 17, 1974. (Appl. Feb. 7, 1970, 1 claim).

An invention for the selective recovery of hydrogen fluoride and sulfur dioxide from waste gas emitted from phosphate fertilizer manufacturing processes is described. Waste gas containing 6.5 wt% water, 3100 ppm HF and 1600 ppm SO₂ at 280 deg is introduced into a cooling tower at 670 N cu m/hr. Hydrogen fluoride solution (9.4 wt%) at 60 deg and water at 25 deg were sprayed from the top of the cooling tower at a rate of 700 l/hr and 63 l/hr, respectively. The resulting gas containing 15.9 wt% H₂O at 60 deg is led to a gas absorbing tower to which water is supplied at 100 l/hr. Liquid containing 1.6 wt% HF and 0.005 wt% SO₂ at 58 deg is released from the bottom of the tower while gas is introduced to a desulfurization tower to which sodium hydroxide solution is supplied. The resulting gas contains no detectable HF and 11 ppm SO₂.

STUDIES CONCERNING THE SORPTION OF FLUORINE COMPOUNDS ON ION EXCHANGERS. (Untersuchungen ueber die Sorption von Fluorverbindungen auf Ionenaustauschern). Text in German. Staub, Reinhaltung Luft, 34(12):442-44S, 1974. 9 refs.

After successful laboratory experiments with anionic ion exchangers concerning sorption of hydrogen fluoride, experiments were earned out in a hydrofluoric acid production plant. The plant emitted 600 cu m waste gas/hr containing .0002-.0006 kg HF/cu m. Through the experimental set-up 300 cu m gas/hr were drawn. The waste gas entered the column which was equipped with two polyethylene grids with an average mesh width of 3mm. The grids carried two layers of anionic ion exchanger with a granulation of 4 to 6mm. The anionic ion

ENVIRONMENTAL PROTECTION IN ALUMINUM INDUS-

TRY. (Kornyezetvedelem az aluminiumpohaszatban). Text in Hungarian. Banyasz. Kohasz. Lapok - Kohaszat, 107(9):399-404, 1974. 7 rets.

Emission sources in the aluminum industry, and possibilities of air pollution abatement are described. Red mud dumps, when dried out, represent a major source of alkaline dust emissions. Calcining plant waste gases, containing sulfur dioxide, carbon monoxide, and red mud particles are cleaned in a system composed of a dust chamber, multicyclone, and electrostatic precipitator. The flue gas SO₂ content can be abated by the use of natural gas or low-sulfur fuel oil and by combustion air preheat. The fluorine, tar, and carbon monoxide emissions from electrolyzers can be abated by the adoption of closed-cycle technology, and wet or dry gas cleaning. In wet gas cleaning, the carbon, tar, and carbon monoxide present in the waste gases are incinerated, after which most of the soot and dust are separated in a cyclone. Further cleaning is done in an electrostatic precipitator and wet scrubber. Scrubbing can be done with water, or by acid and alkaline solutions used consecutively. Dry gas cleaning by means of alumina fluidized beds and bag filters reaches efficiencies of 99.9%.

(Inventor not given.)

POLLUTANT COLLECTION BY IRRADIATION. (Environ-

mental Master Systems, Inc., Canfield, Ohio) Brit. Pat. 1,360,402. 9p., July 17, 1974. (Appl. Oct. 26, 1971, 21 claims). An irradiation method for the collection of paniculate and gaseous pollutants (e.g., sulfur dioxide, nitrogen oxides, carbon monoxide, hydrocarbons, hydrogen fluoride, and hydrogen chloride) from coal-burning and various industrial processes is described that achieves such collection without the undue cost or complexity of prior-art methods. The pollutants are ionized with isotopic irradiation, thereby inducing conglomeration for subsequent collection. The apparatus for removing the pollutants includes a passageway with an inlet and outlet, a means to convey the effluent gases into the passageway inlet, an irradiation zone containing a high energy, high intensity isotope source (cobalt 60) positioned between the ends of the passageway, and a collecting means joined to the outlet passageway outlet to receive the irradiated pollutants. The isotope source is capable of creating a radiation field at energy levels of at least one million electron volts and exposing the pollutants to dosage levels of at least one kilorad.

A UNIT CAPABLE OF ELIMINATION OF FLUORINE AND

SULFUR FROM EXHAUST GAS. (Haien datsu fusso datsuryu

sochi). Text in Japanese. Mitsubishi Jushi Giho (Mitsubishi Plast. Tecb. Rev.), no. 8:78-80, Aug. 1974.

Japan Selcoat Co., Ltd. is planning to put a unit capable of eliminating fluorine and sulfur from exhaust gas on the market. This unit, which is a combination of a cellkit scrubber as gas absorption unit and a pre-coat-type exhaust gas treatment unit using the dehydration and drying method developed by Hiratsuka Environment Research Institute, is characterized by an excellent capacity to remove F and S, low operation costs, simple maintenance and operation, and compactness. The unit consists of a cooling process, absorption process, exhaust gas treatment process, and filtration-dehydration process. Exhaust gas is normally at such a high temperature that it must be

cooled by spraying water prior to the absorption process. If powder dust is present in much quantity, it can be removed with a cooling tower. If a cellkit fan is placed between the cooling tower and the absorption tower, it helps to prevent the smoke duct from being corroded.

Japan Environmental Agency

THE FUTURE OF ENVIRONMENTAL CONSERVATION. In:

Quality of the Environment in Japan, p. 57-80, 1974.

Local air control measures in Japan are evaluated and the scientific research and development upon which conservation is based is discussed. Pollution control on the local level advanced through preventive regulations and pollution prevention agreements with local firms. The use of automatic measurement and concentrated monitoring systems is widespread. Expenditures for anti-pollution measures increased twofold from 1970-1972. In 1972, 432 facilities were ordered to improve pollution control measures. The number of prefectures setting higher standards are tabulated for soot and dust, cadmium and its compounds, fluorine, hydrogen chlorine, and lead its compounds. Problems associated with environmental administration include the prevention of pollution by high speed transportation, long range planning for environmental conservation, and strengthening of environmental controls. Scientific technology on environmental conservation includes: pollution prevention techniques required to minimize emissions from human activities causing pollution; physical, chemical, and biological studies of causes of air pollution and the mobility, composition, and reaction phenomena occurring in these environments; and study and assessment of how pollutants affect man, animals, and plants.

Wilson, H. H.

A SURVEY OF FLUORINE EMISSION FROM CERAMIC

FIRING PROCESSES. J. Aust. Ceram. Soc., 10(3):53-55, Nov.

1974. 28 refs.

The occurrence and control of fluorine emissions during ceramic manufacture are reviewed. Fluorine in exhaust gases is present mainly as gaseous hydrogen fluoride and silicon tetrafluoride and particulate calcium fluoride. Approximately 30-40% of the fluorine is evolved during normal firing, with the amount of emission increasing as the temperature of the process is increased. Fluorine removal efficiencies of over 99% can be achieved with wet scrubbing, though the disposal of the resultant acidic water is a problem. Dry methods of fluorine removal include the use of fluidized-bed reactors, the injection of hydrated lime into the exhaust flue, and adsorption with charcoal. Process modifications involving the removal of fluorides from raw materials or the use of electric heating to reduce the temperature of the glass can also be employed in some sections of the ceramic industry to reduce fluorine emissions.

Feige, N. G.

CORROSION SERVICE EXPERIENCE AND ECONOMICS OF TITANIUM S USAGE IN GAS SCRUBBING EQUIPMENT FOR REFUSE INCINERATORS. Preprint, National Assoc. of Corrosion Engineers, Houston, Tex., 9p., 1974. 8 refs. (Presented at the National Association of Corrosion Engineers, Annual Meeting, Chicago, III., March 7, 1974.)

The economics of titanium usage in gas scrubbing equipment serving refuse incinerators is considered in terms of laboratory corrosion test results and field operation experience. Titanium resistant to incinerator flue gas environments which contain such corrosive materials as hydrogen chloride, sulfur dioxide, sulfur trioxide, trace hydrogen fluoride, and organic acids. The resistance of the metal to attack is adequate over the pH range of 1.5-11 and up to temperatures of 230 F for general pitting attack and 165 F for crevice corrosion. Trace amounts of ferric ions in the system can extend the range of immunity to attack. Economic considerations favor titanium at either end of the scrubber. The inlet area is very sensitive to water flow and temperature flares from the incinerator; and, since the amount of surface is small in this corrosion area compared to the total unit, titanium is a reasonable cost/performance selection. Titanium is also economically favored for the induced-draft fan rotor assembly.

GAS ABSORPTION APPARATUS. (Gasu kyushu sochi). Text in Japanese. (Sluma Denko Co., Ltd., Tokyo (Japan)) Japan. Pat. Sho 49-43468. 3p., Nov. 21, 1974. 1 ref. (Appl. Dec. 22, 1970, 1 claim).

The absorbent holder device for a gas adsorption tower consists of several sheets of plastic or metal nets with three or more bends at angles of 10-45 deg to the vertical line which are placed vertically at equal intervals. The absorbent is applied to nets by spraying absorbent solution from a spray nozzle located at the top of the tower. For example, 10% sodium carbonate solution is sprayed to nets and used for the absorption of hydrogen fluoride. The absorbed substance is removed by spraying water or Na₂CO₃ solution in the case of HF absorption. Advantages of this device are the simple procedure and efficient absorption, since the pressure loss of gas flow is slight due to its net structure.

REDUCTION OF THE POLLUTANT EMISSION FROM INCINERATORS BY DRY SCAVENGING. (Verminderung der Schadgasemissionen von Muellverbrennungsanlagen durch Trockenwaesche). Text in German. VGB Kraftwerkstechnik, 55(4):234-239, April 1975. 13 refs.

The additive mytrid, a caustically burned magnesite with a porous structure to provide a large surface area (fineness: 90% below 90 micron, at least 80% below 60 micron, and at least 70% below 40 micron; specific surface of 15 to 20 sq m/q), was injected into the combustion chamber of an incinerator. The emission of following pollutants from a treated and untreated combustion unit was measured: hydrogen chloride, hydrogen fluoride, sulfur dioxide and trioxide, and the oxides of nitrogen. Each of the two units had a trash throughput of 19 tons/hr. The effect of the additive on the pollutant emission was determined from the difference between the measured pollutant concentrations in the waste gases from the two units. The results are graphically illustrated. With regard to the emissions SO₂, SO₃, HCl, and HF, mytrid had a reducing effect; no effect was observed with regard to the emissions of oxides of nitrogen. The composition of the fly ash from the two units hardly differed. The dust concentration of the cleaned gas did not increase. Further long-term measurements are required.

Rasch, Rudolf

POLLUTANT ELIMINATION FROM FLUE GASES OF INCINERATORS. (Schadstoffeliminierung aus Rauchgasen von Muellverbrennungsanlagen). Text in German. Muell Abfall, 7(4):91-96, 1975. 26 refs.

Waste gas cleaning methods applied to incinerators focus on the removal of hydrogen chloride and fluoride. The hydrogen chloride concentration in the cleaned gas may not exceed 100 mg/cu m air. The maximum air concentration according to new regulations may over long periods of time not exceed 0.1 mg/cu m air. Dry binding of hydrogen chloride to alkaline fly ash or to suitable additives such as ground quicklime, calcium hydrate or limestone, or dolomite and magnesite presently receives great attention but requires further development. If a scrubbing process is selected for elimination of the hydrogen chloride, the flue gases are first cleaned of dust to reduce the sludge quantity at the end of the cleaning process. The benefit of scrubbing is hotly debated primarily because of the waste water problem it creates. A recent process using an endless cloth filter which moves over rollers like a vertically arranged conveyor belt achieved a good retention efficiency for hydrogen chloride.

OPTIMUM WORKING FLUIDS FOR AUTOMOTIVE RANKINE ENGINES. VOLUME II - TECHNICAL SECTION. Monsanto Research Corp., St. Louis, Mo., Environmental Protection Agency Contract 68-04-0030, Rept. APTD-1564, 202p., June 1973. 61 refs. NTIS: PB 239248/AS

Various working fluids for automotive Rankine engines were evaluated in terms of cycle efficiency, toxicity, flammability and combustion products, and stability. Two final candidate fluids were selected as being the most desirable: a 60/40 mol% mixture of pentafluorobenzene/hexafluorobenzene, designated as RC-1, and a 65/35 mol% mixture of water/2-methylpyridine, designated as RC-2. Rat inhalation studies revealed 4-hour median lethal concentrations of 16,000 ppm and 8000 ppm for RC-1 and RC-2, respectively. Combustion tests involving the burning of the working fluids with propane-air demonstrated the production of relatively high concentrations of carbon monoxide (612 + or - 66 ppm) and hydrogen fluoride (746 + or - 80 ppm) for RC-1; unburned hydrocarbons were also high for RC-1 (935 + or - 72 ppm). Combustion of RC-2 was more complete and resulted in much lower concentrations of the above components; however, nitrogen cyanide and nitrogen oxides were emitted in amounts of 0.5 and 79 + or - 6 ppm, respectively. Fluid RC-1 came nearest to satisfying the automotive organic working fluid requirements, with fluid RC-2 being selected as a back-up candidate for automotive use.

REDUCTION OF ATMOSPHERIC POLLUTION BY THE APPLICATION OF FLUIDIZED-BED COMBUSTION AND REGENERATION OF SULFUR-CONTAINING ADDITIVES

(ANNUAL REPORT). Argonne National Lab., 111., Environmental Protection Agency Interagency Agreement EPA-IAG-149(D) and Office of Coal Research Interagency Agreement OCR-IAG-14-32-0001-1543, Program Element 1AB013, ROAP 21ADB-011, ANL/ES-CEN-1007, Rept. EPA-650/2-74-104, 136p., Sept. 1974. 26 refs.

A bench-scale, fluidized-bed combustion pilot plant capable of operating at 10 atmospheres pressure was used to evaluate the effects of operating variables on flue gas sulfur dioxide and nitrogen oxide levels, combustion efficiency, additive utilization, and heat transfer. High retentions of sulfur (greater than 90%) and low NO levels (less than 150 ppm) were achieved with a fluidized bed of dolomite where SO₂ reacted with lime in the dolomite to form calcium sulfate. The combustor was successfully tested using a variety of coals: highly caking, high-volatile bituminous, high ash subbituminous, and low-heating value lignite. The kinetics of the reaction of half-calcined dolomite with SO₂ were first order with respect to SO₂ concentration in the presence of water vapor and approximately three-fourths order in the absence of water vapor. Material balances were obtained for mercury, lead, beryllium, and fluoride; data were also obtained for sodium concentration in the particulate matter entrained in the flue gas from the combustor. EVALUATION OF SYSTEMS FOR CONTROL OF EMISSION
FROM ROCKET MOTORS - PHASE I (INTERIMREPORT).

A.P.T., Inc., San Diego, Calif., Air Force Rocket Propulsion Laboratory and Environmental Protection Agency Interagency Agreement EPA-IAG-R5-0644, Contract 68-02-1328, Task 8, Program Element 1AB012, ROAP 21ADL-010, Rept. EPA-600/2-75-021-a, 57p., Aug. 1975. 5 refs. NTIS: PB 245590/AS

An engineering evaluation of methods for controlling emissions from solid rocket test firings is presented. The primary emissions requiring control are carbon monoxide, hydrogen chloride, hydrogen fluoride and aluminum oxide particles. A pilot scale scrubber currently in operation on a 22,200 newton (5000 lb) motor is examined and appears to require an excessive amount of water if scaled up for a rocket of larger thrust. Scoops appear to provide one simple means of reducing the quantity of scrubbing water required. Pilot-scale tests to determine the technical feasibility of the idea are recommended. (Author abstract modified)

INFLUENTIAL FACTORS IN THE CONTROL OF EFFLUENT EMISSIONS FROM THE BLUFF ALUMINUM

SMELTER. The Clean Air Society of Australia and New Zea-

land, Clean Air Conf. 1975 Proc., Rotorua, New Zealand, 1975, p. 511-527. 6 refs. (Feb. 17-21.)

Procedures for the control and monitoring of particulate and fluoride emissions from an aluminum smelter are described. The monitoring program includes measurements of control equipment efficiency and the determination of fluoride levels in the surrounding air as well as in flora and fauna. Fluoride emissions from pot operation are minimized as a result of the installation of a prebake cell. The emissions from aluminum reduction pots are collected in a common duct and passed through a multicyclone for the removal of particulates. The cleansed effluent is then discharged through a 137-meter high stack at a velocity of 1.6 m/sec. Each pot is completely hooded, and an effluent containment in excess of 97.5% is constantly maintained.

Parekh, Rashmi

EQUIPMENT FOR CONTROLLING GASEOUS POLLU-

TANTS. Chem. Eng./Deskbook, vol. 1975:129-133, Oct. 6, 1975.

Equipment for controlling gaseous pollutants is classified according to the function it performs. Gas liquid absorption processes are carried out in vertical countercurrent flow through packed, plate, or spray towers. The equipment falls into the following categories: dispersed gas: impingement plate scrubbers; dispersed liquid: packed towers, wetted-wall towers; dispersed liquid: spray towers, venturi scrubbers. A major factor in the successful operation of a scrubber is the proper selection of materials for construction. The units are subjected to harsh environments created by industrial gases such as sulfur dioxide, sulfur trioxide, hydrogen chloride, hydrogen fluoride, and chlorine, which form sulfurous, sulfuric, hydrochloric, and hydrofluoric acids as they enter the liquid phase. Materials selections must be based on specific application requirements. Incineration is the simplest route when the gas streams are combustible. Direct flame and catalytic oxidation are the two methods in common use today.

CONTROL TECHNOLOGY FOR SECONDARY ALUMINUM

SMELTERS. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 14p., 1975. 11 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 68th, Boston, Mass., June 15-20, 1975, Paper 75-66.6.)

A dry absorption-filtration system for controlling particulate and gaseous (chlorine, hydrogen chloride, and hydrogen fluoride) emissions from a secondary aluminum smelter is described. The basic component of the system is a baghouse coated with a chromatographic material capable of absorbing acid gases in a gas-solid reaction. The chromatographic coating filters submicron materials prevents submicron particle permeation of the bag filter cloth. Bags are shaken every 3-5 days. Outlet particulate loadings for the system are less than 0.005 grains/standard cu ft, and the opacity of the plume is zero. The average acid gas emission is 10 ppm or less. The bag life is conservatively estimated at 10 yr. The annual operating cost, including amortization, for the system is about \$2.00/ton of aluminum. (Author abstract modified)

Graetz, R.

POSSIBLE METHODS FOR THE CONTROL OF FLUORIDE EMISSIONS AND INFORMATION OBTAINED FROM CONTINUOUS MEASUREMENTS OF FLUORIDE IN FLUE GAS.

(Möglichkeiten zur Beeinflussung der Fluor-Emissionen und Erkenntnisse aus kontinuierlichen Fluor-Messungen im Rauchgas). Text in German. Ziegelind. (Weisbaden), 4:130-138, April 1975. 11 refs.

Methods for the control of fluoride emissions from brickworks are reviewed along with factors affecting the fluoride content of ceramic materials. Fluoride emission control techniques include: the prevention of fluoride discharge from materials being fired, the chemical reaction of gaseous fluoride compounds with other compounds to render the former harmless, and dilution of flue gas by the use of tall stacks. The fluoride content ceramic materials varies in concentration and depends on the chemical and mineralogical constitution and the geological origin of the clays. Thus far, no conclusions on the efficiency of methods for the continuous monitoring of fluorides in flue gas can be drawn.

Swift, W. M., G. J. Vogel, and A. F. Panek

POTENTIAL OF FLUIDIZED-BED COMBUSTION FOR

REDUCING TRACE-ELEMENT EMISSIONS. Preprint, Air

Pollution Control Assoc., Pittsburgh, Pa., 19p., 1975. 8 refs.

(Presented at the Air Pollution Control Association, Annual Meeting, 68th, Boston, Mass., June 15-20, 1975, Paper 75-46.3.)

The potential of fluidized-bed combustion for reducing trace element emissions as compared with conventional coal combustion systems was evaluated using a bench scale, 6-inch diameter, pressurized, fluidized-bed combustor. Overall mass balances for the elements lead, cobalt, iron, potassium, lanthanum, sodium, and scandium possessed material balances of 100 + or - 10%, indicating essentially no losses of these elements by volatilization. Retention of the relatively volatile elements mercury, fluorine, bromine, and arsenic indicated a definite potential for the reduction of emissions of these elements via fluidized-bed combustion. Concentrations of trace elements in coal and fly ash samples from successive stages of gas cleaning devices (primary cyclones, secondary cyclones, and filters) were adjusted to a combustible-matter-free basis and compared for significant differences in concentration between coal and ash samples and for successively finer samples of ash. The concentrations of elements such as barium, cobalt, lanthanum, antimony, scandium, and tantalum showed slight tendencies to increase with decreasing particle size. The lower combustion temperatures of fluidized-bed combustion were apparently effective, however, in reducing the preferential concentration of trace elements in the finer ash particles. (Author abstract modified)

INDUSTRIAL GAS CLEANING BY ION EXCHANGERS. (Oc-

zyszczenie gazow przemyslowych metoda jonitowa). Text in Polish. Ochrona Pracy (Prague), (11):17-18, Nov. 1974. 5 refs.

Results of an investigation on the applicability of ion exchangers to remove acidic impurities from industrial gases are described. The device operates on the principle of sorption of acidic gases by ionic substances with simultaneous and continuous regeneration. The concentration of gases can be arbitrary. The temperature of the gases being cleaned should not be higher than 333 K and a preliminary removal of dust particles is required. The process can use practically all industrial anions capable of absorbing HSO₃ and SO₃ anions from aqueous solutions. The diameter of the anionic particles must be greater than 0.004. The process can have an effectiveness of 99% when it is used for removal of such acidic impurities as sulfur dioxide, nitrogen oxides and hydrogen fluorides. The

process can therefore be used to clean industrial gases from sulfuric acid plants, emissions from phosphate fertilizer plants from glass- works, from aluminum smelting plants.

Kisters, T.

FLUE GAS CLEANING BEHIND REFUSE INCINERATING PLANTS - PROBLEMS AND THEIR SOLUTIONS.

(Rauchgasreinigung hinter abfallverbrennungsanlagen Probleme und Loesungsmoeglichkeiten). Text in German. Aufbereitungstechnik, 16(5):231-236, May 1975.

Techniques and equipment for flue gas cleaning behind waste incinerators are described. The incinerator flue gases usually contain 5-15 g dust, 1000-2000 mg hydrochloric acid, and up to 20 mg hydrofluoric acid per N cu m. The maximum allowable emission concentrations are 100 mg/N cu m for dust and chlorine, and 5 mg/N cu m for fluorine. Suspended matter can be separated most efficiently and economically in electrostatic dust separators which require preliminary flue gas cooling because they can not be operated permanently at temperatures over 300 C. Sulfur dioxide, HCl and HF can be separated by wet absorption or adsorption methods, using water, aqueous solutions of calcium hydroxide or sodium hydroxide, or limestone. Limestone is used most efficiently in fluidized-bed operations. The admission of pulverized limestone into the flue gas is less efficient. The gases require cooling before, and heating after the wet separation of gaseous components.

STATEMENT ON CURRENT PRACTICE FOR THE REDUCTION OF FLUORIDE EMISSION IN THE BRICK AND TILE INDUSTRIES BY SCRUBBING OF THE FLUE GASES. (Fest-

stellung des Standes der Technik zur Verminderung der Fluoremission in der Ziegelindustrie durch Reinigung der Abgase). Test in German. Ziegelind. (Weisbaden), no. 4:155-162, 1974.

Fluoride occurs as a trace element in fuels and in many raw materials for ceramics. It is seldom possible for it to be completely stabilized in the ceramic body during firing. An attempt is therefore made to neutralize the harmful gaseous fluoride compounds in the flue gas. A survey of the literature on the subject presents the processes used to date, both inside and outside the ceramic industries, for the conversion of the gaseous fluoride compounds in the flue gas into harmless com-

EFFLUENTS FROM GAS SCRUBBERS IN INCINERATORS.

(Abswaesser der Gaswaesch von Verbrunnungsanlagen). Text in German. Muell Abfall, 7(S):144-146, 1975.

Problems of flue gas cleaning after trash incinerators and related wastewater problems are discussed. The dust, hydrochloric acid, and hydrofluoric acid emissions from waste incinerators are limited to 100 mg/cu m; 100 mg/cu m, and to 5 mg/cu m, respectively, which requires the separation of dust and of the gaseous pollutants, which can be combined in scrubbers. Due to their high water-solubility, HCl and HF can be separated by means of water. If the scrubber effluents are to be discharged into recipients, the specific water consumption should be increased to 10-15 cm³/ton of waste to obtain a dilute effluent. If the effluent is to be treated before discharge, the water consumption should be minimized, which is possible by recirculation and counterflow processes. Thus, it is possible to obtain an acid with 10% concentration, and to achieve a water entrainment of 0.04 cu m/ton of waste. It is also possible to use lime suspension for flue gas scrubbing without wastewater treatment.

ENVIRONMENT BALANCES AND TRASH PYROLYSIS.

(Umweltbilanzen bei der Abfallpyrolyse). Text in German. Muell Abfall, 7(5):127-131, 1975. (Presented at the Waste Technology Colloquium, 28th Stuttgart, West Germany, March 14, 1975.)

The environmental and energetical balances of trash pyrolysis according to the Destrugas and Goldshoeffe processes are drawn up on the basis of actual measurements on technical-scale pilot plants. The waste gases generated in the Destrugas degassing process at a pyrolytic temperature of 1000 C are scrubbed, and a fuel gas is obtained. With trash with a calorific value of 1900 kcal/kg, 360 kg of gas with a calorific value of 2790 kcal/N cu m are obtained per ton of trash. This gas contains 39.5% hydrogen, 17.6% carbon dioxide, 18.6% water, 21.1% carbon monoxide, 9% methane, and 3.2% other hydrocarbons by volume, as well as 404 mg sulfur oxides, 35 mg hydrochloric acid, 1 mg hydrofluoric acid, 170 micrograms mercury per N cu m, 400 ppm hydrogen sulfide, 59 ppm hydrocyanic acid, and 1185 ppm triethylanone. In the Goldshoeffe process, in which hydrocarbons are cracked at 1200 C in coke bed, and part of the water added is converted into hydrogen, 100 kg of raw waste generated 106.9 kg of cleaned gas with a calorific value of 1400 kcal/N cu m. After scrubbing, this gas contains 51% nitrogen, 20% hydrogen, 14% CO, 8%, CO₂, 3% oxygen, 3% methane, 1% other hydrocarbons, as well as 120 ppm of ammonia, 30 ppm hydrocyanic acid, 20 ppm SO₂, and 10 ppm H₂S. Both processes generate gases which represent hardly any environmental hazard, and the volume of these pyrolysis gases amounts to about 10% of that generated by conventional incineration. The low dust content makes electrostatic precipitators unnecessary. The pyrolysis gas incorporated about two thirds of the energy content of the waste, and 50% of this recovered energy is needed for the pyrolytic process.

AIR POLLUTION BY FLUORINE COMPOUNDS FROM PRIMARY ALUMINIUM SMELTING. 44p., 1973. 18 refs.

Emission of fluorine compounds is the major air pollution

problem of the primary aluminum smelting industry. Typical data regarding quantity and composition of fluorine air pollutants released in the various processes using different types of electrolysis pots are given. Some pots are designed with a hood which allows a considerable fraction of the release to be collected in a relatively concentrated form. Typical data regarding collection efficiencies are exhaust and ventilation requirements for pot rooms are given. Electrostatic precipitators, scrubbers, and bag filters are used for cleaning pot exhaust. Adsorption of hydrogen fluoride on alumina to recover fluorine compounds is used increasingly. The most efficient gas cleaning systems operate at above 90% efficiency. Total emissions obtainable with combination of pots and gas cleaning equipment are calculated. The investment in medium or highly efficient gas cleaning systems ranges from 5% to 10% of the investment in the electrolysis plant. According to data received from 12 countries representing 71% of the aluminum production in the Organisation for Economic Co-operation and Development area, 23% of the production takes place in plants having highly efficient gas cleaning. About 8% is produced in plants having no gas cleaning. (Author abstract modified)

CONICAL SCRUBBERS WITH FLUIDIZED SPHERICAL
PACKING FOR GAS PURIFICATION. Intern. Chem. Eng.,
15(3):530-533, July 1975. 4 refs.

The characteristics and applications of conical scrubbers with fluidized spherical packing (CSS) in spraying and ejection variations are discussed. The packing is fluidized most intensively near the lower base of the cone, and gradually slows down along the height. The upper, slightly mobile layers of spheres serve to partially recover the spray which is formed in large amounts near the lower base of the cone. Upper grids with a layer of spheres having a height of 150 mm are provided for more complete recovery of the spray in the cylindrical part of the units. These grids do not become clogged with residue and have practically no effect on the overall resistance of the scrubber. For spheres of silicon tetrafluoride, hydrogen fluoride, and dust with a diameter of 34-40 mm, the maximum recovery capacity is achieved with a static bed height of HO equals 500-800 mm.

DUST BURNS FREELY SUSPENDED. TRASH AND SEWAGE
SLUDGE INCINERATION PLANT IN KREFELD TAKEN
INTO OPERATION. (Staub verbrennt freischwebend. Muell-
und Klaerschlamm-Verbrennungsanlage in Krefeld in Betrieb
genonunen). Text in German. VDI Nachr. (Ver. Deut. Ingr.)
(Berlin), 29(48):7, 1975.

The new combined waste incinerator and wastewater treatment plant of the city of Frefeld, designed to incinerate 105,000 tons of wastes and 25,000 tons of sewage sludge, is described. The sewage sludge, dried and ground, is admitted to the incinerator together with the vapors generated in the drying and grinding process, and is incinerated freely suspended over the grate. The steam produced is used for electricity generation for the incinerator and wastewater treatment plan!,

<xref image="2000WVDX.TIF|V3|2006:09:28:01:24:34.00|117640|0"> image: </xref>

and the exhaust steam is used for remote heating. The flue gases are dedusted in an electrostatic precipitator, after which they are washed in two stages for the removal of hydrochloric acid in the first stage, and of sulfur dioxide and hydrofluoric acid in the second. The cleaned gases are mixed with hot air before discharge into the atmosphere.

LIBERATION OF FLUORINE-BEARING GASES IN SEMIHYDRATE PRODUCTION OF WET-PROCESS

PHOSPHORIC ACID. (Vydelenie ftoristykh gazov v proizvodstve polugidratnoi ekstraktsionnoi H₃PO₄). Sov. Chem. Ind. (English translation from Russian of: Khim, Prom.), 6(8):507-508, 1974. 5 rets.

The liberation of fluorine-bearing gases during the semihydrate production of wet-process phosphoric acid was studied. About 32% of the fluorine from the apatite concentrate was found in the tail gas given off by the process. The fluorine:phosphorus pentoxide ratio of the gas phase was over 200, indicating that the tail gas can be used for synthesis of a suitable feed for the production of aluminum fluoride. It is necessary to install a system for removing phosphoric acid spray from the fluorine-bearing gas exiting from the concentrators, however, to obtain a fluosilicic acid suitable for aluminum fluoride production.

THE SAMPLING CHARACTERIZATION AND ASSESSMENT

OF SOLID WASTES AS A FUEL. New South Wales Univ., Sydney (Australia), Dept. of Fuel Technology, Convers. Refuse Energy Int. Conf. Tech. Exhib., 1st, Montreux, Switzerland, 1975, 6p. 4 rets. (Nov. 3-5.)

The characteristics of solid wastes that are necessary for the successful conversion of refuse to energy are discussed. The parameters of importance to incinerator design in relation to handling, storage, combustion characteristics, maintenance, plant availability, and air pollution potential include: total weight, bulk density, moisture, calorific value, proximate and ultimate analyses, size distribution, ash fusion characteristics, and the presence of any undesirable elements, such as metals (mercury, arsenic, lead, tin, aluminum, and zinc), sulfur, chlorine, fluorine, phosphorus, nitrogenous wastes and alkalis which may cause fouling, slagging, corrosion, or air pollution problems.

Barber, J. C.

POLLUTION CONTROL IN FERTILIZER MANUFACTURE.

J. Environ. Quality, 4(1):1-11, Jan.-March 1975. 19 refs. (Presented at the American Society of Agronomy, Annual Meeting, 65th, Las Vegas, Nev., Nov. 15, 1973.)

Regulations and standards for air pollution and industrial hygiene affecting fertilizer production are discussed. Technology available for the abatement of air and water pollution and for control of dust in the working environment is described. Technology has not yet been developed to cope with the particulate emission problems at ammonium nitrate and urea prilling towers. Both air and water pollution problems at new nitrogen fertilizer production facilities can be lessened by the selection of low energy scrubbers. Plant tests are currently being made with a low pressure drop impingement type of scrubber. One possible solution for new plants is to granulate ammonium nitrate and urea in equipment which is amenable to particulate emission abatement. Dust scrubber effluents and plant washdown obtained at granular fertilizer plants can be converted into liquid fertilizers; however, the dust collection system should be designed to avoid excessive dust pickup. Much progress has been made toward recovery of by-product fluorine, but by-product gypsum recovery involves large

capital investment and extensive market development. Water pollution is also discussed. (Author abstract modified)

Reissmann, H.

FLUE GAS CLEANING AND FLUE GAS SCRUBBING IN INCINERATION PLANTS. (Rauchgasreinigung und Rauehgaswaesche bei Muellverbrennungsanlagen). Text in German. Preprint, VGB Technical Association of Large Power Plant Operators E.V., Essen, 12p., 1975. 6 refs. (Presented at the VGB Incineration Conference, Hagen and Stuttgart, West Germany, April 4 and 18, 1975.) Problems and possibilities of dust separation and gas scrubbing at municipal and special waste incinerator plants are described. Dry mechanical dust separators are unable to guarantee compliance with the new dust emission standard of 100 mg/N cu m. Therefore, they are used sometimes as a first stage before electrostatic precipitators which reach efficiencies of up to 98-999?. The flue gas temperature in the electrostatic precipitator should be between 250-280 C to prevent hot-temperature corrosion or temperature drops to below the dew point. The efficiency of precipitators is determined not only by the precipitating surface area but also by the spacing between the precipitating electrodes. Wet type dust separators can use an accelerating diaphragm immediately behind the incinerator if the flue gas volume is fairly constant. For fluctuating flue gas volumes, venturi scrubbers with adjustable flow cross-section as a function of the flue gas flow is most suitable. While the carbon monoxide emission can be abated by adequate process control, chlorine and fluorine emissions require flue gas scrubbing with sufficient contact time between the flue gases and the absorbent liquid. Sulfur dioxide, sulfur trioxide and carbon dioxide are also separated partially. Dry methods, i.e., the use of calcia, do not guarantee compliance with the emission standards (100 mg/N cu m for Cl, and 5 mg/N cu m for F).

PREVENTION OF AIR POLLUTION BY USING ACTIVATED ALUMINA SOLID ADSORBENT TO REMOVE PARTICULATES OF LESS THAN 0.5 MICRONS FROM FLUE GASES. (Vulcan Materials Co., Birmingham, Ala.) U. S. Pat. 3,900,298. 6p., Aug. 19, 1975. 5 refs. (App. July 13, 1973, 2 claims). An air pollution control process for the prevention of white smoke in the atmosphere caused by finely divided metal halide solids is described. Particulates less than 05. micron in size are removed from flue gases by passing the flue gases into intimate contact with a solid adsorbent of activated alumina. The solid adsorbent is particularly useful in removing metal halide solids such as aluminum chloride, potassium chloride, sodium chloride, and aluminum fluoride of less than 0.1 micron in size from the gaseous effluent of aluminum processing operations which utilize a gaseous chlorine treatment of molten aluminum. Activated alumina has not been used in any other process because it is widely believed that solid adsorbents are ineffective in removing submicron particulates and that liquid adsorbents, such as caustic or alkaline solutions are needed. B. CONTROL METHODS

143

81772

Kurian, P. C.

POLLUTION PROBLEM AT E.I.D-PARRY LIMITED FERTILISER FACTORY AT RANIPET. Fertiliser News, 18(9): 17-18, Sept. 1973.

Stack emissions generated by a superphosphate and sulfuric acid plant associated with a fertilizer manufacturing operation are described along with methods for their control. The main effluent from the sulfuric acid plant is unconverted or unabsorbed sulfur dioxide which generally does not exceed 0.2%. A maximum conversion of SO₂ to sulfur trioxide is achieved when the plant is operated at a SO₂ input to the converter of 7-7.5%. Emissions are controlled by dispersion using a 30.5-meter high stack. Emissions from the superphosphate plant include silicon tetrafluoride, hydrogen fluoride, hydrogen chloride, and fluorine, with the latter compound being the main pollutant. These gases are controlled by absorption in a spray tower. The absorption efficiency of the scrubber ranges from 65-70%. Unabsorbed gas from the scrubber is discharged through a stack that is 21.3 m above ground level.

81773

Latey, N. G.

POLLUTION IN PHOSPHATIC FERTILISER PLANT. Fertiliser News, 18(7):29-30, July 1973.

Gaseous and particulate emissions generated by superphosphate and sulfuric acid plants associated with a phosphatic fertilizer manufacturing operation are reviewed along with methods for their control. Sulfuric acid plant emissions consist mainly of sulfur dioxide and sulfur trioxide. These pollutants, though uncontrolled, are generally maintained at 0.1-0.12% and 0.01-0.14%, respectively, of the stack gas composition. Fluorine, hydrogen fluoride, and silicon tetrafluoride are the main gaseous emissions generated by the superphosphate plant. These emissions are controlled by a combination of spray scrubbing and wet cyclone treatment. Dust emissions arising from the superphosphate plant are controlled by bag filters.

81944

Achorn, Frank P., Hubert L. Balay, and David G Salladay
FLUORINE RECOVERY FROM SUPERPHOSPHATE PLANTS. Preprint, American Chemical Society, Washington, D. C., 31p., 1975. 5 refs. (Presented at the American Chemical Society Meeting, Chicago, III., Aug. 24-29, 1975.)

Information concerning some of the commercial practices for the recovery of fluorine from superphosphate plants is presented. Possible uses for such recovered F are also discussed in terms of economics and technology. The gas from normal superphosphate plants is usually scrubbed in an impingement scrubber or the more modern venturi type. Concentrated superphosphate plants are also discussed. Plant tests show that water scrubbing in either impingement or venturi scrubbers removes F, in the form of silicon tetrafluoride, effectively from the exit gases of superphosphate plants. Usually the venturi scrubber is more efficient and can utilize weak hexafluorosilane (H₂SiF₆) as a scrubbing medium to remove F effectively from superphosphate plants. A major problem with the recovery of F from superphosphate plants is disposal of the by-products from these systems.

METHOD OF REMOVING HF FROM GASES. (Metallgesellschaft Aktiengesellschaft, Frankfurt am Main (West Germany) and Vereinigte Aluminiumwerke Aktiengesellschaft, Bonn (West Germany)) U. S. Pat. 3,907,971. 8p., Sept. 23, 1975. 5 refs. (Appl. Nov. 15, 1971, 3 claims).

A method for removing hydrogen fluoride from gas streams emitted by electrolysis cells used for the production of alu-

minum is described wherein contact between the gas phase and the solid phase is carried out in an expanded fluid bed to achieve increased removal efficiency over prior art methods. The waste gas is used as the fluidizing medium for an expanded fluid bed of particulate solids capable of taking up hydrogen fluoride. The solids content of the fluid bed chamber and the gas flow parameters are adjusted to maintain a continuous solids concentration gradient throughout a vertical chamber such that the concentration decreases from the bottom to the top of the chamber. A major proportion of the solids removed from the top of the bed and entrained in the gases can be separated from the effluent gas and returned to the chamber

Tsukamoto, Youji and Sadao Kondo

METHOD FOR REMOVING A FLUORINE COMPOUND(S) FROM GASEOUS MIXTURE THEREWITH. (Mitsubishi Gas Chemical Co., Inc., Tokyo (Japan)) V. S. Pat. 3,907,522. 6p., Sept. 23, 1975. 4 refs. (Appl. April 26, 1974, 11 claims).

A method for the efficient removal of fluorine compounds, particularly boron trifluoride, from gas streams is described which precludes the escape of the fluoride hydrate as mist. The gas mixture is first introduced into a gas scrubber of the gas-liquid contacting type. The gas removed from the scrubber is then introduced into a mist-catching device which comprises a porous filter medium (mean pore size of 60 micron or less) and a nozzle or nozzles positioned above the surface of the medium. Water or an aqueous alkaline solution is sprayed on the surface of the filter medium in the same direction as that of the gas stream.

TRASH PYROLYSIS: FOUR PROCESSES ARE RIPE FOR TESTING. (Hausmuell-Pyrolyse: Vier Verfahren koennen erprobt werden). Text in German. Umwelt (Duesseldorf), 5(4):42-50, 1975. 17 refs.

Four different trash pyrolysis processes (Destrugas process, Landguard process, Andco-Torrax process, and Purox process) are described and compared with regard to their technological and environmental advantages. The Destrugas and Purox processes require purification of the pyrolysis gas before combustion, which is not problematic because of the small gas volumes generated, while the Landguard Andco-Torrax processes offer but slight or no environmental advantages over the waste incineration process. Of the four different methods, the Destrugas method is most promising and is expected to become a valid alternative for incineration. In this process, crushed wastes are gradually heated up to 900-1000 C for cracking of the organic components. The process gas obtained contains water vapor, carbon dioxide, hydrogen, carbon monoxide, methane, and small quantities of higher hydrocarbons. The process gases are cooled and scrubbed to obtain a fuel gas composed essentially of hydrogen, CO, CO₂, and

<xref image="2000WVDZ.TIF|V3|2006:09:28:01:24:40.00|108410|0"> image: </xref>

methane, which can be stored for later. The flue gases generated during the combustion of this gas contain 10 ppm of sulfur dioxide plus sulfur trioxide, 0.5 ppm of hydrofluoric acid, 10 ppm of hydrochloric acid, and 10 mg of soot/N cu m.

82918

Nix, Thomas B.

REMOVAL OF FLUORIDES FROM GASES. (Fuller Co., Catasauqua, Pa.) U. S. Pat. 3,876,394. 5p., April 8, 1975. 3 refs. (Appl. Oct. 10, 1973, 5 claims).

A method and apparatus for removing gaseous fluorides from gases evolved from an aluminum smelting furnace are described. The fluorides are removed by achieving intimate contact between finely divided particles of alumina and the fluoride containing gases. Particles of alumina are fed into a stream of gases collected from the aluminum smelting furnaces countercurrent to the flow of gases. The particles of alumina absorb the fluorides and are then separated in a cyclone. The alumina is fed to the smelting furnaces. Preferably two stages are used. In this method, cooling of the evolved gases is not as critical as in prior methods and apparatus for removing gaseous fluorides. (Author abstract modified)

Horvath, Zoltan

ENVIRONMENTAL PROTECTION IN METALLURGY. (Kor-nyezetvedelem a femkohaszatban). Text in Hungarian. Banyasz. Kohasz. Lapok - Kohaszat, 108(7):321-325, July 1975. 17 refs. Sulfur dioxide and fluorine emissions generated in copper, zinc, and lead metallurgy, and methods for their abatement are described. The sulfur dioxide emissions, originating from the ore sulfur content and from sulfur-containing fuels, can be abated by technological improvements, such as reduction of the flue gas volume with high SO₂ concentration; the Kivcet, Worcra, Noranda, and Mitsubishi processes; and the wet processes which totally eliminate the emission problems. The SO₂-containing flue gases are treated mostly with ammonium hydroxide, sodium hydroxide, or calcium hydroxide for SO₂ removal, as exemplified by many new flue gas treatment units at leading metallurgical companies. These measures, including the construction of high stacks, permit at least 95% of the SO₂ to be removed from the flue gases. Fluorine, for which the specific emission with respect to aluminum works is limited to 1 kg/ton of aluminum in the USA, France and other countries, can be abated by improved technological processes or flue gas treatment, consisting of scrubbing with acid, alkaline solution or water, or by adsorption on alumina in a dry fluidized-bed process

Aoki, Toshimitsu

MULTI-HOLE PLATE SCRUBBER. (Mezara shiki senjoto). Text in Japanese. Ebara Jiho (Ebara Times), no. 93:68-70, 1975.

A multi-hole plate scrubber (wet-type dust collector) developed by the Ebara Co. jointly with the Nippon Light Metal Co. is described. This scrubber was developed originally in 1972 for aluminum electrolysis factories, to collect waste hydrogen fluoride (HF) gas, but is now being used in steel refineries, stack desulfurization installations, and ceramic industries. Treatment capacities ranged from 800 cu m/min to 350,000 N cu m/hr. Temperatures ranged from 30 C to 160 C. Sodium hydroxide solution is used to absorb HF, sulfur dioxide, and sulfur trioxide gases. Absorption is made effective by thorough gas-liquid contact by the following means: droplets falling through the multi-hole plate; liquid films, stretched over the holes; gas passing through the films; wet-wall effect by the honeycomb zone. Mist accompanying the treated gas is removed by means of an eliminator, and emitted into the atmosphere. Calcium and dust deposition from the industrial water used in the water supply can adversely affect the effec-

tiveness of the installation. An annual or semi-annual maintenance check is recommended.

WASHING OUT OF METAL OXIDES AND NOXIOUS GASES FROM WASTE INCINERATOR FLUE GASES TO ACHIEVE THE MAXIMUM POSSIBLE DEGREE OF WATER POLLU-

TION PREVENTION. (Auswaschen von Metalloxiden und Schadgasen aus Abfallverbrennungsanlagen unter weitgehender Vermeidung einer Abwasserverschmutzung). Text in German. CIBA-GEIGY AG, Basel (Switzerland), Convers. Refuse Energy, Int. Conf. Tech. Exhib., 1st, Montreux, Switzerland, 1975, 6p. 7 refs. (Nov. 3-5.)

A multi-stage system for the separation of particulate matter, sulfur dioxide, hydrogen chloride and hydrogen fluoride from waste incinerator flue gases, developed by CIBA-GEIGY A.G. is described. The system adopts a controlled counterflow of flue gas and scrubbing liquid. It is composed of a coarse dust separator which also cools the gas and conditions the scrubbing liquid. The second stage is a scrubber for the removal of acid gaseous components and for the wetting of fine suspended dust. The third stage is a fine dust separator in the form of venturi scrubber or other types. The SO₂ content of the flue gas is reduced by over 75%. No alkalies are used in the scrubbing liquid, but it is possible to increase the efficiency by the use of alkalies. The dilute sludge generated is neutralized with the incinerator ashes

AIR POLLUTION ABATEMENT AT FERTILIZER MIXING

PLANTS. Preprint, American Chemical Society, Washington, D.

C., 37p., 1975. 11 refs. (Presented at the American Chemical Society Meeting, Chicago, 111., Aug. 24-29, 1975.)

Air pollution abatement at three types of fertilizer mixing plants are described: ammoniation-granulation, bulk blend, and liquid mix. Emissions include: ammonia vapor and ammonium salts, chlorine vapor and inorganic salts, fluorine compounds, phosphorus compounds, and particulates. The type of air pollution control equipment used depends on plant type, production capacity, and operating conditions and includes cyclone and wet scrubbers, spray dedusters, spray towers, electrostatic precipitators, and filters. The collection efficiencies for various types of this equipment are tabulated.

PROBLEMS OF RELATING ATMOSPHERIC ANALYSES TO EFFECTS OF AIR POLLUTION ON AGRICULTURE. J. Air Pollution Control Assoc. 16, (4) 219-24, Apr. 1966.

This presentation has emphasized the deficiencies of methods of atmospheric analysis and the inadequacy of present understanding of the relationship of air pollution to plant and animal injury. The purpose is to show where improved methods and further research are needed and perhaps to prompt more critical interpretation of atmospheric analysis data. The deficiencies mentioned are generally recognized, but in the desire to obtain a rapid solution to a problem they are sometimes overlooked. This frequently adds to the confusion rather than helping to clarify the situation. Consideration has been limited to fluoride, photochemical air pollutants, and sulfur dioxide. (Author)

A METHOD FOR THE DETECTION AND ISOLATION OF TRACES OF ORGANIC FLUORINE COMPOUNDS IN

PLANTS. (FINAL REPT.) Stanford Research Inst., South Pasadena, Calif., Southern California Labs. Apr. 1963. 20 pp.

A method for the detection and isolation of submicrogram quantities of organic fluorine compounds from plant materials in the presence of much larger amounts of inorganic fluoride is presented. The procedure consists first of a rapid screening step for use with large numbers of vegetable samples and extracts and, second, of a chromatographic step to isolate and characterize any fluoro-organics found. These methods are developed in light of specific chemical characteristics of organic fluorine compounds as a general class. A modification of Soep's quantitative submicro fluoride analytical method is presented as applicable to these isolation methods. Microgram quantities of organic fluorine compounds were found in the plant materials investigated but at a level too low for isolation and identification. (Authors' abstract)

Text in Polish

The thiocyanate method of determination of fluoride ion in air and the zirconium-alizarin method based on the Bumsted reagent were compared. Influence of accompanying substances has been established on the results of analyses performed by the two methods. From the point of view of a toxicologist analyzing a workenvironment, both methods are sufficiently accurate when no interfering substances are present. However, the zirconium-alizarin method is much more sensitive and more specific than the thiocyanate method. Both methods are equally simple. The precision of the determinations carried out by the zirconium-alizarin method was 4% and the sensitivity of the method allowed detection of 5 micrograms of fluorine in a sample. In the case of dust samples containing 80 - 200

micrograms of fluorine, the precision of the determinations was 5%.

A SEMI-AUTOMATED METHOD FOR THE DETERMINATION OF FLUORINE IN AIR AND PLANT TISSUES. Contrib.

Boyce Thompson Inst. Vol. 22(4):207-220, Dec. 1963.

A semi-automated procedure for the analysis of fluoroine in air and plant tissue samples has been developed, based upon the use of the Technicon AutoAnalyzer. Ashed and alkali-fused plant tissue samples are suspended in 25 ml. of water in test tubes and are placed in a large sampler. An aliquot of the sample is automatically pumped into the heated revolving glass helix of a Digestor unit along with 50% H₂SO₄. As the acid-digest mixture passes through the helix, fluoride and water vapor are evolved and are continuously swept from the helix under reduced pressure, pass through a long glass funnel, through a water jacketed condensing coil, and into an impinger. The fluoride sample is continuously pumped from the bottom of the impinger and joins with a stream of lanthanum-alizarin complexone reagent. The mixture then passes through 4 double mixing coils where complete mixing and color development take place. The sample stream then flows to the colorimeter where the absorbency of the solution is measured at 624 millimicron. The impulse is transmitted to a recorder, and a peak is plotted. Absorbency of the peak is proportional to fluorine concentration in the range from 0.10 to 3.2 microgram per ml. of original digest. With a slight modification, air samples, impinged in water, may be directly between the semi-automated and standard distillation methods. In the case of tissue digests, the rate of analysis is 12 per hour, while in the case of air samples, it is 10 samples per hour. (Author summary)

STUDIES ON THE MEASUREMENT OF FLUORIDE IN AIR AND PLANT TISSUES BY THE WILLARD-WINTER AND SEMI-AUTOMATED METHODS. J. Air Pollution Control Assoc. 16(7):367-371, July 1966. (Presented at the 58th Annual Meeting, Air Pollution Control Association, Toronto, Canada, June 20-24, 1965, Paper No. 65-38.)

Determinations of F in plant tissues by the Willard-Winter (WW) and semi-automated (SA) methods have been studied for the presence of determinate and indeterminate errors by multiple linear regression analysis. The results have provided a better understanding of the magnitude of differences between tissue samples required for statistical significance and have suggested that the errors involved are much greater both in number and magnitude than usually assumed. The results have also established that the SA method is a satisfactory alternative to the WW method for determining the F content of plant tissues. Investigations of the sources of error in F determinations by the semi-automated method were carried out, and the results indicated a number of ways of reducing errors. Determinations of the F content of air by three methods were compared and studied to estimate the magnitude and locate the sources of error. Here, too, the results indicated that present estimates of the reliability of determinations of the F content of air may be overrated, and they have suggested that improvement in the mean of collection of HF is the best way of improving reproducibility. ATMOSPHERIC FLUOROMETRIC FLUORIDE ANALYZER.

J. Air Pollution Control Assoc., Vol. 15(5): 195-197, May 1965. A fluoride analyzer originally designed by Wiggins, St. John, Thomas and associates at Stanford Research Institute, has been modified to improve its operational capabilities and reliability so as to operate for periods in excess of six months with virtually maintenance. It measures hydrogen fluoride in the atmosphere in the sub-parts per billion range. The need for the instrument, method of measuring fluoride and the modifications made to improve the SRI instrument are presented. The instrument has been operated in the field for two years beside impingers which obtain daily integrated samples. The impinger samples are subsequently titrated. Satisfactory correlation has been found between the average daily values by the automatic analyzer and the impinger. (Author abstract)

METHODS FOR REDUCING OZONE AND/OR INTRODUCING CONTROLLED LEVELS OF HYDROGEN FLUORIDE

INTO AIRSTREAMS. Intern. J. Air Water Pollution (London), Vol. 9:799-805, Dec. 1965.

Methods and equipment are described for reducing ozone in an atmosphere by the addition of metered levels of nitric oxide. The NO is diluted with 50 vol of nitrogen before addition to the ozone containing airstream to prevent premature oxidant of NO to NO₂ by oxygen of the air. Simple, reliable dispensing equipment for metering hydrogen fluoride into airstreams at the fractions of micrograms per cubic meter level is also described. This utilizes the constant vapor pressure of HF at 0 C from a relatively concentrated HF solution and variable levels of dispensing are achieved by varying the rate at which air is bubbled through the solution. An automatic valve system is described for providing a 24-hr present

schedule of dispensing HF. (Author abstract)

METHOD FOR DETERMINING FLUORINE INTAKE OF DAIRY COWS UNDER FIELD CONDITIONS. J. Dairy Sci. 45, (1) 74-8, Jan. 1962.
This field method enables an investigator to determine if the fluorine intake of a herd is within safe limits for dairy cows. It consists of determining average weights by heart-girth measurements, average milk production, and consumption of hay, concentrates, and silage from Dairy Herd Improvement Association records, or by weighing at the farm. Pasture Consumption is calculated by difference between the total digestible nutrients required and those supplied by other feeds. Water intake is based on Morrison's standard. The fluorine content of feeds and water is determined, and the amount of fluorine ingested is calculated in milligrams per kilogram of body weight. It is possible to determine fluorine ingestion for cows within an accuracy of plus or minus 20% at the 95% confidence limits. During 5 yr., 321 fluorine determinations were made in 60 herds. EXPRESS METHOD FOR ELEMENTAL FLUORINE DETERMINATION IN THE AIR. (Ekspress-metod opredeleniya elementarnogo ftora v vozdukh.) Hyg. Sank. 29, (1) 80-2, Jan. 1964. CFSTI: TT65-50023/1
For purposes of the express analysis under field conditions particular note should be made of the reaction of fluorine with
<xref image="2000WVE3.TIF|V3|2006:09:28:01:24:50.00|111568|0"> image: </xref>

potassium bromide and the subsequent reaction of the free bromine with fluorescein, which produces tetrabromofluorescein (eosin). The reaction is carried out on a solid adsorbent - silica gel - which is thereby colored red and compared with an artificially prepared scale of standards. Data on the fluorine determination by the express method and by the iodometric method are shown. Ten experiments were performed with all these concentrations, and in all cases the sampling rate was 5l/min. The sampling time was chosen in accordance with the fluorine concentration. The maximum error in fluorine determination by the express method is 10-12.5%.

METHODS FOR MEASURING GASEOUS AIR POLLUTATIONS. Staub (English TRANSLATION) 25, (9) 17-22, SEPT. 1965. CFSTI TT 66-51040/9

As the analysis of air pollutants has become a very extensive area of microchemistry, the statements included herein are limited to the principles involved in the analysis of the most important extraneous gases. Empirical, batch and continuous methods are the basic means for investigating gaseous air pollutants. The advantages and disadvantages of these methods are presented. Subsequently, the most important methods used at present for determination of sulfur dioxide, nitrogen dioxide, hydrogen sulfide, fluorides, oxidants, carbon monoxide and hydrocarbons are discussed.

S.R. Craxford

STANDARDISATION OF MEASURING AND CONTROL APPARATUS AND OF METHODS OF MEASURING. European

Conf. on Air Pollution, Strasbourg, 1964. p. 139-146.

From its study of the methods of measurement of air pollutants the OECD Working Party found that the methods adopted on an international basis fit into 3 categories: (1) well established methods suitable for international standardization; (2) methods considered to be of interim nature; (3) methods of known limited application. In general, the sampling procedures are considered to be as important as the analytical in measuring atmospheric air pollutants. The relative importance of air pollutants as revealed from study of national reports remains, since 1957, dusts, or deposited material, smoke, or suspended particulate material, and SO₂. Sulfuric acid and other sulfates, oxides of nitrogen and carbon monoxide, compounds of fluorine and ammonia come next in importance. Greater emphasis in CO concentrations and the effects on health reflects greater concern with automotive emissions. Also, there is growing concern about the effects of polynuclear aromatic compounds which are present in the atmosphere, and of which there are many known carcinogens. Various standard analytical procedures are discussed briefly.

AN IMPROVED DIFFUSION METHOD FOR DETERMINING SUBMICROGRAM AMOUNTS OF FLUORIDE IN BIOLOGICAL SAMPLES. Microchem. J. 8, (4) 407-14, 1964.

A method for fluoride determination has been developed in which a level of 0.0-2.5 microgram fluoride was determined quantitatively from several milligram samples of biological material. This technique allows the drying, ashing, and diffusion of small samples without transfer. The SPADNS-zirconium lake is a sensitive and convenient color reagent. Recoveries of 96 to 102% were obtained.

PROPOSED METHOD FOR SEMI-AUTOMATED ANALYSIS OF FLUORIDE IN PLANT TISSUES. Boyce Thompson Inst. for Plant Research, Inc., Yonkers, N.Y. 1966. 37 pp.

The method described involves dried and ground plant materi-

al which is ashed, alkali-fused, and diluted with water to a volume of 25 ml. The suspended digest and sulfuric acid are pumped into the Teflon coil of a microdistillation device maintained at 170 C. A stream of air carries the acidified sample swiftly through a coil of Teflon tubing to a fractionation column. The fluoride and water vapor distilled from the sample are swept up the fractionation column into a condenser, and the condensate passes into a small collector. The distillate is pumped continuously from the sample collector. Acid and solids are removed from the bottom of the fractionation column and are drawn to waste. The distillate is mixed continuously with alizarin fluorine blue-lanthanum reagent, and the colored stream passes through a 15-mm. tubular flow cell of a colorimeter, and the absorbance is measured at 624 millimicrons. The impulse is transmitted to a recorder. All major pieces of apparatus, with the exception of the microdistillation device, are components of the Techicon AutoAnalyzer.

EVALUATING AIR POLLUTION PROBLEMS (ACCEPTABLE EQUIPMENT AND PROCEDURES). Arch. Environ. Health 2, 228-33, Mar. 1961.

Some of the more common equipment used in making environmental air quality determination, such as Hi-Volume Samplers, Filter Tape Samplers, Gas Samplers, and simplified monitoring techniques, are discussed. Hi-Volume Samplers are frequently used to measure suspended particulate which may consist of smoke, dust, or other solids small enough to remain air-borne for long periods. This includes particulates under 100 microns in diam, and, for the most part, those less than 1 micron in diam. Fiber glass filters commonly used with this sampler collect practically all particulates down to 0.3 micron in diam. The sampler itself consists of a vacuum cleaner motor with mounting to accommodate an 8-in by 10-in filter. Filter Tape Samplers are commonly used in the field studies and usually are equipped with a diaphragm pump to draw air through at a rate of about 7 liters/min. Various automatic instruments are used for the continuous collection and recording of gaseous pollutants. However, various manual or semimanually operated bubbler collection trains have been used in the majority of gaseous measurements. Simplified monitoring techniques are discussed in conjunction with dustfall sulfation rates, H₂S, corrosion and fluoride sampling.

A FIELD EVALUATION OF THE MINI-ADAK m AUTOMATIC, FLUORIDE AIR POLLUTANT ANALYZER. J. Air Pollution Control Assoc. 12, (4) 164-9, Apr. 1962 (Presented at the 54th Annual Meeting, Air Pollution Control Association, New York City, June 11-15, 1962.)

This study has shown that short-term fluctuations in the concentration of fluorides in the atmosphere can be recorded by the use of the Mini-Adak II analyzer, an automatic flow colorimeter embodying an air-reagent contacting cell. The data furthermore showed the comparability of the long-term average atmospheric fluoride concentrations as determined with automatic instrumentation and conventional manual methods. Simultaneous sampling with two Mini-Adak II

C. MEASUREMENT METHODS

149

analyzers and two sequential samplers showed that data provided by the automatic instruments varied less than similar data from the two sequential samplers. Limed filter paper data obtained simultaneously at one sampling site predicted a somewhat lower, but explainable, 30-day average atmospheric fluoride concentration than was experimentally determined by instrumentation and sequential sampling. Selective sampling of the gaseous or particulate fluoride in the atmosphere showed that (a) approximately 87% of the particulate fluorides (retained on type AA Millipore filters) were recorded by the Mini-Adak II analyzer and (b) the average ratio of particulate/gaseous fluorides in the area of study was 1.5.

EXPERIMENTAL STUDIES ON CHRONIC FLUORINE POISONING, n. METHODS OF MICRODETERMINATION OF FLUORINE. Japan J. Ind. Health (Tokyo) 1, (7-8) 97-105, Nov. 1959. Text in Japanese.

A study was carried out to determine the microquantity of fluorine in chronic fluorine poisoning. Both bleaching colorimetry of Th-Alizann and photoelectro-colorimetric titration were improved and the conditions for increasing the accuracy were determined. This method was based on the reaction of the Fluoride ion with Th-Ahzarin lake, utilizing the phenomenon which quantitatively changed with the density of the lake by letting F⁻ form a colorless complexion with +4 Thorium ion. The method used was considered appropriate for determination of microquantity of fluorine. The results obtained are as follows: (1) Titration is suitable as a routine method since the quantity examination line becomes straight. 2) With both methods, measurement will be possible down to 0.1 gamma/25 ml (0.004 ppm). 3) Over the range fluoride ion 0 to 20 gamma/25 ml, repeatability is possible to 95 to 105%. 4) Measurement should be undertaken exactly five minutes after the coloring of the lake. 5) Hydrogen ion concentration greatly affects the accuracy and precision, and this measurement should be taken at exactly pH 3.00. 6) In photoelectro-colorimetric titration, the endpoint was fixed at E 0.080 for improving precision. 7) The extent of the effect of interfering ions was small in Cl, Ca and NH₄ ions, medium in Mg, SO₄, and extremely high in Al and HPO₄ ions.

SAMPLING ATMOSPHERIC FLUORIDES WITH GLASS FIBER FILTERS. J. Air Pollution Control Assoc. 13, (8) 374-7, Aug. 1963.

Glass fiber filters with uniformly low fluoride blanks compared well with impingers for sampling gaseous and particulate fluorides in the various atmospheres. The filters offer a simple and convenient means of collecting total atmospheric fluorides at a minimum cost for equipment and maintenance. Although the only limitation on the size of sample is that enough fluoride be collected for accurate determination, the method described is especially adapted to collecting samples covering 24 or longer. Samplers can be operated for at least a week at most locations without attention. This is frequently adequate for monitoring purposes. Shorter sampling intervals are necessary to establish the extent of short-time fluctuations. The filters showed a tendency to give slightly lower concentrations than impingers when sampling hydrogen fluoride and slightly higher concentrations when particulate fluoride predominated, but the differences were not statistically significant. Care should be exercised in selecting glass fiber filter media for fluoride sampling, however, because wide differences were found in the magnitude and variability of fluoride blanks of different media tested. The use of an aluminum tube apparatus preceding the glass fiber filters offers a means of separating gaseous and particulate forms of fluoride, that is the most

satisfactory of several methods previously tested by the authors. Protection from moisture is essential for proper operation of either the glass fiber filter samplers or the aluminum tube apparatus, but the protection provided must not prevent fluoride from reaching the samplers. The shelters tested did not affect results, and the aluminum tube apparatus worked just as well with the open end down.

FLUORINE AND HYDROGEN FLUORIDE DETERMINATION IN THE AIR WITH A SOLID SORBENT. *Gigiena i Sanit.* 28, (10) 48-50, Oct. 1963. Russ. (Tr.) (Translated by B. S. Levine in U.S.S.R. Literature on Air Pollution and Related Occupational Disease, Vol. 12.) CFSTI: TT 66 61429

No simple and adequately sensitive methods have been described for the determination of fluorine and hydrogen fluoride. Therefore, the first step in this investigation was to select a substance which might completely absorb both components. After some preliminary tests the following absorber solution was selected; Na₂S₂O₃-7, KI-4, and methyl (p-methylaminophenol sulfate) 0.1 per cent by weight. However, successive determinations of the fluoride-ion in this absorber mixture by highly sensitive procedures proved very complicated. For this reason, the present authors decided to use solid absorbers. The first absorber thus tested was silicagel trademarked MSK of granule sizes ranging between 260 and 300 mg, which were impregnated with an aqueous solution of triethanolamine. Best results were obtained with 2 g of the silicagel in a Yavorov or in a U-shaped tube. Fluorine determinations were made colorimetrically by the thorium-thoron method after it had been extracted from the silicagel.

O. Cucchiara, R. Rex, T. Donaghue
THE DEVELOPMENT OF AN INSTRUMENT FOR THE DETECTION OF HAZARDOUS VAPORS. Parametrics, Inc., Waltham, Mass. (Technical Rept. No. AFAPL-TR-65-SO.) June 1965. 54 pp. DDC, AD 465094

A prototype model of an instrument which is capable of detecting low concentrations of hydrogen, fluorine and fluorine-containing oxidizers was developed. The instrument provides an audible alarm within three to five seconds after exposure to near hazardous concentrations of these gases. The alarm concentrations are either 0.5% or 1.0% hydrogen, and .025 ppm of fluorine, chlorine trifluoride or oxygen difluoride. Other detection levels (both higher and lower) could be set if required. The basis of this technique is that the loss of radioactivity of a kryptonated homolog upon reaction with a gas is proportional to the concentration of the reacting gas. The instrument is portable, simple to operate, and reliable. The instrument incorporates the technique of radiochemical exchange using kryptonates. Selectivity is achieved by the utilization of different kryptonated sources for the various gases. Other gases can be detected with this instrument by using appropriate kryptonate homologs. DETECTION OF LIQUID CRYSTAL GASES (REACTIVE MATERIALS). Westinghouse Electric Corp., Pittsburgh, Pa., Research Labs. (Technical Rept. No. RADC-TR-64-569.) Aug. 1965. 127 pp. DDC, AD 620 940

The purpose was to determine whether reactive liquid crystals could be developed that would detect 1 to 10 ppm of certain gases. Satisfactory materials were produced to detect hydrazine hydrate (HH), unsymmetrical dimethylhydrazine (UDMH), NO₂, HNO₃, HF, and HCl. With the exception of HCl and HF, all of the gases could be readily distinguished from one another. Temperature-sensitive detectors were developed which are capable of distinguishing between HH and UDMH at concentrations of 8 ppm. A number of detectors were developed that respond to the oxides of nitrogen, and detection of 6 ppm of NO₂ was satisfactorily achieved. N₂O, which is relatively inert, was found not to react with any of the systems studied. When oxides of nitrogen are present in an atmosphere that contains any water vapor, HNO₃ will be formed. Materials that detected 1 ppm of HNO₃ were prepared and tested. Two detectors were developed that will detect HCl, and HF at concentrations below 1 ppm. However, no simple method for distinguishing between the two was found. The set of reactive cholesteric liquid crystals exhibit a change in color transition temperature upon exposure to the contaminants.

DETERMINATION OF FLUORIDE BY PYROHYDROLYSIS AND AUTOMATED COLORIMETRY. Du Pont (E.I.) De Nemours & Co., Aiken, S. C., Savannah River Lab. (Rept. DP-1004.) Dec. 1965. 15 pp. CFSTI, DP-1004

A pyrohydrolytic-colorimetric method was developed for the determination of fluoride in the presence of high concentrations of interfering elements. Adaption of the colorimetric reaction of fluoride with the lanthanum chelate of alizarin complexone to an automated system gave a minimum detectable limit of 0.050 microgram/ml of fluoride in pure solutions and 25 microgram of total fluoride in samples that required the pyrohydrolytic separation from interferences. The relative standard deviation of the method is better than 1% at twenty times the limit of detection. (Author abstract)

FURTHER EVALUATION OF GLASS FIBER FILTERS FOR SAMPLING HYDROGEN FLUORIDE. J. Air Pollution Control Assoc. 15, (4) 166-7, Apr. 1965.

Tests were conducted to determine the limitations of glass fiber filters in sampling atmospheric hydrogen fluoride. The tests were conducted in a plastic chamber receiving a continuous supply of clean air with HF added. Sets of three two-inch filter discs were used, one behind another in common open-faced holder. Samples were drawn through the filters at about 1.3 cfm for periods of one, two and three days. Tests were made at several different atmospheric fluoride concentrations ranging from 2 to 25 microgram/cu m. Filters with and without latex binder (MSA-CT77225 and MSA-CT77332 respectively) were evaluated simultaneously. Filters without latex binder were more efficient collectors than those with binder. Up to 75 microgram F/sq in. of filter area was collected by a single filter before the loss reached 5%. Two filters, one behind the other, collected over 250 micrograms F sq in. of filter area before loss through them reached 5%. By controlling the sampling rate and time to avoid exceeding the saturation limit, it is possible to use glass fiber filters for sampling over a wide range of fluoride concentrations.

EFFECT OF VOLTAGE VARIATION ON THE PHOTOMETRIC TITRATION OF FLUORIDES WITH THORIUM

NITRATE. Contrib. Boyce Thompson Inst. 19, (3) 289-90, Mar. 1958.

The photoelectric filter photometer used for the titration of fluorides (F) with thorium nitrate (TH(NO₃)₄) is of the balanced type and makes use of two photocells connected in opposition to a sensitive galvanometer. The light bulb of this photometer is connected directly to the 115-v. electric line without any voltage stabilizer. In order to determine the effect of voltage variation, a series of tests was carried out with known amounts of F titrated with Th(NO₃)₄ at five different voltages (90, 100, 110, 120, and 130 v.). The variation in voltage during the determinations did not exceed more than 1%. A variation of 10% in voltage resulted in the following percentage decrease in the titration with 0.0001N Th (NO₃)₄: 2% for 90 to 100 v.; 3.6% for 100 to 110 v.; 4% for 110 to 120 v.; and 6% for 120 to 130 v. Corresponding results with 0.01N Th(NO₃)₄ were: 6% for 90 to 100 v.; 11% for 100 to 110v.; 13% for 110 to 120v.; and 5% for 120 to 130v. The 0.01N Th(NO₃)₄ is generally used for titrating solutions containing more than 200 micrograms F. Titrations were carried out using a voltage stabilizer and the results obtained showed no improvement when compared with the titrations carried out without the voltage stabilizer. When the photoelectric titrator is used with a 0.001N Th(NO₃)₄ solution and the voltage of the line varies within 5%, the instrument can be used without a stabilizer. If the voltage varies over 5%, a voltage stabilizer is recommended, especially if the 0.01N Th(NO₃)₄ solution is used.

IMPROVED APPARATUS FOR THE DISTILLATION OF FLUORINE AS HYDROFLUOSILICIC ACID. Contrib. Boyce Thompson Inst. 17, (8) 489-94, Sept. 1954.

A new type of steam distilling apparatus for the distillation of fluorine as hydrofluosilic acid is described. It is composed of a steam generator made from a 1500-ml flask provided with a safety tube and an outlet which can be closed by a Hofman clamp. A ground glass joint connects a steam generator with the distilling flask. A second joint connects the latter to a Friedrich type condenser. The distilling flask is made from a Pyrex cylinder through which a thermometer passes and dips into the solution. An electric jacket keeps the temperature of the distilling liquid at 135 plus or - 2 C. A multiple distilling apparatus of six units is described. It takes about 75 min. for the collection of 500 ml of distillate, low distilling blanks, good recovery (98 to 101%), and automatic efficient washing.

C. MEASUREMENT METHODS

151

(HF) and silicon tetrafluoride (SiF_4) gases in concentrations of less than one to several hundred parts per billion of air. A closed type conical-shaped absorber of 500-ml. capacity containing 50 ml. of absorbing solution proved efficient (95% recovery of the fluorine (F) for absorbing fluorides from air passed through the absorber at rates up to 70 cu. ft. per hr. A smaller absorber (300 ml.) of similar design containing 40 ml. of absorbing solution was equally efficient with air speeds up to 40 cu. ft. per hr. and, when converted into a distilling unit without transferring the sample, gave 95% recovery of F and an average blank of 1 microgram F. Both absorbers are easy to wash and are less subject to contamination than conventional types previously used. A description is also given of an automatic time-clock sampling unit together with details of the back titration procedure used in fluorine analysis. Recent results indicate that direct titration of the sample with thorium nitrate and determination of the end point by means of a specially designed filter photometer constitute a much faster, more sensitive, and more precise method than visual titration with sodium fluoride (NaF). (Author summary modified)

R. Mavrodineanu J. Gwirtsman

PHOTOELECTRIC END-POINT DETERMINATION IN THE TITRATION OF FLUORIDES WITH THORIUM NITRATE.

Contrib. Boyce Thompson Inst. 18, (3) 181-6, June 1955.

The procedure used in this laboratory for the determination of fluorides in plant tissue and in air is based on the Willard and Winter method. In this method the fluoride is isolated in the form of fluosilicic acid after a perchloric acid steam distillation at 135 C. A description is given of a photoelectric filter photometer functioning as a comparator for the determination of the end point in the titration of fluorides (F) with thorium nitrate ($\text{Th}(\text{NO}_3)_4$) in the presence of sodium alizarinsulfonate. It is a balance type instrument consisting of a nearly monochromatic light source, two glass cells for the solutions, and two barrier-layer photoelectric cells connected in opposition. A mirror galvanometer mounted in parallel acts as a zero indicator. The instrument is directly supplied by the 115-volt line and is stable and sensitive. Its use makes possible the titration of 1 microgram F in 250 ml of solution, one determination requiring 10 minutes. When equipped with adequate supplementary parts it can also be used for the transmission measurements of colored solutions as well as a nephelometer or fluorometer. (Author summary modified)

A SIMPLE METHOD FOR THE DETECTION OF VOLATILE

FLUORIDES IN AIR. Contrib. Boyce Thompson Inst. 18, (1) 82-4, Dec. 1954.

The method commonly used for determining gaseous fluorides at concentrations as low as one ppb or less air requires the use of special equipment and procedures. The present method utilizes dry sampling with a strip of blotting paper impregnated with a suitable reagent, that reacts with hydrogen fluoride (HF) and other volatile fluorides which are readily convertible into HF, such as silicon tetrafluoride (SiF_4) and fluosilicic acid (H_2SiF_6). The degree of bleaching is a function of the concentration of the gas and the duration of exposure. The procedure for impregnation of the paper is as follows: strips of white blotting paper of 0.5-mm. thickness and convenient size are immersed in a solution of thorium nitrate. After draining, they are immersed in a solution of sodium alizarinsulfonate. A rose-colored lake will form on the paper surface. After a short rinsing in distilled water, the paper is dried. The prepared strips, protected from rain, are hung in the desired locations for the detection of atmospheric fluorides. Half of the surface of the strip is covered with a thin vinyl film in order to provide a control. After the absorbing medium (strips) has been

exposed for a given time, it is developed by immersion in a 1/100 N HCl solution and the vinyl film taken off. Any bleaching that occurs on the exposed part, as compared with the control, constitutes a proof of the presence of volatile fluoride (as HF, H₂SiF₆, SiF₄, etc.) in the area. Fluoride concentration in unknown atmospheres may not only be detected but also approximately evaluated by standardizing the sensitive paper exposed for a given time in atmospheres of known fluoride concentration.

SUMMARY OF PROCEDURES USED IN THE CONTROLLED FUMIGATION OF PLANTS WITH VOLATILE FLUORIDES AND IN THE DETERMINATION OF FLUORIDES IN AIR, WATER, AND PLANT TISSUES. Contrib. Boyce Thompson Inst. 21, (8) 453-64, Sept. 1962.

Investigations at Boyce Thompson Institute on the effects of atmospheric fluorides on vegetation necessitated the development of procedures for the controlled fumigation of plants and for the analytical determination of fluorides in plant material, water, and air. These procedures were published as they were developed and modified over a period of several years. This paper summarizes the procedures currently employed and gathers in one place the references to the detailed technical papers necessary to reproduce them.

USE OF SODIUM PEROXIDE FUSION FOR THE DETERMINATION OF FLUORIDES IN VEGETATION. Contrib. Boyce Thompson Inst. 18, (9) 419-20, Dec. 1956.

The procedure for analyzing fluorine in vegetation has been improved in recent years by the development of a new steam-distilling apparatus with electric heating and the use of photoelectric end-point determination in the titration of fluorides with thorium nitrate. In an effort to shorten the time required for the conversion of insoluble fluorine compounds into a soluble ionizable form, a direct fusion of the plant material with sodium peroxide (Na₂O₂) was carried out in a Parr bomb. The results showed that the average time required to complete a direct Na₂O₂ fusion is 30 minutes as compared with 6 hours necessary for the ashing with CaO used in the standard procedure. Both potassium nitrate and potassium perchlorate are recommended for the accelerator, the latter being preferable, particularly if the nitrate content of the sample is high.

DETERMINATION OF FLUORIDES IN PLANT TISSUES, AIR, AND WATER. Anal. Chem. 29, (6) 887-92, June 1957.

Special equipment was developed and analytical procedures were adapted for determination of fluorides in vegetation, air, and water, in order to study the effect of volatile fluorides on vegetation. The equipment includes a steam-distilling apparatus with a complete electric heating system, two types of absorbers for air analyses, one of which also functions as a steam-distilling flask, and a photoelectric filter photometer for titration of fluorides with thorium nitrate. The main advantages are

<xref image="2000WVE7.TIF|V3|2006:09:28:01:25:02.00|119980|0"> image: </xref>

low blanks, fast distillation, quantitative recovery, safe operation, and convenient and efficient washing. Consideration was given to sampling of plant material and effect of silica on the determination of fluorides in vegetation. Results of a cooperative analytical project involving 15 different laboratories are included.

EFFECTS OF GASEOUS AIR POLLUTANTS ON THE RESPONSE OF THE THOMAS SO₂ AUTOMETER. Environ. Sci. Technol. 1, (1) 68-73, Jan. 1967.

A study was made of the quantitative response of the Thomas SO₂ autometer to gases that might coexist with SO₂ as air pollutants. These gases included NO₂, NO, HCl, Cl₂, NH₃, and HF. The gas mixtures were prepared dynamically at the ppm level by a flow mixing method to a high degree of accuracy. Syringe pumps were used to add small quantities of pure gases to a large vol. air stream. The effects of NO₂, NO, and HF on the SO₂ reading were small, but HCl, NH₃, and Cl₂ gave significant response. (Author abstract)

A SOURCE SAMPLING TECHNIQUE FOR PARTICULATE AND GASEOUS FLUORIDES. J. Air Pollution Control Assoc., 18(1):12-14, Jan. 1968. 7 refs. (Presented at the 60th Annual Meeting, Air Pollution Control Association, Cleveland, Ohio, June 11-16, 1967.)

Sampling of effluents that contain fluorides is often hampered by the reactivity of hydrogen fluoride. Although techniques have been developed for sampling ambient air, they are not applicable to stack effluents, which contain higher concentrations of fluoride, water, and particulates. A sampling system for the separation and collection of gaseous and particulate fluoride was devised and tested. In this system a heated glass probe serves as a reactor for converting hydrogen fluoride to silicon tetrafluoride before the particulate is filtered. Laboratory tests have demonstrated quantitative recoveries of hydrogen fluoride after the test mixtures pass through the probe and through filter papers impregnated with sodium bicarbonate. The equipment has performed satisfactorily in field sampling.

METHODS OF MEASURING AIR POLLUTION (PART 6).

Metodi di Misura dell' inquinamento Atmosferico (Sesta Parte. Fumi Polveri (Milan) 1(7): 18-24, Jan. 1967. It.

Two methods for measuring minute quantities of fluorine in the atmosphere are described. 1) Two methods are given for measuring a sample with an impinger. In the photometric method air is introduced in the apparatus containing a normalized solution of 0.1 N NaOH which absorbs the fluorine ions. The ions are then separated in the vapor state and the amount of fluorine determined photometrically. The sensitivity of this method is 3 micrograms F/cu m of air when measured directly, and 0.6 microgram F/cu m when preliminary concentration measurements are made. The metric titration method, less sensitive than the photometric (10 micrograms F/cu m, is used for high fluorine concentrations. Equations are given for both photometric and titration methods from which the concentration of fluorine can be calculated. 2) In micro-diffusion methods, air is passed across a bottle containing gas and pieces of plexiglass on which compounds containing fluorine are absorbed in 0.1 N NaOH. Extraneous substances are eliminated by micro-diffusion and the amount of fluorine is determined photometrically.

THE USE OF WEEDS AS A MEANS OF EVALUATING

VEGETATION DAMAGE CAUSED BY AIR POLLUTION.

Proc. Natl. Air Pollution Symp., 3rd, Pasadena, Calif., 177-90 (1955)

This paper presents the results of fumigations of ten species of weeds which occur more or less commonly throughout the United States, by ammonia, chlorine, hydrogen fluoride, hydrogen sulfide, oxides of nitrogen, and sulfur dioxide. Plants of two different ages and growing under two conditions of available soil moisture were fumigated at two concentrations of each compound. The results are recorded as (1) descriptions and photographs of the markings which were produced on each weed by each fumigant; (2) relative resistance of the various weeds to each fumigant. By using these two types of information it is believed that, in an area where air pollution may be causing markings on vegetation, observation of the markings on some of these weeds will lead to identification of the pollutant and consequently determination of the area over which it is spreading in concentrations sufficiently high to mark vegetation. RECORDING THE RESPONSE OF PLANTS TO VARIOUS AIR POLLUTANTS. J. Air Pollution Control Assoc. 13 (8), 355-9 (Aug. 1963). (Presented at the 55th Annual Meeting, Air Pollution Control Association, Chicago, 111., May 20-24, 1962.) This paper is an outline of experimental procedures and instrument methods employed to measure effects of the air pollutants, fluorides, ozone, and peroxyacyl nitrates (PAN), on citrus trees. The plan calls for the operation of at least three experimental test sites on which 24 citrus trees in plastic enclosures are given six treatments as follows: A - 'Clean air,' B - 'Ambient air,' C - 'Fluoride-free' air, D - 'Ozone-free' air, E - 'Clean air' with fluoride added, and F - 'Fluoride and ozone free' air. Two test sites on lemon trees are in operation at Upland and Cucamonga, California. A third site on Naval orange trees is under construction at Upland, California. Photosynthesis and transpiration measurements are used to supplement long-term growth and yield observations. Inlet and outlet air samples are accumulated in bags for one-half hour periods. The difference in humidity and carbon dioxide is then measured sequentially from the air in the bags. Automatic punchcard recording is provided for plot samples and for the ambient air pollutants which consist of: dioxide, nitric oxide, ozone, total oxidants, and fluorides. These are recorded together with the date, time, temperature, and an integrated value for sunlight. Four IBM cards are punched each hour

C. MEASUREMENT METHODS

153

with positive identification of the data sources both from the punch position and card reference number. Activated charcoal and limestone filters are used to remove oxidant and fluoride phytotoxicants, respectively, from the air entering the plots. The average concentration of fluoride occurring on one day is used to set the hydrogen fluoride concentration metered into the four plots receiving this treatment on the following day. Nitric oxide is diluted 1 to 50 with nitant level increases to react with and inactivate ozone as a phytotoxicant. Twice the stoichiometric amount of NO is used as the level of total oxidants, i.e., for 0.1 ppm total oxidant 0.2 ppm NO is added.

WINDOW MATERIALS FOR USE IN INFRARED ANALYSES

INVOLVING NITROGEN DIOXIDE. Anal. Chem., 31(4):628-629, April 1959. 11 refs.

Calcium fluoride, barium fluoride, and arsenic trisulfide crystals were tested as alternatives to sodium chloride crystals for use as infrared-transmitting materials in spectrophotometric devices designed for nitrogen dioxide determinations. The presence of 0.1% or more NO₂ damages sodium chloride windows in gas cells on a single exposure. Each crystal was subjected to 0.17% NO₂ in carbon tetrachloride for 4 days. Both barium fluoride and calcium fluoride crystals showed no change in surface appearance, whereas the arsenic trisulfide crystal became coated in an hour or less with a greenish yellow deposit at NO₂ concentrations of 0.17% or 0.06%. Barium fluoride showed an additional 4 micron of transmittance range in comparison to calcium fluoride, making it more attractive as a window material in infrared spectrophotometers designed for NO₂ measurements.

MEASUREMENT OF AIR POLLUTANTS. Bunseki Kagaku

(Japan Analyst) (Tokyo) pp. 110R-7R. 1966, Jap.

Important papers published in Japan Analyst in 1964 and 1965 are summarized. The subject is limited to measurement methods of air pollutants known to be toxic to health. Pollutants from stacks and automobile exhausts are covered, including many cyclic hydrocarbons, aldehydes, sulfur oxides, nitrogen oxides, ozone, carbon monoxide, carbon dioxide, fluorine compounds, hydrogen sulfide, lead compounds, and offensive odors. Various sampling methods are described, especially using filtering with glass wool filters, electric dust collectors, gas absorbers, and portable samplers containing silica gel. The pollutants can be measured by electroconductivity methods, colorimetric measurement recorder, gas chromatographic analysis, electron capturing detector, and hydrogen ion detector. The papers summarized do not include those dealing with industrial or occupational environment or mining.

DEVELOPMENT OF AN ATMOSPHERIC MONITORING

SYSTEM (FINAL REPT. JUNE 12, 1958-JUNE 30, 1961).

(Mine Safety Appliances Co., Pittsburgh, Pa., Research and Engineering Division.) (1961). 45 pp. (Kept. No. MSA 301825.)

Atmospheric monitoring devices sensitized to continuously detect and record toxic and higher concentrations of HF, F₂, B₅H₉, N₂H₄, NO₂ and C₁F₃ (missile fuels and oxidizers) have been developed and engineered. An ionization type analyzer sensitive to finely divided aerosols is used as the detecting instrument. Various amine and acid reagents are used to convert the oxidizers and fuels respectively to aerosols. Response times are in the order of seconds and a high degree of specificity has been attained. CONTINUOUS ANALYSIS OF GASEOUS FLUORIDES IN
AMBDZNT AIR AND ON INDUSTRIAL STACKS. Preprint.
Air Pollution Control Assoc., Pittsburgh, Pa. (Presented at the Air Pollution Control Association Annual Meeting, 60th, Cleveland, June 11-16, 1967, Paper 67-75.)
Two sampling methods are discussed for full-range hydrogen fluoride sampling. For ambient use, the SRI fluorescent-quenching method is explained as the one that would reach a low sensitivity of 0.1 ppb. For the high-stack sampling range, an internal electrolysis instrument developed by Baker and Morrison for continuously monitoring fluoride emissions from industrial stacks is described. The tests indicate that the internal electrolysis method can be used effectively for stack fluoride emissions.

AN INTERLABORATORY STUDY OF FLUORINE IN
VEGETATION. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa. (Presented at the Air Pollution Control Association Annual Meeting, 60th, Cleveland, June 11-16, 1967, Paper 67-76.)

An interlaboratory study of fluorine analyses on plant tissues was performed to determine the current levels of within- and between-laboratory precision. Homogeneous, ground, fluorine-containing leaf tissues of alfalfa, citrus, gladiolus, pine, and orchard grass were analyzed by routine methods currently in use in 31 different laboratories. The study indicated that there are wide differences in results from laboratory to laboratory. The wide variations in procedures, techniques, and

<xref image="2000WVE9.TIF|V3|2006:09:28:01:25:08.00|113404|0"> image: </xref>

operating conditions probably account for the relatively large standard deviations between laboratories which ranged from 12.7 to 38%. The results of duplicate determinations indicated that some laboratories have difficulty in obtaining reproducible results. Greater attention to detail, more careful performance of operations, increased use of check procedures, standardization of techniques, and development and use of referee samples would lead to increased agreement in results. Nakamura, J. T. and K. E. Ball
ATMOSPHERIC MONITORING OF TOXIC LEVEL OF MIS-
SILE PROPELLANTS. Am. Ind. Hyg. Assoc. J. 2S(1):77-80,
Feb. 1964.

The problem of toxicity in the over-all missile industry represents both the materials involved and the amassed quantities of these materials. Although most missile fuels and oxidizers are predictable in their behavior, the handling of these relatively common compounds in tonnage lots presents problems which have not been explored and therefore cause due concern. Spill tests, conducted at the Edwards Rocket Research Laboratories, releasing up to half-ton quantities of such propellants as fluorine, nitrogen tetroxide, hydrazine, UDMH, chlorine trifluoride, and pentaborane have been conducted. In some tests, fuels and oxidizers were spilled together. The purpose being to determine the magnitude of the hazard; that is, the aspects of explosion and fire as well as toxicity and pollution. The following are felt to be reasonable requirements for a tentative atmospheric monitoring arrangement: (1) accuracy plus or minus 25%, (2) range capable of at least two orders of magnitude, preferably more, (3) speed of Response 90% of final reading or more in less than 10 seconds, (4) specificity - the instrument need not be 100% specific for a particular fuel or oxidizer since in many cases there is little chance of any other material being in the vicinity. Common solvents, degreasing fluids, oil, gasoline and materials of this nature should not cause an interfering signal. A fuel concentration should not inhibit the response of incorporated into a detection system. These 'extras' might include explosion-proof design, malfunction-indicating devices and elaborate centralized readout systems. For many application, a may provide adequate information. The choice specifications for a detection system should be governed by the specific problem involved and the type of information required, choice specifications for a detection system should be governed by detectors and spot-check devices. In a few applications, required.

COMPARATIVE ABSORPTION TESTS FOR DETERMINATION OF GASEOUS AIR CONTAMINANTS IN WASH BOTTLES. (Vergleichende Absorption-sversuche zur Bestimmung gasformiger Luftverunreinigungen in Waschflaschen.) Z. Anal. Chem. 226 (4), 352-61 (1967). Ger.
Comparative gas-absorption tests are described using air contaminated with CO₂, HCl, NH₃, SO₂, and air samples from production plants containing fluorides. The concentrations were in the range of the Maximum Allowable Concentrations and below. Three kinds of gas washing bottles have been employed: 1) Impinger washing bottles, recently recommended for air analyses; 2) ordinary Drechsel washing bottles; 3) washing bottles with porous glass discs containing a foam formation agent. The effect of the Impinger equalled that of the Drechsel type. With HCl, NH₃, and SO₂ there was no difference between Impinger and foam absorption bottle, but with CO₂ and air samples containing fluorides foam absorption showed up to ten times higher absorption efficiencies. Corresponding analyses of open-air samples containing fluorides are being conducted. (Author summary)

CALIBRATION OF LIMED FILTER PAPER FOR MEASUR-

ING SHORT-TERM HYDRO- GEN FLUORIDE DOSAGES.

THE EFFECT OF TEMPERATURE, HUMIDITY, WIND

SPEED, AND DOSE. Am. Ind. Hyg. Assoc. J., 28(3):254-249,

May-June 1967. 5 refs.

Limed filter papers were exposed to analyzed concentrations of hydrogen fluoride under controlled conditions of temperature, dew point, concentration, windspeed and time. The exposed papers were analyzed for their fluoride content. Within the limits of accuracy of the test setup, the following conclusions are made: Temperature, dew point, concentration, and time have little or no effect on absorption. Dose has little or no effect on absorption until dosages in excess of 400 to 600 ppm min, dependent on windspeed, are reached. Within the limits of 3 to 18 mph, absorption varies with dosage according to a given equation. (Authors' abstract)

REPORT OF TOXIC EFFECTS OF FLUORINE FOLLOWING

SHORT-TERMINHALATION. Miami Univ. School of

Medicine, Coral Gables, Fla., Dept. of Pharmacology, Contract

NGR10-007-012, Rept. CR- 76741, 73p., May 31, 1966. NASA:

N66-32296

In order to broaden the knowledge of the hazards of short-term exposures to fluorine from rocket propellants, experimental animals were exposed to fluorine for short periods of time. The concentrations in the exposure chamber were extremely important. Since suitable analytical methods were not available, they were developed. Special equipment, including a chamber for exposures, was designed and built to handle fluorine safely. Colorimetric methods were used for the measurement of the concentrations of fluorine and fluorides in the air of the exposure chamber. Analytical methods for fluorine in air, using gas-liquid chromatography, were pursued. A thermal conductivity detector measured the fluorine, but was not sensitive enough for these purposes. Indirect measurement of fluorine, by conversion to chlorine, with a thermionic flame detector appeared to be satisfactory. Signs of intoxication

C. MEASUREMENT METHODS

155

from high concentrations of fluorine in air were marked irritation of the mucous membranes of the eyes and respiratory tract. The skin of the animals showed some irritation at the concentrations used. The LC50 (concentration calculated to kill 50% of the animals) was determined for 5, 15, 30, and 60 minutes of exposure in both rats and mice, for 15 and 60 minutes in guinea pigs, and for 5 and 30 minutes in rabbits. There were no significant differences between the LC50's for the different species. Following sublethal exposures, effects in the lung were observed immediately. Effects in the kidney (and in the liver) were observed first on the seventh to fourteenth day following exposure. Pathology in the lung or kidney occurred from exposure to almost the same concentration. Exposure to higher concentrations was necessary before pathology was observed in the liver. Concentrations at or below 100 ppm for 5 minutes, 70 ppm for 15 minutes, 55 ppm for 30 minutes, or 45 ppm for 60 minutes caused no apparent effects in the animals.

DETECTION OF FREE FLUORINE IN THE ATMOSPHERE
BY 1131 RADIOTRACER ANALYSIS. Intern. J. Appl. Radiation Isotopes, Vol. 18, p.183-191, March 1967. 6 refs.
The chemical displacement reaction, in which combined fluorine combines with free iodine to yield combined iodine and free fluorine, has been evaluated as a means of detecting and measuring free fluorine in the atmosphere. The objectives of this program have been to determine the chemical properties of this reaction at micro-concentration levels, to develop the calibration techniques which will produce a working analytical procedure, and to predict the potential service of this system as a compact, portable type instrument for performing atmospheric determinations on field locations. The basic experimentation involves passing atmospheric gases through alkali iodide columns tagged with radioactive 1131, which is released and captured in a sodium thiosulfate solution upon exposure to calibrated quantities of fluorine contamination. Determining quantitative amounts of fluorine in ppb quantities, instantaneous recording of the atmospheric contamination, discriminating between elemental and combined fluorine, and instrument portability are the favorable features sought with this radio release technique. (Authors' abstract)

Farrar, George H.
MANUAL PROCEDURES FOR THE ESTIMATION OF ATMOSPHERIC FLUORIDES. J. Air Pollution Control Assoc., 17(11):738-741, Nov. 1967. 18 refs.
Manual methods for the determination of air-borne fluorides, including the discrimination of gaseous and particulate forms, are reviewed. Published methods are re-examined and comparative sampling data presented, to point out advantages of some newer techniques in sampling, separation, and quantitation. There are several alternatives to the classical methods of

sampling and determination of air-borne fluorides. The bulky, fragile, liquid-filled scrubbers can be replaced with simple, rugged, dry collectors. When separation of interfering ions is necessary, ion exchange can generally affect it for a fraction of the cost in time and equipment required for Willard-Winter distillation. And finally, the wide range of sensitivities afforded by instrumental methods, either spectrophotometric or electrometric, can eliminate the need for developing a career man to titrate fluoride. Unfortunately, there seems to be no alternative to vigilance in reducing the errors in measuring air sample volumes and avoiding contamination from equipment and reagents.

Bond, A. M., and T. A. O'Donnell

DETERMINATION OF FLUORIDE BY ATOMIC ABSORP-
TION SPECTROMETRY. Anal. Chem., 40(3):560-563, March
1968. 14 refs.

Fluoride ion depresses the absorption of magnesium in the air-
coal gas flame, the change in absorbance of the magnesium
resonance line at 2852 Å being proportional to the fluoride
concentration over the range 0.2-20 microgram/ml. In the
absence of interfering ions, principally sulfate and phosphate,
the effect can be used to determine fluoride ion in this concen-
tration range. An alternative, though somewhat less sensitive,
technique is based on the enhancement of zirconium absorp-
tion by fluoride ion in the nitrous oxide-acetylene flame; this
allows the determination, with a high degree of freedom from
interference, of fluoride ion over the range 5-200 micro-
gram/ml. In the presence of phosphate, which interferes with
the zirconium method, a similar enhancement of titanium ab-
sorption can be used for fluoride determinations in the range
40-400 microgram/ml. These atomic absorption methods for
fluoride determinations have been found to be considerably
more rapid than more classical methods and in many cases can
be used directly without prior separation of fluoride. Their ap-
plication has been demonstrated in the analysis of a wide
range of inorganic fluorides. (Author's abstract, modified)

1967. 1 ref. 1967. 1 ref. CFSTI, DDC: AD 652849 CFSTI, DDC:
AD 652849

The subject of this report is the development of a portable system for the detection of low concentrations of nitrogen tetroxide (N₂O₄), fluorine (F₂), and unsymmetrical dimethylhydrazine (UDMH) in air. The detection system is based upon the change of electrical resistivity of thin metal films when exposed to these gases. Silver metal films coated with appropriate salts proved to be applicable to the detection of all three gases; however, the following sensitized metal films were found to be optimum: for N₂O₄, silver; for F₂, copper; and for UDMH, gold. Using the best film and salt combinations found to date, N₂O₄ could be monitored over the range of 0.1 to 50 ppm, F₂ over the range 1.0 to 50 ppm, and UDMH over the range 10 to 100 ppm, with a standard deviation of about 20 percent. The effects of temperature over the range 50 deg. to 90 deg. C and of humidity from 10 to 90 percent on the response characteristics of the thin film sensors were found to be significant but within the tolerance limits. Means for reducing these effects were suggested which, if successful, would, in effect, make this detection system practically independent of changes in the environment. A portable breadboard readout instrument was designed and fabricated for use with the sensors to form an integrated detection system for personal protection. (Authors' abstract)

Ubl, Z.

UNIFIED METHODS FOR THE ANALYSIS OF POLLUTANTS IN THE FREE ATMOSPHERE. Acta Hygienica, No.

1, Suppl, 1966. 84p. 24 refs.

Methods for the analysis of pollutants in the air are presented with precise and complete notes dealing with procedure, apparatus, reagents, and possible problems. Procedures are given for determining the following compounds in the air: SO₂, CO, NO₂, NO_x, sulfuric acid aerosols, Cl₂, H₂S, Pb compounds, CS₂, phenol, As, F₂, NH₃, soot, Mn compounds, SiO₂, and formaldehyde. Also discussed are methods of air sampling, calibration methods, calculations, sensitivity and error in the determinations interferences from other compounds, and the principle involved in the method.

SEPARATE DETERMINATION OF FLUORINE AND ALUMINUM COMPOUNDS IN AIR IN AND AROUND FACTORIES. ((Razdel'noe opredelenie ftoristykh i alyuminievykh soedinenii v vozdukh proizvodstvennykh pomeshchenii i okruzhayuschikh territorii.)) Hyg. & Sanit. (English translation of: Gigiena i Sanit.), 33(1-3):212-216, Jan.-March 1968. 5 refs. CF-

STI: TT 68-50449/1

A method for the separate determination of hydrogen fluoride (gaseous and mist) fluorides (NaF, AlF₃, NaAlF₆) and aluminum oxide when they are simultaneously in the air was studied. Two methods, one desorptional and one chemical, were elaborated for separate determinations of HF, fluorides and Al₂O₃ from a single air sample. Conditions were determined for combined sampling of air with minimum adsorption of HF on the filter. The solubility of aluminum fluorides in water was demonstrated to be drastically reduced by roasting, so that the aerogel must be extracted from the filters with 0.2 N alkali solution.

DETERMINATION OF FLUORIDE IN AIR AND STACK GAS SAMPLES BY USE OF AN ION SPECIFIC ELECTRODE.

Anal. Chem., 40(11):1658-1661, Sept. 1968.

An analytical procedure for the determination of water-soluble fluoride in air and stack gas samples using a specific-ion electrode is described. Gaseous and particulate fluoride in ambient

air are collected by filtration and chemisorption on membrane filters impregnated with sodium formate. Data pertaining to the collection efficiency and the dissolution of collected fluorides from ambient air samples are presented. As little as 0.25 part per billion fluoride in air can be measured with this procedure. Gaseous fluorides in stack gas are collected by reaction with a hot glass probe to form gaseous silicon tetrafluoride, which hydrolyzes in water to form soluble fluosilicic acid. Results obtained with the electrode and the Spadns-Zirconium Lake Method for fluoride in stack gas were compared, and at the 0.05 significance level, no difference existed in the two methods. This relatively new analytical tool, as applied to the analysis of air pollutants, has been shown to be rapid and convenient, and appears to be less susceptible to interferences than other methods presently available for the measurement of fluoride. A NEW CONTINUOUS AIR MONITOR FOR FLUORIDES.

Preprint, Royce Thompson Inst. for Plant Research, Inc., Yonkers, N. Y., ((15)) p., 1968. 9 refs. (Presented at the 61st Annual Meeting of the Air Pollution Control Association, St. Paul, Minn., June 23-27, 1968, Paper 68-86.)

An efficient scrubber for removing water-soluble fluorides from air on a continuous basis has been developed. More than 95 per cent of hydrogen fluoride in the microgram to milligram per cubic meter range is transferred to aqueous solution at air flow rates up to 25 liter per minute. An Orion fluoride combination electrode was used to obtain continuous measurement of the fluoride content of aqueous solution present in the scrubber. Response to atmosphere containing as little as 0.5 micrograms fluoride per cubic meter can be obtained. Use of an Orion meter and proper adjustment of air and liquid flow rates can provide a direct readout in micrograms fluoride per cubic meter over a 100-fold range in concentration. Evaporation of solution during scrubbing is, however, a major source of error. Efforts are currently being made to overcome this difficulty. (Authors' abstract)

THE SEPARATION OF GASEOUS AND SOLID FLUORINE

COMPOUNDS DURING AIR-QUALITY MEASUREMENTS.

Staub (English translation), 28(7):26-31, July 1968. 4 refs. CF-STI: TT 68-50448/7

A method for the separation of gaseous and solid fluorine compounds is described in the case of immission measurements. Solid fluorine compounds are separated from gaseous compounds with the help of a quartz filter head by using diaphragm filters. This filter is installed before the absorption arrangement for gaseous fluorine compounds. Dust deposited on the filter is prepared, together with the filter, for fluoride determination. By weighing the filter it is also possible to carry out a dust content determination. The separation method permits the amounts of gaseous and solid fluorine compounds to be expressed with sufficient accuracy in the case of immission measurements. (Author's summary, modified)

STUDIES ON AIR POLLUTANTS. I. ANALYTICAL METHODS. ((Die Untersuchung von Luftverunreinigungen. I. Analysenmethoden.)) Text in German. Bundesgesundheitsblatt, (10):145-150, May 12, 1967. 71 refs.

This detailed review of the apparatus and techniques used for air pollution measurements deals with both sampling and analytical methods. A distinction is made between empirical or discontinuous and continuous methods of sampling and it is pointed out that only the latter can yield readily interpretable results. In connection with gas sampling techniques, the value of an impinger for increasing the rate of dissolution of gaseous pollutants is discussed. Methods are then described for the quantitative determination of SO₂, SO₃, NO₂, NO, CO, H₂S, HP, and NH₃, and brief mention is made of the techniques of gas chromatography and flame ionization detection for traces of organic compounds. The two principal techniques for estimating the total particulate content of the air are dust-fall and dust-concentration determinations. The latter which depends on photoelectric measurement of the particle density after filtration is more difficult to perform, but more interesting from the health point of view.

APPLICATION OF A BETATRON IN PHOTONUCLEAR ACTIVATION ANALYSIS. Aktiebolaget Atomenergi (Stockholm), AE-333, 1968. 19 refs.

Determinations of iodine in Pharmaceuticals and of fluorine, lead, and mercury in pure compounds were made by photonuclear activation analysis, with a betatron accelerator used as the irradiation facility. The accelerator yields a lower photon flux density than a linear accelerator but has great flexibility with regard to beam direction. Uniform irradiation of the samples was achieved by inserting a rotating sample holder device in the brehmstrahlung beam of the betatron. The detection limits obtained for iodine, fluorine, lead, and mercury were 50, 3, 400, and 15 micrograms, respectively. It is concluded that the betatron has practical applications in the field of pharmacy but is unsuited for lead analyses in pollution studies of air, water, and food. It could be used for the determination of mercury in various biological materials, though better results are expected to be obtained by conventional neutron activation techniques.

INDUSTRIAL APPLICATIONS OF THE SEMI-AUTOMATED FLUORINE ANALYZER. Am. Chem. Soc., Div. Water, Air, Waste Chem. Preprints, 7(1):235-236, 1967.

A semi-automated method of fluoride analysis is based on flashing an acidified sample to a fractionating column, sweeping the distilled fluoride and water to a microcondensor, and mixing the condensate with alizarin fluoride blue-lanthanum reagent. The mixture is then passed to a colorimeter which measures absorbance at 624 millimicrons. The impulse received is recorded on a chart indicating optical density. Samples of air and liquid plant effluents are analyzed directly or after proper dilution to the concentration range of 0.40-4.0 micrograms F/ml. Good results are also obtained when the method is used to monitor phosphate products requiring strict control of fluoride levels.

Jacobson, Jay S.

PERMEATION TUBES AS GASEOUS HYDROGEN FLUORIDE SOURCES. Am. Chem. Soc., Div. Water, Air, Waste Chem., 7(1):232-234, 1967.

The permeation tube technique offers a simple means of obtaining standards for trace gas analyses, since the tubes are

calibrated gravimetrically. The constructions of permeation tubes for delivering known amounts of gaseous fluoride at a constant rate is described. Sources of gaseous fluoride, the resistance of tubing to chemical attack by fluorides, and various techniques of sealing tubes are evaluated. Developmental work indicated that permeation tubes can be constructed containing pure, liquid hydrogen fluoride in polyethylene or polypropylene tubing under specified sealing techniques; at present, however no foolproof sealing method is known. The best combination of materials and techniques was used to calibrate tubes gravimetrically under controlled temperatures to determine whether losses in weight were occurring and whether weight losses were relatively constant with time. Repeated weighing of different tubes gave weight losses of 80 to 210 micrograms/hr per tube or 10-14 micrograms/hr per sq cm of diffusing surface for polypropylene tubes and 3-5 micrograms/hr per sq cm of diffusing surface for polypropylene tubes. A third phase of the work still in progress, involves determining whether the reductions in weight are a direct and exact measure of permeation of gaseous fluoride. The future value of permeation tubes as standards for atmospheric fluoride measurements appears to depend on the reduction of variability and on establishing the constancy of permeation over long time intervals.

COMPARATIVE STUDIES OF FLUORINE-CONTAINING
EMISSIONS. ((Vergleichende Untersuchungen uber Fluorhaltige
Immissionen.)) Text in German. Stadtehygiene, 19(6):114-11S,
June 1968.

Three methods determining the presence of fluorine compounds as phytotoxic air pollutants are under consideration: (1) air analysis, (2) precipitate analysis, and (3) plant studies. In the past, proof of damage was accepted if fluorine concentrations in the leaves of damaged plants were higher than those in plants in unpolluted areas. Recently air measurements were made at 7 stations in a recreation area containing large forests and several water surfaces, at the same time as dust studies of precipitates from washed and unwashed birch, popular, and plantain leaves. The differences found in the fluorine values (0.5-1.0 microgram F/N cu m in the air and 25.8

<xref image="2000WVED.TIF|V3|2006:09:28:01:25:22.00|117229|0"> image: </xref>

mg F/sq.m. in the precipitate) may be partially attributed to the filtration effect of forests (particularly with aerosols) which results in reduced emissions (the authors' belief). An increased concentration of fluorine in plants is neither proof of increased fluorine in the air nor the cause of plant damage. Leaves from plants both with and without damage showed an increased fluorine content with little difference between values. The most common fluorine compound, calcium fluoride, does not cause plant damage and occurs only as a dust which is trapped by dense forests. Because of this, the point of collection is important when measuring for fluorides. Fluoride emissions in industrial concentrations are difficult to determine because of small fluoride emissions coming from many directions.

FLUORIDE DETECTOR DEVELOPED IN CANADA. Can.

Chem. Process., 52(10):86-88, Oct. 1968.

Trace amounts of fluorides in the atmosphere can be detected by means of an automatic analyzer developed by the Ontario Research Foundation and now being built commercially by Leigh Instruments of Ottawa. The analyzer uses a Na_2CO_3 -coated absorber tube to collect the gaseous fluorides. These are then flushed from the tube with a modified Megregian solution (a zirconium-eriochrome cyanine complex), and the amount of the fluoride ion is determined photometrically. The analyzer operates unattended continuously, except for weekly recharging of reagents, and can detect gaseous fluorides in ambient air when concentrations are as low as 0.1 microgram of fluoride ion per cu m or approximately 1 part per billion.

THE DETERMINATION OF ATMOSPHERIC FLUORIDES

USING THE FLUORIDE ION ELECTRODE. Preprint, American Society for Testing and Materials, Philadelphia, Pa., 23p., 1968. 6 refs. (Presented at the Conference on Air Quality, Plainfield, Vt., 1968.)

The application of a fluoride-selective electrode as a new analytical tool for measuring the concentration of fluorides in ambient air is described. This electrode consists of a laser-type, single-crystal membrane of europium-doped lanthanum fluoride, which is highly specific for the fluoride ion. When used in conjunction with a calomel reference electrode, it gives a Nernstian response over a concentration range of more than four orders of magnitude. The electrode is very useful in easily and rapidly measuring atmospheric fluorides collected on glass fiber filters. This is of extreme importance, as this instrument can then be applied to the samples routinely collected by the National Air Surveillance Networks (NASN) or similar surveillance agencies. Virtually all of the fluoride that is collected on both glass fiber filters and membrane filters is water soluble, indicating that this method can replace the slow and tedious colorimetric procedures. Another important factor is that all the fluoride collected on glass fiber filters is biologically active. The electrode is stable and quite reproducible. Sensitivity of the electrode is comparable to that of SPDNS method. The fluoride ion activity measured in aqueous extracts of atmospheric particulates was directly related to the total fluoride concentration in the atmosphere. Using the electrode technique, the fluoride concentration at NASN sites (both urban and nonurban) during the 1966 sampling year were surveyed. Data are presented for samples collected at 150 stations over a 12-month period. A cursory examination of the data shows a possible relationship between certain sources and observed fluoride levels. MEASURING METHODS. (2). Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 2(1):80-87, 1967. Translated from Japanese. 32p.

Experimental procedures employed in atmospheric contaminant studies are briefly reviewed and evaluated. They concern the following: measurement of atmospheric acrolein; measurement of aerosol weight distribution with a cascade centrifuge; determination of NO₃-N in water collected in deposit gauges; continuous colorimetric measurement of atmospheric formaldehyde; measurement of SF₆ employed as a tracer of exhaust gas; simple determination of trace quantities of atmospheric fluoride with alkalized filter paper; and determinations of the correlation between concentrations of aerosols and radon. Also reported are measurements of air particle pollutants with a self-recording impactor; a survey of air pollution based on automatic recorders; the use of a telemeter system to transmit data from the automatic recorders; the development of a stabilized high voltage power source for the measurement of size distribution and concentration of particles in the atmosphere and in flue gas; measurements of atmospheric trace metals by emission spectrophotometry and atomic absorption spectrophotometry; measurements of particles with high volume samplers; studies of the efficiencies of shelters used in the PbO₂ candle method for sulfation rate measurements; and a procedure for measuring aldehyde concentrations in the atmosphere.

Wallar, Margaret A. and Normal A. Huey
EVALUATION OF A STATIC MONITOR OF THE ATMOSPHERIC ACTIVITY OF SULFUR OXIDES, NITROGEN DIOXIDE, AND CHLORIDE. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 13p., 1969. 3 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 62nd, New York, June 22-26, 1969, Paper 69-90.)
A static, multipurpose monitor for acidic gases was developed and tested under field conditions. The collection device is a 4.8 centimeter inside diameter plastic petri dish containing a filter impregnated with 1 ml 30% potassium carbonate solution. The dish is placed in the open air in an inverted position. After exposure, the filter is removed for analysis and placed in a 50-milliliter test tube, covered with distilled water and heated in a boiling water bath for 15 min. The sample is then diluted to a known volume and filtered. The filtrate is analyzed for oxides of sulfur, oxides of nitrogen, chloride and/or fluoride by the barium sulfate turbidimetric method, the diazotizing method, the mercuric thiocyanate method, and the use of a specific ion electrode respectively. The carbonate plate was exposed in parallel with the lead plate in the Cincinnati metropolitan area, at selected sites in the Port Huron, Michigan-Sarnia, Ontario Saturation Study, in the Philadelphia-Trenton area, and on the Interstate Surveillance Network. The oxides of sulfur results compare favorably with existing sulfation data. The carbonate plate seems to be a satisfactory indicator of the activity of oxides of nitrogen, chloride, and fluoride in the atmosphere.

A COMPARATIVE STUDY OF THE DETERMINATION OF
FLUORIDE ON LIME PAPER BY A COLORIMETRIC
METHOD AND THE SPECIFIC ION ELECTRODE METHOD.
Preprint, California State Dept. of Public Health, Berkeley and
California Air Resources Board, 8p., 1969. 13 refs. (Presented at
the Conference on Methods in Air Pollution and Industrial Hy-
giene Studies, 10th, San Francisco, Calif., Feb. 19-21, 1969.)
Comparison of a colorimetric and a specific ion electrode
method for the determination of fluoride on lime paper in-
dicates that the static lime paper technique is greatly simplified
by the use of the specific fluoride electrode. Lime papers can
now be analyzed quickly and easily by simple extraction and
direct meter reading. One hundred samples can be analyzed
easily in an 8-hour day with great accuracy and specificity.
The extreme sensitivity of the Orion Meter allows for ambient
air area studies as well as source effluent tracer studies. Stan-
dardization of the Orion Meter is described. (Author summary
modified)

Bourbon, P. and J. Alary
DETERMINATION OF FLUORIDE POLLUTION BY A
RAPID TECHNIQUE UTILIZING PAPER IMPREGNATED
WITH SODA. (Evaluation de la pollution fluoree par une
technique rapide utilisant des papiers impregnes de soude). Text
in French. Bull. INSERM, 24(1):23-30, Jan.-Feb. 1969.
Previously, Whatman paper impregnated with lime had been
used to determine fluoride pollution in an aluminum factory.
The same technique using paper impregnated with a 1 N solu-
tion of soda gave better recovery of fluoride than lime paper
in tests made in six locations over a period of six months.
After exposure, the papers were lacertated and extracted with
water. Fluoride was determined colorimetrically either directly
on an aliquot of the washings, or after distillation to minimize
interfering impurities. Although the distillation method gave
slightly better results, the direct method was simpler and more
applicable to industrial usage.

Guerrant, Gordon O.
METHOD AND APPARATUS FOR CONTINUOUS MONI-
TORING OF FLUORIDE EFFLUENT. (USS Agri-Chemicals,
Inc., Pittsburgh) U. S. Pat. 3,461,043. 3p., Aug. 12, 1969. 5 refs.
(Appl. May 3, 1965, 7 claims).
The invention relates to a process and apparatus for the con-
tinuous monitoring of fluoride effluent by internal electrolysis.
It is particularly suited to the remote monitoring of fluoride
evolution in phosphate fertilizer manufacturing processes or to
the determination, either in the field or on plant premises, of
fluorides in waste gases. Monitoring is accomplished by con-
tacting fluoride-containing gas with a dilute acid electrolyte,
which forms a film on the tubing walls on which the fluoride is
absorbed, and then passing the electrolyte from which gas has
been removed through an electrolysis cell provided with elec-
trodes for spontaneously generating current flow, withdrawing
the electrolyte, and measuring the current flow. Since the elec-
trolyte flows by gravity into the tubing, minimum electrolyte
volume is required for absorption of gaseous fluorides to pro-
vide maximum response.

MANUAL METHODS AND AUTOMATIC CONTINUOUS IN-
STRUMENTS FOR MEASUREMENT OF GASEOUS AIR
POLLUTANTS. (Gasujo taiki osenshitsu no sokutei to sono
sokuteikiki). Text in Japanese. Kogai to Taisaku (J. Pollution
Control), 5(10):785-796, Oct. 1969. 36 refs.
In order to prevent air pollution, measurement of pollutant
concentrations must be continuously performed. In this report,

both continuous monitoring and manual analyses of typical air pollutants are reviewed. Numerous methods are tabulated and most of them are explained, with particular attention to continuous methods and apparatus. Sulfides are measured manually by colorimetric analysis with rosaniline or barium molybdate, by the lead per oxide method, or by test paper methods. Sulfides are also measured continuously by means of solution conductance (Thomas autometer) or by optical absorption with rosaniline or with iodine-starch. Carbon monoxide is measured manually with palladium sulfate and ammonium molybdate, by gas chromatography, or by the hopcalite method. It is measured continuously by infrared or ultraviolet absorption of reduced mercuric oxide. Nitrides are measured manually by the Saltzman or the Jacobs method, or with ortho-tolidine sulfate. Hydrogen sulfide is measured manually by methylene blue and continuously by a colorimetric filter paper method. Hydrocarbons are measured manually by gas chromatography and continuously by flame ionization detectors. Formaldehyde is measured manually by colorimetric analysis with a chromotropic acid or with acetylacetone, or by the MBTH method. Ozone is measured manually by the phenolphthalein or the potassium iodide method and continuously by coulometric titration or by optical absorption with potassium iodide. Fluorides are measured manually by colorimetric analysis with thorium neothron(?) or lanthanum alizarin complex and continuously by filter paper fluorescence. Actual Tokyo data on changes in the concentrations of carbon monoxide, nitric oxide, and nitrogen dioxide are tabulated.

DETECTION OF FLUORINE ON THE NANOGRAM SCALE;
INORGANIC AND ORGANIC FLUORINE COMPOUNDS.

Mikrochim. Acta (Vienna), no. 4:870-881, 1969. 6 refs.

Simple techniques are described for detecting fluorine on the nanogram scale. They are based on the evolution of hydrofluoric acid as revealed by an alizarin-3-methylamine-N,N'-diacetic acid-cerium(III) complex reagent and the use of a Pyrex capillary siliconized to prevent the glass from retaining hydrofluoric acid at ordinary temperatures. The methods are suitable for the detection of fluoride in waters, minerals, salts, and organic compounds including complex pharmaceutical preparations and plastics. Even 150 pg of fluorine can be revealed in a 1:500,000 solution of the reagent.

METHOD AND APPARATUS FOR DETECTING GAS.

(Leesona Corp., Warwick, R. I.) U. S. Pat. 3,470,071. Sp., Sept. 30, 1969. 5 refs. (Appl. July 11, 1966, 15 claims).

The increasing industrial use of hydrogen cyanide derivatives, which emit only a faint odor, and the increasing military use of organophosphorous compounds require a rapid and portable gas detection system. Previously suggested electrolysis systems need a great deal of ancillary equipment for circulating the electrolyte and for scrubbing and circulating air. They

<xref image="2000WVEF.TIF|V3|2006:09:28:01:25:30.00|114949|0"> image: </xref>

are not conveniently manufactured. A detector for sensing these and other noxious gases is described that operates by spontaneous electrolysis and has a spontaneous alarm unit and a high electrode-electrolyte-gas contact area. It is easily manufactured in compact form. The detector comprises an anode, a cathode, an electrolyte, and an external circuit in which the warning signal connects the anode and cathode. The anode and cathode contain liquid impermeable and gas permeable polymer membranes coated at one surface with a catalytic layer. The catalytic layer of the cathode is electrochemically active with respect to the oxygen of its environment and invariant to the gas being detected, while the catalytic layer of the anode includes a material reactive to the gas to be detected. Each catalytic layer is in contact with the electrolyte and each membrane, with the atmosphere. The electrolyte is an oxine; the polymer membranes, polytetrafluoroethylene; the catalytic layer of the anode, a mixture of hydrophobic polymer particles, silver or gold; and the catalytic layer of the cathode, a mixture of hydrophobic polymer particles and platinum black. The system is also capable for detecting hydrogen sulfide and hydrogen fluoride gases.

THE DETERMINATION OF TOTAL FLUORIDE IN AIR BY
USING A MICRODIFFUSION TECHNIQUE. Analyst,
94(1119):493-499, June 1969. 14 refs.

A method is described for the determination of total fluoride, in the form of dust, fume or vapor, in industrial atmospheres; it is applicable over a wide range of fluoride concentrations. After collection on an alkali-impregnated filter-paper, the fluoride is released specifically in a micro-diffusion vessel and trapped by an alkaline coating on the inside of the lid of the vessel. The alkali is quantitatively transferred to a standard flask and the fluoride determined spectrophotometrically or visually with the lanthanum - alizarin fluorine blue reagent. The apparatus used is simple and the manipulation time required is less than 30 min per sample, although the microdiffusion stage requires a minimum of 16 hr (overnight) for completion. (Author's Abstract)

Brandt, C. Stafford
FLUORIDE ANALYSIS. Intern. J. Air Water Pollution (London), vol. 7:1061-1065, 1963. 49 refs.
Methods and procedures for the detection and estimation of fluoride are reviewed. Difficulties associated with separating the particulate fluoride from gaseous fluoride are considered. The most satisfactory method developed to date is to collect the fluoride in a bubbler, fix it with alkali, and analyze the sample by water techniques. The need to fix fluoride samples with lime during drying and ashing has been established for plant materials but not for animal tissues. For analyzing plant and animal tissues and aqueous acidified solutions from air samples, isolation based on ion exchange resins has found increasing applications. For estimation of low levels of fluoride, after isolation from the sample, various colorimetric and spectrophotometric methods are replacing titration procedures. There is still no adequate automatic air monitoring instrument for fluorides, though field tests of a recorder based on the quenching of fluorescence on an impregnated tape appear promising. The detection limit is expected to be less than 0.1 micron F/cu m. Recently developed automatic systems for high level concentrations are subject to a wide variety of interferences.

Buck, M. and H. Stratmann
A METHOD TO DETERMINE VERY SMALL CONCENTRATIONS OF FLUORINE IONS IN THE ATMOSPHERE. (Bin
Verfahren zur Bestimmung sehr geringer Konzentrationen von
Fluor-Ionen in der Atmosphaere). Brennstoff- Chem. (Essen),

46(8):231-235, Aug. 1965. 13 refs. Translated from German. Franklin Inst. Research Labs., Philadelphia, Pa., Science Info. Services, 19p., Sept. 18, 1969.

A method was described by which fluorine ions are collected and absorbed in prepared silver tubes to determine very small F(-) concentrations in the air. After separation of the fluorine ions from interfering substances by water vapor distillation, the F(-) concentration is determined photometrically by the alizarine complex method. The distilled amounts of F(-) are absorbed in a small amount of diluted sodium lye. No water vapor condensation occurs at this process. The relative detection threshold of this method under standard conditions is 0.7 micrograms F(-)/cu m. The standard deviations were found to be + or - 0.4 micrograms F(-)/cu m in a concentration range from 2-10 micrograms F(-)/cu m. The sampling equipment can be easily installed in a truck so that the method is particularly suited for emission measurements which require sampling at different locations. As compared to the impinger method, this method has the advantage of having greater sensitivity and accuracy and is simple to handle. (Author summary modified)

Nichols, P. N. R.

THE SIMPLE MODIFICATION OF A COMMERCIAL SULPHUR DIOXIDE METER FOR THE DETERMINATION OF OTHER ATMOSPHERIC POLLUTANTS. Chem. Ind. (London), 1654-1655, Sept. 26, 1964. 12 refs.

A modified commercial sulphur dioxide meter used for routine determination of contaminants in the atmosphere is described and illustrated. The design of the instrument suggests that, by a suitable choice of reagent and optical filter, it could be readily adapted for the measurement of other atmospheric pollutants. Among the pollutants of interest were hydrogen sulfide, nitrous fumes, fluoride, chloride, free chlorine, and organic chloro-compounds. Conditions under which all these pollutants were successfully determined, with an estimate of the sensitivity attained, are given in a table. Air suspected of contamination with sulfur dioxide is passed up a counter-current absorption column down which is flowing a starch-iodine reagent. The reagent is partially decolorized by the sulfur dioxide; the change in color is measured photometrically and related directly to the concentration of sulfur dioxide. The out-of-balance current produced from the two photocells is measured on a galvanometer.

FINE POWDERS (DUSTS) IN NATURE AND IN INDUSTRY, THEIR DETERMINATION AS CONTAMINANTS AND DETERMINATION OF FLUORINE COMPOUNDS IN THE AIR. (Feine Teilchen (Staeube) in Natur und Technik, ihre Bestimmung als Verunreinigungen und der Nachweis von Fluorverbindungen in der Luft). Text in German. Ber. Deut. Keram. Ges., 45(11):551-556, Nov. 1968. 9 refs.

The morphological significance of particles for their properties and the demonstration of industrial powders in the form of photographs and samples was presented. Electron diffraction is an important method because it allows a clear identification of extremely fine particles. Kaolinite and illite can be distinguished from each other or amorphous silica can be detected

<xref image="2000WVEG.TIF|V3|2006:09:28:01:25:34.00|121195|0"> image: </xref>

in Kaerlich clay. Contaminants in the air surrounding an aluminum factory were collected and electron-optically studied. Crystalline impurities in the atmosphere and the type and bonding of fluorine compounds in the exhausts of furnaces and kilns was also investigated with an electron-optical device. An unequivocal determination was made possible by examining cell sizes in the selected area of diffraction and by measuring the angles between the different lattice directions. The results showed that chlorides, sulfates, and fluorine compounds were present in the air above the North Sea and in the exhaust gases of an aluminum smelting furnace. (Author summary modified)

DETERMINATION OF FLUORINE BY PROMPT (GAMMA)-
RADIATION FROM PROTON BOMBARDMENT. PART I.
THEORY AND EXPERIMENTAL METHOD. Analyst (Cam-
bridge), 94(1114):1-6, Jan. 1969. 19 refs. PART II. RESULTS.
94(1114):7-14, Jan. 1969. 5 refs.

The general principles governing the quantitative measurement of fluorine by proton bombardment are described. An expression for the limit of detection is derived; the importance of the stopping cross-section is discussed, and experimental arrangements are described. Part II presents the experimental results. The practical application of the nuclear reaction $F(19)(p, \alpha\gamma)O(16)$ to fluorine determination is outlined. Analysis in liquid and gaseous phases suffers from the need to use a proton transmission foil; in principle, solids can be analyzed inside the accelerator vacuum, but powder targets are handled more easily by using a foil. Sulfur hexafluoride diluted with xenon was used in gas mixture studies. Fluorine in gases can be determined at relatively high levels (5-100%) by a simple system that could easily be adapted, by the use of thicker foils and higher bombarding energies, to reach much lower levels. Determinations in liquids were carried out in the range 20 ppm to 10% of fluorine in aqueous solutions. Interferences are not important, except for aluminum and possibly lithium. The theoretical limits of detection are in good agreement with those observed in practice, being about 20 ppm for the particular background and experimental arrangement used. Saltzman, Bernard E.
PREPARATION AND ANALYSIS OF CALIBRATED LOW
CONCENTRATIONS OF SIXTEEN TOXIC GASES. Anal.
Chem., 33(8):1100-1112, 1961. 20 refs.

The development and testing of analytical methods for the accurate determination of low concentrations of various toxic gases are described. All-glass flow systems were preferred for the dilution of gases with purified air, since such systems avoid serious errors from surface adsorption or reaction with impurities. Several practical flow dilution systems are described and diagrammed, as well as an asbestos plug flow-meter which was found useful for metering flows varying from a few hundredths of a milliliter to a few milliliters per minute; motor-driven glass syringes can also be used for metering gas (and liquid) flows in these ranges, but have the disadvantage of intermittent operation. Rotameters are convenient for metering gas flows greater than 10 ml/min, but because of calibration difficulties are considered secondary rather than primary measuring devices. In an evaluation of chemical analytical methods, it was found that many of the methods available were based on assumptions derived from studies conducted either at high gas concentrations or in liquid solutions; various difficulties are encountered when such methods are critically tested at low concentrations. The methods finally selected were first tested for sensitivity for samples of reasonable size- results consistent with both sample volume

and test gas concentration; adequate absorption efficiency with the available sampling equipment; and adequate stability of reagents and final solutions. The role of sampling absorption efficiency is developed mathematically, and midget sampling equipment described. Finally, methods are given for each of the following gases: ammonia, arsine, bromine, carbon dioxide, carbon monoxide, chlorine, chlorine dioxide, ethylene oxide, hydrogen chloride, hydrogen cyanide, hydrogen fluoride, monoethanolamine, nitric oxide, nitrogen dioxide, phosgene, and stibine.

THE MICRODETERMINATION OF FLUORIDE IN VEGETA-

TION. J. Air Pollution Control Assoc., 19(6):439-442, June

1969. 16 refs.

This paper describes a micro method for the determination of the fluoride content of plant materials, particularly the leaves. The samples are dried and ground to a fine powder. 50 mg. samples are burned in oxygen in 250, ml separatory funnels or in 300, ml Erlenmeyer flasks. The gaseous products of the combustion are absorbed in 0.1N NaOH in the closed funnel or flask and transferred to a small covered plastic dish in which the fluoride is diffused to tiny droplets of 3N NaOH solution distributed over the lower side of a tight fitting cover. The diffused fluoride is dissolved in water and determined colorimetrically by the SPADNS reagent. (Author's Abstract)

PERTAINING TO THE DIAGNOSIS OF DAMAGE INDUCED

BY FLUORINE-FUMES. (Zur Diagnose von Fluor-Rauchschaden.) Translated from German. Phytopathol. /., 5(2):195-206, (1932). 15 refs.

An analytical method of analysis to verify fluorine (F) damage to plants is needed because F action shows neither unique nor consistent symptoms. Fluorine compounds attack fruits or enter plants through leaf stomates and decompose into hydrofluoric acid, which then acts on the mesophyll or spongy parenchyma. Several microchemical methods are used for F determination, two of which are particularly suitable for qualitative detection in plants. In the color method of Feigl and Krumholz, F is indirectly identified by the analysis of a process distillate for volatile silicon fluoride. Here, silicon is identified by an analytical method imparting a blue color to the solution. The second method crystallizes F as Na₂ Si F₆. Both techniques are shown to be sensitive to small amounts of F, 0.005 mg and 0.05 mg per 100g of dry leaves, respectively, but the latter is simpler and more direct. Experiments with various plants show that in nearly every case neither method gives deceptive, false positive results from naturally present F. It appears possible, however, to get negative results for F presence from plants previously damaged by F in earlier stages of development and from fruits damaged by extremely small amounts of F. Experiments also show that plants exposed to soils with unusually large amounts of apatite or phosphate fertilizer containing fluorides do not pick up detectable amounts of A and show no F damage. Seed germination is inhibited when the concentration of a soluble fluoride (e.g. NaF) is between 0.1 and 0.5 percent. Conveniently, soluble F components from soil can only be detected in the few cases when toxic effects are present. Thus, the simpler

162

Na₂SiF₆ crystallization test is recommended for standard examinations, and the color test for cases where damage from a minute quantity of F is suspected and a negative crystallization test results.

EFFECTS OF FLUORINE. RESULTS OF INVESTIGATIONS
WITH PLANTS AND ANIMALS. (Bestimmung von Fluor in
pflanzlichen, tierischen und anorganischen Substanzen, sowie in
Waessern und Luft.) Translated from German. Franklin Inst.
Research Labs., Philadelphia, Pa., Science Info. Services, Con-
tract No. CPA 22-69-30, Project No. C 2439, 31p., 1968. 41 refs.

In the method for determining fluorine which like most others is based on distillation according to Willard and Winter, all error sources have been eliminated which may exist during sampling, grinding, ashing, treatment of the ash, distillation, and concentration of the distillate. Furthermore, almost F-free calcium oxide has been prepared which must be added prior to ashing to a number of samples of animal origin. For the determination of fluorine, distilling equipment was used which operates automatically to a large extent, is easy to handle, and was developed in cooperation with the aluminum plant Rheinfelden. The apparatus for concentrating distillates with very low fluorine contents works almost automatically. The method was tested with various synthetic solutions as well as with a number of internationally conducted ring analyses over several years. Today the method together with the equipment is used in many laboratories both in this country and abroad for the determination of fluorine in organic, inorganic and other materials.

SYNERGISM BETWEEN FLUORINE EMISSION AND
OTHER AIR POLLUTANTS. (Ueber den Synergismus von
Fluorimmissionen mit anderen Verunreinigungen der Luft.) Text
in German. Staedtehygiene (Uelzen/Hamburg), 20(4):82-85,
April 1969. 11 refs.
Previous measurements of fluorine emissions in various locations at Duisberg had indicated that there was little correlation between fluorine concentrations and extent of plant damage. A new series of measurements at three locations conducted over a series of four years indicated that while the total fluorine emissions were at no time excessively high, the amount of plant damage varied with the percentage of soluble fluorine salts. The relative proportion of soluble salts in turn was a function of the pH, the lower the pH the higher the percentage of soluble salts. It is concluded that only the soluble fluorides are phytotoxic and hence that the total fluorine level is not a proper basis for forecasting potential plant damage.

Harriss, Robert C., and Harold H. Williams
SPECIFIC-ION ELECTRODE MEASUREMENTS ON BR, Cl
AND F IN ATMOSPHERIC PRECIPITATION. J. Appl.
Meteorol., 8(2):299-301, April 1969. 10 refs.
Electrodes have been used to investigate sources of and variations in the halogen content of atmospheric precipitation from Hamilton, Ontario, an industrial city. A series of sampling stations was established in the area extending from the industrial center of the city to the agricultural area approximately 10 miles west. Samples of major snow accumulations and rain were collected in January, March, and June 1968. In March 1968, multiple samples were collected at individual sites to investigate time dependent variations in snow chemistry. Bromide and fluoride were determined using specific ion electrodes. Chloride determinations were made with a silver billet electrode and by mercuric nitrate titration with diphenyl-carbazone indicator-buffer. The reference electrode used was a

dual-glass junction saturated calomel. A vibrating reed electrometer was used to measure changes in potential developed by the electrode pairs. There is a large variation in concentration ranges of all the halogens analyzed. In two of the January storms the fluoride concentration is more than an order of magnitude higher in precipitation from the industrial area than in the surrounding agricultural areas, indicating a local source of pollution. One sample which represents the last precipitation of the storm, has a high Br/Cl ratio indicating the Cl is removed in the early precipitation. The range in halogen concentration for rain samples was very similar to the data presented for snow. From these preliminary studies, it can be concluded that specific ion electrodes provide a rapid, precise, and relatively inexpensive method for the analysis of bromide, chloride, and fluoride in atmospheric precipitation.

DETECTION OF SUB-PPM QUANTITIES OF CHLORINE

TRIFLUORIDE IN AIR BY ELECTRON CAPTURE GAS

CHROMATOGRAPHY. J. Gas. Chromatog., 5(10):533-535,

Oct. 1967. 9 refs. (Presented at the American Chemical Society, National Meeting, 152nd, Division of Water, Air and Waste Chemistry, New York, Sept. 1966.)

The storage in naval vessel magazines of missiles supplied with liquid propellants requires the development of rapid automatic detection systems to provide adequate warning of the presence in shipboard spaces of hazardous concentrations of toxic vapors from such propellants. The applicability of gas chromatography to the detection of the propellant oxidizer chlorine trifluoride in air was studied. Sub-ppm concentrations in a 1-cubic centimeter air sample introduced directly into the chromatograph without requiring time-consuming concentration procedures could be detected rapidly with an electron capture detector. A linear response was obtained in the range of 0.05 to 1.0 ppm volume and detectability of less than 0.01 ppm was indicated. A sample introduced into the chromatograph by an automatic gas sampling valve was detected by monitoring a peak with a retention time of 0.95 min. Details of apparatus and operating procedures are given. The method is suitable for automatic, continuous monitoring of hazardous environments such as laboratory, plant, and shipboard storage areas. AUTOMATIC STEAM DISTILLATIONS OF FLUORIDE

INTO SMALL VOLUMES. Preprint, National Lead Co. of

Ohio, Cincinnati, 15p., Feb. 7, 1969. 4 refs. (Presented at the Pittsburgh Conference on Analytical Chemistry and Applied Spectroscopy, Cleveland, Ohio, March 2-7, 1969, Paper NL-CO1039.)

A rapid method is described for separating fluorides from interfering ions without excessive dilution, in which a controlled-temperature Willard-Winter type still is combined with a new distillate recycler. Fluorides are trapped out of the distillate with thorium, after which the distillate is boiled and the steam reintroduced into the still. In this manner, the fluorides are removed from the samples in 20 minutes and isolated in a form that requires no further preparation prior to the

<xref image="2000WVEI.TIF|V3|2006:09:28:01:25:40.00|119855|0"> image: </xref>

C. MEASUREMENT METHODS

163

color development. The apparatus developed for this distillation is relatively simple and inexpensive, and the fluorides are separated into less than 20 ml of distillate. Fluoride concentrations of less than 1 microgram/ml can be determined accurately. The recycling still is especially well suited for the determination of micro quantities of fluoride in samples containing large amounts of interfering materials. The small volume of distillate produced makes the apparatus several times more sensitive than ordinary Willard-Winter type stills. It has no boiler to fill and no receiver cup to overflow if forgotten. Because of automatic temperature control, automatic timing, and automatic shutdown features, very little of any analyst's time is required for operation. (Author abstract modified)

STUDIES ON HYGIENIC CHEMISTRY OF AIR POLLUTION

(I). MEASUREMENT OF FLUORIDE IN THE AMBIENT AIR.

(Taikioseri booshitsoo no eiseikagakoo ni kansooloo kenkyu (1) Taiki chu no fookkabootsoo no sokootei ni tsooite). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 4(1):112, 1969. (Proceedings of the Japan Society of Air Pollution Annual Meeting, 10th, 1969.)

To give a basis for measuring fluorides in air, which may be discharged from aluminum, fertilizer, glass, and soda industries and influence especially plants, the following experiments were performed, using the lanthanum -ALC method for quantitative analysis. For gaseous fluorides, first the effect of concentrations of dilute sodium hydroxide solution (the absorbent), its absorbing velocity, and absorbed amount on the collection efficiency were examined. Secondly, to know the extent of the interference by other ions coexisting in samples, separation by distillation with several kinds of reagents, like phosphoric acid-perchloric acid, silica-perchloric acid or sulphuric acid-silver sulphate, was tested. The temperature determined the amount of separated fluorides and the removable interfering ions. The sampling of particle fluorides usually involves filters, some of which, include fluorides in a considerable amount, which require to be eliminated before quantitative analysis.

METHODS OF STUDY OF ATMOSPHERIC AIR FROM THE

HYGIENIC POINT OF VIEW. (Metody sanitarnego badania

powietrza atmosferycznego). Text in Polish. Wydawnictwa

Metodyczne Panstwowego Zakladu Higieny (Methodologic Study

Govt. Dept. Hyg.) no. 10, 141p., 1968. 82 refs.

Methods of determining pollutants, the admissible concentration of which was limited by Polish legislation, and determining a number of other atmospheric pollutants which in excessive amounts are either hazardous to health or cause damage by corrosion are reviewed. Determination of air dustiness, chemical analysis of dust, and determination of sulfur dioxide, sulfur trioxide, carbon disulfide, nitrogen dioxide, nitric oxide, fluorine, chlorine, hydrogen chloride, ozone, phenol, benzene, chlorobenzene, and aniline are presented. A description of each method includes principles of the method, its limitations, a description of the apparatus, procedure of sample collection, and data evaluation. The apparatus required usually are not expensive and complicated, but they have to be precise and well calibrated because of the extremely low concentrations measured. The reagents used have to be of high purity. Most of the methods described were verified and tested on the laboratory scale and in routine determination of pollution. Thus no difficulty should be encountered in their application.

AUTOMATIC SENSING AND RECORDING OF AIR POLLU-

TANTS ON CITRUS TREES. Biomed. Sci. lustrum., vol. 1:45-52, 1964. 6 refs. (Presented at the First National Biomedical Sciences Instrumentation Symposium, Los Angeles, Calif., June 14-17, 1963.)

Various instrument techniques used for measuring and for controlling air pollutants with respect to experiments with citrus trees in Southern California are described. The automatic punch card recording system is used to record date, time of day, plant transpiration, apparent photosynthesis by carbon dioxide exchange, nitrogen dioxide, nitric oxide, ozone, total oxidants, hydrogen fluoride, temperature, and integrated light recording. The punch card recording permits automatic handling of data on the IBM 1620. The master timer and valve control unit controls operation of the CO₂ and moisture analyzers. It collects 30 min inlet and outlet air samples from 12 plots. These samples are stored in plastic bags and in the succeeding 30 min are fed into the CO₂ infrared analyzer and a humidity analyzer. Oxides of nitrogen are recorded continuously by a colorimetric method based on a diazotization reaction with the Griess-Saltzman reagent. Ozone as well as other oxidants are also measured colorimetrically by the potassium iodide reaction. Hydrogen fluoride is determined by observing the quenching of the fluorescence on magnesium oxinate impregnated filter paper tape. An Eppley pyrheliometer is used to measure the light received on a horizontal surface. Twelve temperatures are recorded by the logger directly by thermocouples connected to the input of the scanner.

METHODS FOR THE SANITARY INVESTIGATION OF ATMOSPHERIC AIR DEVELOPED BY THE SECTION OF SANITATION LABORATORIES FOR THE PROTECTION OF ATMOSPHERIC AIR. (Metody sanitarnego badania powietrza atmosferycznego opracowanie zespolu Pracowni Sanitarnej Ochrony Powietrza Atmosferycznego). Wydawnictwa Metodyczne Panstwowego Zakladu Higieny (Methodologic Study Govt. Dept. Hyg.), no. 4(26); issue no. 10, 149p., 1968. 78 refs. Translated from Polish. Franklin Inst. Research Labs., Philadelphia, Pa., Science Info. Services, Oct. 14, 1969.

Methods are presented for determining atmospheric pollutants, with the exception of carbon monoxide and gasoline, the concentrations of which are defined by Polish law. In addition, methods are given for the determination of pollutants present in the atmosphere in quantities sufficient to create sanitation problems or to cause plant damage and corrosion to buildings. Some of the methods have been checked and tested extensively in the laboratory and in the field. Others have not yet been widely tested but are included for their potential usefulness in laboratory studies. The methods include the measurement of dust collected by the deposition method with respect to tars, sulfates, free silica, heavy metals, calcium, and fluorine. The other methods are the aspiration and contact methods for sulfur dioxide; the method employing thorium nitrate and eriochromecyanin R for sulfur trioxide-sulfuric acid; the para-aminodimethylaniline method for hydrogen sulfide; methylene blue and diethylamine and copper methods for carbon disulfide; the Saltzman method for nitrogen oxides; titration with thorium nitrate and colorimetric determination with eriochromecyanin and zirconium oxychloride for fluorine; o-tolidine for chlorine; titration for hydrogen chloride; buffered potassium iodide and the Heigal method for ozone; the Schryver method for formaldehyde; para-aminodimethylaniline

<xref image="2000WVEJ.TIF|V3|2006:09:28:01:25:44.00|130347|0"> image: </xref>

and diazo-p-nitroaniline for phenol; nitration for benzene and chlorobenzene; and the indophenol method for aniline.

ULTRAVIOLET ABSORPTION FOR SO₂ STACK MONITOR.

(Shigaisen kyushuho ni yoru arisan gasu sokuteiho ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 4(1):25, 1969. (Proceedings of the 10th Annual Meeting of the Japan Society of Air Pollution, 1969.)

An exposition is presented of a high-concentration sulfur dioxide monitoring device that can also be applied toward environmental air quality measurements. The apparatus essentially depends on the absorption of ultraviolet light by sulfur dioxide at the wavelengths in the range of 280 to 305 millimicrons where there is a large depression in the absorption spectra. The specification of the device as well as the diagram of the electrical connections of various components are presented. By changing the wavelength specification of the device, other gases such as nitrogen dioxide, hydrogen sulfide, acetone, benzen, ammonia, fluorine, chlorine, bromine, and methylformaldehyde can be measured. The test run showed that there was little interference from substances such as nitrogen dioxide, steam, and carbon dioxide; the linearity of the concentration versus the meter swing was good. The zero-span drift was minimal and the response speed was around 90% in a minute interval, depending on the flow rate.

Yu, Ming-Ho and Gene W. Miller

GAS CHROMATOGRAPHIC IDENTIFICATION OF FLUOROORGANIC ACIDS. Environ. Sci. Technol., 4(6):492-495, June 1970. 9 refs.

Gas chromatographic techniques are described for the separation and identification of fluoroacetate and fluorocitrate from fluoride injured plant tissue and organs of animals suffering from severe fluorosis. Methylfluoroacetate was prepared from monofluoroacetate, and trimethylfluorocitrate was prepared from monofluorocitrate. Samples of crested wheat grass were collected within 2 miles of an industrial phosphate plant, air-dried, and ground in a mill. Plants grown in a greenhouse in the absence of fluoride were used as controls. Kidneys and hearts were obtained from horses and cattle showing severe fluorosis. Tissue was extracted with 95% ethanol in a Soxhlet apparatus. The methyl esters of organic acids were separated in columns packed with 10% polyethylene glycol 6000 or 10% Reoplex 400 on Chromosorb W solid phase using a flame ionization detector. The results indicate the presence of fluoroacetate and fluorocitrate in forage crops collected near the phosphate plant. This suggests that atmospheric fluoride may be incorporated by plants into the organic form with the formation of toxic fluoroacetic and fluorocitric acids.

SPECTROPHOTOMETRIC DETERMINATION OF ATMOSPHERIC FLUORIDES. Environ. Sci. Technol. 4(6):487-491, June 1970. 11 refs.

The lanthanide-alizarin complexan-fluoride reaction was investigated and an improved procedure for the spectrophotometric determination of atmospheric fluorides was derived. The suggested sampling procedure eliminates the interference of diverse ions and molecules commonly present in the atmosphere. The method involves adding standard fluoride, 10.0 ml of alizarin complexan, 10.0 ml of Ce(III), 25.0 ml of acetone, then diluting to 100 ml. The test solution is allowed to stand for 90 min, after which absorbance is determined at 618 micrometers, using 1-cm cuvettes. The method has a sensitivity of 0.0019 microgram fluoride per sq cm and is reproducible within plus or minus 0.003 microgram per ml at the 95% confidence level for known fluoride concentrations of

0.400 microgram per ml. The procedure is uniquely suitable for the determination of actual fluoride concentrations in ambient atmospheres at ppb levels. (Author abstract modified)

ANALYSIS OF MISCELLANEOUS MATERIALS. 1. DETERMINATION OF FLUORIDE IN DUST SAMPLES. National Bureau of Standards, Washington, D. C., Microchemical Analysis Section, TN-505 p. 83-84, Oct. 1969.

The versatility of the fluoride ion-selective electrode was demonstrated by its application to the determination of fluoride in a sample dust. The analysis of fluoride in the sample was performed using combustion in an oxygen flask. Three determinations were made on 0.2 to 0.3 g samples. The mean sensitivity of the method was 88 ppm. The oxygen flask employed was a polycarbonate flask. Diethylene glycol was added to the sample to aid combustion. The absorbant was a potassium nitrate solution. A fluoride ion-selective electrode and a plastic silver-silver chloride reference electrode were used for the direct potentiometric determination of the fluoride. The electrode system was calibrated with standard fluoride solutions from 0.001 to 0.00001 M.

Durst, R. A

CONSTRUCTION AND CHARACTERISTICS OF A FLUORIDE ION-SELECTIVE MICROELECTRODE. National Bureau of Standards, Washington, D. C., Microchemical Analysis Section, TN-505, p. 79-82, Oct. 1969.

The feasibility of constructing a fluoride microelectrode suitable for studies of microliter volumes of sample solutions was demonstrated. Although still about two orders of magnitude larger than the smallest glass electrode, further miniaturization of the electrode is possible along lines that could lead to intracellular fluoride determinations. The microelectrode is constructed from a polyethylene tubing drawn out to a 2-mm neck at the lower end. In its final form, the microelectrode tip is an exposed conical portion of lanthanum fluoride crystals of approximately 1.5 microliter volume. The crystal is insulated with polystyrene coil dope. The electrode employs a silver-silver chloride internal reference electrode and a NaF-KCl (each 0.1M) reference solution. The response of the electrode to fluoride activity deviated from Nernstian response in the micromolar range, but was 59.5 mV/pF in the more concentrated solutions. All measurements were made on macro volumes of stirred solutions (approximately 25 ml) against a normal-size saturated calomel electrode. By using the microfluoride electrode in conjunction with a microcapillary reference electrode, measurements could be made on 2-microliter volumes.

C. MEASUREMENT METHODS

165

A method for determining fluoride concentrations in plant materials is described. The sample is ashed and fused with sodium hydroxide. After the addition of a citrate buffer, the solution is pumped through the cells of four fluoride crystal-membrane measuring electrodes. The liquid flow recombines in the cell of a calomel reference electrode filled with sodium citrate-sodium chloride. This reference electrode exhibits a more steady potential than those filled with potassium chloride. The fluoride potential is then recorded on a digital pH meter. In order to determine the influence of interfering ions, different salt additives were added to 50 ml of a calibration solution with a concentration of 1.10 to the minus fourth power $N/F(-)$ and the change of the potential measured.

A SIMPLE FIELD TEST FOR THE DETERMINATION OF HYDROGEN FLUORIDE IN AIR. *Analyst*, vol. 93:821-826, Dec. 1968. 6 refs.

A field method is described for determining hydrogen fluoride vapor in air at concentrations up to 20 micrograms of hydrogen fluoride per liter. The gas is collected in an acidic solution of zirconium-Solochrome cyanine R reagent and the observed bleaching of the color is compared with standards. The apparatus used is simple to operate and the time required for a determination is less than 5 min. However, in view of the interfering effects of aluminum and phosphate, the field test is not recommended for the testing of industrial atmospheres polluted with fluoride-containing dusts. (Author abstract modified)

Okita, T., R. Sugaoui, and K. Kaneda

MEASUREMENT METHOD OF ATMOSPHERE HYDROGEN FLUORIDE BY FILTER PAPER IMPREGNATED WITH ALKALI. (Alkali Ioshihoh ni yo oo taiki chu hookkasooiso no sokooteihoh). Text in Japanese. *Taiki Osen Kenkyu* (J. Japan Soc. Air Pollution), 4(1):111, 1969. (Proceedings of the Japan Society of Air Pollution Annual Meeting, 10th 1969.)

Atmospheric hydrogen fluoride (HF) determination with sampling by alkalized filter paper was examined. Alkalized filter papers are prepared by soaking filter papers of about 5 cm in diameter in 10.5 and 1% of Na_2CO_3 and K_2CO_3 solution and drying them in a dryer for 2 hours. Their collection efficiencies are obtained using a setup, which consists of an HF generator (HF permeation tube and diluted hydrofluoric acid), thermometers, two pieces of filters prepared in the above manner, a flowrator, and a pump, in this order. Concentrations of HF are varied from 0.005 to 1.00 ppm with a flow rate of 5, 10, 15, and 20 l/min. These filter papers undergo extraction by water to produce sample solutions, to which are added 10% Alfusson and acetone; their light absorption rates are measured. The collection efficiencies of filter papers do not show significant differences between those impregnated with Na_2CO_3 and one with K_2CO_3 , within the concentration ranges of HF tested, and also with the flowrates used. However, alkali of higher concentration tends to decrease the light absorption rate. HF of more than 0.005 ppm can be determined by this method with the following conditions: 1% Na_2CO_3 or K_2CO_3 for alkali, 20 l/min for flowrate, and 120 minutes for sampling time. This method shortens the sampling time required by the impinger method by one-tenth.

Mori, M., S. Ito, and H. Ogino

AUTOMATIC MEASUREMENT OF HYDROGEN FLUORIDE IN AIR BY COLORIMETRIC METHOD. (Taiki chu fookka sooiso no ienzokoo sokootei). Text in Japanese. *Taiki Osen Kenkyu* (J. Japan Soc. Air Pollution), 4(1): 113, 1969. (Proceedings of the Japan Society of Air Pollution Annual Meeting, 10th, 1969.)

The automatic measuring method of a small amount of fluorides developed by Adams et al (1959), which uses a zirconium-eriochrome cyanine-R method modified by Megregian is modified to reduce sampling volume through an increase in sensitivity of the colorimetry. To do this, a little lower dosage of reagent is used than the original method, a concentration of hydrochloric acid which gives a relatively small variation in the absorption spectrum of the agent, and 556 millimicron of the measuring wave length for the instrument. The time-variation of the indicated color is stable enough to permit intermittent measurements in an hour. As far as interfering substances are concerned, Al(3)(+) and CO4(2)(-) do not give any significant influence for the measurement in air.

PROCEDURE FOR DETERMINING THE ATMOSPHERIC CONTENT OF GASEOUS POLLUTANTS, AND A MEASURING CELL FOR THE APPLICATION OF THIS METHOD.

(Precede pour determiner la concentration d'une atmosphere en gaz polluants et cellule de mesure pour la mist' en oeuvre du precede). Text in French. (Commissariat a l'Energie Atomique, Paris (France).) Swiss Pat. 450,763. 4p., Jan. 31, 1968. (Appl. June 9, 1965, 6 claims).

A procedure is described for continuous determination of the atmospheric content of halogens, halogen acids, hydrocyanic acid, and gaseous cyanide derivatives. Measurement is via an electric current proportional to the concentration, which is generated in an electrolyte previously exposed to the air to be measured and contained in an electric cell. The device has a wide range of measurement. It can detect quantities of fluorine dissolved in the electrolyte in the range 0.2-150 micrograms per milliliter. This corresponds to an atmospheric concentration of hydrogen fluoride between 0.05 micrograms per liter and 35 micrograms per liter. Further refinement could increase the sensitivity to 0.025 micrograms per liter of HF in the atmosphere. One electrode of the detecting cell is made of aluminum, silver, or platinum, while the second electrode is made of stainless steel and is internally coated with platinum or nickel. The cell is designed with a concave structure of the electrodes, permitting a large surface of exposure to the electrolyte.

Hertzog, D.
AUTOMATIZATION OF CHEMICAL ANALYSES OF THE POLLUTION CONTROL LABORATORY. (Automatisation des analyses chimiques du laboratoire de controle de pollution). Text in French. Technicon (France), Services Industriels, p. 3, 1970 (?).

An automatic analyzer, 'Auto Analyzer' is described. The 'Auto Analyzer' can operate on a succession of samples or continuously and incorporates a peristaltic proportioning pump which allows the introduction of samples at a constant rate and their continuous mixing with the specific reagents required for the analysis. The samples are conveyed to different

<xref image="2000WVEL.TIF|V3|2006:09:28:01:25:52.00|116008|0"> image: </xref>

modules in which specific chemical operations are performed. Such as mixing of the reagents, continuous filtration incubation, heat conditioning distillation, extraction, and phase separation. The result of each reaction is measured by a differential colorimeter the readings of which are continuously recorded. In the laboratory, 10 to 40 samples per hour can be analyzed. In continuous operation, the different fluids to be analyzed are introduced successively into the Auto Analyzer by a set of electrically operated valves controlled by a programmer. One to twelve channels can be controlled during a one-hour cycle. At intervals, a calibrating sample is introduced and measurements obtained on it are used to correct automatically the routine measurements. An analysis program can be changed to another within less than 30 minutes. The used methods of determination of ammonia, cyanides and oxygen are briefly outlined. Among the automated analyses, the following are cited: hardness, alkalinity, sulfates, nitrates, nitrites, ammonia, chlorides, iodides, cyanides, fluorides, phosphates (alkaline and alkaline-earth), metabolic substances, phenols, aldehydes, DCO, and detergents.

ACCEPTABLE EQUIPMENT AND PROCEDURES-FOR EVALUATING AIR POLLUTION PROBLEMS. Preprint, Industrial Hygiene Foundation of America, Inc., Pittsburgh, Pa., 1960. 17 refs. (Presented at the Industrial Hygiene Foundation, Engineering Conference, Oct. 27, 1960.)

When choosing equipment to make air quality measurements, it is necessary to estimate the possible pollutants as well as the degree of accuracy and thoroughness with which they must be measured. Availability and reliability of equipment, cost of operation, and skill required for satisfactory results are also factors to be considered in equipment choice. The hi-volume sampler, which consists of a vacuum cleaner motor with suitable mounting to accommodate an 8 by 12-in. filter, is frequently used to measure suspended particulates which may consist of smoke, dust, or other solids sufficiently small to remain airborne for long periods of time. Fiber glass filters commonly used with this sampler collect practically all particulates down to 0.3 micron in diameter, while the simplest analysis is that for total weight of material collected on the filter. Results of analysis of suspended particulate samples collected from 1953 to 1957 by the National Air Sampling Network are presented tabularly. Automatic strip filter paper samplers commonly use a diaphragm pump to draw air through a portion of the filter tape at a sampling rate of about seven liters per minute. The amount of smoke or other suspended particulate collected with this type equipment shows up as various shades of gray; light transmission, sampling time, and flow rate are used to compute results. A major modification in this type of sampler employs a membrane filter tape instead of Whatman filter paper. Laboratory gas washing bottles, bubblers, impingers, and midget impingers are used with a wide variety of both commercial and home-made equipment for collecting gas samples. The Thomas Autometer and Titrilog are designed for determination of sulfur compounds; the MSA Lira uses infrared absorption measurements to determine carbon monoxide concentrations in air; and the Kruger apparatus has been used to measure nitric oxide and nitrogen dioxide. Dustfall samplers are designed to collect the coarse particulates and droplets which settle out more or less rapidly near sources of emission. The lead peroxide candle sampler provides a simple, economical method of estimating sulfation rates of the ambient atmosphere. Hydrogen sulfide will blacken lead bearing materials, and this principle has been employed to estimate its presence in the atmosphere. Some of the corrosive effects of pollutants may be evaluated by a test based on weight gain that occurs when a thin iron disc is exposed to the atmosphere. Lime-treated filter papers have been used to determine comparative fluoride levels in the environ-

ment.

LITERATURE REVIEW OF METROPOLITAN AIR POLLUTANT CONCENTRATIONS- PREPARATION, SAMPLING AND ASSAY OF SYNTHETIC ATMOSPHERES. (FINAL REPORT). Stanford Research Inst., Menlo Park, Calif., Contract DA 18-064-404-CML-123, S.R.I. Proj. SU-1816, 193p., Nov. 30, 1956. 82 refs.

A literature review of metropolitan air pollutant concentrations and of the preparation, sampling, and assay of synthetic atmospheres is presented. Measured concentrations of gaseous and particulate pollutants in the atmosphere, including sulfur dioxide, hydrogen sulfide, nitrogen dioxide, ammonia, formaldehyde, hydrocarbons, chloride, carbon monoxide, ozone, fluoride, hydrogen fluoride, carbon dioxide, gross particulates, and dust fall are tabulated. Calculated emissions from centers of population are presented for industrial and public processes, including combustion of coal, oil, and natural gas, incinerators, automobile exhausts, power plants, and metallurgical operations. Data on measured and calculated air pollution concentrations throughout the world are given. Methods for injecting pollution simulants into a test chamber, such as ozone generators and aerosol dispensers, are mentioned. Sampling and analytical procedures are described for the particular problem of testing static atmospheres for bacteria. Sampling equipment consists primarily of an impinger preceded by a millipore filter. Analytical procedures include ultraviolet absorption, high volume sampling, glass fiber filters, and colorimetric, gravimetric, iodimetric, spectrophotometric, Saltzman, and electrochemical methods.

Stuttgart Univ. (West Germany), Inst. fuer Verfahrenstechnik und Dampfkesselwesen

KEEPING THE AIR PURE. (Reinhaltung der Luft). 58p., 1968. 25 refs. Translated from German. Belov and Associates, Denver, Colo., 80p., Feb. 5, 1970.

A review of technical articles relating to air pollution is presented. Sampling techniques and statistical evaluation of results are discussed. The effects of gaseous impurities on humans and plants are briefly mentioned. Maximum emission values for nitric oxide, nitric acid, chlorine, hydrogen chloride, hydrogen sulfide, and sulfur dioxide are tabulated. Measurement methods, including filters, absorption bottles, and various continuous methods are described. SO₂ is generally measured by the silica gel method, the West Gaeke method, the 'Ultragas 3' method, the Pico-flex instrument, or by infrared spectrophotometry. Isopropanol is a good absorption medium for sulfur trioxide. Dewpoint measurement and detectors are mentioned. NO₂ can be measured by the Saltzman method, and by photometric or colorimetric means. Measurement of H₂S and fluorine emissions may be done by the sodium hydroxide method. Methods for carbon monoxide and dioxide are mentioned. Organic compounds are measured by gas chromatography. Methods for measuring and counting dust contaminants, and stack sampling are discussed. Optical and electrostatic methods of determining smoke shade are described. The Konimeter, impinger, and dust fall methods are considered. A discussion of plume behavior, including stack height, turbulence, diffusion, and winds, is presented. Several laws regarding emissions are mentioned.

REPORT ON THE 'UNIVERSAL' AIR POLLUTANT
ANALYZER. Washington State Univ., Pullman, Inst. of
Technology, P.H.S Contract 66512, 37p., Sept. 4, 1957. 26 refs.
The development, design, and construction is described of a
basically versatile automatic instrument system potentially ap-
plicable to the sampling, analysis, and recording of levels of
any atmospheric pollutant for which colorimetric methods are
available or can be devised. Conditions which may be easily
varied include air sampling rate, reagent, light wave band from
short ultraviolet through the visible range, reagent flow rate,
temperature of the air-reagent contactor system, and optical
system. The design is suitable for producing dosimeter or con-
tinuously integrated records; a prototype analyzer was con-
structed for each recording method, although the instrument is
basically intended as a dosimeter, based on the varying time
span necessary to accumulate equivalent pollutant concentra-
tions. The Zirconium-Eriochrome Cyanine R reagent for
fluoride and the Starch-Iodine Blue reagent for sulfur dioxide
were modified for use in the analyzers. The reduced stability
of these reagents under continuous air aeration for periods ex-
ceeding 4-12 hrs limits the pollutant concentration which may
be accumulated by a single reagent charge. This appears, how-
ever, to be desirable from the viewpoint of field application.
In field testing, simultaneous comparisons were made with
commercially available instruments for sulfur dioxide and
hydrogen sulfide. The dosimeter showed greater sensitivity of
these two pollutants than the other instrumental methods.
Recommendations are included for further research/study in
seven areas to improve the accuracy, versatility, and reliability
of the system and to reduce its cost.

RESEARCH IN CHEMICAL COMPOSITION OF SOME
FORMS OF ATMOSPHERIC PARTICLES. Chicago Univ., 111.,
Dept. of Meteorology, NIH Grants RG-4521 and S-12(C), TN-5,
54p., Dec. 15, 1956. 16 refs.
Procedures are described for identifying the chemical composi-
tion and size of airborne particles. The basic technique in-
volves the capture of the particles in a specially treated gel.
Reagents in the gel produce a physico-chemical reaction
known as the Liesegang reaction. The products of the reaction
precipitate in the form of rings. Identification of the particles
is made by one or more of three factors: the character of the
pattern of the precipitate, the color of the precipitate, or its
change of color. Tests were developed for particles containing
the following substances: chlorides, soluble iodide, soluble sul-
fide, soluble ferrocyanide, soluble sulfates, nitrates, potassium
ion, soluble silver, fluorides, lead and all heavy metals. Details
are given for the preparation of the gels to be used for specific
tests, and techniques for the capture of particles are discussed.
(Electrostatic precipitation, impactor, and millipore filter). Ex-
periments conducted to study the production of sulfate parti-
cles by the burning of wood or coal are discussed briefly, and
a technique for the capture of small water droplets and analy-
sis of the salt which may be dissolved in them is described.

Meador, Marston C. and Robert M. Bethea
SYRINGE SAMPLING TECHNIQUE FOR INDIVIDUAL
COLORIMETRIC ANALYSIS OF REACTIVE GASES. En-
viron. Sci. Technol., 4(10):853-855, Oct. 1970. 11 refs.
A flow apparatus for continuously producing small quantities
(up to 280 l /hr) of humidified air containing known amounts of
atmospheric contaminants is described. Contaminant levels up
to 400 ppm nitrogen dioxide, sulfur dioxide, and chloride are
reproducibly maintained for periods in excess of eight days by

use of Teflon permeation tubes filled with the desired material. A comparison of the standard bubbler technique and glass and polypropylene syringe gas sampling showed the polypropylene syringe technique to be superior for NO₂ analysis (0.07-60 ppm) by the Lyshkow-modified Saltzman method. The improved syringe technique was extended to the colorimetric analysis of SO₂, Cl₂, and hydrochloric and hydrofluoric acids in dynamically polluted air. The Lyshkow method for SO₂ is applicable in the range 0.17-50 ppm. The orthotolidine method for free chlorine is applicable in the range 0.12-50 ppm. The modified method of Lawaskai, Utsumu, et al, for HCl is satisfactory for 0.5-50 ppm HCl. The bleaching reaction of Andrew and Nichols is marginally acceptable for 5-50 ppm HF. Zwenig, Eugene A.

PRELIMINARY ASPECTS OF AN AIR POLLUTION

PROBLEM. Florida Univ., Gainesville, Coll. of Engineering,

Thesis (M.S.), June 1954, 96p. 106 refs.

A project intended to determine a practicable method of fluoride appraisal in micrograms/cu l of air is reported. The meteorological considerations involved are discussed, and definitions and assumptions are established pertaining to the interrelationship of the atmospheric transport mechanism and field sampling results. A sampling plan and sampling method are described. Laboratory techniques for the analysis of samples and the elimination of interferences are detailed. Two analytical methods, thorium-alizarin titration and spectrophotometry, are concluded to be useful as potential standard techniques, but neither is established as adequate. The principal conclusion offered is that more work is required in all areas. Fluoride measurements obtained in the vicinity of an unidentified potential pollution source and from control stations in areas presumed to be free of fluoride pollution are presented tabularly. Control station readings are uniformly zero while the test station readings range from 0 to 2.6 micrograms/cu l.

DETERMINATION OF TRACES OF SULFUR, FLUORINE,

AND BORON IN ORGANIC MATERIALS BY OXYGEN

BOMB COMBUSTION. Anal. Chem., 33(12):1760-1762, Nov.

1961. 12 refs. (Presented at the conference on Analytical

Chemistry and Applied Spectroscopy, Pittsburgh, Pa., Feb.

1961.)

A platinum-lined Parr oxygen calorimeter bomb was successfully employed for quantitative decomposition of organic samples. Water is introduced into the bomb prior to combustion and the resulting combustion products are absorbed in the water. This aqueous liquid may then be analyzed for trace quantities of the desired cation or anion by standard microanalytical methods. The technique permits the combustion of a much larger sample (one gram) than the oxygen flask method. Results of trace analyses of synthetic fluoride, boron, and sulfur samples are presented in tabular form. Exceptionally good results were obtained for sulfur.

ION-EXCHANGE METHOD FOR DETERMINATION OF
FLUORIDE IN POTABLE WATERS. Anal. Chem., 36(3):577-
579, March 1964. 6 refs.

A simple, accurate, and rapid ion-exchange method is described for removing interferences from waters containing low concentrations of fluorides. The method is based on the adsorption of fluoride in an acetate resin slurry, formation of a beryllium-fluoride complex, and removal of the adsorbed fluoride by a beryllium- eluting solution. With this technique, 20-30 water analyses a day can be performed with a precision and accuracy of plus or minus 0.1 mg/l. Thus the results obtained by the method are comparable to those for standard distillation procedures. The saving in time and equipment is considerable.

TENTATIVE METHOD OF ANALYSIS FOR FLUORIDE
CONTENT OF THE ATMOSPHERE AND PLANT TISSUES
(MANUAL METHODS). 12204-01-68T. Health Lab. Sei.,
6(2):64-83, April 1969. 22 refs.

General precautions are given when analyzing for fluoride to prevent contamination by extraneous fluoride from such sources as sampling and laboratory apparatus, reagents, and from exposure to laboratory dust and fume. Directions are outlined in detail for sample preparation of particulate fluorides, gaseous fluorides (dry and wet collectors), and vegetation. Five analytical methods are described: isolation of fluoride by Willard-Winter distillation, ion exchange, and diffusion, and fluoride determination by titrimetric and spectrophotometric techniques. For each of these, the principle of the method, range and sensitivity, interferences, precision and accuracy, apparatus, reagents, and laboratory procedure are given, as well as calibration and standards, calculation, and effects of storage. The method is termed tentative until it is adopted as standard.

TENTATIVE METHOD OF ANALYSIS FOR FLUORIDE
CONTENT OF THE ATMOSPHERE AND PLANT TISSUES
(SEMIAUTOMATED METHOD). 12204-02-68T. Health Lab.
Sci., 6(2):84-101, April 1969. 23 refs.

A method described for the analysis of fluorides wherein the suspended digest and sulfuric acid are pumped into a Teflon coil of a microdistillation device maintained at 170 C. A stream of air carries the acidified sample rapidly through a coil of Teflon tubing to a fractionation column. The fluoride and water vapor distilled from the sample are swept up the column into a condenser, and the condensate passes into a small collector. The distillate is pumped continuously from the sample collector and is mixed continuously with alizarin fluorine blue-lanthanum reagent. The colored stream passes through a 15-mm tubular flow cell of a colorimeter, and the absorbance is measured at 624 millimicrons. The impulse is transmitted to a recorder. The colorimetric and distillation systems of the method are discussed. The normal range of analysis is from 0.1-4.0 micrograms F/ml, although the upper limit can be extended with modified procedures. The standard error or a single determination is between 2 and 8 micrograms, depending on the kind of plant tissue and the level of fluoride. Indirect accuracy determinations show no significant deviations from linearity. Frequent checks for precision and accuracy of the method are required. Details are given of interferences, apparatus, reagents, procedure (including tissue preparation, ashing and alkali fusion, automated analysis, maintenance, and problem detection), calibration and standards, calculation, and

effect of storage. The method is termed tentative until it is adopted as standard.

MICRODETERMINATION OF FLUORIDE USING AN IMPROVED
DISTILLATION PROCEDURE. Anal. Chem.,
37(10):1276-1278, Sept. 1965. 7 refs.

A versatile microdistillation procedure was developed for separating microgram levels of fluoride from anions and cations that interfere in colorimetric fluoride procedures. The distillation is carried out from a phosphoric acid medium with a microdistillation flask modified to minimize the carryover of phosphate and sulfate. The fluoride in the distillate is determinable by a number of colorimetric methods. In the study reported, the improved distillation-separation procedure was coupled with an Alizarin Complexone spectrophotometric measurement of fluoride. This resulted in a reliable method that appears to be suitable for a wide variety of samples. Of the 42 diverse ions tested (most of them at the 500 to 1 diverse ion-to-fluoride molar ratio), only borate and silicate interfered seriously. Based on 22 determinations at the 20-microgram fluoride level, the standard deviation of the combined distillation-spectrophotometric procedure is 3.0%.

ISOLATION AND DETERMINATION OF MICROGRAM
AMOUNTS OF FLUORIDE IN MATERIALS CONTAINING
CALCIUM AND ORTHOPHOSPHATE. Anal. Chem.,
34(10):1296-1298, Sept. 1962. 13 refs. (Presented at the American Chemical Society, Division of Analytical Chemistry, 141st Meeting, Washington, D. C., March 1962.)

Up to 4 micrograms of fluoride can be separated from dental enamel by gaseous diffusion of hydrogen fluoride from a perchloric acid solution of the sample in a polypropylene Conway diffusion dish. The HF is trapped in sodium hydroxide, while the resulting fluoride is determined spectrophotometrically by an improved zirconium-SPADNS (4,5-dihydroxy-3-(p-sulfophenylazo)-2,7-naphthalenedisulfonic acid, trisodium salt) bleaching method. Accuracy and reproducibility of the entire method are to plus or minus 0.05 microgram of fluoride at the 1 microgram level and plus or minus 0.07 microgram at the 3 microgram level. (Author abstract)

Brownley, Floyd I., Jr. and Charles W. Howie, Jr.
SPECTROPHOTOMETRIC DETERMINATION OF
FLUORIDE IN WATER. Anal. Chem. 32(10):1330-1332, Sept.
1960. 8 refs.

A spectrophotometric method for the determination of fluorides in water is described which is based upon the colored complex formed between thorium and phenylfluorone. Experiments were designed to establish the optimum pH, optimum development time, and best ratio of color-producing reagents, and to ascertain the interferences from ions normally found in surface water. A pH of 3.6 was selected as best, since the absorbance was more nearly a linear function of the fluoride concentration at this pH. Color development appears to be almost instantaneous and absorbance is constant for at least an hour. However, necessary manipulation time for 10 or more samples would preclude the use of periods shorter than 25 min. A ratio of 2 ml of thorium nitrate solution to 2 ml of phenylfluorone solution was selected to produce a colored solution which would not be so optically dense as to be insensitive to small amounts of fluoride. When it became apparent that iron would interfere seriously, it was decided to eliminate completely all cations through the use of an ion exchange resin.

Tufts, Barbara J.
A METHOD FOR IDENTIFYING PARTICULATE FLUORIDE
COMPOUNDS. Anal. Chim. Acta, vol. 23:209-214, 1960. 13
refs. (Presented at the American Chemical Society, Air Pollution
Symposium, Sept. 1959.)

A method is described for identifying particulates containing fluorides and other complex fluorine compounds such as fluosilicate in samples collected on membrane filters. The filter is treated with lead chloride to precipitate lead chlorofluoride at each fluoride-containing spot, and this microspot is identified by examination in a light microscope. Sulfate and phosphate, which also precipitate if present, can be distinguished and do not interfere. The fluoride precipitates are best seen as anisotropic white crystals in the optical microscope with crossed polars. They show polarization colors, which are especially distinctive in precipitates greater than 10 micron in diameter. Calibrations are given for the fluorides and the more insoluble salts, relating the original particle size to the reaction site size. Thus the mass of the particles can be calculated. Results of some field tests in an area of fluoride pollution are given, and compared with standard testing procedures. Samples containing hydrogen fluoride cannot be shipped or stored but must be reacted immediately after collection. (Author summary modified)

Stanford Research Inst., Menlo Park, Calif.
ACTIVITIES OF THE NASA-SPONSORED SRI TECHNOLOGY
APPLICATIONS TEAM IN TRANSFER OF AEROSPACE
TECHNOLOGY TO THE PUBLIC SECTOR. Contract NASw-
1992, NASA Rept. CR110238, SRI Quarterly Progress Rept. 2,
61p., 1970. CFSTI: N70 30531

In reporting a continuing program of aerospace technology transfer to the public sector, problems are reported in three principal categories; air pollution, criminalistics, and transportation. In the air pollution category, problem statements no.

10-16 are presented. These include the need for a rapid inspection technique to test compliance of motor vehicles with emission standards; a monitor for atmospheric fluorides; a method for disposal of waste wood; stabilization of mine and smelter waste piles; an instrument to measure atmospheric ozone; a monitor for atmospheric beryllium; and a sulfuric acid mist collector. The results of computer searches for relevant material for these and nine previously submitted air pollution problems are included. Reports of contact with user organizations include five reports of visits to west coast air pollution control organizations for the purpose of explaining the services offered and obtaining preliminary statement of problems. Two program problems are discussed, the variation among reference reviewers' opinions of the relevancy of specific references to a given problem, and the failure of the computer searches to find relevant references.

Brown, Harry

A NEW INSTRUMENT FOR THE MEASUREMENT OF GASEOUS FLUORIDES TO LESS THAN ONE PART PER BILLION. Preprint, Leigh Instruments Ltd., Carleton Place (Ontario), lip., 1969. (APCA Paper 69-119.)

An automated fluoride analyzer is described that will collect continuous air samples for a week and permit gaseous fluorides to be determined in the low ppb range, for which some states have already issued regulations. The method used by the instrument is an extension of the coated-tube method, where a tube coated with sodium carbonate collects the gaseous fluoride for subsequent detection by colorimetric analysis. A sodium carbonate solution is automatically pumped to one pipette and modified megregian colorimetric solutions to two other pipettes. After the pipettes are filled, a valve releases the sodium carbonate through the absorber tube and an air pump draws in air through a heated intake tube. Measurements are derived by washing the absorber tube with the colorimetric solution and then, to obtain a reading, comparing this tube with a dual cell photometer supplied with colorimetric solutions that have not been exposed to fluorides. Concentrations are measured in microgram F/cu m as a function of time, and two hour sampling periods are recommended for levels in the very low ppb range.

West, Philip W.

ANALYTICAL METHODS FOR THE STUDY OF AIR POLLUTION. Pure Appl. Chem., 21(4):439-447, 1970. 21 refs.

A general discussion of the requirements of air pollution analytical techniques is presented, followed by descriptions of specific techniques for sulfur dioxide, nitrogen oxides, ozone, and hydrogen fluoride. Other inorganic gases and the category of organic gases are mentioned as being within the realm of air pollutants. The subject of particulate measurement is touched upon with some degree of emphasis on both organic and inorganic carcinogens. The applications of microscopy, mass spectroscopy, and several other instrumental techniques are briefly mentioned. The principal thesis is that a need exists for increasingly sensitive and specific methods of analysis for continuous monitoring, field test, and critical or definitive studies.

Adams, Donald F.

A QUANTITATIVE STUDY OF THE LIMED FILTER PAPER
TECHNIQUE FOR FLUORINE AIR POLLUTION STUDIES.

Intern. J. Air Water Pollution (London), 4(3/4):247-255, 1961.
12 refs. (Presented at the American Chemical Society, 136th
Meeting, Atlantic City, N. J., Sept. 1959.)

Some statistical relationships are presented between lime paper fluoride levels and experimental hydrogen fluoride atmospheric concentrations at constant air flow rates. The lime-impregnated papers were prepared by dipping Whatman No. 2, 11.0 cm filter paper in 10 g/liter of Fisher 'low in fluorine' lime. They were then dried to 50-60 C, hung in a phytotron plant growth chamber, and exposed to hydrogen fluoride in a chamber with a light source. At the end of each lime paper exposure period, the papers were removed from the fumigation chamber, dried for 24 hours at 70 C, weighed, ashed, distilled, and analyzed using a thorium nitrate titration. Correlation between the fluoride accumulated by the lime papers and the exposure indexes is quite high as indicated by the linear and curvilinear r values of 0.946 and 0.069. The data show an average fluoride collection rate of 7.6 micrograms F(-)/d sq m/day/micrograms F(-)/cu m. Results are discussed in relation to previously published literature relating fluoride accumulation in lime paper exposed to industrial air pollution under field and greenhouse conditions. Additional data are presented which show that the fluoride concentration in a greenhouse atmosphere is significantly decreased over relatively short distances through processes of surface adsorption and foliar pickup (Author abstract modified)

Nardozzi, M. J. and L. L. Lewis

PYROLYTIC SEPARATION AND DETERMINATION OF
FLUORIDE IN RAW MATERIALS. Anal. Chem., 33(9):1261-
1264, Aug. 1961. 11 refs.

Because fluoride separations from raw materials by distillation are difficult as well as lengthy, another separation technique was evaluated which consists of passing moist oxygen over the sample in a heated tube, sweeping the fluoride released through the tube, and collecting the fluoride in a suitable medium for determination. A quartz combustion tube is employed and heated to 1000 C. The sample is mixed with tungstic oxide as a reaction accelerator, while oxygen is passed through the system at a rate of about 1200 ml per min. When the samples contain less than 0.1% fluoride or also contain acidic substances, then the slower spectrophotometric method must be used in place of titration. Thorium chloranilate is a very useful reagent for the spectrophotometric determination of fluoride because acetate, sulfate, sulfite, nitrate, nitrite, chloride, bromide, iodide, and thiosulfate ions do not interfere, and phosphate and molybdate interfere only when present in amounts equal to or in excess of the fluoride concentrations. To overcome the interference of iron and aluminum in samples of slag, the samples should be treated prior to pyrolysis to cause hydrolysis or the fluoride should be determined titrimetrically. However, errors arise when sulfur is present in titrimetric determinations.

Harris, W. E.

AMPEROMETRIC TITRATION OF FLUORIDE WITH
THORIUM USING A ROTATING PALLADIUM ELECTRODE. Anal. Chem., 30(5): 1000-1003, May 1958. 14 refs.

The amperometric titration method for determining traces of fluoride is performed in a solution containing potassium bromide, potassium sulfate, and aerosol, and buffered with monochloroacetic acid and sodium monochloroacetate. Best results are obtained with about 100 to 200 gamma of fluoride per 100 ml of solution, although as little as 20 gamma in 100 ml can be determined. Moderate amounts of chloride, nitrate,

sulfate, perchlorate, borate, calcium, or magnesium cause no interference but large amounts slightly decrease the sensitivity. Aluminum and more than 1 mg/1 of phosphate interfere. Reagents, apparatus, and the recommended procedure are indicated. (Author abstract)

24022

Crocket, David S. and Robert A. Grossman
INTERACTION OF AMMONIUM FLUORIDE MULLS AND DEPOSITED FILMS WITH SODIUM CHLORIDE PLATES. Anal. Chem., 34(11): 1505-1506, Oct. 1962. 7 refs.
Anomalous absorption peaks were found when ammonium fluoride was run as a mull, as well as when it was deposited as a film from anhydrous methanol. All spectra were run using a Beckman I-R5 spectrophotometer, while the x-ray powder photograph of the surface scrapings from sodium chloride plates was taken using CuK-alpha radiation. The ammonium fluoride run, both as a mull and as a film deposited from methanol, gives only a spectrum comparable to ammonium chloride. In order to get any indication at all of the presence of ammonium fluoride, it was necessary either to precipitate the ammonium fluoride from anhydrous methanol solution with dry ether, or to dry the ammonium fluoride for extended periods of time at a temperature just below the sublimation temperature, and then to prepare the mulls in a dry box.

SPECTROPHOTOMETRIC DETERMINATION OF FLUORIDE BY ZIRCONIUM-ERIOCHROME CYANINE R. Anal. Chem., 36(8): 1684-1685, July 1964. 11 refs.
The fluoride concentration range which is most suitable for spectrophotometric determination using original and modified Megregian zirconium-Eriochrome Cyanine R reagents was determined. A standard solution containing 100 ppm of fluoride was prepared by dissolving 0.2221 gram of 99.5% pure sodium fluoride in water and diluting it to 1 liter, while other standard solutions were prepared by diluting aliquots of this solution to proper volumes. Per cent transmittance readings of reagent A (Eriochrome Cyanine R) and reagent B (Zirconium Chloride) were obtained at 528 millimicrons, maintaining the temperature within 25 plus or minus 1 C. Considering both the minimum relative concentration error and the linear absorbance-concentration range, Megregian's original reagent appears suitable for use in the determination of about 1.0 to 1.4 ppm of fluoride. However, from the same considerations, a modified reagent containing 1 volume of reagent A and 2 volumes of reagent B will be suitable for determining about 2.0 to 3.0 ppm.

C. MEASUREMENT METHODS

171

acidulation of phosphate rock. An improved apparatus and the analytical procedure are discussed. Sodium and calcium fluorides, or even the slightly more complex calcium fluosilicate dihydrate, show little difference in the rate of fluorine distillation from perchloric acid at 125 C. A rate of about 15% per minute for each of these salts is indicated by the slope of the main branches of the curves. While phosphate rock may not be regarded as a simple compound, the fluorine in the rock, for the most part, behaves as calcium fluosilicate while a relatively small proportion of it behaves like fluorine in Pembroke clay. The initial rate for the first and second fluoride ions of aluminum fluoride trihydrate is about one third the rate for fluorine in sodium fluoride, or approximately 5% per minute. Results obtained with this equipment indicate that the interference of aluminum in the steam distillation of fluorine from perchloric acid solutions of aluminum-bearing rocks is caused by the formation of acid-soluble complex ions of aluminum, fluorine, and possibly other elements that greatly reduce the partial pressure of fluorine compounds in the gas phase above the distilling acid solution. A procedure for simultaneous double distillation to speed up the operation is described. (Autho abstract modified)

McCabe, Louis C.

ATMOSPHERIC POLLUTION. Ind. Eng. Chem., 45(8):105A-108A, Aug. 1953. 6 refs.

Various filter media were evaluated with respect to certain air sampling requirements by the dioctyl phthalate smoke penetration meter. Several properties and applications are presented tabularly for chemical filter papers, membrane filters, feltlike and mineral fiber papers, and all-glass papers. At the same meeting of the American Society for Testing Materials (July 1953), another paper described some instrumentation and analytical techniques which had proved useful in the study of air pollution with particular reference to the Windsor-Detroit area. A continuous recording analyzer for trace quantities of hydrogen fluoride in the atmosphere is based on a test in which a metal oxinate fluoresces under ultraviolet light, and the fluorescence is quenched by exposure to hydrogen fluoride. In order to study the relationship between smog occurrence and oxidant concentration, a continuous recorder was constructed which produces a record in terms of ozone equivalents. The oxidant recorder consists essentially of a countercurrent absorption tower of glass beads as the air-liquid contacting device. Air containing ozone, nitrogen oxides, or other oxidants liberates iodine from a buffered, neutral potassium iodide solution. The light transmission of the resulting yellow solution is measured by a double-cell colorimeter at 3600 A.

FLUOROMETRIC DETERMINATION OF SMALL

AMOUNTS OF FLUORIDE. Anal. Chem., 25(6):960-964, June 1953. 15 refs.

Methods are described for the fluorometric determination of traces of fluoride with a precision equal to or better than previous methods and which are less subject to anion interference. Experimental equipment comprised a Lumetron fluorometer and a Beckman pH meter. A Corning 5860 primary filter was used for the isolation of the desired excitation band and a Corning 3389 secondary filter for the fluorescence band. Most of the methods previously described for the fluorometric detection or determination of aluminum were studied: those using morin, quercetin, 8-quinolinoI, Eriochrome Blue Black B, which is an isomer of Pontachrome Blue Black R, and Eriochrome Red B. Superchrome Garnet Y was also studied. The methods finally developed depend upon the fact that the intensity of fluorescence of the compounds formed on

reaction of aluminum chloride with the dihydroxyazo dyes, Eriochrom Red B and Superchrome Garnet Y, is decreased on addition of fluoride. Plots of intensity of fluorescence versus pH show a maximum at pH 4.8, while the intensity decreases slightly with increase in the buffer concentration. Effects of concentration and purity of dyes were also determined. The intensity of fluorescence increases linearly with increase in concentration of ethyl alcohol and decrease in temperature. The methods were tested by analyzing solutions of pure sodium fluoride both before and after a Willard- Winter distillation.

METHODS FOR THE DETECTION OF TOXIC SUBSTANCES IN AIR. HYDROGEN FLUORIDE AND OTHER INORGANIC FLUORIDES. Booklet 19, 15p., 1970. 5 refs.

Apparatus, procedures, reagents, and where applicable, interferences are given for two tests for determining fluoride concentrations in factory atmospheres. The primary object is not to obtain an extreme degree of accuracy but to give a rapid indication of whether or not the atmosphere is dangerous, as determined by comparison with government-established threshold limit and ceiling values. The occurrence and toxic effects of fluorides are briefly described. The first method described is a field test in which hydrogen fluoride is collected in an acid solution of zirconium-solochrome cyanine R complex and the observed bleaching in color is compared with glass color standards. The second is a simple laboratory method to determine total inorganic fluoride in air, in which hydrogen fluoride and fluoride-containing dust and fume are collected on an alkali-impregnated paper which is placed in a micro diffusion vessel. Acid is added and the released hydrogen fluoride is trapped by an alkaline coating on the inside lid of the vessel. The alkali is quantitatively transferred to a volumetric flask, lanthanum-alizarin fluorine blue reagent added and the fluoride determined either spectrophotometrically or visually by comparison with a set of glass color standards.

Adams, Donald F., Robert K. Koppe, and Norman E. Matzek

COLORIMETRIC METHOD FOR CONTINUOUS RECORDING ANALYSIS OF ATMOSPHERIC FLUORIDE. TEST CHAMBER AND INTERFERENCE STUDIES WITH THE MINI-ADAK ANALYZER. Anal. Chem., 33(1):117-119, Jan. 1961. 19 refs. (Presented at Meeting of the American Chemical Society, 138th, Division of Water and Waste Chemistry, New York, Sept. 1960.)

The tolerance of a low fluoride (micrograms/cu m or ppb atmospheric concentration range) reagent to other pollutants is delimited; the reagent is incorporated in a recently reported automatic continuous measurement and recording method using the Mini-Adak Analyzer for atmospheric fluorides. The reagent consists of a zirconium-Eriochrome Cyanine R complex. Statistical comparison was made between the continuous Mini-Adak record and manual air sampling and analysis data of controlled test chamber atmospheres. Instrumental analysis of chamber atmospheres revealed a fine structure of changing diurnal concentrations not previously possible with the long-term averaging-type sampling. The minimum sensitivity of the fluoride reagent is stated as any combination of micrograms of

<xref image="2000WVER.TIF|V3|2006:09:28:01:26:12.00|126155|0"> image: </xref>

F per cu and minutes of exposure time, yielding a value of 30. Recent improvements in the photometric circuitry have reduced the sensitivity factor to 7.5. Los Angeles smog-type gases appear to be compatible with the reagent. The reagent may be subject to interference from phosphate, sulfate, and aluminum. However, phosphate appears to offer the only significant source of error under typical field sampling conditions. The Mini-Adak analyzer with the low fluoride reagent has an approximate 18% analysis efficiency for submicron cryolite.

Senkowski, B. Z., E. G. Wollish, and E. G. E. Shafer
RAPID DETERMINATION OF ORGANICALLY BOUND
FLUORINE. Anal. Chem., 31(9):1574-1576, Sept. 1959. II refs.
A rapid and simple procedure is described for the determination of organically bound fluorine. In a Schoeniger borosilicate glass flask, the sample is burned in the presence of a small quantity of sodium peroxide. This is directly followed by colorimetry using zirconyl-Eriochrome Cyanine R complex; absorbance is determined photometrically by Megregian's procedure. Small quantities of phosphates do not interfere, but larger proportions require a Willard-Winter distillation. Less than 1 hour per determination is required, unlike previous methods which required a separation procedure following decomposition of the sample. The experimental procedure is described in detail. NEW FLUORIDE RECORDER. Res. Ind. (Stanford Res. Inst.),
11(3): 10, May 1959.

A recorder is mentioned which measures concentrations of fluorides as low as one or two parts per ten billion. It works on the principle of a differential photometer—that is, photoelectric cells measure the difference in reactions on adjacent areas of a fluorescent tape. One of these areas is reacted on by a air sample containing hydrogen fluoride, and the other by a sample from which the hydrogen fluoride has been removed.

Bartlett, John C., Doris Kavanagh, and Ross A. Chapman
THE DETERMINATION OF THE FLUORIDE CONTENT OF
EDIBLE BONE MEAL. Can. J. Chem. Eng., vol. 33:348-355,
1955. 17 refs.

Fluoride is determined in edible bone meal by igniting a sample at a temperature between 550 and 750 C. A Willard and Winter distillation from perchloric acid is used to separate fluoride from interferences, and the amount of fluoride in the distillate is measured by the amount of bleaching of a ferric salicylate solution at a pH of 3.1. The optimum conditions of acidity and reagent concentration were investigated and the effects of interfering substances were determined. An optimum weight ratio of ferric iron and salicylic acid is 0.404, which corresponds to 1.00 on a molar basis. Calibration and details of the procedure are discussed; the standard error of the method as applied to bone meal is plus or minus 2.3%. (Author abstract modified)

Deutsch, Samuel
OVERCOMING THE EFFECT OF MANGANESE DIOXIDE
IN FLUORIDE DETERMINATIONS. Anal. Chem., 27(7):1154-
1155, July 1955. 3 refs.

Both manganese dioxide and chlorides in vegetation samples interfere with the modified Willard-Winter method for the microdetermination of fluoride. Liberation of chlorine during distillation hampers the titration of fluorides by a partial or complete bleaching of the alizarin red indicator. The addition

of 3% hydrogen peroxide in the fluoride distillation flask before the start of distillation eliminates this interference. Tests of the reproducibility of fluoride recovery in the presence of 3% hydrogen peroxide as a reductant showed that addition of 3% hydrogen peroxide did not interfere with fluoride recovery or subsequent titration. (Author abstract)

Adams, Donald F., Robert K. Koppe, and Homer J. Dana
AN AUTOMATIC ATMOSPHERIC FLUORIDE ANALYZER
WITH POTENTIAL APPLICATIONS TO OTHER POLLUTANTS. J. Air Pollution Control Assoc., 9(3): 160-168, Nov. 1959. 23 refs.

Two separate prototype analyzer units were constructed and assembled within a single metal enclosure to permit convenient, simultaneous development and field testing of reagents for the determination of sulfur dioxide and hydrogen fluoride in the atmosphere. Each versatile analyzer consists of two fundamental components: a colorimeter capable of either triggering a time stamp upon development of a pre-selected photocell output equivalent to some concentration of the pollutant which has been absorbed in the reagent (dosimeter model) or driving a recorder (the continuous recording model); and an air-reagent contacting system in which a continuously circulating volume of reagent contacts a sampled air stream until a pre-selected concentration of the desired pollutant has been absorbed by the reagent. Fluoride reagent is prepared by adding 200 ml of acidified zirconium solution to 500 ml of distilled water, followed by 200 ml of a dye solution. Then 3.00 g Surfynol 82 are added, and the mixture is diluted to 1 liter. Two drops of Dow-Corning Anti-foam A Emulsion are then added. Successful field and laboratory tests have been earned out with this analyzer and fluoride reagent.

DIRECT SPECTROPHOTOMETRIC FLUORIDE DETERMINATION. Anal. Chem., 34(10):1308-1312, Sept. 1962. 11 refs. (Presented at the American Chemical Society, Division of Analytical Chemistry, 141st Meeting, Washington, D. C., March 1962.)

Fluoride reacts with the wine-red cerium(III)-alizarin complexone (1,2-dihydroxyanthraquinon-3-ylmethylamine-N,N-diacetic acid) complex to produce a lilac-blue color. As the basis for a colorimetric method for microgram levels of fluoride, two ratios of cerium(III) to alizarin complexone are used. A 1:1 mole ratio gives high tolerance for common anions that do not complex cerium (III) as well as for many cations. A 1:2.5 ratio gives increased tolerance for complexing anions such as sulfate and phosphate. These effects are explained by a con-

COMPLEXOMETRIC DETERMINATION OF FLUORIDE

WITH CERIUM(III). Anal. Chem., 33(12): 1655-1657, Nov.

I%1. 6 refs. (Presented at the Analytical Chemistry Conference in Nuclear Reactor Technology, 4th, Gatlinburg, Tenn., Oct. 12-14, 1960.)

A method is presented, involving a pyrolysis separation and a cerium precipitation-EDTA titration measurement, which is applicable to a variety of samples containing fluoride complexing metals such as zirconium, uranium, aluminum, and beryllium, and high concentrations of nitrate and chloride. Quantitative recovery of 5 to 40 mg portions of fluoride was obtained by pyrolyzing at 950 C for 10 min using a moist air flow of 2.5 liters/min. Addition of aluminum nitrate to the sample controls the release of fluoride from volatile samples and also serves as an accelerator for others. Cerous fluoride is precipitated stoichiometrically at pH 1.75 with a measured excess of cerium(III), and the excess cerium is back-titrated with EDTA ((ethylenedinitrilo)tetraacetic acid) to an arseneazo-cresol red end point. Sulfate and phosphate interfere seriously in the precipitation. The computed standard deviation for a single determination based on 6 replicate determinations at the 24 and 36 mg levels of fluoride was 0.42 mg.

AIR POLLUTION CONTROL: HEALTH ASPECTS AND MICROTÉCHNIQUES. Trans. N. Y. Acad. Sci., Ser. 2, 18(4):289-297, Feb. 1956. 28 refs.

The greatest source of air pollution in New York City is burning fuels. The relationship of air pollution to health is dramatically indicated by the episodes in the Meuse Valley, in Donora, Pa., in Poza Rica, Mexico, and in London, England. The principal category of microanalysis in air pollution studies is the determination of very small amounts of a substance in a large volume of air. The principle of deposition is used for sootfall or dustfall sampling. Absorption methods for air sampling are of two types: impingers and absorbers. Filtration methods include the high-volume sampler, the automatic paper tape samplers, and millipore filters. Condensation and adsorption are also employed in collecting work. The peroxide method is preferred over the alkaline iodide or colorimetric method in analyzing sulfur dioxide. Sulfur trioxide can be measured by direct titration and gravimetrically. Infrared spectrometry is the method of choice for determining carbon monoxide; however, the CO tube colorimetry method has been adopted by some investigators. The method commonly used for nitrogen oxides involves estimating by the phenodisulfonic acid method. Ammonia and ammonia compounds are trapped in a bubbler containing sulfuric acid and are estimated by nesslerization. Methods of analysis are described for aldehydes, cyanides, fluorides, ozone, hydrogen sulfide, lead, hydrocarbons, and other components.

EFFECT OF COLD STORAGE ON THE FLUORIDE CONTENT OF ALFALFA. J. Agri. Food Chem., 5(5):377-379, May 1957. 4 refs.

The tediousness of determinations of fluoride in vegetation samples, coupled with a frequent need to gather a large number of samples in a short time, usually require? storage of samples prior to analysis. Tests using alfalfa samples were conducted to determine the effect of storage at 0 F for four to six weeks on fluoride content. Stored samples showed more variation than unstored samples but no consistent change in fluoride content. The variation can be reduced by adding lime to stored samples. Samples stored in a tight container do not gain or lose moisture consistently. (Author abstract)

Thomas, M. D. and R. E. Amtower

THE MICRODETERMINATION OF FLUORIDE IN VEGETATION. Air Pollution Control Assoc. J., 19(6):439-442, June 1969. 16 refs.

The determination of fluorine in vegetation is generally carried out by a modification of the Willard-Winter method. This method gives satisfactory results, but it is rather laborious and time-consuming and requires considerable equipment. For microchemical work on very small vegetation samples or fractions such as chloroplasts, in which the total fluorine available is usually of the order of a few micrograms, other techniques are required. A micro method for the determination of the fluoride content of plant materials, particularly the leaves, is described. The samples are dried and ground to a fine powder. Fifty mg samples are burned in oxygen in 250-ml separatory funnels or in 300-ml Erlenmeyer flasks. The gaseous products of the combustion are absorbed in 0.1N sodium hydroxide in the closed funnel or flask and transferred to a small covered plastic dish in which the fluoride is diffused to tiny droplets of 3N sodium hydroxide solution distributed over the lower side of a tight fitting cover. The diffused fluoride is dissolved in water and determined colorimetrically by the SPADNS reagent. The sensitivity of the method is directly proportional to that of the SPADNS dye used to measure the fluoride.

Heilingoetter, R.

ANALYTICAL METHODS USED TO DETERMINE DAMAGE BY ACIDS IN THE ATMOSPHERE. (Die chemische Untersuchungsmethoden des Luftsaureschaedenexperten). Text in German. Chemiker-Zeitung, 51(45):429-433, June 8, 1927.

The three methods available for the assessment of damage caused by atmospheric acids are the so called leaf and needle ash analysis which directly measures damage caused to plants, atmospheric acid analysis by which the harmful content of acids can be measured on the spot and the qualitative determination of small quantities of acid in the atmosphere. The first method is based on the accumulation of acid in the exposed plants. In the ash of such exposed plant material (needles of conifers for example) water-soluble sulfuric acid, chlorine, fluorine, and nitrogen are determined and the excess over normal levels is calculated. The second method, analyzing air acidity directly, uses a series of absorption bottles filled with different absorbent liquids designed to retain carbon dioxide, sulfur dioxide, sulfur trioxide, nitrogen oxides, ammonia, chlorides and hydrochloric acid which are then measured by appropriate analytical methods and the respective acidity is calculated. Toxicity limits are for SO₂ 3 mg/cu m, for N₂O₄ 50 mg/cu m, for NH₃ 30 mg/cu m, for HCl 110 mg/cu m, for

<xref image="2000WVET.TIF|V3|2006:09:28:01:26:18.00|122674|0"> image: </xref>

C12 64 mg/cu m and for HF 0.00033 vol %. The qualitative method uses cotton cloth dipped in a barium hydroxide solution and in lime water to determine the presence in the atmosphere of SO₂ and of F respectively.

Mandl, Richard H., Leonard H. Weinstein, Gilbert J. Weiskopf, and Judy L. Major
THE SEPARATION AND COLLECTION OF GASEOUS AND PARTICULATE FLUORIDES. Preprint, International Union of Air Pollution Prevention Associations, 37p., 1970. 19 refs. (Presented at the International Clean Air Congress, 2nd, Washington, D. C., Dec. 6-11, 1970, Paper CP-25A.)
The separation of gaseous from particulate fluorides in ambient air is essential for the enforcement of air quality standards by governmental agencies and may also be important in monitoring experimental fumigations under laboratory or field conditions. Two methods were selected for extensive study. The bicarbonate-coated tube coupled with a membrane filter for collection of particulate fluoride proved successful. The most useful combination was a 7-rnm I.D. by 122 cm Pyrex glass tube with an Acropore AN-800 filter and a sampling rate of 14.1 liters per minute (0.5 cfm). An automatic paper tape sampler was developed also in which the air sampler is drawn first through a citric acid-treated Whatman No. 52 prefilter to remove particulate fluorides and then through a sodium hydroxide-treated Whatman No. 4 paper for collection of gaseous fluoride. Both methods have been tested in the laboratory and in field plot experiments. (Author abstract modified)

Jacobson, Jay S. and Laurence I. Heller
SELECTIVE ION ELECTRODE ANALYSIS OF FLUORIDE IN VEGETATION. Preprint, International Union of Air Pollution Prevention Associations, 17p., 1970. 38 refs. (Presented at the International Clean Air Congress, 2nd, Washington, D. C., Dec. 6-11, 1970, Paper CP-25B.)
Many laboratories carry out fluoride analyses of vegetation to determine the sources, distribution, and effects of atmospheric fluorides. The techniques and procedures used vary widely from laboratory to laboratory, but all are laborious and provide many sources of error. The fluoride ion electrode offers the possibility of circumventing conventional ashing, fusion, and distillation techniques. Therefore, methods of extracting vegetation and performing potentiometric analyses were evaluated. A procedure was developed which employs sequential extraction of dried, pulverized vegetation with 0.05 N sulfuric acid followed by 0.05 N ammonium hydroxide. After neutralization, pH 7 acetate buffer and sodium citrate are added to the slurry to control pH and ionic strength and to mask potential interfering agents. Analyses were performed with continuous stirring on the suspension of vegetation with an Orion combination fluoride-reference electrode and an appropriate electrometer. Standard fluoride solutions containing all reagents were also analyzed to provide a calibration curve from 0.05 to 10.0 ppm w/v fluoride. In this manner, vegetation samples containing 20 to 2000 ppm w/w fluoride could be analyzed. The accuracy of the extraction-potentiometric method was verified by several techniques. The amount of fluoride found by analysis was directly related to amount of sample taken, and recovery of known amounts of added fluoride was better than 95%. A correlation coefficient of 0.9994 was obtained when measurements by this method were compared with those by conventional methods. The relative standard deviation of replicate analyses in the 20-370 ppm range was 5.7%. However, the absolute accuracy of the method is not known because primary standards are not available. Collaborative studies are planned to determine whether this rapid and simple technique can be recommended as a suitable substitute for conventional techniques. (Author abstract modified)

Liberti, Arnaldo and Marco Mascini
CONTINUOUS MEASUREMENTS OF ATMOSPHERIC POLLUTANTS BY MEANS OF SPECIFIC ION MEMBRANE ELECTRODES. Preprint, International Union of Air Pollution Prevention Associations, 23p., 1970. 3 refs. (Presented at the International Clean Air Congress, 2nd, Washington D. C., Dec. 6-11, 1970, Paper CP-31G.)

Information is presented which is directed to the utilization of specific ion membrane electrodes to measure atmospheric pollutants. As these electrodes measure the activity of an ion in solution, they can be used either to follow the variation of concentration of an ion which is directly absorbed from the air or of an ion of a solution reacting with a certain pollutant. Various experimental devices are presented to perform either a continuous or an intermittent determination by a direct measurement or by a coulometric titration. Typical examples are the continuous measurement of fluoride in stack gases and the ozone and total oxidants determination in the air. The use of a fluoride selective electrode permits continuous recording of the fluoride content of stacks; gases are adsorbed into a cell containing a buffered solution where a fluoride selective membrane electrode and a saturated calomel electrode are set. The potential difference is continuously measured. Lower fluoride concentration may be determined by passing the adsorbing solution into a titration cell. The neutral potassium iodide procedure for total oxidants determination can be carried out electrometrically with various apparatus. Air is drawn into a cell where an iodide membrane electrode records the iodide concentration; other examples of analyses where membrane electrodes may be used include the monitoring of sulfur dioxide, hydrogen sulfide, and hydrogen cyanide. C. MEASUREMENT METHODS

175

mate. The concept of parent population denotes the maximum possible number of observations which pertain to one definite property or to a group of properties and which can be distinguished by some kind of description or definition from other correlated observations. Applying the method of the stratified sample to air quality measurement projects, one has to proceed by first dividing into strata the parent population of all measurements of a given area and in a given time interval, in such a way that within the individual strata the quantities observed are as homogeneous as possible, with the mean values between the strata differing as much as possible. A fluorine measurement program is used to illustrate this method. Often, a certain sample variable cannot be determined and its mean value calculated, except with considerable experimental expenditure, while an auxiliary variable which shows a high correlation to the sample variable proper can be investigated without difficulty. Frequently, it is inconvenient or impossible to encompass the parent population of an auxiliary variable in order to derive its mean value. Nevertheless, it may be useful to introduce an auxiliary variable, to investigate it using a large sample size and, by means of the regression estimate, to infer from its own mean value on the mean value of the main variable having a smaller sample size.

SAMPLING ATMOSPHERIC FLUORIDES WITH GLASS
FIBER FILTERS. J. Air Pollution Control Assoc., 13(8):374-
377, Aug. 1963. 8 refs.

The use of glass fiber filters for collecting atmospheric fluorides and separating particulate and gaseous fractions was investigated. Because of their low fluoride blanks, MSA type 1106-B filters were selected for study. These filters are placed in open-faced metal holders coated with polyvinyl plastic and air is drawn through them with a rotary, pressure-vacuum, vane-type pump. A second filter used as backing between the filter and filter support reduces the possibility of sample contamination by the holder. The fluoride is isolated from the sampling filter by distillation from perchloric acid: no ashing or fusion is necessary unless the fluoride being determined is very nonreactive. If less than 30 micrograms of fluoride are anticipated, the fluoride is concentrated from the anion exchange resin method and measured spectrophotometrically. Larger amounts are titrated with thorium nitrate; alizarin is used as indicator. The glass fiber filters were compared with impingers in tests conducted in three different types of atmospheres: (1) in a controlled atmosphere with hydrogen fluoride; (2) on an industrial plant property where both gaseous and particulate fluorides were present; and (3) in an urban residential commercial district. There was no statistically significant difference between the average fluoride concentrations obtained by the two sampling methods. Of the separation methods studied, the most effective was the use of an aluminum tube apparatus preceding the glass fiber filters. When both this apparatus and an impinger were placed in an atmosphere where about 70% of the fluoride was in particulate form, the average measured particulate concentrations for each method were almost identical. The results indicate that the filters offer a reliable, simple, and convenient method of collecting total atmospheric fluorides at a minimum cost for equipment and maintenance.

A review of the literature on methods of analysis for fluorine compounds is presented, covering the period from 1816 to 1950. This second of three parts discusses the following methods: determination by formation of thorium fluoride (continued from Part I), by zirconium fluoride, lakes of zirconium, and by fluosilicic acid. The isolation of fluoride as the volatile fluosilicic acid is also considered at length, including alkimetric titration of fluosilicic acid.

METHODS OF FLUORINE AND FLUORIDE ANALYSIS - III.

Nucleonics, 9(2):51-58, Aug. 1951. 217 refs. Part I. Ibid., 8(6):24-33, June 1951. 146 refs. Part II. Ibid., 9(1):40-49, July 1951. 153 refs.

A review of the literature on methods of analysis for fluorine compounds is presented, covering the period from 1816 to 1950. This last of three parts discusses the perfluoric acid and fluosilicic acid methods as well as analysis of fluorocarbons, volatile fluorides, and elementary fluorine. Spectrochemical and miscellaneous analytical methods are treated briefly. References are given for determination of fluorides in specific industrial materials, soils, and human tissues.

25631

FLUORIDE FOILERS. Chem. Eng. News, vol. 34:1506, 1509, March 26, 1956.

It is now standard procedure for any plant facing a potential fluoride effluent problem to maintain constant checks on vegetation and animals in its vicinity, not only to monitor the effluent control system but also to have a continuing factual record available if complaints are received. To permit plant chemists to check on the accuracy of their analytical techniques without running replicate analyses, a series of 35 standardized fluoride samples has been developed. They are derived from a broad range of minerals, vegetation, and animal tissue commonly found in industrial fluoride problems—soils, ores, slags, dusts, fertilizers, feeds, hays, pine needles, tree barks, etc. Samples, which cost \$13 each, are available with fluoride concentrations of from 5 to 1500 ppm.

AN AUTOMATIC HYDROGEN FLUORIDE RECORDER
PROPOSED FOR INDUSTRIAL HYGIENE AND STACK

<xref image="2000WVEV.TIF|V3|2006:09:28:01:26:24.00|111640|0"> image: </xref>

MONITORING. Anal. Chem., 32(10): 1312-1316, Sept. 1960. 12 refs. (Presented at the American Chemical Society, Division of Water Sewage, and Sanitation, 136th Meeting, Atlantic City, N. J., Sept. 1959.)

The increasing use of fluorine and fluorides in industrial processes requires the close surveillance of the fluoride content of the air in working areas and adjacent environs. Conventional sampling and analytical techniques are time consuming and not suitable for an alarm system to warn personnel of the presence of objectionable exposure levels. A method is needed for continuously and instantaneously recording changes in the fluoride content of both indoor and outdoor air. Fluoride levels from 0.1 to 200 mg per cu m are determined by measuring the color change produced by the reaction between the green iron-ferron (8-hydroxy-7-iodo-5-quinoline-sulfonic acid) complex and fluoride ions. A method of automating this technique is suggested. (Author abstract modified)

25668

SPECTROPHOTOMETRIC DETERMINATION OF FLUORIDE ION. In: Manual of Standard Procedures. Atomic Energy Commission, New York, Health and Safety Lab., Rept., TID-4500, 5p., Sept. 1970. 1 ref. NTIS: NYO-4700(3rd Ed.) In the method described, the determination of fluoride ion depends upon fluoride quenching of the thorium-chrome Azurol S lake. Fluoride ion in the range of 0.1 to 90 microgram may be determined in sodium hydroxide solutions used in air sampling, and in air filters, water, or urine samples. A spectrophotometer and distillation apparatus, as diagrammed, are required. Data are given on special reagents, sample preparation, and determination procedure. Ions such as sulfate, phosphate, uranium (VI), iron (III), aluminum, and beryllium interfere but can be removed by the distillation procedure. Only chloride interferes before and after distillation of fluorine.

Cholak, J.
CURRENT INFORMATION ON THE QUANTITIES OF FLUORIDE FOUND IN AIR, FOOD, AND WATER. A.M.A. Arch. Ind. Health, 21(4):312-315, April 1960. The significance of the result of a determination of fluoride in the investigation of the behavior of the fluoride ion in biological material depends partly upon the techniques and precautions employed in collecting the sample and partly upon the precision of the analytical procedure that is employed. The general analytical technique involves three procedures: the conversion of the fluoride into soluble, inorganic form by means of an ashing step usually carried out at 600 C; the separation of fluoride as hydrofluosilicic acid from interfering ions by the Willard and Winter distillation procedure, and the estimation of the quantity of fluoride in the distillate. This estimation may be done by determining the bleaching effect of the fluoride ion on colored metal dye complexes by a titration procedure. Further details of fluoride determinations are described, and concentrations are presented tabularly for fluorides in air, food, and water.

Adams, Donald F.
FURTHER APPLICATIONS OF THE LIMED FILTER PAPER TECHNIQUE IN FLUORINE AIR POLLUTION STUDIES. J. Air Pollution Control Assoc., 7(2):88-91, Aug. 1957. 11 refs. The exposure of lime-treated filter papers under protection of wooden shelters has been suggested as an inexpensive technique for detecting atmospheric fluorides and delineating areas of fluoride pollution. In the present investigation, data were obtained on comparative fluoride levels in different shelters, on the relationship between average monthly lime paper

fluoride levels and fluoride accumulated in herbage during the growing season, and on the reliability of the lime paper technique in measuring the relative intensity of fluoride pollution from one year to another. Under similar conditions of exposure, only small differences in fluorine content of treated papers may exist between duplicate shelters; the correlation between the fluoride in the lime papers and the ground cover vegetation for a wide range of fluoride exposure levels is high enough to predict with reasonable accuracy even the fluoride content of heterogeneous herbage throughout the growing season. The reliability of the lime papers in measuring relative fluoride pollution from one year to the next was substantiated when observed diminutions in fluoride pollution reflected by comparative lime paper fluoride levels were found to be due to a reduction of fluoride emissions rather than variations in wind patterns.

Silverman, Louis and Mary E. Shideler
SPECTROPHOTOMETRIC DETERMINATION OF BERYLLIUM AND FLUORIDE USING CHROME AZUROL S. Anal. Chem., 31(1):152-155, Jan. 1959. 14 refs. (Presented at the American Chemical Society Meeting, 132nd, New York, Sept. 1957.)

Chrome Azurol S (the sodium salt of 3'-sulfo-2',6-dichloro-3,3'-dimethyl-4-hydroxyfuchson-5,5-dicarboxylic acid) was applied to the spectrophotometric determination of beryllium and fluoride. The colored beryllium-Chrome Azurol S complex is formed at pH 6.0 in the presence of a pyridine-hydrochloric acid buffer, which enhances the sensitivity of the dye to beryllium and increases the sensitivity of the metal-dye complexes to fluoride. The procedure described can be used to determine from 1 to 30 gamma of fluoride per 50-ml vol with a precision of plus or minus 1 gamma, and from 0.2 to 10 gamma of beryllium per 50 ml vol with a precision of plus or minus 2 gamma. Studies were made on the variables of the system, interferences, and on an ion exchange method of separate uranium form beryllium. (Author abstract modified)

Nakazawa, Akira
ON HYDROGEN FLUORIDE AIR POLLUTION MONITORING DEVICE. (Fukka suisogasu taiki osen kanshi sochi ni tsuite). Text in Japanese. Bunseki Kiki (Analysis Instr.), 8(8):546-549, Aug. 1970.

In a new device for analyzing hydrogen fluoride, air to be tested is continuously exposed to the reagent, the chlorate solution of zirconium eriochrome cyanine R. In proportion to the concentration of fluoride in atmosphere, zirconyl fluoride is produced, and the reagent loses its color. The degree of color loss is measured by a colorimeter to obtain the amount of fluoride in the atmosphere that came in contact with the reagent. The analyzer, which is illustrated in a flow diagram, has the dimension 90 by 40 by 40 cu cm and weighs 60 kg. Its operation requires 100V AC and about 300W power. Control, measurement, reagent tank, and power as well as pump sections are all housed in one cabinet. The measurement section includes the colorimeter among other mechanisms. The operation of the analyzer consists of setting the timer (100 min), adjusting the air intake to 10 l/min, and letting the machine auto-

<xref image="2000WVEW.TIF|V3|2006:09:28:01:26:28.00|117961|0"> image: </xref>

matically record the concentration of fluoride in the atmosphere. The value of concentration can be obtained by comparing the data to the calibration line. An example of a measurement is shown; the concentration is almost zero at night, and increases from morning to the afternoon and decreases in the evening. The reliability of the device is accurate to 1 ppb, and can also be used for measuring trace amounts of gases such as sulfur dioxide, chlorine, and nitrogen oxides.

Yamate, Noboru

MEASUREMENT OF GASEOUS AIR POLLUTION. (Gasujo taiki osenshitsu no solutei). Text in Japanese. Bunseki Kiki, (Analysis Instr.), 8(8):536-545, Aug. 1970. 34 refs.

Manual and continuous methods of measuring the major gaseous pollutants are reviewed. Manual methods employed for analyses of sulfur oxides are the rosaniline, molybdic acid-barium, lead peroxide, and detector filter paper methods. Continuous methods are the iodine starch-light absorption, rosaniline light absorption, an electroconductivity method. The Saltzman and naphthylethylene diamine methods are employed for manual analyses of nitric oxide and nitrogen dioxide; and the Saltzman light absorption method is used for continuous analysis. Carbon monoxide is manually analyzed by infrared analysis, gas chromatography, detector tubes, and the hopcalite method; it is continuously analyzed by infrared analysis, gas chromatography, the mercuric oxide method, and the hopcalite method. The manual method of analyzing hydrogen sulfide is the methylene blue method; the continuous method; and the filter paper coloring method. Hydrocarbons are measured manually by gas chromatography and continuously by hydrogen flame ionization. Aldehydes are measured manually by the chromotropic acid, acetylacetone, and MBTH methods; and continuously by the light absorption method. Ozone and all oxides are measured manually by the iodimetric and phenolphthalein methods and continuously by the coulometric and light absorption methods. The thorium neotrine and lanthanum alizarine complex methods are used for manual measurements of fluorine compounds; fluorescent and light absorption methods are used for continuous measurement. The orthotolysin and light absorption methods are used, respectively, for manual and continuous analyses of chlorine. Respective manual and continuous methods of measuring hydrogen chloride are the thiocyanic acid-mercuric salt and electroconductivity method. The manual method for hydrogen cyanide is the pyridine-pyrazolone method. For manual measurements of hydrogen cyanide, the Indo-phenol and Nessler methods are employed.

Heuser, Stanley G.

VOLUMETRIC DETERMINATION OF CONCENTRATIONS OF SULFURYL FLUORIDE IN AIR. Anal. Chem., 35(10):1476-1479, Sept. 1963. 4 refs.

The reaction of the fumigant sulfonyl fluoride with alkalis is discussed, and two volumetric methods of determining its concentration in air are described. The first method involves titration of excess NaOH with 0.05N HCl, using thymolphthalein as indicator. The second method involves titration of excess barium hydroxide with 0.1N HCl, again with thymolphthalein as indicator. In the first method, the amount of carbon dioxide absorbed by the reagent has to be calculated by direct titration of excess alkali in another aliquot of the sample. In the second method, CO₂ present in the atmosphere is precipitated as barium carbonate together with the fluoride. If determination of CO₂ is not required, titration with HCl is replaced by direct addition of a standard amount of acid in excess to sample and reagent blank. The amount of SO₂F₂ present is then obtained directly by difference in titrations with 0.02N Ba(OH)₂. Recoveries of SO₂F₂ in normal air by both methods are tabu-

lated, as are results obtained by the first method when 1.5 to 2.5% by volume CO₂ was present. Collectively these results show substantially correct recoveries of the two gases by either method, either individually or in admixture without mutual interference. However, the second method is preferred for accurate measurements of low concentrations of SO₂F₂, since the calculation is made independently from that for CO₂.

Spindler, Donald C. and Mona Franck Smith
SPECTROCHEMICAL DETERMINATION OF FLUORINE IN
PORCELAIN ENAMEL FRITS. Anal. Chem., 30(9): 1130-1332,
Aug. 1958. 8 refs.

Porcelain enamel frits, which are the basic material for porcelain enameling, are selected glasses of widely varying composition. These molten glasses are fritted by air or water quenching to form brittle flakes or granules. Fluorine may be added to a glass batch as an alkali silicofluoride or fluorspar. Fluoride aids in smelting the raw bath and increasing the opacity of zircon enamels. Fluorine losses occur during smelting as silicon tetrafluoride, boron trifluoride, and alkali fluorides. Rapid comparison of porcelain enamel frits is facilitated by spectrochemical determination of fluorine. Calcium carbonate and graphite are mixed with the sample to produce calcium fluoride bands. The intensities of the band head at 5291.00 Å, corrected for background are compared with those of chemically analyzed standards. The range of fluorine covered is from a few tenths to 6% in frits. Some factors considered are the emulsion, amperage, time of exposure, and band components. Various amounts and kinds of additives are evaluated. (Author abstract modified)

Yasuda, Stanley K. and Jack L. Lambert
CELLULOSE SUPPORTED THORIUM-ALIZARIN RED S
REAGENT FOR FLUORIDE ION DETERMINATION. Anal.
Chem., 30(9): 1485-1489, Sept. 1958. 14 refs.

The reagent and procedure described are the result of a study of colorimetric methods to produce color in solution directly proportional to fluoride ion concentration. Fluoride ion in concentrations to 15 ppm reacts selectively with the reagent to release the thorium-Alizarin Red S chelate (absorption maximum, 520 micrograms) into solution. Concentration limits for a number of possible common interfering ions were determined. A polymeric structure of the reagent and a mechanism for the ion exchange reaction are proposed. The combining ratio of thorium to dye was 1 to 2 by gravimetric and spectrophotometric methods. Chelation of thorium through a carbonyl oxygen and the 1-hydroxy group in the Alizarin Red S was substantiated by infrared absorption data. The method should be convenient for rapid visual or spectrophotometric determination of fluoride ion within the conditions specified. (Author abstract modified)

Ivie, J. O., L. F. Zielenski, M. D. Thomas, and C. R.
Thompson
ATMOSPHERIC FLUOROMETRIC FLUORIDE ANALYZER.

J. Air Pollution Control Assoc., 15(5): 195-197, May 1965. 7 refs.

<xref image="2000WVEX.TIF|V3|2006:09:28:01:26:30.00|118914|0"> image: </xref>

A fluoride analyzer is described which can be operated for longer than six months with virtually no maintenance and which measures atmospheric hydrogen fluoride in the sub-ppb range. Parallel air streams are drawn into the analyzer through glass tubes, one coated with NaHCO_3 and the other clean. The coated tube absorbs hydrogen fluoride, but the clean tube allows it to pass. The air streams are drawn through adjacent spots of sensitized paper tape made by dipping chromatography paper in MgOH solution of 8-hydroxyquinoline and magnesium acetate. The resulting magnesium salt of 8-hydroxyquinoline fluoresces when illuminated with ultraviolet light. The visible fluorescence is quenched by hydrogen fluoride, thus providing a quantitative measure of fluoride. The difference in emitted light from the two areas of a tape is monitored by reflecting the two beams of light on balanced photomultiplier tubes. In field measurements, satisfactory correlation has been found between average daily values obtained with the automatic analyzer and impingers.

Nichol, A. A., H. M. Benedict, J. L. Byrne, and C. P. McCarty

THE DETERMINATION OF THE FLUORIDE CONTENT OF NATURAL VEGETATION. *J. Air Pollution Control Assoc.*, 6(4):239-243, Feb. 1957. 1 ret. (Presented at the 49th Annual Meeting of the Air Pollution Control Association, Buffalo, N. Y., May 20-24, 1956.)

Procedures are described for carrying out a valid sampling and analytical program to determine how far from a source fluorides are found in plants in concentrations sufficient to cause injury to livestock. Subjects include selection of species and sampling sites, portion of the plant and amount of material to be collected, sampling errors, preparation for analysis, moisture determination, and storage factors. The standard Willard and Winte method for analysis of fluoride in vegetation is reviewed, as well as sources of analytical errors, and the use of specially prepared standard samples for checking the chemical analysis results. Plotting the analytical results on a map and drawing isofluors to connect points with the same fluoride concentrations will produce a map which makes it possible to ascertain at a glance how far from a source the fluoride concentration has been raised above the safe feeding level. The results may also be used to evaluate the effectiveness of emission controls and to indicate emission reductions necessary to produce desired distribution limits, but interpretation must take into effect seasonal variations, in plant concentrations caused by periods of rapid or slow growth of the plant.

ULTRAVIOLET SPECTROPHOTOMETRIC DETERMINATION OF SULFATE, CHLORIDE, AND FLUORIDE WITH CHLORANILIC ACID. *Anal. Chem.*, 30(1):202-205, Feb. 1958.

9 refs. (Presented at the Conference on Analytical Chemistry and Applied Spectroscopy, 8th, Pittsburgh, Pa., March 1957.)

Time intense absorption of solutions of chloranilic acid in the ultraviolet region provides the basis for the spectrophotometric determination of trace amounts of sulfate, chloride, and fluoride. Sulfate is determined by reaction with barium chloranilate in 50% ethyl alcohol, buffered at pH4 (absorption measured at 332 micrograms); chloride, with mercuric chloranilate in 50% methyl cellosolve and .05N in nitric acid (absorption measured at 305 micrograms); and fluoride, with strontium chloranilate in 50% isopropyl alcohol, buffered at pH4 (absorption measured at 332 micrograms). Limit of detection is 0.06 ppm for sulfate, 0.05 ppm for chloride, and 5 ppm for fluoride. The procedures for sulfate and chloride provide greater sensitivity, with fewer interferences, than currently available methods. The procedure for fluoride is subject to interference from most anions but rapid in limited routine uses. The method can be applied to other anions. (Author abstract)

Howard, O. H. and C. W. Weber

A PORTABLE CONTINUOUS ANALYZER FOR GASEOUS

FLUORIDES IN INDUSTRIAL ENVIRONMENTS. A.M.A.

Arch. Ind. Health, 19(3):355-364, March 1959. 1 ref.

Details are given of the development and design of an inexpensive portable fluoride analyzer for the continuous monitoring of fluorides in working atmospheres. The instrument is based on the fact that the current from an aluminum-platinum 'internal electrolysis' cell is a function of the fluoride content of an acetic acid electrolyte, after the sampled air has been scrubbed with the electrolyte. Thus, controlled flows of the fluoride-contaminated air and an electrolyte-scrubbing solution are passed concurrently through a scrubber where the fluoride is absorbed into the solution. The air then exhausts to the atmosphere while the solution flows through a detector cell containing aluminum and platinum electrodes. The resulting current is a function of the fluoride concentration of the air and can be measured on a simple microammeter, recorded on a strip-chart recorder, or used to actuate an alarm device. In-plant results reveal concentration peaks not resolved by present methods of analysis. The analyzer responds to all substances which form fluoride ion in aqueous solution and is specific for fluoride in the presence of common air contaminants, including chloride below 100 microgram per liter. The range of the instrument is 0.1 to 10 microgram of fluoride per liter of air with a higher upper limit available through proper selection of air and solution flows. Modification is expected to make the instrument applicable to air pollution levels of parts per billion.

REPORT ON INTERSOCIETY COMMITTEE FOR

DEVELOPMENT OF MANUAL OF METHODS FOR AM-

BIENT AIR SAMPLING AND ANALYSIS. J. Assoc. Offic.

Anal. Chemists, 52(2):349-350, 1969.

The major activity of committee and subcommittee meetings of the Association of Official Analytical Chemists during the past year has been concerned with a manual of methods for ambient air sampling and analysis. After final editorial revisions for format and style, methods will be available for publication as follows: arsenic, silver diethyldithiocarbamate method; benzo(a)pyrene, thin layer chromatography, spectrophotofluorometric determination, and spectrophotometric determination; benzo(a)pyrene and benzo(k)fluoranthene, column chromatography and spectrophotofluorometric determination; chloride, mercuric nitrate titration; fluoride, autoanalyzer and lanthanum-alizarin; fluoride, manual and titrimetric and spectrophotometric procedures; nitrogen dioxide manual spectrophotometric procedures; lead-210, beta counting of bismuth-210 daughter; radon-222, filter paper, alpha and beta counting, charcoal adsorption, alpha and gamma counting. Twelve additional methods which are in the final stage of approval by the Intersociety Committee deal with carbon monoxide, chlorine, formaldehyde, aromatic hydrocarbons, lead, and sulfur dioxide.

Council for Scientific and Industrial Research, Pretoria (South Africa), Air Pollution Research Group
ANNUAL REPORT 1960-1970. APRG-2, 14p., 1970. 25 refs.
The present task of the Air Pollution Research Group is to gather facts, to maintain a well-run monitoring and measuring system, and finally, to observe the trends in air pollution and understand their causes. Information obtained in this manner can serve as a basis upon which decisions can be made and control measures can be taken in South Africa by the authorities concerned. During the past year a study of mathematical representations of the ways in which pollutants are dispersed from factory stacks has been completed. A new light weight temperature measuring radiosonde has been developed and constructed. The national air sampling network has been expanded to include two additional towns so that monitoring of smoke and sulfur dioxide is now being done in seven major cities and towns in South Africa. A recent survey made in Johannesburg has once again demonstrated that the smoke emission from diesel vehicles in South Africa is substantially larger than that from vehicles in Europe. Two new studies have been undertaken, one which is concerned with the identification and measurement of trace elements in urban and industrial environments, and another which is aimed at the identification of gaseous organic pollutants in order to reveal the presence of undesirable but thus far unidentified pollutants. Some twenty trace elements, including lead, magnesium, vanadium, barium, chromium, and cobalt, have been identified in the atmosphere of Pretoria. The mobile laboratory which has been used for the survey of traffic pollutants has been equipped also for the measurement of nitrogen oxides. A smoke survey made in Pretoria revealed some of the primary smoke sources, and a study of the effect of fluoride on sugar cane has produced novel information on the reaction of the cane plant to fluoride. Finally, micro-meteorological surveys were carried out at various sites proposed for industrial development.

26729

MEASUREMENT IN PLANTS. (Messungen in Werken). Translated from German. Belov and Associates, Denver, Colo., 6p., Nov. 10, 1970.

Earlier measurements with an infrared analyzer showed that sulfur dioxide emissions from a cement oven increased when the concentration of alkali oxides evaporating from the fuel was too low to bind the SO₂ formed in the gas phase of the oven to potassium sulfate or sodium sulfate. There was a linear relationship between the alkali/sulfur balance and the analytically determinable composition of the oven gas phase and the SO₂ emission. These findings were confirmed by six further balance measurements on four Lepol ovens and two gas suspension heat exchange ovens. In related experiments, crude powder, fuel, clinker, and dust, removed within the limits of the alkali/sulfur balance measurements, were examined for their fluorine content. Many times the percentage of the fluorine brought into the cement clinker, and the corresponding 2 to 13% in the oven dusts, were determined to be bound. As a rule, the lower the dust circulation in the oven, the higher in the fluorine binding in the clinker.

Nielsen, Harold M.
THE DETERMINATION OF FLUORIDE IN SOFT TISSUE, BONE, AND URINE. A.M.A. Arch. Ind. Health, 21(4):316-317, April 1960. 8 refs.

Although the Willard-Winter procedure is a reliable means for isolating fluoride from ions that interfere with its estimation by titrimetric and spectrophotometric procedures, fairly large amounts of distillate must be collected to ensure quantitative recovery. An ion-exchange procedure is described to concentrate the fluoride to a volume which can be measured accurately.

rately. Resin in the chloride form is added to a column 1 cm in internal diameter and 2.5 cm in height. The resin is converted to the acetate form by percolation through 25 ml of a solution (1 M) of sodium acetate, swelling to a height of about 3 cm. A suitable column for tissue analysis is made by fusing a 3 inch length of borosilicate glass tubing to the bottom of a 28 by 200 mm culture tube. These 200 ml columns, with reservoirs of about 30 ml capacity, are used for the determination of fluoride in bone and urine. Fluoride is estimated by the Megre-gian method. Reagent A is 0.1% of eriochrome cyanine R in distilled water, and reagent B is 0.0175% of zirconyl nitrate dihydrate in 1:1 hydrogen chloride. Calcium and phosphate in bone can also be determined in the same sample.

Miller, V. L., D. F. Allmendinger, Folke Johnson, and Dorothy Policy

LIME PAPERS AND INDICATOR PLANTS IN FLUORINE

AIR POLLUTION INVESTIGATIONS. Agr. Food Chem., 1(7):526-529, June 24, 1953. 9 refs. (Presented at the American Chemical Society Northwest Regional Meeting, Pullman, Washington, June 12-13, 1953.)

Industrialization has increased the possibility of air contamination for effluent fluoride in a number of areas in the state of Washington. An inexpensive method for detecting atmospheric fluoride and delineating areas where it may be an economic factor with respect to farming is represented by the use of lime-treated filter paper and gladiolus plants, whose growing season substantially corresponds to that for forage in western Washington. The correlation between fluorine in forage and that in exposed lime paper and gladiolus leaves is shown to be above that required for statistical significance. Similarly, the correlation between fluorine in lime paper and gladiolus and injury index of gladiolus is such that fluorine in gladiolus or the injury index can be predicted with a high degree of accuracy from the fluorine content of lime paper. This method of investigation may prove valuable in locales where uniform coverage of an area is desired or where no vegetation is available for sampling atmospheric fluoride on a year-round basis.

AN ATMOSPHERIC HYDROGEN FLUORIDE RECORDER EMPLOYING DRY COLLECTION AND ION ELECTRODE.

Preprint, *Journal of Public Health*, Tokyo (Japan) and Denki Kagaku Keiko Co. (Japan), 7p., 1970 (?).

A new instrument for measuring concentrations of hydrogen fluoride in air can clearly distinguish concentrations on the order of 1 ppb and also accurately measure concentrations of 5-6 ppb. Air is drawn in through a spiral tube and the hydrogen fluoride gas is collected on a dried alkali coating applied to the tube surface. The collected hydrogen fluoride is then washed off by a buffered solution and carried to the measuring cell, where the electromotive force is measured by fluorine ion activity electrodes. The spiral tube and dry collection method reduce the errors associated with the bubbling method of collection, while the fluorine ion activation electrodes have a high degree of selectivity. When air was sampled at 30 l/min for one hr, 1 ppb consistency of atmospheric hydrogen fluoride gas was recorded at 24% and 5 ppb at 62%.

A PORTABLE CONTINUOUS ANALYZER FOR GASEOUS FLUORIDES IN INDUSTRIAL ENVIRONMENTS. A.M.A.

Arch. Ind. Health, 19(3):355-364, March 1959. 1 ref.

An inexpensive portable fluoride analyzer which was developed for the continuous monitoring of environmental atmospheres is described. The design and development of the analyzer are discussed and inplan results which revealed fluoride concentration peaks that are not resolved by present methods of analysis are presented. The instrument is based on the fact that the current from an aluminum-platinum 'internal electrolysis' cell is a function of the fluoride content of an acetic acid electrolyte, after the sampled air has been scrubbed with the electrolyte. The analyzer responds to all substances which form fluoride ion in aqueous solution and is specific for fluoride in the presence of common air contaminants, including chloride below 100 micrograms per liter. The range of the instrument is 0.1 microgram to 10 micrograms of fluoride per liter of air with a higher upper limit available through proper selection of air and solution flows. The analysis is precise to plus or minus 7% of the measured equilibrium value at the 95% confidence level. The lag is about 3 minutes for reaching 75% of the total signal change. The instrument, which could be used with an alarm device, is capable of continuous operation for indefinite periods, with attention limited to replenishment of the scrubbing solution every 30 hours and renewal of the recorder chart. (Author summary modified)

Hendrickson, E. R.

AIR SAMPLING. In: Air Pollution. Arthur C. Stern (ed.), Vol. I, New York, Academic Press, 1962, Chapt. 11, p. 389-433. 50 refs.

Problems encountered in sampling and common equipment needs are reviewed, and specific methods of sampling aerosol contaminants and gaseous contaminants are individually discussed. The aerosol sampling methods evaluated include filtration, impingement, sedimentation, electrostatic precipitation, and centrifugal methods; the gaseous contaminant sampling methods include adsorption, absorption, freezeout, and grab sampling techniques. Also reported are simplified techniques helpful in providing preliminary information on sulfur dioxide, gaseous fluorides, hydrogen sulfide, and ozone.

Schneider, W. and E. Schoffmann

COMPARATIVE INVESTIGATIONS OF FLUORINE-CONTAINING IMMISSIONS. (Verleichende Untersuchungen uber Fluorhaltige Inunissionen). Staedtehygiene (Uelzen/Hamburg), 19(6):114-115, June 1968. 5 refs. Translated from German. Belov and Associates, Denver, Colo., 5p., Nov. 19, 1970.

In the past, fluorine determinations were assumed to be reliable if damaged leaves were ascertained to have a higher fluorine value than similar samples from unexposed areas. However, as determined by fluorine sampling in a wooded recreation area, an increased fluorine content in ashed plant leaves neither demonstrates the occurrence of fluorine compounds in air nor the cause of plant damage. Since the most frequently occurring fluorine compound, calcium fluoride (fluorite), appears only as dust, dust precipitation measurements should be carried out. Because these dusts would be trapped in thick tree stands, the selection of measuring stations should be carefully evaluated. In heavily wooded areas, no fluorine concentrations worth mentioning can be determined from air sampling.

Blyum, I. A. and D. P. Shcherbov

ESTIMATION OF THE SENSITIVITY OF FLUORIMETRIC DETERMINATION. J. Anal. Chem. USSR (English Translation from Russian of: Zh. Anal. Khim.), 22(4):584-589, May 1967. 15

refs.

The sensitivity threshold of fluorimetric determinations is set by two independent values--the 'instrumental' and 'analytical' sensitivity thresholds. A method is suggested for computing these values and assessing them experimentally. Based on the application of the method to fluorimetric determination of basic dyes, the sensitivity of a determination can be improved by reducing the analytical threshold through improvement of the stages involved in chemical preparation of reagents. Equations are given for choosing optimum conditions for any reagent or for making a comparison between reagents of the same type. In general, the value of the analytical threshold is approximately proportional to the ratio of the analytical background and calibration factor. (Author abstract modified)

Organization for Economic Co-operation and Development, Paris (France), Air Management Research Group
TECHNICAL PROBLEMS IN MEASUREMENT AND MONITORING. Rept. EX.40131, 61p., Feb. 10, 1970. 89 refs.
Factors influencing the research policy on the measurement and monitoring of air pollution include recognition of the internal combustion engine as a major source, routine monitoring of specific industrial pollutants, potentially hazardous occupational conditions, atmospheric tracing and fluctuating levels, and recent developments in technology. Emerging administrative requirements of measurement are discussed, as well as priorities in research. Continuous monitoring networks are described, and predictive models are considered. Sampling and analytical techniques for asbestos, carbon monoxide, fluorides, heavy metals, fuel additives, organic compounds, nitrogen oxides, oxidants and ozone, sulfur compounds, odors, and pesticides are presented, including spectrometry, fluorescence, polarography, chromatography, Saltzman method, iodimetric methods, photometric methods, and others. Current research on the measurement of particulates below 10 micron is described. Emission inventories are described, and the principal areas of deficiency in technical capabilities are disclosed.

ABSTRACTS OF TENTATIVE METHODS ADOPTED BY THE INTERSOCIETY COMMITTEE ON MANUAL OF METHODS FOR AMBIENT AIR SAMPLING AND ANALYSIS. J. Assoc. Offic. Anal. Chemists, 54(1):223-237, Jan. 1971.
Tentative methods adopted by the Intersociety Committee for the analysis of air samples are abstracted from the following issues of Health Laboratory Science: vol. 6, no. 2(1969) and vol. 7, no. 1 (1970). The methods concern the arsenic content of atmospheric particulate matter; the chloride, fluoride, lead-210, nitrogen dioxide, radon-222, and sulfur dioxide content of the atmosphere; the continuous monitoring of atmospheric oxidant with amperometric instruments; through C5 atmospheric hydrocarbons; polynuclear aromatic hydrocarbon content of atmospheric particulate matter; microanalysis for benzo(a)pyrene in airborne particulates and source effluents; chromatographic analysis for benzo(a)pyrene and benzo(k)fluoranthene in atmospheric particulate matter; spec-

Nielsen, J. P. and A. D. Dangerfield
USE OF ION EXCHANGE RESINS FOR DETERMINATION
OF ATMOSPHERIC FLUORIDES. A.M.A. Arch. Ind. Health,
11(1):61-65, Jan. 1955. 2 refs.

Methods for the determination of fluorides in the atmosphere in the 0 to 10 parts per billion range are only partially satisfactory because of the minimum quantity which must be present in the sample if accurate results are to be obtained. This requirement leads to long, expensive sampling periods and makes it impossible to obtain information on short-time variations in the fluoride concentration. An analytical procedure is presented which involves the absorption of fluoride ion on an anion exchange resin, followed by elution with a small volume of sodium hydroxide. This enables the analyst to eliminate interfering cations and to concentrate all the fluoride into a small volume of solution without evaporation. The usual isolation of fluoride for titration by distillation is eliminated, along with the variable reagent and system blanks. The method was used in a study of the efficiency of removal of particulate and gaseous fluoride from the air passing through experimental greenhouses. (Author abstract modified)

Willard, Hobart H. and Charles A. Morton
FLUOROMETRIC DETERMINATIONS OF TRACES OF
FLUORIDE. Anal. Chem., 24(5):862-865, May 1952. 15 refs.
(Presented at the Southwide Chemical Conference, Atlanta, Ga.,
Oct. 16-18, 1950.)

Two fluorometric methods were developed for determining trace amounts of fluoride with greater sensitivity than is possible with the common colorimetric methods. Both methods depend on the competitive complexing of aluminum by fluoride and organic reagents which fluoresce with aluminum. One method is based on the fluorescence of aluminum oxinate in chloroform extracts. Maximum fluorescence for 1 micromole of aluminum or less in 50 ml of chloroform is obtained at pH 4.7 and with an oxinate concentration of 0.025%. The method detects 0.5 to 20 micrograms of fluoride; but its precision is adversely affected by the necessity of extraction and by interfering ions. The second method is based on the decrease in fluorescence of an aluminum-morin complex measured in 50% alcohol at pH 4.9. The method will estimate down to 0.2 micrograms of fluoride with excellent precision. For low fluoride ranges, the aluminum content of the complex should be 27 or 25 micrograms per 100 ml. Precision of the method at both concentrations for sodium fluoride solutions is noted.

Levaggi, D. A. and M. Feldstein
MICRODETERMINATION OF FLUORIDE IN VEGETATION
BY OXYGEN BOMB COMBUSTION AND FLUORIDE ION
ELECTRODE ANALYSIS. Preprint, Air Pollution Control Assoc.
Pittsburgh, Pa., 17p., 1970. 9 refs. (Presented at the Air
Pollution Control Association, Annual Meeting, 63rd, St. Louis,
Mo., June 14-18, 1970, Paper 70-66.)

A procedure for the microdetermination of fluoride in vegetation is proposed which utilizes the oxygen flask combustion technique. Fluoride analysis has been performed traditionally using the Willard-Winter method, which is lengthy and laborious, involving various steps, and large quantities of equipment. Sample size requirements are on the order of a gram or more, making the procedure useless for determining low

fluoride concentrations in small samples. Thus, the fluoride selective ion electrode was investigated in combination with oxygen combustion. Gaseous products of combustion are absorbed in 10 ml of 0.05 N sodium hydroxide spiked with 1.00 microgram of fluoride. Analysis of the fluoride is performed directly on the absorption solution after addition of a combination complexing buffer solution, using a specific fluoride ion electrode. The sensitivity of the electrode is such that 0.2 microgram of fluoride can be easily detected. A complete analysis can be performed in one half hour, with a minimum amount of equipment. Added oxidant is required in the combustion step for some vegetation samples to completely free the fluoride from its organic matrix. (Author abstract modified)

Benedict, Harris M.

FIELD SAMPLING FOR THE PRESENCE OF FLUORIDES

IN FORAGE CROPS. Preprint, Air Pollution Control Assoc., Toronto, Ontario Section, Air Pollution Control Assoc., Pittsburgh, Pa., TR-7 Agricultural Committee, and Ontario Dept. of Energy and Resources Management, Toronto, Air Management Branch, 19p., 1970. 21 refs. (Presented at the Impact of Air Pollution on Vegetation Conference, Toronto, Ontario, April 7-9, 1970.)

A field sampling program that has been successfully used for almost 20 years to obtain information on fluorides in forage crops is described. The program uses a coordinate system for locating and identifying the sampling sites. This system provides a uniform geographic reference for all phases of the field surveillance programs; facilitates the transfer of investigational data from notebook to maps; and enables quick reference between laboratory data and geographic origin of any one sample. Methods employed to assure a representative sample and an accurate analysis are noted together with methods of tabulating analytical results into readily useable form and of interpreting the assembled data. Data are presented on monthly variation of fluoride levels in plants, the reduction of fluoride levels by rainfall, and on the comparative fluoride content of different grass and alfalfa species.

Waclawik, Jerzy and Stefan Waszak

METHOD FOR DETERMINING CONTINUOUSLY SMALL CONCENTRATIONS OF GASEOUS HALOGENATED COMPOUNDS AND OF HYDROGEN HALIDES IN AIR AND IN

OTHER GASES. (Assignee not given.) U. S. Pat. 3,546,079. 3p., Dec. 8, 1970. 6 refs. (Appl. Feb. 8, 1967, 6 claims).

A method is described for continuously determining gaseous halogenated organic compounds such as trichloroethylene, tetrachloroethylene, chloroform, methyl bromide, or phosgene, and hydrogen halides such as hydrogen chloride, hydrogen bromide, or hydrogen fluoride. Known methods are mostly qualitative, laborious and time-consuming, but the present method overcomes these disadvantages by converting the halogen combined in the organic compound into a free halogen. This is accomplished by passing the compound continuously through a furnace filled with a palladium catalyst at about 800 C. Then the combustion products from the furnace are passed through a tube filled with a bromide-bromate mixture or an iodide-iodate mixture or through a washer filled

<xref image="2000WVF1.TIF|V3|2006:09:28:01:26:44.00|121656|0"> image: </xref>

with an aqueous solution of the respective salts. Free halogen can be determined by known methods, preferably in the galvanic cell of a gas analyzer.

Nielsen, H. M.

DETERMINATION OF MICROGRAM QUANTITIES OF

FLUORIDE. Anal. Chem., 30(5):1009-1011, May 1958. 10 refs.

The determination of trace amounts of fluoride in the quantities found in some animal tissues is difficult, especially when the sample size must be restricted. By employing an ion exchange technique for concentrating the fluoride and freeing the solution from interfering ions, 1- to 10-gamma quantities can be estimated with a precision within 5% of the fluoride present. The procedure involves suspending a portion of anion exchange resin in chloride form in distilled water, decanting the fines, and adding the resin slurry to borosilicate tubes to make columns 2 cm in height. The resin is converted to acetate form by the addition of sodium acetate to the column, and the fluoride is removed from the resin by stepwise elution with increasing concentrations of sodium acetate, beginning at 0.1M solution. Effluent is collected in 5-ml fractions and absorbances are read in a spectrophotometer at 527.4 micrograms. Fluoride values are determined from a curve prepared by plotting absorbance readings of standard fluoride solutions made to volume with 0.2M sodium acetate solution against the concentration of fluoride. Fifty to 70 ml of 0.2M sodium acetate are required to remove interfering phosphate and 25 ml of 1M acetate to remove chloride and sulfate. Then the method is applied to the determination of fluoride in atmospheric samples, the samples need only be percolated through the resin. The fluoride is removed and estimated as outlined above.

Rowley, R. J., J. G. Grier, and R. L. Parsons

DETERMINATION OF FLUORIDE IN VEGETATION. Anal.

Chem., 25(7): 1061-1065, July 1953. 4 refs. (Presented at the Pittsburgh Conference on Analytical Chemistry and Applied Spectroscopy, Pittsburgh, Pa., March 2-6, 1953).

There has been a general belief that fluoride can be satisfactorily recovered from ashed vegetation by double distillation, first with sulfuric acid, then with perchloric acid. Measurement of the fluoride is usually based on the reaction between fluoride and thorium nitrate in the presence of sodium alizarin-sulfonate indicator. Recent work has shown that ashing of vegetation containing appreciable amounts of silica may result in unreactive combinations of fluoride, from which fluoride cannot be separated. Two modifications of eliminating low recoveries resulting from fixation associated with the ashing treatment are alkali fusion of ash and collection of 500 ml of distillate. These procedures, which are described in detail, were applied to synthetic vegetation samples (grass hay, red clover hay, timothy, and apple leaves) to which fluoride was added. The percentage recoveries are listed and noted to be satisfactory. Alkaline fusion completely liberated the combined fluoride, while a single distillation with perchloric acid was adequate for isolating the fluoride in a form suitable for measurement. The modifications described thus offer appreciable savings in time as well as increased accuracy.

SAMPLING AND AUTOMATED ANALYSIS OF GASEOUS

FLUORINE IMMISSIONS. (Probenahme und automatishche

Analyse gasfoermiger Fluor- Immissionen). Text in German.

Staub-Reinhalt. Luft, 31(1):1-8, Jan. 1971. 34 refs.

Gaseous fluorine compounds especially hydrofluoric acid are phytotoxic, air sampling thus must include all molecular disperse fluorine compounds after the removal of particulates. The electrometric fluorine determination using an ion-selective

lanthanum electrode yields tests results in a form easily handled by digital computers. The electrode yields a potential which is equivalent to fluorine ion activity in the test solution washing the lanthanum fluoride membrane. Calcium fluoride or cryolite raise the potential only to the extent to which they go into solution. Metal ions present which would form fluorine complexes and thus reduce the fluoride ion activity are inactivated by a hydrochloric acid-citrate buffer of appropriate pH. The standard potentials of individual lanthanum fluoride electrodes are not uniform and each electrode must be individually calibrated. A calomel electrode is used as a reference electrode in the potential determination. The lower limit of measuring range is 0.07 microg F(-)/cu m. For a fluorine content between 1 and 50 microg F(-)/cu m the standard deviation for the method is about 3.5%. The apparatus, the sampling and measuring procedure and calculation of results are described.

Eguchi, T.

ELECTROCHEMICAL ANALYSIS METER. (Denki kagakushiki bunseki kei). Text in Japanese. Denshi Kagaku (Electron. Sci.), 21(2):61-70, Feb. 1971. 6 refs.

Several electrochemical devices for measuring environmental pollutants are described. One instrument incorporates the principle of electrolytic conductivity to measure atmospheric sulfur dioxide concentrations. Air sampled at a controlled constant speed is passed through a filter to an adsorption tube into which dilute hydrogen peroxide is continuously introduced. When present in the sampled air, SO₂ reacts to form sulfuric acid, concentrations of which increase in proportion to the amount of SO₂ present. Since the sulfuric acid changes the electrolytic conductivity of the solution, changes in conductivity before and after contact indicate the SO₂ concentration of the sampled air. A new method for measuring electric current uses coulometric analysis to obtain a concentration of a sample by consumed electric charge when a titration reagent reacts on the sample for equivalence. This method is employed for measuring both SO₂ and oxidants. A galvanic coulometric method and a polarization current method are also used to measure oxidant concentration. An ion selection electrode is used to measure fluoride and hydrogen cyanide. In combination with a calomel reference electrode, this electrode picks up the concentration of a specific ion in solution as the potential difference. Another device utilizes a fuel cell to measure nitrogen oxide and SO₂ concentrations.

MEASUREMENT OF DELETERIOUS GAS. (Yugai gasu no sokuteihoho). Text in Japanese. Preprint, Society of Electrochemistry, Tokyo (Japan), Kanto Div., 24p., 1971. (Presented at the Seminar on Air Pollution, Tokyo, Japan, Feb. 3-4, 1971, Paper 5.)

The photometric determination of deleterious gases is considered, as well as the analysis of heavy metals in the atmosphere by an atomic absorption method, and the determination of atmospheric concentrations of organic solvents by gas chromatography. According to the type of gas to be measured, sampling and preparation of test chemical solutions are in-

<xref image="2000WVF2.TIF|V3|2006:09:28:01:26:46.00|118920|0"> image: </xref>

licated. Measuring procedures are presented for hydrogen sulfide, sulfur dioxide, ammonia, hydrogen fluoride, nitrogen dioxide, nitrogen dioxide plus nitric oxide, hydrogen chloride, chlorine, oxidants and ozone. The chemical analyses of heavy metals includes the determination of mercury, lead, cadmium, zinc, copper, iron, and manganese. For example, mercury vapor is absorbed in a sulfuric acid potassium permanganate solution and heated slowly for 30 min. A hydroxylamine solution is added to decolor the potassium permanganate, and a stannous chloride solution is added to reduce the mercury. Vaporized by circulating air, the mercury is absorbed by an absorption cell and measured at 253.7 millimicrons. The gas chromatographic method is introduced for the measurement of acetone, chloroform, carbon tetrachloride, cyclohexene, tetrachloroethane, phenol, and other organic solvents in the atmosphere.

DETERMINING FLUORIDE AIR CONCENTRATIONS--BY EXPOSING LIMED FILTER PAPER. Am. Ind. Hyg. Assoc. Quart., 18(2):145-148, June 1957. 5 refs.

During a recent Stanford Research Institute air sampling program in an area where atmospheric concentrations of fluoride existed, several experiments were carried out with the filter paper technique and compared to fluoride air sampling using water-filled scrubbers. The papers were lime treated by being soaked in a saturated solution of low fluoride lime and then oven-dried. Analyses of the filter paper for fluoride were carried out using a modified ion-exchange technique. In addition to the area which contained a large industrial fluoride source, three greenhouses were available which were similar except for the fluoride concentrations which existed inside. The tests show that the filter papers should not normally be expected to give a quantitative picture of fluoride air concentrations comparable with that obtained by the usual air sampling techniques. However, in an area in which fluoride air concentrations are high, filter papers will usually pick up more fluoride than will papers similarly exposed in an area with lower fluoride concentrations. Changes in the conditions of exposure, either in air concentrations or wind and weather conditions, apparently alter the rate at which the filter paper picks up fluoride from the air. Some aspects of this technique, such as the relatively close agreement between papers exposed side by side over the same period, are encouraging. (Author summary modified)

Pack, M. R., A. C. Hill, M. D. Thomas, and L. G. Transtrum

DETERMINATION OF GASEOUS AND PARTICULATE INORGANIC FLUORIDES IN THE ATMOSPHERE. (American Society for Testing and Materials, Philadelphia, Pa., Am. Soc. Testing Mater. Spec. Tech. Publ. no. 281:27-44, 1959. 25 refs. Problems encountered in sampling and analyzing low concentrations of atmospheric fluorides are reviewed, and techniques are described that gave good results in extensive sampling programs. A Greenburg-Smith type impinger efficient collection of both gaseous and particulate fluorides, except possibly sub-micron particles. Good separation of gaseous and particulate fluorides was achieved by drawing the air sample through aluminum tubes or sodium bicarbonate-coated glass tubes. The gaseous fluorides were adsorbed on tube surface and the aerosol passed on into a subsequent impinger. Molecular membrane filters were also efficient for separating the different forms of fluoride, if properly used. Filter paper and an electrostatic precipitator gave poor separation because they picked up appreciable amounts of hydrogen fluoride along with the particulate fluoride. Hydrogen fluoride was absorbed as efficiently in water as in alkaline solution. Air samples containing only a few micrograms of fluoride can be accurately analyzed

by isolating the fluoride by distillation or by use of anion exchange resins followed by titration or spectrophotometric analysis. For determining certain insoluble fluorides, distillation and titration are probably preferable. The choice of methods will depend on the concentrations of fluorides present, the objectives of sampling, equipment available, and the particular abilities of the personnel involved. (Author summary modified)

Biheller, Johann and Werner Resch

A SAMPLING AND MEASURING METHOD FOR THE ROUTINE DETERMINATION OF FLUORINE IN THE ATMOSPHERE NEAR THE GROUND. (Erprobung einer Sammel-

und Messmethode fuer die routinemaessige Bestimmung von Fluor in der bodennahen Atmosphaere). Text in German. Staub, Reinhaltung Luft, 31(1):9-11, Jan. 1971. 15 refs.

Since atmospheric fluorine concentrations are of the order of 1 micron/cu m, a large air sample is desirable. The method proposed aspires about 28 cu m air by a polystyrol filter impregnated with a 10% sodium formate solution in 50% alcohol designed to retain gaseous hydrogen fluoride. The diameter of the circular filter is 100 mm. Following aspiration, the filter is dissolved in ethyl acetate with a buffer and fluorine activity is determined by a fluorine-ion selective electrode. The measuring apparatus consisting of the F-electrode, the control electrode, and a pH meter must be calibrated with solutions of known F concentrations. The zero value of an impregnated polystyrol filter is approximately 0.3 micron F/dm sq filtering surface.

SOME ASPECTS OF FLUORINE DETERMINATION ACCOMPLISHED BY NEUTRON ACTIVATION OF 14 MEV IN

POLLUTED PLANTS. (Quelques aspects du dosage du fluor par activation sous neutrons de 14 MeV dans des vegetaux pollutes). Text in French. C. R. Acad. Sci. Paris, Ser. D 264(23): 2668-2671, June 5, 1967. 8 refs.

The fluorine content in polluted apple tree and grapevine leaves was determined chemically and by radioactivation of F and the results compared. The chemical analysis followed the Willard and Winter method and determined fluorine colorimetrically (fluoride ion plus cerium-alizarine complex chelate). The radioactivation method involves the activation of a vegetable sample in a flux of neutrons of 14 MeV and simultaneous gamma spectrometric measurement of F-19. Under the conditions described, 1 mg F induce 700 impulses in the gamma spectrometer. The comparative quantities determined by the two methods were in three samples, 1389 and 1471, 1343 and 1633, 1412 and 1499 mg F respectively; thus, agreement was good. The radioactivation method has the advantage of instantaneous results but cannot be used for F levels below 200 microgram per 1 g sample.

CALIBRATION AND FIELD TEST OF THE ATMOSPHERIC HYDROGEN FLUORIDE RECORDER. (Taikichu fukkasuiso jidukirokukei no kakusei to yagaishiken ni (suite). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 5(1):87, 1970. (Proceedings of the Japan Society of Air Pollution, Annual Meeting, 10th, 1970.)

Dynamic calibration of a hydrogen fluoride recorder was performed; calibration of both the collection device and the analyzer is necessary for an automatic fluoride analyzer. An appropriate HF concentration from an HF permeation tube was simultaneously led to the automatic analyzer and to an Na₂CO₃ filter so that measurements could be compared. The flow rate was 30 l/min for each, and the tubes were mainly of Teflon and Taigon. The correlation coefficient for the two sets of data was 0.83, and the regression equation was y equals $0.97x$ plus 0.25, where x constitutes measurements from the automatic analyzer and y those from the Na₂CO₃ filter. In a field experiment, samples were taken from aluminum electrolysis and phosphorus fertilizer plants in Naoetsu, Niigata Prefecture.

EQUIPMENT AND INSTRUMENTATION FOR AIR SURVEYS. Fla. Eng. Ind. Expt. Sta. Bull., no. 83:21-26, 1956. 8 refs.

Many of the important substances causing air pollution lend themselves to measurement with continuous and automatic sampling. Several instruments have been developed for continuous measurement of sulfur dioxide in the air. One of these, the Thomas Autometer, is shown schematically; the basic principle of measurement which this device employs is electrolytic conductivity. Unfortunately, other gases which may be present in the sampled air, along with sulfur dioxide, will also produce changes in the conductivity. Operation of the Autometer is described, and it is commercially available in either of two versions: the 'integrating type' and the 'nonintegrating type.' Another approach to the problem of instrumentation for sulfur dioxide sampling is the Titrilog, which operates by titration of the atmospheric contaminant with the titer generated electrolytically. A noncommercial photometric sulfur dioxide recorder uses a starch-iodine solution which is decolorized as air samples containing sulfur dioxide are bubbled through. A continuous fluoride analyzer is described. The magnesium salt of 8-hydroxyquinoline fluoresces under ultraviolet light, and it has been demonstrated that the fluorescence is quenched by minute concentrations of hydrogen fluoride. Several instruments have been described to monitor smokes, dusts, and mists, which depend on the light-scattering properties of particles in suspension.

Okita, Toshiichi, Ryuichi Sugai, and K. Kaneda
SEPARATION AND SUBSEQUENT DETERMINATION OF
ATMOSPHERIC PARTICULATE AND GASEOUS
FLUORIDES. (Gasujo oyobi ryushijo fukkabutsu no hunrisoku-
teiho). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air
Pollution), 5(1):88, 1970. (Proceedings of the Japan Society of
Air Pollution, Annual Meeting, 11th, 1970.)

The effects of gaseous fluorides (mainly hydrogen fluoride)
and particulate fluorides on plants are quite different, and the
separation of the two types is desirable. Separation by filters
was attempted. Millipore AA filters are the most appropriate
for capturing the particulates and letting the gas through 100%.
A polypropylene filter allowed 50% of the particulates to
penetrate and was not appropriate. Neither was Teflon
LSWPO because it contained fluorine. Tests of tubes for gas
capture indicated that aluminum pipes have low intake velocity
and, with their length extended, can collect 100% of the gas.
Collection efficiency was the best for a glass spiral containing
1% dried Na₂CO₃ solution.

Jacobson, Jay S. and Laurence I. Heller
A SIMPLE, RAPID POTENTIOMETRIC METHOD FOR THE
ESTIMATION OF FLUORIDE IN VEGETATION. Environ. Let-
ters, 1(1):43-47, 1971. 3 refs.

A new method has been developed for the estimation of
fluoride in vegetation, which employs a selective ion electrode
for measurement of fluoride obtained by acid extraction from
pulverized plant tissue. Current methods for the determination
of fluoride in vegetation usually employ high temperature ash-
ing and alkaline fusion, distillation, and analytical measure-
ment of fluoride. These techniques are complex and time-con-
suming. Leaves of apple, alfalfa, barley, sorghum, several
grasses and weed species, and pine needles were analyzed
both by potentiometric analysis after extraction and by a stan-
dard both by potentiometric analysis after extraction and by a
standard method. Statistical analyses indicate a correlation
coefficient of 0.988 between measurements obtained by the
new and old methods, but evidence of incomplete extraction
of fluoride from tissue was found. The experimental procedure
for the new technique is indicated.

Serper, Allen
A LOOK AT THE METHODS FOR MEASURING AIR POL-
LUTANTS. Eng. Mining J., 172(4):124-128, April 1971.
The two types of measurement usually needed for airborne
pollutants are source testing and air quality. Gases commonly
measured by colorimetric methods include ozone, sulfur diox-
ide, nitrogen dioxide, and hydrogen fluoride. The principle of
colorimetry is based on the measurement of the iodine
released from the reaction of a particular oxidant with potassi-
um iodide in a neutral, buffered solution. Improvements in
sensitivity of coulometric titration cells have led to the
development of several commercial coulometric systems for
continuous SO₂ monitoring. The improved version of the cou-
lometric cell is designed to respond to bromine oxidizable or
<xref image="2000WVF4.TIF|V3|2006:09:28:01:26:54.00|119210|0"> image: </xref>

titratable sulfur compounds that occur in very low concentrations. The iodometric system is based on the generation or liberation of iodine by ozone, and the consumption of iodine by sulfur dioxide in an iodide solution. New pollution monitors for the detection of SO₂, nitric oxide, and NO₂, may utilize sealed electrochemical sensors, thus requiring no handling of chemicals. With infrared analyzers, the percent of radiation absorbed is proportional to the concentration of the component of interest in the sample. Operation of an electroconductivity analyzer is based upon the principle that a noxious gas will ionize in pure water, thus decreasing the electrical resistance of the water. The basic principle of ionization analysis is the ionization of hydrocarbons in a hydrogen flame. Stack sampling, isokinetic sampling for particulates, and continuous monitoring systems are also reviewed.

THE MICRO ANALYSIS OF FLUORINE BY THE LINEAR

WASH-OUT TYPE OVEN AND ITS APPLICATION. (Senjo

chushutsugata obun niyoru fusso no biryo sokutei to sono oyo).

Text in Japanese. Sangyo Igaku (Jap. J. Ind. Health), 13(2): 120-127, March 1971. 30 refs.

A linear wash-out oven was developed from microanalyses of fluorides. The procedures used are similar to the ring-oven technique but with higher sensitivity in detection and with more convenient operations. Organic substances were ashed in an oxygen combustion flask, and the fluoride was detected with aluminum chromzrol S complex following recovery from interfering substances by the diffusion method. From 0.08 to 4 times 100,000 ppm were successfully quantitated with 90% recovery; the standard deviation relative to the expected amount of four repetitive measurements was less than 30%. The method was applied to fluoride determination in rice crops harvested within 10 km of an aluminum refinery. The highest concentration was found in bran powder (122 ppm). Full grains contained up to 32 ppm, while cleared grains averaged 2.91 ppm. Fluoride concentrations decreased with distance from the refinery. Fluoride in cleared grain can easily be dissolved in water, then vaporized and removed from the grain on cooking. The average fluoride intake would be 240 micrograms if the daily consumption of polluted rice totaled 1500 g. Yet this amount does not exceed the average intake of approximately 180-240 micrograms among normal adults in rural districts of Japan, the total intake daily being estimated as approximately 1.6-2.1 micrograms.

Ixfeld, H.

MEASUREMENT OF FLUORINE IMMISSION IN THE

NORDRHEIN-WESTFALEN STATE. (Fluor-Immissionsmes-

sung im Lande Nordrhein-Westfalen). Text in German. VDI

(Ver. Duet. Ingr.) Ber., no. 164. p. 71-75, 1971.

To determine the phytotoxic effect of fluorine concentrations, the State Institute for Emission Control and Land Conservation in Essen instituted beginning with January 1971 a fluorine concentration measuring program involving about 1000 measuring stations situated between Cologne and Duesseldorf-Neuss. The measurements are discontinuous (spot checks) where the stations are near to each other, continuous where the distance between stations is considerable. The program also measures organic substances in the atmosphere by the silica gel method and dust concentration by the impactor method and by the membrane filter method. A comparison of measuring results obtained by the sorption method (sorption of gaseous fluorine compounds by silver balls coated with layers of sodium carbonate) with results obtained by the Impinger method disclosed that the latter method yielded up to 400% higher results because it also measured fluoride particles while the sorption method registered only gaseous fluorine compounds. For this

reason, sampling was done with a filtering device which eliminated coarser particles. Such a preliminary filter (Herpertz-Topf filter) reduced the discrepancy between the results obtained by the two methods to 10-20%. This arrangement thus selectively measures only gaseous fluorine compounds with a maximum of 10% fluorine in particle form. Because about 200 samples have to be analyzed daily, an automatic device using lanthanum fluoride electrodes has been developed. The potentials are measured by a digital pH meter.

Konno, Nobuya, Yasuko Morikawa, and Saburo Yanagisawa
EXAMINATION OF QUANTITATIVE ANALYSIS METHOD
OF FLUORINE IN VEGETABLE SAMPLES. (Shokubutsu
shiryo chu no fusso teiryō ho no kento). Text in Japanese.
Preprint, Japan Chemical Society, Tokyo, lp., 1971. (Presented
at the Japan Chemical Society, Annual Meeting, 24th, Tokyo,
1971, Paper 3341.)

Experiments were conducted comparing fading methods, the zirconium eleaochromecianin R (Zr. ECR) method, the lantern alizarin complexion (La ALC) colorimetric method, and the potential difference measurement method, using fluoride ion electrodes for the quantitative analysis of vegetable samples. After pulverizing the sample, calcium oxide is added, heated to 600 C, ashed (4-5 hours), dissolved in sodium hydroxide and distilled from 50% sulfuric acid, at 145-150 C to obtain 600 ml in 3-4 hours. The Zr. ECR method utilizes the fluoride ion interference with the color change. It was found that 0-1 ppm fluorine could be analyzed. Interfering ions included sulfate, bisulfate, iron, aluminum, and biphosphate. The Zr. ECR method is very rapidly affected by temperature, so that reproducibility is difficult. The La-ALC method utilizes the fact that the fluoride ion forms a complex with La-ALC, and the color is measured. The complex of La-F-ALC was extracted with N-diethylanilineisoamylalcohol, and the degree of light absorption was measured. Major interference were those which form complexes with Al, and Fe. The relationship of the logarithm of the concentration to the potential difference are linear so that at very low concentrations, a curve is formed making quantitative analysis difficult. Using a fluoride ion electrode up to 0.002 ppm was analyzed. The electrode is sensitive to Al(2+) alone, but when F(-) exists together with Al(2+), there is a large error. Of the three methods, La-ALC was superior with respect to precision and sensitivity. The ion electrode method is easier to manipulate, and is sensitive. Therefore, using both methods, sufficient sensitivity and precision can be obtained.

Hermann, P.
EXPERIENCES WITH FLUORINE EMISSION MEASUREMENTS. (Erfahrungen bei Fluro-Emissionsmessungen). Text in German. VDI (Ver. Deut. Ingr.) Ber., no. 164:101-107, 1971. 12 refs.

Measurements of emissions of gaseous fluorine compounds made at som small and medium sized industrial plants within the last seven year showed results between 1 g F/hr and 1000 g F/hr. The analytical determination of small fluorine concentrations, be it by photometry or with the fluorine specific electrode, does not present any problem. No satisfactory method has as yet been found for separating particulate from gaseous compounds. Therefore, fine dust may have been included in

<xref image="2000WVF5.TIF|V3|2006:09:28:01:26:58.00|126247|0"> image: </xref>

the recorded results of the gaseous fluorine concentration. On the other hand, it may be assumed that reactions of hydrofluoric acid with alkaline dust substances change the true record of the original gaseous fluorine emission. The development of a useful method of separating the dust from the gaseous fluorine compounds appears to be very desirable. In present arrangements for sample taking of fluorine bearing exhaust gases in industrial plants, the gases are often being tapped prior to entering a common chimney which serves to collect waste gases from several shops. The set-up for sample taking starts with a quartz tube which adjoins the gas exhaust pipe at right angles, and can be heated up to 400 C. The gas to be tested is then lead through a quartz wool filter, into absorption bottles made of quartz and containing a caustic soda solution. A gas circulating pump and a gas meter complete the set-up.

Moser, E.

MEASUREMENT OF GASEOUS AND PARTICULATE

FLUORINE EMISSIONS. (Messung von gas- und staubfoer-migen Fluor-Emissionen). Text in German. VDI (Ver. Deut. Ingr.) Ber., no. 164:91-99, 1971,

The emission from manufacturing plants which produce or process fluorine bearing products usually comprises a gaseous part and a particulate part. The gaseous part contains predominantly hydrofluoric acid, whereas the fluorine compounds in the dust may be composed of sodium fluoride, aluminum fluoride, cryolite, sodium silicofluoride, and calcium fluoride. With regard to the gaseous components, for instance in the case of an electrolytic aluminum smelting plant, where the emission of pollutants rises diastically at the time of metal pouring, charging of raw materials, and changing of electrodes, it is necessary to extend the sample taking at least over one complete cycle. For determination of peak concentrations, short time sampling is advised. In a plant with installed air purification, the air has to be sampled at points of entry and of exit of the purification system. An automatically working system of sample taking is described. The apparatus is divided into two groups, one of which is mounted directly next to the measuring point and comprises the filtering apparatus and gas absorption bottles, including a drip separator and a heater for the filters. The second group, connected by a hose line to the first, and conveniently located on the floor, comprises the pump arrangement with valves, thermometer, flow meter, and other necessary instruments. Tubular filters are lately being preferred to flat ones, due to their larger surface and better adaptability to the mounting of electric heaters. Absorption of gaseous HF in the bottles is best effected by a caustic soda solution.

Hendrickson, E. R.

SIMPLIFIED TECHNIQUES IN AIR POLLUTION MEASUREMENT.

J. Sanit. Eng. Div. Proc. Am. Soc. Civil Engrs., p. 1776-1 to 1776-8, Sept. 1958. 15 refs. (Presented at the American Society of Civil Engineers, Industrial Health Conference, Atlantic City, N. J., April 1958, Paper 1776.)

Air collection techniques for aerosols include filtration, electrostatic precipitation, thermal precipitation, or impingement; for gases and vapors, absorption, adsorption, or freeze-out are usually employed. The sample is then analyzed. Several recording instruments have been developed for common pollutants. However, practically all sampling programs are a compromise between what is desirable and what is economical or convenient. Simplified techniques generally cost less and result in cumulative indications. The lead peroxide candle is a simple method for measuring sulfur dioxide. The rate of reaction varies inversely with the wind velocity. Increases in temperature and humidity also increased the reaction rate. Spanish moss and limed filter papers can determine fluoride content. Also,

lead acetate impregnated papers or tiles can detect hydrogen sulfide. Another simplified technique is the use of rubber strips for the determination of ozone. The time of the rubbers cracking or crack depth can be used to indicate the amount of ozone exposure. An ozonometer is a more refined device.

TESTS WITH A SAMPLING AND MEASUREMENT
METHOD FOR ROUTINE DETERMINATION OF FLUORINE

IN THE LOWER ATMOSPHERE. (Erprobung einer Sammel-
und Messmethode fuer die routinemaessige Bestimmung von
Fluor in der bodennahen Atmosphaere). Text in German. Staub,
Reinhaltung Luft, 31(1):9-11, Jan. 1971. 15 refs.

A polystyrene filter impregnated with 10% sodium-formate
solution in 50% alcohol was used to sample fluorine in the
lower atmosphere. Preliminary results with this filter indicated
that it had a high resistance, particularly at high humidity. A
maximum of only 4 to 5 cu m/min air could be drawn through
the filter. At low humidity, the throughput was 200 to 400
l/min. The filter was therefore modified, after which 12 experi-
ments were carried out. For three experiments, the filter
received 7.5/mg impregnation. This quantity was then raised to
15, 150, and 300/mg per filter. The experiments showed that a
filter with a surface of 78.5 sq cm and containing 300/mg Na-
formate absorbs more than 99% of the hydrogen fluoride
present. At lower Na-formate quantities, the filter resistance
drops but the percentage of HF absorbed is reduced. The con-
tent of F ion in the samples was determined by dissolving the
filter in ethyl acetate, agitating with a buffer, and analysis with
an F-ion selective electrode. Fluorine analyses in Graz, Linz,
and Vienna show the method is highly sensitive and suitable
for routine measurements.

We fluorides is passed into a solution of constant ionic strength buffered at pH 5.5. Any hydrolyzable fluorides present are decomposed to form a solution of fluoride ions, the concentration of which is measured with a fluoride activity electrode. By equating the concentration of the fluoride ions in the hydrolysis solution to the volume of sulfur hexafluoride gas sampled, the concentration of hydrolyzable fluorides present in the sulfur hexafluoride can be calculated. Details of design and calibration, and comparison with other methods, are given.

DETERMINATION AND EVALUATION OF LOW CONCENTRATIONS OF INDUSTRIAL AIR POLLUTANTS. (Zur Bestimmung und Bewertung niedriger Konzentrationen industrieller Luftverunreinigungen). Text in German. Chemiker. Z. (Heidelberg), 9S(10):452-455, 1971. 17 refs.

Common methods for the determination of small concentrations of sulfur dioxide, fluorides, oxides of nitrogen, and odorous substances are discussed. For SO₂ the highly selective and sensitive West and Gaeke colorimetric method, employing rosaniline, is used. Fluorides are also determined by colorimetry, using alicarine-complexone and lanthane nitrate. Recently, fluoride-selective electrodes have also been used. For the analysis of NO₂ and NO, sensitive methods are available which uses azo dyes. More recently the so-called Saltzman-reagent, N-(1-naphthyl)-ethylene diamine and sulfanilic acid, has been preferred. Gas chromatography is used to determine odorous substances. The sensitivity of this method could be greatly increased by the recently developed technique of reversion gas chromatography. The substances to be analyzed are concentrated in a tube which is filled with a suitable adsorption agent. The beginning and the end of the tube filling can be cooled and a heating sleeve can be moved across the entire tube. The method operates periodically and a complete chromatogram is obtained every 15 min. In the first period, the air sample is passed through the tube with the two cold zones in action. In the second period, the heating sleeve is moved across the tube at a speed which is below the sampling speed.

EXPERIMENTS FOR SEPARATION OF GASEOUS AND SOLID FLUORINE COMPOUNDS IN EMISSION MEASUREMENTS. (Versuche zur Trennung von gasfoermigen und festen Fluorverbindungen bei Emissionsmessungen). Text in German. VDI (Ver. Deut. Ingr.) Ber., no. 164:85-89, 1971.

In the last 20 years, the main area of interest with regard to emissions originating from iron and steel industries has been dust and sulfur dioxide. A variety of methods of measurement were developed and perfected. The handling of fluorine emissions, however, has been dealt with only more recently. It confronts the researchers with problems which are substantially different from the SO₂ testing, largely because of the chemical properties of fluorine, the most reactive electronegative element. Due to its secondary valences, it easily forms several addition and complex compounds and combines readily with other elements to form stable compounds. Methods are available for the analytical determination of the overall fluorine content in solid and liquid materials, even in smallest concentrations. However, in view of the different behavior of gaseous and solid fluorine compounds, it appears desirable to separate the two. In this connection, a test set-up for waste gases was developed which includes a filter of quartz glass fiber material for retaining the dust particles. The size of the filter is MF150, and it will retain particle sizes from one micron up. For gas absorption, the waste gas stream passes through two or more impingers. Also included in the flow system is a heating mantle which surrounds the filter which

dries the gas mixture and keeps the filter dry, the reason being that at increased humidity, gaseous fluorine compounds are being partly adsorbed by the components of the test system. This has to be counteracted to avoid greatly incorrect measurement results. Since the rate and volume of gas flow is being recorded by a gas meter, the values of fluorine concentrations established by analysis can be readily converted and expressed in mg/cu m of the tested gas.

DUST MEASUREMENT AT THE PNEUMATIC APPLICATION OF CONCRETE (GUNIT TORKRET) IN UNDERGROUND CONSTRUCTION SITES. (Staubmessungen beim Auftragen von Spritzbeton (Gunit, Torkret) in Untertagebauten). Text in German. Staub, Reinhaltung Luft, 31(2):56-57, Feb. 1971. 3 refs.

Dust generated by the pneumatic application of concrete was measured because of the occurrence of several cases of silicosis among the workers. A microsorban filter (diameter nine cm) and a standard impinger were used for sampling. The air throughput was three to six cu m/hr with the microsorban filter and 1.7 cu m/hr with the impinger. After dust was determined, the quantity the dust samples were subjected to a sedimentation analysis for determination of grain size distribution. Absolute alcohol was used as a dispersion fluid. The approximate quartz content of the samples was determined by evaporation with hydrofluoric acid and microscopically in the phase contrast. Measurements were taken at six different places. An average dust concentration of 50 mg/cu m was measured, of which 15 mg/cu m belonged to fine dusts of less than five micron.

Mascini, Marco

ION-SPECIFIC FILM ELECTRODES: A NEW ANALYTICAL METHOD FOR MEASURING WATER AND AIR POLLUTANTS. PART U: DATA OBTAINED FROM ANALYSIS WITH FILM ELECTRODES AND INDUSTRIAL EQUIPMENT. (Elettrodi a membrana specific! per ioni: una nuova metodologia analitica per la misura degli inquinanti dell'acqua e dell'aria. 2. Risultati analitici con elettrodi a membrana e modelli industrial! d'impiego). Text in Italian. Inquinamento, 13(2):21-29, March 1971. Part I. Ibid., 13(1), Jan.-Feb. 1971. Ion-specific film electrodes are prepared by pulverizing insoluble salts containing the ion that is of interest to the researcher, and intimately mixing this powder with a thermoplastic polymer which is then pressed out to form a very compact film in a heat presser at a temperature of about 100-150 C and a pressure of about 200-300 atm. This film is then welded to a tube made of the same polymer as that contained in the film. Experimental data are given for tests with electrodes specific for halide, sulfide, silver, and cyanide ions. Practical application is made to the determination of hydrogen fluoride gas contained in the stack gases of an aluminum plant, using polarographic measurements.

ANALYSIS OF INORGANIC GASEOUS POLLUTANTS. In: Air Pollution. Arthur C. Stern (ed.), Vol. 2, 2nd ed., New York, Academic Press, 1968, Chapt. 17, p. 53-114. 103 refs.

<xref image="2000WVF7.TIF|V3|2006:09:28:01:27:06.00|120159|0"> image: </xref>

Inorganic gaseous pollutants represent an important class of substances in analysis of samples for air pollution control purposes and for the assessment of ambient air quality. Methods for the detection of short period average and maximum concentrations in the ambient air must be sensitive and accurate in the microchemical or ultramicrochemical range. Other desirable features of a method should include a high degree of specificity, ease of calibration, and minimum interference from other contaminant gases present in the air sample. Of the available methods for sulfur dioxide analysis, those commonly employed in ambient air sampling are conductimetric, titrimetric, colorimetric, turbidimetric, and iodimetric. Procedures for the analysis of sulfuric acid mists and hydrogen sulfide are also indicated. The most sensitive method for the determination of nitrogen dioxide in the atmosphere is based on the Griess-Ilosvay reaction in which a pink-colored dye complex is formed between sulfanilic acid, nitrate ion, and alpha-naphthylamine in an acid medium. A procedure for the determination of nitric oxide is also indicated. Two general methods have been recommended for the determination of oxidants and ozone: one is based on the use of a neutral, buffered potassium iodide solution as absorbent, while the second method involves the absorption of the sample in an alkaline solution of potassium iodide in which the interference due to sulfur dioxide is eliminated by treatment with hydrogen peroxide. In general, methods for the analysis of fluorides in air consist of sample collection, preparation of the sample by evaporation and by ashing to destroy organic matter, and steam distillation with perchloric acid to separate the fluoride from interfering substances, followed by colorimetric estimation by titration or by spectrophotometric procedure. Procedures are also described for the analyses of chlorine and hydrogen chloride, hydrogen cyanide and cyanides, ammonia and ammonium compounds, carbon monoxide, and carbon dioxide. Continuous analysis is discussed.

Monterio, S. Cerquiglioni and A. Pepe
COMPARATIVE STUDY OF METHODS FOR THE DETERMINATION OF AIRBORNE FLUORIDES. *Pure Appl. Chem.*, 24(4):707-714, 1970. 17 refs. (Presented at the International Symposium on the Chemical Aspects of Air Pollution, Cortina d'Ampezzo, Italy, July 9-10, 1969.)

Some methods for the determination of gaseous and particulate fluorine compounds present in the air as pollutants are described and compared. Particulates were collected by means of membrane filters; gaseous compounds were sampled by absorption in alkaline solution. The operation included air and stack sampling, the separation of fluoride from interfering substances, and its final determination. Results obtained for the separation of fluoride by distillation and by other microdiffusion techniques are presented. The application of various methods to the subsequent determination of fluoride are also discussed. Spectrophotometric methods were used for the final quantitative determination of the fluoride content. It is concluded that when an aluminum smelter is involved, the mean amounts of fluoride, collected in a five kilometer area surrounding the plant, are higher than five micrograms, with values as high as 375-500 micrograms for 24 hours of sampling. Kanto Regional Analysis Panel (Japan)
ANALYSIS METHODS FOR FACTORY EFFLUENTS, MINE WASTE WATER, EXHAUST GAS, ETC. (Kojo haisui, ko haisui. haigasunado no bunsekiho). Text in Japanese. *Ryuisan (J. Sulphuric Acid Assoc. (Japan))*, 24(3):33-43, March 1971. p. 33-43.

Analytical methods specified in existing laws and regulations as well as those adopted by individual industrial firms were surveyed to determine prefectural criteria for noxious gas

emissions and appropriate methods for analyzing exhaust gas. Criteria are given for total sulfides (ground-level density), ammonia, carbon monoxide hydrogen chloride, chlorine, cyanic hydrogen, nitrogen dioxide, hydrogen fluoride, benzene, phosgene, formaldehyde, hydrogen sulfide, toluene, and phenol in Tokyo, Osaka, Kanagawa, Fukuoka, and Saitama. The analytical methods are tabulated according to the compound to be determined. Legal references and measuring ranges are indicated. The methods include the neutralization titration, titration, and barium chloranilide methods for analysis of total sulfides; the iodine titration, electroconductivity, infrared-absorption, and detection tube methods for SO₂; the iodine titration, methylene blue absorption photometric, and detection tube methods for H₂S; the naphthyl ethylene diamine absorption photometric and phenol sulfonic acid absorption photometric methods for the naphthyl ethylene diamine absorption photometric, continuous analysis (absorption photometry), and detection tube methods for NO₂; the thorium nitrate-neothorin titration, and lanthanum-alizarin complex-ion absorption photometric methods for F compounds; the ortho tolidine absorption photometric detection tube, and continuous analysis methods for Cl₂; the thiocyanic acid mercuric absorption photometric silver nitrate titration, neutralization titration, and electroconductivity methods for HCl.

Durst, Richard A.
ION-SELECTIVE ELECTRODES IN SCIENCE, MEDICINE,
AND TECHNOLOGY. Am. Scientist, 59(3):353-361, May/June
1971. 15 refs.

Ion-selective electrodes have wide utility for potentiometric measurements in such areas as pollution monitoring, public health, and biomedical research. About 20 different ion-selective electrodes are commercially available. These are listed according to cations and anions detected and according to membrane type: solid-state, heterogeneous, or liquid ion exchange. Although these electrodes can be used only for solution studies, i.e., the species of interest must be ionic, systems have been developed for the determination of pollutants in gases. In these systems, provision is made for scrubbing the gases with suitable reagents. The quantity of gas and reagent are measured with flow transmitters, and the resulting concentration of the soluble component is measured in the flow-through cell. Such systems have been used for monitoring sulfide and cyanide, fluoride, and hydrogen chloride produced the pyrolytic decomposition of chlorocarbon polymers.

SEPARATE DETERMINATION OF INORGANIC FLUORINE

GASEOUS COMPOUNDS AND WATER SOLUBLE

AEROSOLS IN THE ATMOSPHERE. (Razdel noye

opredeleniye neorganicheskikh gazoobraznykh soedineniy ftora i aerorozoley, rastvorennykh v vode, v atmosfernom vozdukh).

Text in Russian. Gigiena i Sanit., 36(6):58-61, 1971. 3 refs.

Analyzed air was filtered through a material (acetyl celluloid filter AFA-KhA) on which only aerosols (solid fluorine compounds) were collected. These were subsequently washed off the filter with water of varying temperatures. The gaseous compounds were collected in an absorber. Fluorine ions in both the aerosol and gaseous phase were determined by the reaction with a titanochromatopre reagent. Fluorine compounds, poorly soluble in water, were washed off the filter with hot water. In the testing, 96-99% of fluorine substances soluble in water at room temperature were recovered from the filter. The sensitivity of the method is two micrograms of fluorine ions per five ml of solution. The effect of other ions on the determination was studied.

Fukui, Shozo

METHOD OF MEASUREMENT OF HARMFUL MATTERS

IN AIR. (Kuki chu no yugaisei busshitsu no sokutei hoho). Text

in Japanese. Bunseki Kiki (Analysis Instr.), 9(8):43-59, Aug.

1971. 1 ref.

Various measurement methods of harmful matter in the atmosphere are examined. The orthotolidine method is described for chlorine determination, but there is no reliable method for a high incidence of pollution by chlorine gas. The neutral iodine potassium method for ozone and oxidants; the atom light absorption method for cadmium; the pyridine pyrazole and palladium quinolinol methods for hydrogen cyanide; the dithizone and atom light absorption methods for mercury; and the diazotation and Saltzman methods for nitrogen oxides are reviewed. The atom light absorption method is generally used for lead and zinc, since it is simple and accurate. Sulfur dioxide is trapped with sodium chloride and mercuric chloride in solution; rosaniline formaldehyde is then added, and the mauve color is determined. Fluorides or hydrofluorine are measured by colorimetry, i.e., the lanter-auzarin complex ion method. The 3-methyl-benzo-thiazolon- hydrazone method, which is most sensitive, and the chromotropic method are used to measure formaldehyde. Hydrogen sulfide is determined by the methylene blue method, the molybdenum blue method, and the starch iodine method. The methylene blue method gives a unique reaction and involves less obstruction. A new method for trapping sulfides is examined.

ENVIRONMENTAL POLLUTION ANALYSIS -- ESPECIALLY

ON THE BASIC APPROACH TOWARD IT. (Kogai

bunseki ? Tokuni sono kangaekata ni tsuite). Text in Japanese.

Bunseki Kiki (Analysis Instr.), 9(7):3-9, July 1971. 13 refs.

The basic characteristics of an environmental pollution analysis are discussed to clarify the basic approach required for an analysis that is usually of complex nature. Often organic and

inorganic analyses must be performed simultaneously. Moreover, an analysis is more than simply qualitative or quantitative. A qualitative analysis intended simply to detect a polluting element in air or water is often meaningless; very often the toxicity of a particular element depends on its chemical state. Therefore, microanalysis or, more properly, trace analysis is required to detect extremely toxic substances. If possible, pollution should be continuously monitored and analyzed. The most dependable of current measuring devices are, theoretically, those employing ion-selective electrodes. Sampling, pretreatment, and measurement methods, together with measurable range and references, are tabulated for different air pollutants. The methods are as follows: dust (particulates), reflection factor or transmittivity measurement; sediment, gravimetric analysis; precipitation density, X-ray, light-dispersion, and gravimetric. X-ray microprobe analysis, fluorescent X-ray analysis, radiometry, emission spectrochemical analysis, atomic absorption spectrochemical analysis, absorption photometry, polarography, and gas chromatography are used for metals and other noxious elements. For carbon monoxide or carbon dioxide measurements, conductometry, coulometry, visible absorption photometry, and ultraviolet absorption photometry are used. Turbidimetry, coulometry, and conductometry are used for hydrogen sulfide measurements. Coulometric titration and absorption photometry are used for oxidant measurements. Nitrogen dioxide or nitric oxide measurements use visible radiation absorption photometry. Organics are measured by gas chromatography. Ammonia, aldehydes, fluorine, phenyl acetate, mercury, tetraethyl lead and hydrogen cyanide use visible radiation absorption photometry.

ROMELL'S REACTION FOR THE RAPID DETECTION OF TOXIC GASES IN THE AIR. (La reazione di Romell per il saggio rapido di gas tossici nell'aria). Text in Italian. Boll. Sta. Patol. Veg. Rome, 21(2):117-122, 1941. 1 ref.

Analysis of the air in the vicinity of two plants suspected of emitting toxic gases revealed that Romell's reaction is suitable for the detection of minimal concentrations of hydrofluoric, hydrochloric and sulfurous acid. Identification of these acids can be accomplished either by means of a marginal color change or by the discoloration of a paper filter impregnated with a one percent Delafield hematoxylin solution. According to experimental data, a certain relationship was established between the appearance of the colorimetric reaction and the distance from the emission center. However, the variations of the marginal color changes from one determination to the next did not allow a quantitative determination of the concentrations of the gas in the air. The same was true for the qualitative identification of the particular gas present.

CONTINUOUS CONTROL OF IMPURITIES IN ATMOSPHERES. (Control continu d'impuretes dans les atmospheres). Text in French. Technicon Corp., Ardsley, N. Y., Proc. Synip. Automation in Analytical Chemistry, 3rd, New York, 1967, p. 365-370. (Nov. 13-15.)

<xref image="2000WVF9.TIF|V3|2006:09:28:01:27:12.00|119568|0"> image: </xref>

In processing semi-conductors, continuous control of the purity of the inert gases and atmospheres used is necessary to ensure that constant properties of materials are maintained, since impurities such as hydrogen sulfide, sulfur dioxide, hydrochloric acid, and hydrofluoric acid can greatly damage production. A technique of gas analysis which ensures rapid response, sensitivity, reproducibility, and simultaneous analysis of gas derived from several sampling locations is described that is based on the application of colorimetry to the technique of the Auto-Analyzer Technicon. The apparatus consists of an Auto-Analyzer Technicon which comprises a contact column, proportioning pump, colorimeter, and recorder; an air pump with adjustable output; a multi-channel Technicon programmer; and gas distribution control panel. Impurities are analyzed in nitrogen, air, hydrogen, and furnace atmospheres rich in hydrogen. An operating cycle, comprising the successive determination of an impurity in these gases, takes one hour and is programmed in advance. The lapse between sampling and recording is 20 minutes, ensuring complete development of the colorimetric reaction.

Eggebraaten, V. L. and L. E. Miller

DETECTION OF FREE FLUORINE IN THE ATMOSPHERE

BY 1(131) RADIOTRACER ANALYSIS. Intern. J. Appl. Rad.

Isotop. (London), 18(3):183-191, March 1967. 6 refs.

The chemical displacement reaction, $F_2 + 2I(-)$ yields $I_2 + 2F(-)$ was evaluated as a means of detecting and measuring free fluorine in the atmosphere. The objectives were to determine the chemical properties of this reaction at micro-concentration levels, to develop the calibration techniques which will produce a working analytical procedure, and to predict the potential service of this system as a compact, portable type instrument for performing atmospheric determinations on field locations. Atmospheric gases were passed through alkali iodide columns tagged with radioactive iodine (131), which is released and captured in a sodium thiosulfate solution upon exposure to calibrated quantities of fluorine contamination. Favorable features of this radio release technique include determination of quantitative amounts of fluorine in ppb quantities, instantaneous recording of the atmospheric contamination, discrimination between elemental and combined fluorine, and instrument portability. The disadvantages of the 1(131) system stem from the fact that the isotope must be used in non-occupational areas. (Author introduction modified)

USE OF SELECTIVE FLUORIDE ELECTRODE IN CONTROLLING THE PRODUCTION OF HYDROGEN

FLUORIDE. (Pouziti selektivni fluoridove elektrody pri kontrole vyroby kyseliny fluorovodikove). Text in Czech. Chem. Prumsyl (Prague), 21(46):388-389, 1971. 4 refs.

A procedure is described for determining total fluorine in waste calcium sulfate and in the waste gas formed in the production of hydrogen fluoride from a fluorite concentrate. Analysis is based on measuring the potential of a selective electrode (Crytur 09-17) in a suitably treated sample solution. The procedure facilitates control of hydrogen fluoride production. DETERMINATION BY THE SEPARATION OF GASEOUS

AND PARTICULATE FLUORIDE. (Gasu jo oyobi ryiishi jo fukkabutsu no bunrisokuteiho). Text in Japanese. Niigata-ken Eisei Kenkyusho Shudankai Shoroku (Niigata Prefect. Public Health Lab. Meet. Abstr.), 1970:14-15, 1970.

Results of fluoride determination as a particulate, using filter paper, and in gaseous form, adsorbed by aluminium, glass spiral, and unglazed tubes, were examined. For collecting par-

ticulate fluoride, seven filters millipore were compared; AA had the smallest gas absorption. For the separation of gaseous fluoride, the almost 100% HF gas was collected by the glass spiral tubes. Separation of gaseous and particulate fluoride was effected by passing particulate fluoride through the tube and then collecting the fluoride on alkaline filters. On the assumption that the rate of particulate to total fluorides was 50-70%, when 4 ppb total fluorides were in the air, particulate and gaseous fluorides were separated with millipore and alkaline filters at 20 ml/min and determined by the analysis of ion electrodes.

THE DETECTION OF DAMAGE CAUSED BY FLUORINE

EXHALATIONS. (Zur Diagnose von Fluor-Rauchschaeden).

Text in German. Phytopathol Z., 5(2):195-206, 1933. 19 refs.

Industrial fluorine emission do not disperse as widely as sulfur dioxide emissions; 1 km away from the source no noticeable damage attributable to fluorine could be detected. Since fluorine-induced damage to plants is not characteristic and cannot be detected by botanical inspection, a microchemical analysis is necessary. Two methods are suitable. The Feigl and Krumholz method volatilizes fluorine in the form of silicon fluoride and determines Si in the distillate. The sodium fluosilicate crystal method processes plant substance with silica sand and sulfuric acid. With a sodium acetate solution easily the escaping silicon fluoride forms discernible hexagonal crystals. The natural fluorine content of the plant substance does not interfere with either method or does fluorine-rich soil from fluorine-containing phosphates. Whether fluorine damage undetectable by either method can occur is an unresolved question. If the Na₂SiF₆ crystal method, which should be applied first in case of fluorine plant damage, does not yield conclusive proof then a somewhat more sensitive method (the molybdatebenzidine color method) should be employed. If the crystal method is negative but the molybdate method positive, fluorine damage is considered proven.

THE MEASUREMENT OF ATMOSPHERIC FLUORIDES BY

REACTION WITH SELECTED FILTER MATERIALS. Warren Spring Lab., Stevenage (England), Rept. LR 130(AP), 14p., Aug. 1970. 12 refs.

Glass fiber and silver membrane filters were used to absorb gaseous fluoride at atmospheric concentrations. Compared with the standard impinger method, the collection efficiency was below 50% and the absorbed fluoride was hard to remove. The glass fiber filter contained high intrinsic levels of fluoride which could not be removed without destroying the filter. (Author abstract modified)

C. MEASUREMENT METHODS

191

A standard method for sampling and analyzing fluorine compounds in the atmosphere is presented. The sample is collected by an impinger. The fluoride is then distilled to remove interfering matter and the distillate is analyzed by colorimetry and read on a spectrophotometer. Equipment design and process description are included.

Ministry of Commerce and Industry (Japan), Dept. of Environmental Pollution
MONITORING APPARATUS FOR AIR POLLUTION. (Taiki osen ni kansuru sokutei kiki). Text in Japanese. In: A Survey of Industrial Pollutant Disposal Machines - 1971. p. 178-181, Dec. 1970.

Various air pollutant measuring equipment are reviewed. In the atmosphere, settling particles, suspended particulates, sulfur oxides, and toxic gases such as hydrogen sulfide, nitrogen oxides, hydrogen chloride, and hydrogen fluoride are monitored. Deposit gauges, hi-volume samplers, and the lead dioxide method are explained as methods of measuring suspended particulates. For measurement of pollutants from specific emission sources, Ringelmann's chart is used. According to the Japanese Air Pollution Control Law, dust or soot emission is determined by the weight of particles contained in one cu m of air at air pressure one, and the method of measuring designated by the Japanese Industrial Standard Law is the filter method of collection, using a dust tube filled with glass wool or a filter paper, suspended in flue gas, and weighing the soot. The apparatus for this method comprises a scale, a dust collector, a vacuum pump, and a flowmeter. Sulfur dioxide content in stack gases is calculated from the weight of fuel, and one kg of heavy oil with S % sulfur content is 0.7 S N cu m. A non-dispersion infrared analyzer is used for carbon monoxide, carbon dioxide, hydrocarbons, and sometimes nitric oxide from automobiles. The total bag method, the constant volume sampler method, and Diesel smoke filters are briefly mentioned.

Chovin, P.
ATMOSPHERIC POLLUTION AND ANALYTICAL CHEMISTRY. (Pollution atmospherique et chimie analytique). Bull. Soc. Chim. France, no. 5:2191-2215, 1968. 339 refs. Translated from French. Naval Intelligence Command, Alexandria, V'a.. 64p., Dec. 15, 1970.

Domestic heating systems, industrial heating plants, and motor vehicles are the three major sources of pollutants. The most important substances emitted are sulfurous gas, hydrogen sulfide, dust, nitrogen oxides, ammonia, fluorine compounds, ozone, peroxyacetyl nitrates, carbon monoxide, hydrocarbons, tars, and aldehydes. Methods for the determination of these compounds are indicated and described.

Hagiwara, Toshiaki
MEASURING APPARATUS FOR TOXIC GASES. (Yudoku gasu no sokutei kiki ni (suite)). Text in Japanese. Nenryo Oyobi Nensho (Fuel and Combustion), 38(12):1217-1220, Dec. 1971.
The principles, mechanism, and characteristics of various toxic gas measurement apparatus and one flue-gas sulfur dioxide analyzer are briefly discussed. One apparatus is specifically for hydrocyanic acid (HCN), hydrogen sulfide (H₂S) and chlorine (Cl₂) detection. Its principle is the electrochemical reaction between electrolyte and the specific elements in the air. The range of detection is 0-50 ppm for H₂S and HCN, and 0-5 ppm for Cl₂. The circuit condition is excellent, the battery does not have to be replaced for more than two years, and the electrolyte has to be replenished only once in two weeks or 20 days; it is compact and installation is possible anywhere. The carbon monoxide alarm is often used in a tunnel or an un-

derground parking lot. The sample air is sucked in by a pump and is burned; then the temperature change is detected. The range of detection is 0-500 ppm, the alarm point can be set for less than 50 ppm. It is characterized by compact size and a device which makes the internal installation of an automatic timer possible. The traceable gas ionization analyzer is used mainly for the detection of traceable leakage of such gases as hydrogen chloride, hydrogen fluoride, phosgene, ammonia, and nitrogen dioxide. The mixture of the sample gas and a reagent is led into an ion chamber in an aerosol form, and the decrease of ion current is detected. This analyzer can detect various types of gases by changing the reagent. Depending on the nature of the gas, traceable amounts of ppb order can be detected. There is no danger of effects on human health, and the analyzer may be used without permission.

SOURCE TESTING FOR AIR POLLUTION CONTROL. Wil-
ton, Conn., Environmental Research and Applications, Inc.,
1971, 228p. 532 refs.

Source testing for air pollution control is reviewed with respect to basic procedures, terminology, operating and theoretical principles, gas flow measurements, sampling trains, principles and methodology of particulate sampling, gaseous sampling, continuous monitoring, and special applications of various techniques. Measurements of stack gas parameters prior to sampling are discussed for determinations of temperature, pressure, moisture content, and gas composition using such instruments as thermometers, thermocouples, thermistors, wet or dry bulbs, condensation methods, Orsat analyzers, pilot tubes, anemometers, tracers, balloons, and various meters. Instrumentation for particulate sampling includes sampling probes, flowmeters, wet impingers, filters, centrifugal separators, and electrostatic and thermal precipitators. Particulate sampling trains are examined with respect to specific contaminants (polynuclear hydrocarbons, fluoride compounds, mists, tars, and droplets); combustion sources, e.g., boilers, incinerators, open burning, pulp and paper plants, lime kilns, kraft recovery furnaces, chemical processing, and metallurgical operations; and particle size analysis using impingers and cascade impactors. Sampling techniques for gases containing sulfur oxides, hydrogen sulfide, mercaptans, total sulfur, nitrogen oxides, ammonia, chlorine compounds, carbon monoxide, and organic gases and vapors include absorption into a liquid phase, using sample probes and impingers; collection in fabric bags; adsorption on a solid; and freeze-out techniques. Subsequent analytical methods include wet chemical analysis (turbidimetry, colorimetry, potentiometry, polarography, iodimetric methods, and Orsat analysis) and instrumental analysis (gas chromatography, spectrophotometry, flame ionization, and mass spectrometry). Special applications for the techniques include determination of odor thresholds of flue gases, measurement of acid deposition onto metal surfaces, the presence of radioactive materials, and bacterial emissions to the atmosphere. Pertinent source test data and sources of equipment are included.

AUTOMATED CHEMICAL ANALYSIS OF AIR AND WATER

POLLUTION. Preprint, Dept. of Commerce, Washington D. C., and Water Pollution Control Federation, Washington, D. C., 13p., 1971. (Presented at the Technical Conference on New Technology in the Solution of Practical Problems in Air and Water Pollution Control, Tokyo, Japan, Dec. 9, 1971.)

The contribution of automated pollution analysis of impinged samples, continuous single channel systems, and comprehensive mobile laboratories to the study of man's environment is discussed. A typical flow diagram for fluoride in waste water illustrates the use of basic automatic analyzer modules. Water quality assessment and the monitoring of organic wastes in waste water are discussed, as well as the periodic or cumulative sampling of air quality. Recent technical developments in instrumentation and application are presented. However, automated analysis in itself cannot make any contribution to the study of the environment we live in, without the proper personnel utilizing the techniques that are available, and producing meaningful interpretation of the vast amount of data so obtained. (Author conclusions modified)

IONIZATION METHODS OF MONITORING AIR POLLU-

TION. Zh. Vses. Khim. Obshchestva im. D. I. Mendeleeva, 15(5):514-519, Oct. 9, 1970. 38 refs. Translated from Russian in: Atmospheric Studies at Chemical Enterprises - USSR, p. 68-80, March 9, 1971. Joint Publications Research Service, Washington, D. C. NTIS: JPRS-52566

Aerosol-ionization and flame-ionization detectors for monitoring microadmixture in air are discussed. Aerosol-ionization detectors have high sensitivity, low inertia, and the possibility of selective control of a broad class of gas components. The essence of aerosol ionization is the fact that the controlled component of the gas mixture is selective and converts quantitatively into the aerosol state. The aerosol particles formed are detected in the ionization chamber with a radioactive ionization source. American-made aerosol-ionization instruments measure from approximately 0.01 to 10 mg/cu m of hydrogen fluoride, prussic acid vapor, phosgene, and tetraethyl lead present in the air of industrial facilities. Stationary and portable versions of the analyzers are available. Soviet aerosol-ionization detectors provide for the continuous monitoring of nitrogen oxides (0-10 mg/cu m). In contrast to aerosol-ionization detection, flame-ionization detection is specific only for organic substances. The detectors operate on the principle of ionization of molecules in the organic substances in the hydrogen flame and subsequent measurement of the magnitude of the ionization current. As gas analyzer sensors, they are used without chromatographic columns. Advantages of using the detectors for analyzing organic admixtures on air are their simplicity, absence of sorption storage for controlled microadmixture, and sensitivities of 0.01 to 0.001 mg/cu m.

MONITOR GRID: PHOSPHATE PLANT S POUND OF POL-

LUTION PREVENTION. Chem. Week, 1956:60-61, Dec. 1, 1956.

A five-year study of air and water pollution is being conducted in the area where a triple superphosphate plant will be constructed. The purposes of the study, based on data collected by automatic sampling equipment at a series of monitoring stations, are to determine air and water pollution levels before the new plant begins operations and to check on performance of the control equipment being built into the plant. A weather station measures micrometeorologic parameters at ground level

and 300- and 600-ft altitudes. At four air sampling stations, analyses are made for fluorides, sulfur dioxide, and sulfuric acid mist; paniculate analyses are made monthly from samples collected at eight dust fall stations. Plant indicators will also be used. In-plant pollution control equipment is briefly described.

DEPARTMENT IV. Schriftenreihe Landesanstalt Immissions
und Bodennutzungsschutz Landes Nordrhein-Westfalen (Essen),
no. 21:27-39, 1970 (?). Translated from German. Leo Kanner
Assoc., Redwood City, Calif., 26p., March 1971.
In addition to projects designed to determine and evaluate the
effects of emissions on plants, emphasis has been placed on
studies designed to derive air quality criteria as the basis for
establishing emission limits as well as experiments on the re-
sistance of plant species which are important to the economy
and to public health. Phytotoxic hydrogen fluoride concentra-
tions were determined, as well as fluorine enrichment in plant
organs as a function of exposure height and wind speed. Using
the results of fumigation and field experiments, a detection
method of sulfur dioxide effects on plants was worked out.
Transplanted lichens, grass cultures, leaf-pigment analysis, the
inhibiting action of fluorine ions on enzymes, and other indica-
tors of air pollution are discussed. A new method which util-
izes an ion specific electrode for the quantitative determina-
tion of fluorine levels in plants is described.

C. MEASUREMENT METHODS

193

electrometric method is approximately 3% and significantly lower than that of the conventional photometric procedure. The automated system permits the number of analyses to be doubled compared with the manual electrometric procedure and, since the distillation stage is omitted, tripled in comparison with the photometric procedure. Substances other than F(-) do not interfere with the electrometric method. In the case of air samples containing nonsoluble F(-) compounds, the method yields lower values than photometric methods. It is, therefore, used to analyze the phytotoxic portion of F(-) compounds in air.

Mori, Masaki, Shonosuke Ito, Hiroshi Ogino, and Hiroyoshi Morita

FLUORIDE ANALYZER IN STACK GAS. (Konodo fukkabut.su jido kirokukei). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 6(1):99, 1971. (Presented at the National Council Meeting of Air Pollution Studies, 12th, Nagoya, Japan, Oct. 27-29, 1971.)

An instrument to determine hydrogen fluoride in stack gas up to 2.0 ppm was developed. Sample gas flows at 10 l/min through a filter into the absorption section where it contacts with a buffer solution with a pH of approximately 5.5, which is fed there at 1 ml/min. The buffer solution absorbs the HF and is led into a measuring cell, where the concentration of the gas is determined by means of a fluoride ion electrode and a comparative electrode. The scale of a recorder is made linear to the gas concentration through inverse logarithm amplifier. The response time to 90% indication is approximately 2 min for about 1.5 ppm HF.

37515

Okita, Toshiichi, Hiroshi Ogino, Masaki Mori, and Jinkichi Miyai

AN ATMOSPHERIC HYDROGEN FLUORIDE RECORDER ON THE FLUORIDE ION ELECTRODE. (Taikichu fukka suiso jido kirokukei - Fusso ion denkyoku ni (suite). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 6(1):98, 1971. (Presented at the National Council Meeting of Air Pollution Studies, 12th, Nagoya, Japan, Oct. 27-29, 1971.)

The characteristics of the electrode potential of the fluoride ion electrode, which is a probe for an atmospheric hydrogen fluoride recorder, was examined. With an increase in the concentration of the pH buffer solution, which is used to buffer the effect of sodium carbonate collecting hydrogen fluoride, the potential tends to be more stable, although its response becomes slower. When the ion strength is increased by the addition of sodium chloride, more stable potential and more rapid response are obtained. Carbonate ion of sodium carbonate does not interfere with the measurement. Ethyl alcohol is recommended for cleaning the electrode, the performance of which has deteriorated during its use.

Liberti, A. and M. Mascini

DETERMINATION OF FLUORIDES IN POLLUTED AIR BY USE OF AN ION SPECIFIC ELECTRODE. Fluoride, 4(2):49-56, April 1971. 11 refs. (Presented at the International Society of Fluoride Research Conference, Annual, 3rd, Vienna, Austria, March 22-24, 1970.)

A membrane electrode specific for the fluoride ion greatly simplifies the analytical determination of fluoride in a variety of samples, including polluted air and stack effluents. The main advantage of the electrode is the elimination of time-consuming distillation procedures for the separation of fluoride: determination is by direct potentiometry or, preferably, by potentiometric titration. Total fluoride, gaseous and particulate, in ambient air or stack gases, is sampled by drawing air through a membrane filter impregnated with sodium formate.

The collected material is dissolved in water. Depending on the volume of air and the extent of pollution, a fluoride concentration of 0.1-5 ppm is obtained. In this range, the electrode yields a linear response proportional to the fluoride activity. With respect to the total fluoride concentration, the direct potentiometric measurement is subject to interference of other ions affecting fluoride activity. The accuracy of determination is greatly increased by potentiometric titration in a sodium fluoride solution and by plotting the experimental values with the Gran function. Stack gases can be continuously monitored by this method.

Kasparov, A. A. and V. G. Kiriy
ON THE METHODS OF DETERMINING BORON FLUORIDE
IN THE AIR. (K. voprosu o metodakh opredeleniya ftoristogo bora v vozdukh). Text in Russian. *Gigiena i Sanit.*, 37(1):57-59, 1972. 4 refs.

An improved method for the determination of boron fluoride in low concentrations in the air, applied in sanitary paxis, is described. The method is based on the hydrolysis of BF₃. The determination is made on the basis of boron ions following the distillation of the fluorine, by means of 1,1-diantrimide indicator. The necessary reagents are 98% sulfuric acid, an indicator solution with sulfuric acid, while the standard solution of bone acid contains boron in a concentration of 1 mg/ml. The sampling is made by two absorbers containing distilled water. The flow rate applied is 60 l/hr at a sample volume of 30-60 l. The fluorine distillation is made by means of sulfuric acid of 98% in oil bath of 140-150 C. About half of the liquid should be evaporated, while the fluorine forms volatile fluosilicic acid with silicon in the presence of sulfuric acid as a catalyst. The boric acid losses are unimportant. The analysis is made by means of 98% sulfuric acid and indicator. After heating in boiling water bath and cooling down, the determination is made by comparison with a standard or by the colorimetric method, using red filter. The calibration curve is plotted from standard solutions with different concentrations. The test with distilled water showed good accordance of the results. The sensitivity is 0.2-0.3 micrograms of boron or 1.5-2.0 micrograms of BF₃, with a maximum error of 5-10%.

positionsgefaess fuer hoehere Pflanzen zur biologischen Indika-
tion von Luftverunreinigung). Text in German. *Wasser Luft
Betrieb*, 16(3):96-97, March 1972. 6 refs.

The exposure equipment for measuring fluorine emissions comprises a container resting on a pole. The container is made of plastics and is composed of a supporting container and a plant cultivation container. In the bottom of the outer supporting container, two borings provide for air circulation and water outflow. The container is screwed to the pole, an iron tube. The supporting container has a latex coating to reflect solar radiation. The plant cultivation container consists of a lower chamber holding about 3000 ml water for the water supply of the grass culture. The upper chamber holds the growth substrate and a ceramic cylinder for automatic irrigation. The two chambers are separated by a perforated palate. Excess water
<xref image="2000WVFD.TIF|V3|2006:09:28:01:27:28.00|119416|0"> image: </xref>

which collects in the substrate can pass through this plate into the water supply chamber, and from there to the supporting chamber where it runs off through the boring. The size and shape of the exposure set-up should not be too large so that a simple iron rod, which is driven 60 to 80 cm into the soil, is a sufficient support.

UNITS FOR MONITORING WATER AND AIR- THE AUTO-MATIC ANALYZER. (Geraete zur Ueberwachung von Wasser und Luft - die kontinuierliche Durchflussanalyse). Text in German. Preprint, 6p., 1972. (Presented at the Fachtagung Umwelt (Verschmutzung, Frankfurt/Main, West Germany, March 21-24, 1972.)

An autoanalyzer is described which can be used in the field of air pollution for determining sulfur dioxide, nitrogen dioxide, nitric oxide, aldehydes, hydrogen sulfide, fluoride, chloride, ammonia, and hydrochloric acid. It can be used in the field of water pollution to determine ammonia, the C.O.D., chromium, copper, cyanide, fluoride, water hardness, nitrite and nitrate, silicates, sulfate and total inorganic phosphate. Autoanalyzers perform all steps of the manual method from sampling to data recording fully automatically, including pipetting, heating-up, and measuring. Manual analysis starts with pipetting, which is performed by the autoanalyzer by the sampler and the pump.

If the manual analysis requires filtration, this can be carried out by the autoanalyzer by means of a continuously-operating filter or it can be replaced by dialysis. The entire system of the autoanalyzer is composed of individual components which permit rapid adjustment and provide highest flexibility. Several components in a waste gas flow can be determined simultaneously by dividing the sample flow.

ANALYSIS METHODS APPLIED TO POLLUTANTS. (Kogai kankei no bunsekiho to kaisetsu). Text in Japanese. 122p.. Feb. 1972.

Various methods of analyzing heavy metals in the air, stack gases, water, and soil are reviewed. With regard to stack gas tests, atomic absorption spectrophotometry is explained for measuring cadmium, lead, and chromium. For measuring chlorine, the use of orthotolidine as a reagent is discussed. For analyses of fluorine, hydrogen fluoride, and other fluorides, lanthanum-alizarin complex ion method is discussed. For analyses of hydrogen and other cyanides, the pyridine-pyrazolone method and iron electrode method are discussed. The rosaniline test is explained for measuring sulfur dioxide and for detecting sulfur oxides in general the neutralization method, arsenazo III method, and chloranil acid barium test are discussed. The naphthylethylenediamine method is explained for the analyses of nitrogen oxides and nitrogen dioxide. For hydrogen sulfide, the methylene blue method, and for ammonia, the indophenol method and Nestler method are discussed. Gas chromatography is used for analysis of benzenes, toluenes, xylenes, trichloroethylene, phenols, mercaptans, monosulfides, disulfides, and aliphatic acid amines. For measuring formaldehydes, the chromotrope acid method and acetylacetone method are used. The tetra-aminoantipyrine method is also used for phenol measurement, and the p-aminodimethylaniln method is used for mercaptans. For measuring aliphatic amines, picric acid may also be used.

MEASUREMENT OF GASEOUS FLUORINE COMPOUNDS

IN THE OUTDOOR AIR AND IN INDUSTRIAL WASTE

GASES. (Messung gasfoermiger Fluorverbindungen in der Aus-senluft und in Industrieabgasen). Text in German. Tech. Ueberwach. (Duesseldorf), 13(2):42-45, Feb. 1972. 29 refs.

For the measurement of fluorine emissions, the dual paper tape sampler and the bicarbonate coated tube were developed in the U. S. In West Germany, the sorption method has been developed in which the gaseous fluorine compounds are absorbed on a thin sodium carbonate layer which covers silver balls. These balls are in a quartz tube. For separation of the coarse dust a synthetic cylinder is attached to the inlet. The air is drawn on at a speed of 0.8 to 1.0 cu m/hr. For the analysis, the alizarine-Komplexon-Method or a fluoride sensitive electrode is used after distillation. For the measurement of fluorine emissions various sampling equipment is available, such as the Rheinfelder apparatus, the apparatus of the National Center for Air Pollution Control, and the apparatus of the Rhine-Westphalian Technical Inspection Association. The Rheinfelder sampler can be used at relatively low waste gas temperatures (100 C) and a sampling speed of 0.4 cu m/hr. The sampling pipe is of stainless steel, the dust is collected on a heated paper filter. For gas absorption special scrubbers of plexi-glass are used. For analysis the photometric detection via the lanthane complex of the AC is mostly used in West Germany. A comparison of this method with the method of thorium nitrate titration revealed no significant differences. In the U. S. the circonmm-SPADNS method is frequently used. All these methods require the prior separation of interfering components, such as heavy metal ions, oxidizers, and various anions. A separation of solid and gaseous fluorine compounds can be only approximately achieved.

MEASUREMENTS OF AIR POLLUTION BY FLUORIDE BY

MEANS OF THE LIME TREATED FILTER PAPER

METHOD. (Lime treated filter paper ho ni yoru fukkabutsu no ta taikiosen sokuteiho). Text in Japanese. Kankyo Hoken Report. (Environ. Health Rept.), no. 8:23-30, Jan. 1971. 22 refs.

Measurements were carried out for fluoride within a radius of 5 km from the aluminium factory, which was considered as a source of pollution, using the Lime Treated Filter Paper method reported by Miller, and Adams, and also the followup measurements were taken to prove the usefulness of this method. Paper filter No. 51A was used in the LTP method. The filters were treated with 1% lime suspension and when they were dried, exposure was made. Two or three LTP were placed in the air screen at six spots which were located in the different distances and directions from the source of pollution. The variation coefficient of the values obtained from within the premises of the factory was 22.3%. The variation coefficients of values in the polluted area outside of the factory were 3.8 - 8.9% and the average of them of 8.7%. As for the relationship between the exposure duration of LTP and the accumulated amount of fluorine, decreased amounts were observed on the eighth week. Any correlation was not seen between the values obtained by the LTP method and the fluorine amount in soluble components by the dust fall method.

Yanagisawa, Saburo

ESTIMATION OF FLUORIDES BY MEANS OF LANTHANIUM-ALIZARIN COMPLEXONE METHOD. (Rantan azarin compurekuson ho ni yoru fukkabutsu no teiryō ho). Text in Japanese. Kankyo Hoken Reporto (Environ. Health Kept.), no. 8:11-13, Jan. 1972.

The lanthanum-alizarin method is a highly sensitive method to analyze fluoride compounds of exhaust gas estimating fluorides according to colorimetric determination. The ALC-La-F substance was extracted by a N, N-diethylaniline-isoamylalcohol solution, and the degree of extinction was measured by a photometer. Changes were observed in the degree of extinction due to aluminum, copper, iron, and hypophosphate among coexisting cations and anions. Studies were made on the quantity of buffer solution which was added upon extraction, and commotion time. It was possible to elevate the sensitivity of measurement up to 1.4 ppb

MEASUREMENT OF GASEOUS FLUORINE COMPOUNDS IN THE ENVIRONMENT AIR AND IN INDUSTRIAL WASTE

GASES. (Messung gasfoermiger Fluorverbindungen in der Aus-senluft mid in Industrieabgasen). Text in German. Tech. Ueberwach. (Duesseldorf), 13(2):42-45, Feb. 1972. 29 rets. Different techniques for the measurement of fluorine compounds are reviewed. Practical emission measurements are made by means of sorption techniques with preliminary separation of coarse particles. The techniques using a sodium bicarbonate-coated tube and dual paper tape sampler have been improved by the Boyce-Thompson Institute (Yonkers, N. Y.) to facilitate the separation of gaseous and particulate fluorine compounds. The analysis can be made by distillation or fluoride-sensitive electrode. Sampling on NaCO₃ coating and analysis by the alizarin technique and fluoride-sensitive electrode were carried out. Quartz probes with quartz filters are useful in sampling for emission measurements. Different types of samplers are described. In fluorine ion determination, both the alizarin and thorium titration methods give reliable results. The SPADNS method is preferred in the U. S. When using a fluoride-sensitive electrode, special attention should be given to the aluminum ion concentration. The standard deviation for concentrations of 15-34 mg F/cu m, from combustion processes, lies in a range of plus or minus 0.6-2.8 mg F/cu m. The results of emission measurements are given.

Hildebrandt, P. W.

AIR POLLUTION MONITORING. Hort Science, 5(4):243-244, Aug. 1970.

Techniques for monitoring pollutants in the ambient air and monitoring with relation to effects on vegetation and materials are reviewed. Limits of applicability, efficiency, operating principles and problems reviewed for fluoride sampling using filters and impingers; automated sulfur dioxide analyzers based on colorimetric (West and Gaeke), coulometric, and conductivity methods; colorimetric and coulometric techniques, the potassium iodide method, and SO₂ scrubbers for defining oxidant and ozone concentrations; infrared spectrometry for carbon monoxide analysis; high volume samplers and fiberglass filters for measuring suspended particulates; and particle fallout measurements. In addition to measuring the contaminants, effects monitoring using sulfation candles, rubber cracking, indicator plants, visibility measurements, dye and fabric deterioration, and dust fall is often used.

Kanagawa Prefectural Government (Japan), Dept. of Pollution Countermeasures

ANALYTICAL METHOD RELATED TO ENVIRONMENTAL

HAZARD. (Kogai kankei no bunsekiho to kaisetsu). Text in Japanese. 122p., Feb. 1972.

Analytical methods which were adopted by the Center of Public Nuisance in Kanagawa Prefecture were explained. The analysis of soil, biological samples, exhaust gases, and metallic components in air were discussed. Items for analysis differed more or less by samples. In drainage, soil, and biological samples, the analysis of lead, cadmium, mercury, copper, zinc, iron, manganese, nickel, fluoride, chromium, arsenic, cyanide, and phenol and measurements of BOD, COD, and pH were discussed. In exhaust gases, the analysis of Cd, Pb, Cr, F, chlorine, CN(-), sulfur dioxide, total sulfur, hydrogen chloride, nitrogen oxides, ammonia, hydrogen sulfide, benzene, toluene, xylene, tetrachloro-ethylene, phenol, mercaptans, organic sulfides, and amines were discussed. The analysis of metallic components such as Cd, Cu, Pb, Mn, Ni, and Fe in air samples by the atomic absorption method was explained. It was emphasized that the above mentioned methods were adopted based on the experiments. Basic theories of simple methods of analysis were explained for beginners at the end of the report.

Allen, Nelson and N. Howell Furman
DETERMINATION OF FLUORINE BY PRECIPITATION AS
TRIPHENYLTEV FLUORIDE. J. Am. Chem. Soc., vol. 54:4625-
4631, Dec. 1932. 16 refs.

Fluorine determination through quantitative precipitation as triphenyltin fluoride is examined. The method is suitable for small quantities of fluorine (below 0.04 g) but has several disadvantages in that the reagent is uncommon and expensive, is insoluble in water, and is slightly soluble in alcohol. Large amounts of foreign salts may also cause co-precipitation of the reagent and give high results. Advantages include the crystalline form of the precipitate for easy filtering and quick washing, stability, and speed. Experimental procedure and treatment are discussed.

Allen, Nelson and N. Howell Furman
A POTENTIOMETRIC TITRATION METHOD FOR
FLUORINE. J. Am. Chem. Soc., vol. 55:90-05, Jan. 1933. 16
refs.

A method for fluorine determination is described involving the precipitation of cerous fluoride through a new application of the ferriferrocyanide electrode. The method gives good results for fluorine concentrations within 0.1-50 mg. Small amounts of foreign salts may be present, but too large amounts mask the equivalence point. Ions which precipitate cerous cerium must be absent. Experimental procedures and results of fluorspar analysis are discussed. (Author summary modified)

NOTIFICATION NO. 984. MEASUREMENT METHODS TO BE DETERMINED BY THE GOVERNOR AS SPECIFIED.... (Kokuji). Kanagawa-Ken Koho (Off. Gaz. Kanagawa Prefec.), no. 81:1-12, Nov. 10, 1971. Translated from Japanese. 57p. Measurement methods for use under the Enforcement Regulations of the Kanagawa Prefecture Environmental Pollution Prevention Ordinance are presented. Atomic absorption photometry is described for the measurement of cadmium and lead compounds. The pyridine-pyrazolene method is described for measurement of cyanogen, as well as an ion-electrode method. A diphenylcarbazine method is outlined for the determination of chromium, and a silver diethyldithiocarbamate method is indicated for arsenic. A reduction vaporization method of atomic absorption photometry is cited for total mercury, and gas chromatography with an electron capture-type detector can be used for measuring mercury alkyl contents. Phenol contents can be determined by a 4-aminoantipyrine method; copper, zinc, iron, and manganese by atomic absorption photometry; and chromium by the diphenylcarbazine method. Nickel can be determined by atomic absorption photometry, and a lanthanum-alizarin method can be used to measure fluorine content.

Haul, Hans van
DETECTION OF SOME AIR POLLUTANTS BY MEANS OF KALE (BRASSICA OLERACEA ACEPHALA) AS INDICATOR PLANT. (Nachweis mehrerer Luftverunreinigungs-komponenten mit Hilfe von Blätterkohl (Brassica oleracea acephala) als Indikatorpflanze). Text in German. Staub, Reinhaltung Luft, 32(3):109-111, March 1972. 18 refs. Air pollutants such as fluorine, chloride, sulfur, and lead were determined by means of the kale (Brassica oleracea acephala) used as plant indicator in nine localities in the Ruhr area. The plants, exposed over a succession of years in the periods from early August until mid-November, showed no visible symptoms of damage. Leaf tissue samples were analyzed for all pollutants. The leaf fluorine content, determined by an electrometric method, was slightly to considerably elevated with 12-10 mg/100 g of dry substance, compared with a natural content of 3 mg/100 g. Chloride content, determined by the potentiometric titration method, was up to four times higher than

normal. The sulfur determination, carried out according to Stratmann's microanalytic method, revealed a maximum of 1.83% of S, compared with the normal value of 0.97-1.33%. This may be the result of persistent, fairly low sulfur dioxide concentrations. The lead concentrations, determined by an inverse-polarographic method, were highly elevated in all but two cases. A value of 116 ppm in a plant near a highway was measured. Besides the above pollutants, many aromatic hydrocarbons such as benzo(a)pyrene can be identified by means of kale.

Thomas, Moyer D. and James O. Ivie

AUTOMATIC APPARATUS FOR THE DETERMINATION OF SMALL CONCENTRATIONS OF SULFUR DIOXIDE AND OTHER CONTAMINANTS IN THE ATMOSPHERE. Interdepartmental Committee on Air Pollution, Washington, D. C., Air Pollut., Proc. U. S. Tech. Conf., Washington, D. C., 1950. p. 567-569. 10 refs. (May 3-5, Louis C. McCabe, ed.)

Automatic and portable apparatus for the determination of small concentrations of sulfur dioxide, other gases, and aerosols in the atmosphere are critically reviewed. Each type of apparatus has advantages and disadvantages for particular purposes. The accumulation SO₂ analyzers are useful when 30-minute average concentrations are adequate, though short time fluctuations can be approximated. The instantaneous-type sulfur dioxide analyzers show the short time fluctuations more clearly but require an accumulating feature for ease in summarizing the recording. Modifications of the apparatus for determination of hydrogen sulfid and other sulfur compounds of organic chlorine compounds are suggested. Hydrofluoric acid can be measured. An automatic sulfuric acid aerosol analyzer is described. The performance of portable apparatus for determining sulfur dioxide and aerosols is compared with that of the automatic analyzers. Continuous recording is essential to a complete picture of atmospheric contamination at any location. (Author summary modified)

Tsunoda, Fumio

WET COLLECTOR DETERMINATION OF WATER SOLUBLE FLUORIDE IN THE AIR BY THE ALIZARIN COMPLEXON EXTRACTION ABSORBANCE METHOD. (Arizarin Kompurekuson chushutsu kyukodoho ni yoru Taiki chu Suiyosei Fukka butsu no Shishiki hoshu sokuteiho). Text in Japanese. Kankyo Hoken Reporto (Environ. Health Rept.), no. 8:31-32, Jan. 1972. 1 ref.

The air was sampled by a regular air collector and after a test material absorption fluid in the sampling tube was filtrated, the alizarin complexon mixed solution was added to it to give a blue-purple color. Then, N, N-diethylaniline-isoamylalchol solution was added, and it was shaken and left to separate into two layers. The aqueous solution layer was thrown away. Next, to remove the turbidity in the remaining organic layer, the solution of acetic sodium trihydrate salt and glacial acetic acid in pure water was poured, stirred, and left to separate into two more layers. Again the aqueous solution layer was thrown away. The remaining organic layer was taken into a 10 mm cell and the absorbance was measured by comparison with a blank obtained through the same treatment without adding fluorine. Based upon the fluorine standard solution, a calibra-

Brown, Harry

A NEW INSTRUMENT TO READ GASEOUS FLUORIDE IN AMBIENT AIR DOWN TO FRACTIONS OF A MICROGRAM
CU M. Instr. Metals. Ind., vol. 21, 4p., 1971.

A new instrument designed to measure the amount of gaseous fluoride which may escape into the atmosphere from phosphate fertilizer plants, aluminum smelters, and certain incineration, brick, chemical, and glass works, is described. The absorber assembly or carousel consists of three glass tubes in a rotating assembly; these align to steer the airflow or solutions through the correct tube. One tube is in the air stream, and collects the fluoride gas from the air drawn through it by a vacuum pump from the atmosphere. The intake tube feeding into this sampling tube is heated to prevent condensation, which would result in dust buildup causing erratic fluoride readings. Once a sample has been collected, the three-tube assembly rotates, bringing the next tube to the air sampling position and placing the tube with the current sample in a position to be washed by a measured amount of colorimetric solution, supplied by bellows pump. This solution, containing the sample, is mixed and passed to a photometer for measurement. The MK II design allows unattended operation for long periods (over 1 wk) and produces a faithful record of the ambient air level measurements of this pollutant down to .02 microgram/cu m. A new monitoring approach is suggested using the MK n Satellite Sensing Unit, where fluoride levels about the perimeter of an industrial site can be measured, to construct Isofluons on an area map.

MEASUREMENT OF HYDROGEN FLUORIDE USING FILTER METHOD AND SEPARATE DETERMINATION OF GASEOUS AND PARTICULATE FLUORIDES. (Filta ho ni

yoru fukkasuiso sokuteiho oyobi gasujo oyobi ryushijo fukkabut-su no bunri sokuteiho). Text in Japanese. Kankyo Hoken Reporto (Environ. Health Kept.) no. 8:19-22, Jan. 1972.

For efficient collecting and separating of gaseous and particulate hydrogen fluoride, the method using alkaline filters prepared with sodium carbonate and potassium carbonate was described. Filters prepared with 1% alkaline solution have little effect on the absorbance of the alizarin complexon method and give a good collecting yield. Hydrogen fluoride is produced using various dilutions of hydrofluoric acid under 0-5 C and 20-30 C, and also using permeation tube of HF under 3-5 C and 20-30 C. Concentrations of HF obtained by both ways is 0.05-1.0 ppm. As a determination of particulate fluoride compounds, the milipore filter AA is the best for the efficient collecting and filtering nearly 100% of hydrogen fluoride. A milipore AA filter which is 50 mm in diameter and an alkaline treated filter are connected setting the flow volume at 20-30 l/min. Particulate fluoride compounds and gaseous hydrogen fluoride are measurable by this method at the sensitivity of 1 microgram/cu m and 1 ppb/2 hr. Either the Alphon method or fluoride electrode method are applicable for analysis. The temperature and humidity are independent of the collecting yield. The concentrations of fluoride compounds in the atmosphere were determined in the area of an aluminum refinery in Niigata City using alkaline filter method.

DeMaio, Larry

CALIBRATING TRACE GAS ANALYZERS WITH PERMEATION TUBES. J. Environ. Technol., 19(5):37-41, May 1972. 8 refs.

The permeation tube method for preparation of reliable, known, low concentration gas mixes has advantages over dynamic and static gas blenders. No expensive or complicated equipment is needed and accuracy is equal to or exceeds other methods. It can be considered a primary standard since it is based on weight loss per unit time. Fluorinated ethylene propylene copolymer teflon tubing was filled with n-butane and sealed with steel balls. Assuming a pickup air-flow rate of 1 to 2 cfm and room temperature, typical values of tubing length are 25 cm for 3 ppm and 225 cm for 27 ppm, permeation rates are invariable for a particular lot of tubing. Such tubes have been used successfully for anhydrous ammonia, nitrogen dioxide, anhydrous hydrogen fluoride, phosgene, hydrogen sulfide, and sulfur dioxide. Calibration takes only 4 hours. Tube life is approximately 6 mos.

Desbaumes, Paul, Eric Desbaumes, and Claude Imhoff
USE OF A FLUIDIZED SILICAGEL POWDER BED ABSORBER FOR THE MEASUREMENT OF FLUORINE EMISSIONS AND IMMISSIONS. (Emploi d'un absorbeur a lit fluidise de poudre de gel de silice pour la mesure des emissions et ininiissions de fluor). Text in French. Pollut. Atmos. (Paris), 14(53):56-61, Jan.-March 1972. 6 refs.

A portable fluidized silicagel powder bed absorber, developed for the sampling of fluorine emissions, was tested in an artificial atmosphere and in an aluminum plant area, and compared to conventional alkaline absorbers. The silicagel powder was impregnated with 3% alcoholic solution of triethanolamine, and then dried at 100 C. The sampling rate applied was 2 l/min. A comparative test of three different techniques for the extraction of the fluoride from the silicagel (maceration, maceration with simultaneous agitation, and elution) revealed the superiority of the latter method which had a maximum efficiency of 99%, depending on the amount of hot water used. Tests with different hydrofluoric acid concentrations revealed a slight decrease (below 99%) in the absorbing capacity of the fluidized silicagel bed absorber for concentrations exceeding 5 mg of F/cu m. The fluorine determination in samples from an aluminum plant area was made by means of the Belcher-West-Sulzberger method, using alizarine complexon and a sodium hydroxide solution as standard solutions.

Gutsche, B. and R. Herrmann
SIMPLIFIED FLUORINE-SPECIFIC DETECTOR FOR GAS CHROMATOGRAPHY. (Vereinfachter fluorspezifischer Detektor fuer die Gas-Chromatographie). Text in German. Z. Anal. Chem., 259(2): 126-127, April 1972. 3 refs.

A fluorine-specific flame detector described earlier was simplified by using an interference filter for the wavelength 529 nm. The detection limit was improved through this measure on the average by a factor of 1.58. Experiments with chlorine showed that the detection limit could be improved by a factor of four. The operating principle of the detector is based on the enrichment of an argon flow with metallic calcium vapor which is passed to a hot flame together with the gas chromatographic fraction.

A FLUORINE-SPECIFIC DETECTOR FOR GAS CHROMATOGRAPHY. (Ein fluorspezifischer Detektor fuer die Gas-Chromatographie). Text in German. Z. Anal. Chem., 258(4):273-277, 1972. 7 refs.

A detector is described in which a stream of metallic calcium in argon is brought into a small acetylene-oxygen flame. If fluorine compounds are added, calcium fluoride bands are observed in the flame. These can be employed for qualitative and quantitative analysis of fluorine in gas chromatographic fractions. The standard deviation was plus or minus 2.7% for flame spectrometric indication and plus or minus 2% for gas chromatographic indication. Possibilities for further development of this method are discussed.

SAMPLING, SEPARATION AND FLUORINE DETERMINATION TECHNIQUES IN ALUMINUM MANUFACTURING

PLANT-PRODUCED ELECTROLYSIS DUSTS. (Metodika otbora prob, otdeleniya i opredeleniya ftora v elektroliznykh pylyakh alyuminiyevogo proizvodstva). Text in Russian. Zavodsk. Lab. (Moscow), 38(3):278-281, 1972. 3 refs.

Various filter materials were tested and optimum conditions of fluorine separation and determination were determined. The dust samples were collected with a 0.074-micron filter made of carbon fibers. The retention for finely dispersed dust was above 99%. Preliminary extraction of hydrocarbons by benzene or trichloroethylene was followed by high-efficiency hydroxyrolytic separation in the presence of vanadium pentoxide as catalyst. The optimum conditions for the above procedure were a maximum temperature of 1100 C in the reaction zone, 95 C in the steam generator, a vapor-air mixture flow rate of 1.2 l/min, a dust sample-to-catalyst ratio of 1:1, and a reaction time of 60 min. The hydrogen compounds of fluorine that were obtained were absorbed in a basic solution. A current measurement method, based on the Zirconium substitution of iron ions in their fluoride complexes, was used for analysis. Titration with zirconium oxichloride was made after hydrochloric acid was added. The recording of the equivalent points provided high accuracy. A platinum electrode and saturated calomel were applied as reference electrode.

AN IN-SITU MONITOR FOR HCL AND HF. Preprint, American Chemical Society, Washington, D. C.; American Inst. of Aeronautics and Astronautics, New York; Environmental Protection Agency, Washington, D. C.; Inst. of Electrical and Electronics Engineers, New York; Instrument Society of America, New York, N. Y.; National Aeronautics and Space Administration; and National Oceanic and Atmospheric Administration, 7p., 1971. 12 refs. (Presented at the Joint Conference on Sensing of Environmental Pollutants, Palo Alto, Calif., Nov. 8-10, 1971, Paper AIAA 71-1049.)

A modified nondispersive infrared technique, gas filter correlation (GFC) was established as a sensitive and specific means of measuring pollutant concentrations in the presence of interfering gases. The basic idea of GFC is that a pollutant gas matching the spectral characteristics of the pollutant to be detected can be used in a reference cell and thus provide high specificity. A theoretical analysis of the GFC technique is presented. Experimental results given demonstrate that the technique can be used to measure hydrogen chloride and hydrogen fluoride concentrations of less than 0.1 ppm. (Author abstract modified)

41491

Feldstein, M. and D. A. Levaggi

THE DETERMINATION OF ATMOSPHERIC FLUORIDE WITH A SPECIFIC ION ELECTRODE. Preprint, American Chemical Society, Washington, D. C.; American Inst. of Aeronautics and Astronautics, New York; Environmental Protection Agency, Washington, D. C.; Inst. of Electrical and Electronics Engineers, New York; Instrument Society of America, New York, N. Y.; National Aeronautics and Space Administration; and National Oceanic and Atmospheric Administration, 4p., 1971. 13 refs. (Presented at the Joint Conference on Sensing of Environmental Pollutants, Palo Alto, Calif., Nov. 8-10, 1971, Paper AIAA 71-1116.)

Lime-coated filter paper can replace the use of indicator plants and proves to be an inexpensive and reliable method for detecting atmospheric fluoride. A large number of exposure sites are necessary to assure accuracy. A fluoride electrode and an expanded pH meter can be used for the rapid measurement of fluoride concentrations down to 0.02 ppm. Normal background concentrations are under 10 micrograms/mo; fluoride sources increase values to as much as 150 micrograms/mo.

41624

Monteriolo, S. Cerquiglini and A. Pepe
COMPARATIVE STUDY OF METHODS FOR THE DETERMINATION OF AIRBORNE FLUORIDES. Pure Appl. Chem., 24(4):707-714, 1970. 17 refs.

Gaseous and particulate fluorides from an aluminum plant were analyzed over a 2-yr period. The sampling, separation, and measuring procedures used in the study are described. Particulate and gaseous emissions were collected separately using a stack sampling technique in which samples are collected on a membrane filter followed by absorption in alkaline solution. The membrane filter was nearly 100% effective in collecting the particulate of the aerosol. Retention of gaseous F could be reduced to 2.4-4.9% when the stack effluent was preheated with a heating chamber which surrounds the filter holder. Preheating also enabled the use of high filtration velocities (250-600 l. gas/hr). After collection, F was separated from interfering substances by steam distillation with sulfuric acid and by microdiffusion. The microdiffusion process was preferred because of decreased operator time and recovery of larger amounts of F. The F concentration was determined by a spectrophotometric method based on decoloration of alizarin-zirconium lake which permits determination of 0.2-20 micrograms with an accuracy of plus or minus 0.06 micrograms for a 10-ml sample. The OCDE method which involves formation of a F- chelate with lanthanumalizarin complexonate was used for comparison. Results obtained by the two methods are in good agreement although the OCDE method has a better sensitivity for smaller concentrations while the alizarin-Zr method has a wider range of application. Since the mean amount of F collected in an area surrounding an Al smelter can be as high as 375-500 micrograms for 24 hr sampling the alizarin-Zr method was preferred for routine determination in the particular case of Al smelting pollution.

C. MEASUREMENT METHODS

199

Analytical methods for the determination of sulfur oxides, carbon monoxide, chlorine, hydrogen chloride, fluoride, nitrogen oxides, cadmium, and lead are reviewed. Flame photometric detectors for sulfur dioxide analysis were studied. The sample was mixed with oxygen, and then burned with hydrogen flame, and the intensity of the absorbed light of wavelength at 394 millimicron was measured. By this method, the SO₂ can be determined as low as the ppb levels. Flame ionization detection for CO and carbon dioxide determination as methane is also considered. The limits for chlorine discharge, hydrogen chloride, and fluoride emissions are set at 30, 80, and 1-20 mg/cu m, respectively; methods for determinations of these pollutants at or below these levels are included. Although no regulations are established for odorous compounds, the list will include ammonia, methyl mercaptan, ethyl mercaptan, dimethyl sulfite, diethyl sulfite, hydrogen sulfite, methyl amine, ethylamine, trimethylamine, butylene, butyric acid, acetone, and acrolein.

Tsuchihira, Kazuyoshi

MEASUREMENT METHODS IN PUBLIC NUISANCE--ESPECIALLY ON MEASUREMENT METHODS PROVIDED BY THE REGULATIONS FOR PUBLIC NUISANCE. (Kogai no sokuteiho?Kogaiho kankeihoreichu no kensaho o chushin ni site) Text in Japanese. Nippon Eiseikensa Gishikai Zasshi (Jap. J. Med. Technol.), 21(5):524-S32, May, 1972.

Measurement methods are divided into two types. One for measuring environmental factors and the other for examining man's health. Pollutants are classified into dust, soot, suspended particulate matter, dust fall, sulfur oxides in smoke, sulfur oxides in air, harmful substances such as cadmium and its compounds, bases, hydrogen chloride, fluorine, hydrogen fluoride, silicon fluoride, lead and its compounds, nitrogen oxides, carbon monoxide, lead compounds, nitrogen oxides contained in automobile exhaust gases, oxidants, and 28 special deleterious substances including ammonia, hydrogen sulfide. Measurement methods for each pollutant are discussed based on the Air Pollution Control Law. As for dust fall and special deleterious substances, measurement methods have not been settled. Measurement methods of noise level based on the Noise Regulation Law are stated.

42375

X-RAYS USED IN AIR POLLUTANT DETECTION. (Roentgenstrahlen als Detektive der Luftverschmutzung). Text in German. Technica, 21 (10):909, May 1972.

A Diemens Sequence x-ray Spectrometer with tabulator control is used for the x-ray fluorescence analysis of air pollutants at an air pollution monitoring station in West Germany. This technique, suitable for the detection and quantitative determination of elements with atomic numbers ranging from 9 (fluorine) through 92 (uranium), permits comprehensive test series to be performed automatically in relatively short time. The aerosol samples (precipitation or filter deposits) are irradiated with high-intensity X-rays, and the spectral breakdown of the secondary radiation thus generated is made by means of an analyzer crystal to determine the composition of the sample and the quantitative proportion of certain elements. Automatic evaluation of nine preselected spectral lines is possible, whereas the tabulator control can be extended to a maximum of 36 spectral lines. The data are punched on punch cards for central data processing. Highly sensitive detection methods for sulfur and fluorine have been elaborated.

42926

COMMUNITY AIR SAMPLING. In: Air Pollution Manual. Part I. Evaluation. Detroit, American Industrial Hygiene Assoc., 1960, Chapt. 8, p. 77-94. 78 refs.

Two important factors in measuring the concentration of a pollutant in the atmosphere are the specificity and the sensitivity of the instrumentation available for measurement. Other important factors in sampling are the time period over which each sample is taken, the number and size of samples to be collected, location of sampling stations, and alteration of collected substances during and after collection. Effects of elevation and topography, diurnal variations, and seasonal variations are considered. The choice of instruments to evaluate air pollution levels will vary according to the condition being assessed and the use to be made of the data. Dustfall sampling is described. The sampling of air particulate matter may be accomplished by filter samplers, impingement apparatus, precipitators, and photometric instruments, as well as by other aerosol sampling devices such as the beryllium air monitor and pollen sampling apparatus. Methods of collecting gaseous matter are indicated, including instrumentation for the determination of sulfur dioxide, carbon disulfide, hydrogen sulfide, cyanides, fluorides, nitrogen oxides, ozone and total oxidants, carbon monoxide, and trace organic gases. In any community type sampling program for air pollution evaluation, the meteorology and topography of the area are extremely critical.

42928

CHEMICAL PROCEDURES. In: Air Pollution Manual. Part I. Evaluation. Detroit, American Industrial Hygiene Assoc., 1960, Chapt. 10, p. 111-131. 234 refs.

The analysis of particulate matter collected from the atmosphere involves consideration of aspects other than chemical content; for instance, one of the most important indices followed in air pollution assessment is the atmospheric loading/unit of surface area and/unit of volume. The introduction of new techniques, such as electron microscopy, has made it possible to carry out more searching assessment of the morphology and other physical properties of particulates. Aluminum and aluminum oxide may be determined spectrographically and colorimetrically, while procedures based on the formation of molybdenum blue or reactions with silver diethyldithiocarbamate in pyridine can be used to determine arsenic. Spectrographic, fluorometric, and colorimetric procedures can be used to identify beryllium, while a spectrographic and an electrochromatographic technique are available for boron determinations. Analytical methods are also indicated for the determination of calcium, cadmium, carbon monoxide, chlorine, chromium, fluorine, iron, lead, magnesium, manganese, nickel, the nitrogen oxides, ozone, peroxides, and other oxidants, silicon dioxide and silicates, sulfur dioxide, sulfur trioxide, sulfuric acid, hydrogen sulfide, and zinc. The identification and quantitative determination of organic substances is discussed, with particular reference made to organic acids, aldehydes, amines, hydrocarbons, ketones, phenols, proteins, quinones, and sulfur compounds.

Task 1V014501B53A-13, ECOM-5085, 8p., Oct. 1966. 1 ref.

NTIS: AD 644817

A reagent has been discovered whereby the techniques of dispersion staining microscopy and spot testing may be combined to distinguish halite (sodium chloride) from quartz in atmospheric dust samples. The reagent, referred to as the 4BR reagent, is a solution of ethyl salicylate, phenol, 1-bromonaphthalene, and mercurous perchlorate. The preparation of the reagent and its application are discussed. The use of 4BR improves the accuracy and ease of counting quartz particles in samples of atmospheric dust by excluding halite from the count. The reagent obviates polarized light and rotation of the microscope stage in distinguishing halite from quartz. The differentiation of these two minerals by dispersion staining microscopy is a problem with the smaller particles. The simultaneous determination of submicron particles of quartz, halite, other soluble chlorides, fluorides, bromides, iodides, and sulfates may be possible by modifying the composition of the reagent. Zurlo, N.

METHODS FOR THE DETERMINATION OF FLUORINE COMPOUNDS IN THE WORKING AND ENVIRONMENTAL ATMOSPHERE OF ALUMINUM REDUCTION PLANTS.

Preprint, American Inst. of Mining, Metallurgical and Petroleum Engineers (AIME), New York, N. Y., 15p., 1971. (Presented at the American Institute of Mining, Metallurgical and Petroleum Engineers, Annual Meeting, 100th, New York, Feb. 26-March 4, 1971.)

During electrolytic production of aluminum, gases and dusts may escape into the atmosphere and, of these, dusts of solid fluorine compounds and of its gaseous derivatives are of special interest. Fluorine checks must be performed in the air around the plants, in the area of the work departments, in the urine of the workers, and in plants. Routine methods for accomplishing these analyses use both microdiffusion with sodium hydroxide absorption and colorimetric analysis and an electrode sensitive to fluorine ions. Equipment, calibration, and analytical procedures are described.

Katz, Morris

THE STANDARDIZATION OF METHODS OF SAMPLING

AND ANALYSIS. Intern. Clean Air Conf. Proc., England, 1959, p. 147-152. 26 refs.

For purposes of sampling and measurement, air pollution can be classified as particulate matter, gaseous or vapor products, and radioactive compounds. Various sampling and analytical procedures in use and the criteria for the procedures are discussed. Items suggested for international standardization include the definition of terms and units, dustfall, smoke and suspended particulate impurities, sulfur dioxide, nitrogen oxides, ozone or oxidants, hydrocarbons, carbon dioxide and carbon monoxide, aldehydes, and fluorides. Measurement methods for dustfall, suspended impurities, sulfur dioxide, and fluoride are reviewed. The planning of air pollution surveys, selection of sampling sites, choice of instruments and sampling methods, analytical procedures, and the treatment and correlation of data should receive coordinated attention and clarification.

Katz, M.

GAS ANALYSIS. In: Measurement of Air Pollutants. Guide to the Selection of Methods. Geneva, World Health Organization, 1969, Chapt. 4, p. 42-48, 116-123. 282 refs.

Analytical methods that are highly specific for given gaseous compounds are limited to the measurement of intrinsic properties of the molecule, to the formation of unique reaction products or complexing agents, or to the prior removal of interfering substances by precipitation, reaction, distillation, di-

alysis, or filtration. When such procedures are not available, the analytical techniques and methods of calibration must be rigidly standardized. The overall nature of community air pollution and its sources has an important bearing on the validity of nonspecific analytical data. The most common gaseous pollutants include sulfur dioxide, hydrocarbons, nitrogen oxides, carbon monoxide, ozone, phosphates, chlorine, fluorides, nitrates, and cyanides. In evaluating and selecting methods for gas analysis the paramount parameters include the efficiency of sample collection; the stability of the reagents and reaction products; the ease of calibration; and the degree of simplicity, specificity, sensitivity, reproducibility, and accuracy of the procedure. Automatic monitoring and sampling instruments use three general methods: continuous sampling, batch-type sampling, and dosimetric sampling. The methods may be based on principles of electrolytic conductivity, electrolytic titrimetry, measurement of electrolytic current or potential, colorimetry, turbidimetry, photometry, fluorimetry, and infrared or ultraviolet absorption spectrometry. Operating characteristics are reviewed for spectrometry, gas chromatography, neutron activation analysis, flame ionization detectors, clathrate compounds containing tritium, and neutron activation, have provided new methods for analyzing gases in the atmosphere.

Katz, M.

RAPID METHODS FOR THE IDENTIFICATION AND MEASUREMENT OF AIR POLLUTANTS. In: Measurement of Air Pollutants. Guide to the Selection of Methods. Geneva, World Health Organization, 1969, Chapt. 6, p. 54-59, 116-123. 282 refs.

Indicator tubes and test papers, ring oven methods, and biological indicators are reviewed as rapid methods for the identification and measurement of air pollutants. Indicator-tube methods can detect minute amounts of gas in a short time by means of portable and inexpensive equipment. A pollutant gas causes a change in the color of a reagent packed in the tube; comparison with color standards or measurement of the length of discoloration can be used to determine the concentration of the gas. To achieve quantitative results, a known volume of air must be drawn through the tube at a constant rate; other gases present in the air must be removed. Potential sources of error include variations in tube diameters, temperature variations, and inaccurate estimation of stain length or color intensity. Test-paper methods may be used for qualitative or semi-quantitative measurement of gaseous pollutants; the paper is exposed to the atmosphere for a known time, and the degree of color change is measured by comparison with color standards. The ring oven technique is a convenient method for studying aerosol pollutants; the samples are collected on paper tape and the analyzing steps are conducted directly on the tape placed on the ring oven. This method will detect inorganic ions in nanogram to microgram quantities, and accuracies of 80-90% can be attained by simple visual matching with a series of standard rings. Biological indicators

C. MEASUREMENT METHODS

201

are useful in detecting low concentrations of toxic gases that are difficult to detect by other simple means. Chemical analyses of leaves or studies of symptoms can aid in assessing the nature and magnitude of many pollutants, including sulfur dioxide, fluorides, chlorine, hydrogen fluoride, ammonia, hydrogen sulfide, photochemical smog, ozone, hydrocarbons, sulfuric acid aerosol, smokes, and metal compounds as particulate matter. Lichens as indicators of pollution in urban areas are also examined.

Katz, M.

NONAUTOMATIC METHODS FOR THE DETERMINATION

OF AIR POLLUTANTS. In: Measurement of Air Pollutants.

Guide to the Selection of Methods. Geneva, World Health Organization, 1969, Annex 4, p. 67- 99, 116-123. 282 refs.

The basic principles and procedures, sensitivity, apparatus, and reagents for various nonautomatic methods for the determination of particulate and gaseous pollutants in air are reviewed. Substances reported to cause interference are also included. Methods for analysis include spectrophotometry, the MBTH method, the distillation method, colorimetry, the fluorimetric method, spectrographic methods, the indicator tube method, iodine pentoxide method, infrared spectrometry, a microdiffusion method, nephelometric methods, the Saltzman method, turbidimetry, the West and Gaeke method, the conductimetric method, polarography, and the lead peroxide method. The pollutants which may be determined by the specified methods include acrolein, aliphatic aldehydes, ammonia, arsenic, beryllium, cadmium, carbon disulfide, carbon monoxide, chlorine, chromium trioxide and salts of chromic acid, inorganic fluorides, formaldehyde, hydrochloric acid, chlorides, hydrogen cyanide, hydrogen sulfide, lead, manganese, methanol, nitrates, nitric oxide, nitrogen dioxide, oxidants, phenols, particulate sulfates, sulfur dioxide, and sulfuric acid mist.

Katz, M.

AUTOMATIC SAMPLING AND MONITORING INSTRUMENTS.

In: Measurement of Air Pollutants. Guide to the Selection of Methods. Geneva, World Health Organization, 1969, Annex 5, p. 100-113, 116-123. 282 refs.

The basic principles, sensitivity, and operating procedures of various automatic instruments for the sampling of air and the monitoring of gaseous contaminants are reviewed. Substances reported to cause interference are also included. The methods include colorimetry, infrared spectrometric methods, potentiometric methods, electrolytic galvanometric methods, fluorimetry, conductimetric methods, the potassium iodide method, titrimetric methods, coulometry, ultraviolet spectrometry, photometric methods, and iodimetric methods using impingers and bubblers for sampling. The gaseous contaminants to which these methods are applicable include carbon monoxide, hydrocarbons, hydrogen cyanide, hydrogen sulfide, hydrogen fluoride, nitric oxide, nitrogen dioxide, oxidants, ozone, and sulfur dioxide.

Jahr, Jorgen

A NEW DOUBLE FILTER METHOD FOR THE SEPARATE DETERMINATION OF HYDROGEN FLUORIDE AND DUST-

LIKE FLUORIDES IN THE AIR. (Eine neue Doppelfiltermethode zur separaten Bestimmung von Fluorwasserstoff und staubfoermigen Fluoriden in der Luft). Text in German. Staub, Reinhaltung Luft, 32(6):248-252, June 1972. 2 refs.

The method was developed for personal sampling, but is also suitable for other purposes. The air is drawn through two successive filters in one holder. The first filter is untreated, the second impregnated with sodium formate. Particulate

fluorides are collected quantitatively on the first filter, whereas hydrogen fluoride is found on both. By heating for 20 hr at 75 C in the closed filter holder, the HF collected on the untreated filter is transferred quantitatively to the second, impregnated filter. Leaching the two filters separately after the heat treatment allows the determination of the fluoride ion on each filter by the use of a fluoride-ion specific electrode. The suitable range of the method is approximately from 0.4 micrograms F (-) and upwards for the particulate, and between 0.4 micrograms and 5 mg for HF. (Author summary modified)

Fischer, G. and H. Brantner

STUDIES OF THE AIR-POLLUTANTS IN THE GRAZ AREA, 6TH REPORT: INVESTIGATIONS INTO THE CORRELATIONS BETWEEN THE SULFATE CONTENT AND FLUORIDE CONTENT OF THE LEAVES OF FAGUS SILVATICA (COPPER BEECH), AND THEIR SIGNIFICANCE FOR THE DEMARCATION OF EMISSION-AREAS IN LARGE TOWNS. (Studien ueber die Luftverunreinigungen im Raume Graz 6. Mitteilung: Untersuchungen ueber die Korrelativen Beziehungen zwischen dem Sulfat- und Fluorgehalt im Laub von Fagus silvatica L. (Rotbuche) und ihre Bedeutung fuer die Abgrenzung von Immissionsgebieten in Grossstaedten). Text in German. Zentralbl. Bakteriол., Parasitenk., Infektionskr. Hyg., Abt. 1: Orig., Reihe B, 155(5-6):435-444, 1972. 22 refs. Determinations were made of the sulfate ion content of leaf samples of Fagus silvatica L., which had grown in districts characterized by different emission concentrations. The values thus obtained were compared with the fluoride contents determined in parallel thereto. The highest concentrations of ions were found in the densely built-up regions. The fluoride ion content gradually decreased through the less densely built-up suburbs toward the open country, but the sulfate ion values remained unchanged throughout the suburban region, and then fell to normal values in the open country. If the sulfate and fluoride values found in the urban area are compared with those found in the open country, the difference is found to be significant. The calculation of the correlation coefficients for the individual groups showed a relationship that lay in the same direction but was not very close in any instance. The lowest correlation coefficient was obtained from the comparison of the fluoride and sulfate values in the urban area. Thus these two parameters are completely independent of each other. The variation of the fluoride concentration in the foliage closely corresponds to the distribution that has been discovered on the basis of lichen, urine, and sulfur dioxide analyses. Therefore, the determination of fluoride in plant samples is preferred to that of sulfate, for the qualitative determination of the extent of emission area in large cities. STUDIES ON AIR POLLUTION IN THE GRAZ REGION. 5TH REPORT: THE EFFECT OF EMISSION OF FLUORINE ON THE GREEN AREAS OF A LARGE TOWN. -EXPERIMENTAL INVESTIGATIONS ON FAGUS SILVATICA L. (COPPER BEECH). (Studien ueber die Luftverunreinigungen im Raume Graz 5. Mitteilung: Der Einfluss von Fluorinunissionen auf die Gruenflaechen einer Grossstadt.- Experimentelle Untersuchungen an Fagus silvatica L. (Rotbuche)). Text in German. Zentralbl. Bakteriол., Parasitenk., Infektionskr. Hyg., Abt. 1: Orig., Reihe B, 155(5-6):42S-434, June 1972. 8 refs. <xref image="2000WVFL.TIF|V3|2006:09:28:01:27:56.00|120892|0"> image: </xref>

Leave samples for fluoride determination were taken from Nov. 1 to Dec. 1 of 1969 and 1970. In the entire period little precipitation fell. For the chemical analysis 5 g of dried pulverized leaves were wetted with 20 ml of calcium hydroxide solution, dried again, and ashed. The ash was then mixed with 60 ml of 75% sulfuric acid. After transfer to the distillation apparatus, 5 ml of 5% perchloric acid were added. After distillation, bidistilled water was used for dilution; 5 ml of the diluted substance was mixed with 5 ml buffer. The fluoride concentration was determined by means of an ion specific electrode. The highest fluorine levels were found in the dense city area and the directly adjoining suburban zone. Peak values between 27 and 48 ppm fluoride ions were measured in the dense northern and northwestern sections of the city. An explanation for this can be given by considering the meteorological conditions during the summer months. Winds from south to southeast prevail in this period. All air pollutants from the southern city areas are transported toward the northern and northwestern mountain barriers. In this area there are several large industries which pollute this section of the city. The mountain barrier prevents the dispersion of the polluted air. Pollutants are transported only by thermal buoyancy and on the few days with winds from the west or northwest.

PROBLEMS OF MEASURING EMISSION OF GASES AND THEIR CONCENTRATIONS IN POWER STATIONS AND THEIR SURROUNDINGS. (Problems der Emissions- und Immissionsmessung von Gaskonzentrationen in Kraftwerken und deren Umgebung). Text in German. GIT (Glas-Instrum.-Tech.) Fachz. Lab., 16(6):729-733, June 1972. 5 refs.

The specific problems of measuring pollutant concentrations at and around thermal power plants and waste incinerators, as well as suitable measuring techniques are described. Power plant stacks of 80-100 m height have an action radius of about 3 km at wind speeds of 3-4 m/sec. Sulfur dioxide, carbon dioxide, and dust concentration recording is required for steam boilers with capacities exceeding 150 tons/hr. Carbon dioxide measurements are usually made by means of infrared absorption techniques. The measurement of the ultraviolet absorption represents a highly selective method for determining SO₂ concentrations in a range of 0-2000 ppm, and also conductivity measurements and photometric procedures are suitable for SO₂ determination. Waste gases from waste incinerator plants may contain 0.5-3 mg of SO₂, 20-100 mg of sulfur trioxide, 0.2-1 g of hydrochloric acid, 0-10 mg of Hydrofluoric acid, 0-1 g of chlorine, 0-100 mg of phosgene, and 0-2 of nitrogen oxides/cu m. The sampling is made at a temperature of 800-1000 C. The sampling for HCl and HF should be made by means of a heated tube, and for SO₂, nitrogen dioxide, and nitric oxide by means of a gas cooler and membrane filter. Ion-sensitive electrodes are used for HF and HCl determination, and photometric or conductivity measurement procedures are suitable for the selective determination of chlorine and phosgene. Infrared and ultraviolet absorption techniques are used for SO₂ and NO₂, while SO₃ can be determined by means of conductivity measurement or photometry, using isopropanol as the reagent.

Ogihara, T.

MEASURING APPARATUS FOR TOXIC GASES. (Yudoku gasu no sokutei kiki ti. tsuite). Text in Japanese. Nenryo Oyobi Nensho (Fuel and Combustion), 38(12):1217-1220, 1971. Several effective apparatuses for measurements of toxic gases are introduced. The TOXGAKD is designed for the detection of hydrogen cyanide, hydrogen sulfide, and chlorine based on the fact that electric current occurs when these components react with an electrolyte. The measurement ranges are 0 to 50 ppm for HCN and H₂S, and 0 to 5 ppm for Cl₂, and the

response is instantaneous. The CO-ALARM, N701 is for the continuous monitoring of carbon monoxide in air. The measurement range is 0 to 500 ppm and the accuracy less than 1 % of FS. The time of response is less than 45 seconds. The BIL-LION-AIRE is for the detection of trace gas in air or in a process gas flow, especially for C12 from 0 to 50 ppm, phosgen from 0 to 50 ppm, hydrogen chloride from 0 to 10 ppm, hydrogen fluoride and ammonia from 0 to 50 ppm, and nitrogen oxides from 0 to 300 ppm. The accuracy is about + or -2% of FS, and time of response is 10 seconds. Detectors for combustible gases for preventing explosions and for sulfur dioxide are also mentioned.

44285

ENVIRONMENTAL MONITORING GOES AUTOMATIC.

Mod. Power Eng., 66(6):62-63, June 1972.

Automatic monitoring of air quality on municipal and national levels and its advantages for predicting future pollutant concentration levels are discussed. Modern monitoring systems can provide remote, unattended monitoring of air and water quality, gather meteorological data, and give alarms or immediate on-line transmission of data to a central point to allow prompt corrective action to be taken. A typical installation monitors meteorological data. Automatic sampling and monitoring instruments are available for parameters concerning typical air quality measurements including: sulfur dioxide, nitrogen oxides, particulate matter, hydrocarbons, chlorine, fluoride, ozone, and mercury. The city of Toronto, Canada is duplicated in a mathematical model used by the air quality branch of Environment Ontario to demonstrate and predict the relationships between various air quality factors in the city. There is also the nucleus of a central environmental monitoring system operating on a national basis. The national air quality surveillance system brings together data collected from air monitoring stations across Canada for computer analysis and comparison. Operations of this system are presently limited largely to analysis and reporting of data. If emissions of all plants could be measured on a minute-by-minute basis by the appropriate pollution control authorities, there could be no better protection against uninformed and biased attacks by environmental groups and environment quality control agencies.

STUDIES ON HYGIENIC CHEMISTRY OF AIR-POLLUTANTS (1). MEASUREMENT OF FLUORIDES IN THE AIR.

(Taiki osen busshitsu no eisei kagaku ni kansuru kenyu (1): taikichu no fukkabutsu no sokutei ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 4(1):112, 1969. (Presented at the Japan Society of Air Pollution, Annual Meeting, 10th, Tokyo, Japan, 1969, Paper 111.)

The effects of types and concentration of absorbent for gaseous fluorides (usually dilute sodium hydroxide) on absorption speeds and quantity of fluoride absorption were examined. Co-existing ions in the atmosphere act as obstacles in measuring fluorides. Since ions could not be separated, an estimate was obtained from the lab measurements of ions, and limits of influences were determined. The fluoride steam distillation

<xref image="2000WVFM.TIF|V3|2006:09:28:01:27:58.00|122699|0"> image: </xref>

C. MEASUREMENT METHODS

203

separation method was examined. As a result of a recovery rate test, the temperature of distillation was found to influence fluoride separation and elimination of obstacles. When measuring particle fluorides, the amount of fluoride contained in the filter influences the measurement in the air. An analysis of a sampling filter showed that a considerable amount of fluoride was contained in the filter itself.

Largent, Edward J.

CHEMICAL ANALYSIS OF TRACE QUANTITIES OF FLUORIDE. In: Fluorosis. The Health Aspects of Fluorine Compounds. Columbus, Ohio State Univ. Press, 1961, Chapt. 11, p. 101-108.

In the Willard and Winter method for separating a fluoride from interfering substances, the ashed biological sample is boiled in a distilling flask with an acid, sulfuric or perchloric. Water is added as drops of liquid or as a jet of steam and the operation continues until all of the fluoride has been distilled out of the ash. The volumes of distillate may vary between 100 and 500 ml. Once fluoride has been separated from the ashed sample, it may be assayed by measuring its bleaching effect on certain colors. The thorium-alizarin titration is the fastest colorimetric procedure for measuring fluoride in distillate. Several techniques have been used for carrying out the thorium-alizarin titration, including back titration, direct titration, and titration against a permanent color standard. The entire analytical procedure from collection of samples to titration of distillate is described in detail. Reliability of determinations is quite satisfactory for samples of air, water, urine, feces, and bone.

Lemoine, R

MONITORING METHODS FOR THE GASEOUS EF-FLUENTS OF ALUMINUM PLANTS. Preprint, American Inst. of Mining, Metallurgical, and Petroleum Engineers (AIME), New York, N. Y., 10p., 1972. (Presented at the American Inst. of Mining, Metallurgical, and Petroleum Engineers Annual Meeting, New York, Feb. 26-March 4, 1971.)

The methods used by aluminum plants to monitor gas-scrubbing processes are still rather empirical and the rigorous distinction between gaseous and solid fluorides is not possible due to the lack of precise knowledge of the adsorption and desorption properties of the solids. It is very difficult to get an accurate measure of the gas flow, and thus to know the actual amount of released fluorides. There is a pressing need for international standardization, mainly in sampling methods, to allow the aluminum producers to make process comparisons. These same difficulties exist for ambient air measurements of gaseous and solid fluorides. The relative toxicities of the solid fluorides are not well understood. Two general approaches exist for measuring the atmospheric concentration of gaseous fluorides. Automatic apparatus give punctual short-term data, but this data requires further data processing and the equipment is expensive. The inexpensive static methods in existence yield abundant but inaccurate data. Sampling procedures are discussed and special precautions for avoiding the common pitfalls of fluoride determination are outlined.

Jackson, Melbourne I.,.

PARTICLE-MOLECULE COLLECTION BY SONIC FLOW

IMPINGERS. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 31p., 1972. 20 rcfs. (Presented at the Air Pollution Control Association, Annual Meeting, 65th, Miami, Fla., June 18-22, 1972, Paper 72-6.)

A convenient, inexpensive, and sufficiently accurate method of sampling molecular and near micron and submicron particles, is described. Utilization of two sonic-flow impingers in a series is predicted to collect 98 to 99% of a phosphoric acid aerosol having a mass median diameter of 0.7 micron. The first impinger simultaneously collected 90 to 98% of the aerosol and 95% of molecular fluoride compounds in a field test. On the same aerosol, the standard Greenburg-Smith impinger had a low collection performance, less than 65% at sonic velocity. The utilization of a fust impinger at sonic flow greatly simplifies sampling procedures by the need for a test meter and associated pressure and temperature measurements. Also, for small particle sizes, isokinetic sampling is not necessary and sampling line losses by deposition are less than 1%. The low initial cost of the sampling units and the low manpower requirements for setting up and supervising sampling make possible the taking of a number of samples sufficient to establish emissions over extended intervals of time. The equipment is especially suited to locations having multiple emission sources, or for locations requiring simultaneous sampling of many points. (Author abstract modified)

ADSORPTION INDUCED ELECTRODE POTENTIAL (AIEP)

CELLS FOR GAS AND VAPOR DETECTION. Preprint, General Foods Corp., White Plains, N. Y. and City Coll., New York, Dept. of Chemistry, 27p., 1969 (?). 11 refs.

Adsorption Induced Electrode Potential (AIEP) cells, can, by the judicious choice of electrode material and cell electrolyte, be made sensitive to either ionizable or non-ionizable vapors. The principal feature of the cell is a partially-exposed sensing electrode which permits the gaseous sample to react at the exposed electrode without prior dissolution of the vapor in the bulk electrolyte. The basic designs of AIEP cells for detection of halogen ions, acidic vapors, alcohols and aldehydes, aromatic compounds, pyrolytic products of halogenated solvents, hydrogen fluoride and its salts, carbon dioxide, ketones of low molecular weight, hydrogen sulfide, and basic vapors are described. Operational factors, including choice of electrochemical reaction, selection of detection potential, cell calibration, consideration of cell response mode and response time, and cell lifetime and sensitivity are discussed. The present AIEP concept is applicable to relatively volatile compounds (boiling point less than 180 C) because the cells cannot operate at high temperatures for any significant period of time. In addition, the vapor must be soluble in the cell electrolyte, otherwise it will be preferentially desorbed from the gas/liquid interface back into the vapor phase. The exception to this is

<xref image="2000WVFN.TIF|V3|2006:09:28:01:28:02.00|120171|0"> image: </xref>

the case where the vapor reacts chemically with the electrolyte to produce an electroactive species.

CONTRIBUTION TO THE STUDY OF THE FLUORINE-CARBON REACTION. III. DETECTION AND ANALYSIS OF ELEMENTARY FLUORINE. (Contribution a l'etude de la reaction fluor-carbone. III. - Detection et analyse du fluor elementaire). Text in French. Bull. Soc. Chim. France, no. 6:2203-2207, June 1972. 10 refs.

An instrument and method for the detection of elementary fluorine in air are described. The method is based on the variations in the electric conductivity of activated carbon caused by fluorine-contaminated air. Because a single carbon-filled measuring cell loses its reactivity to fluorine within a few hours, due to humidity forming hydrofluoric acid with elementary fluorine, a double-cell detector was developed. The air sampled at a rate of 7 l/min is first cooled to -30 C and then heated to 50 C before entering the first, non-selective measuring cell. Readings induced by agents other than elementary fluorine in the first cell are canceled by the selective second measuring cell which is filled with fresh activated carbon. The detection of fluorine concentrations of 0.04-8 ppm takes 1 min. The grain size of the activated carbon ranges from 0.200 to 0.315 mm. No interference due to water vapor, hydrochloric acid, and chlorotrifluoromethane was observed.

45760

D.P.R. APRIL 15, 1971, NO. 322: REGULATION FOR THE IMPLEMENTATION OF LAW NO. 615 OF JULY 13, 1966 DEALING WITH AIR POLLUTION CONTROL MEASURES APPLICABLE TO INDUSTRY. (D.P.R. 15 Aprile 1971, N. 322: Regolamento di esecuzione della legge 13 luglio 1966, N. 615, recante provvedimenti contro l'inquinamento atmosferico, limitatamente al settore dell'industria). Text in Italian. Igiene Sanita Pubblica (Rome), 27(9-10):429-432, Sept.-Oct. 1971. The implementation regulation described, issued by the Ministero della Sanita, Direzione Generale Igiene Pubblica, is based on emission control at ground level where it has the strongest impact on public health. The law requires that its provisions be taken into consideration as early as the planning stage of the construction of an industrial enterprise, and that the best available pollution control technology be employed. All construction plans must be submitted to a regional committee which must render a decision within 60 days. Air samples must be drawn from around each enterprise at an altitude between 1.5 and 3 m above ground or above each obstacle. The regulation contains 13 supplements: supplement 1 and 2 deal with test instruments and test procedures; no. 3, with the determination of suspended inert particulates; no. 4, with SO₂ determination; no. 5 with the colorimetric determination of chlorine; no. 6 with the determination of hydrochloric acid; no. 7 with the potentiometric and colorimetric determination of fluorine compounds; no. 8 with the colorimetric and potentiometric determination of hydrogen sulfide; no. 9 with the colorimetric determination of nitrogen oxides; no. 10 with the determination of suspended lead in the atmosphere; no. 11 with the spectroscopic determination of carbon monoxide; no. 12 with the determination of hydrocarbons from refineries by flame ionization methods; and no. 13 with the determination of free crystalline silica in particulate emissions by an X-ray diffraction method. In the choice of techniques three criteria have been considered: sampling efficiency, analytical specificity, and sensitivity, and feasibility of performing the test in a laboratory equipped with conventional instruments.

Luiga, Peeler, Reel Liiv, and Roman Ott
INVESTIGATION OF THE LA/AC COLORIMETRIC
METHOD FOR THE DETERMINATION OF AIRBORNE
FLUORIDES. Preprint, Air Pollution Control Assoc., Pitts-
sburgh, Pa., 13p., 1972. 5 refs. (Presented at the Air Pollution
Control Association, Annual Meeting, 65th, Miami, Fla., June
18-22, 1972, Paper 72-1.)

The influence of various test conditions was investigated in
the lanthan-alizarin complexan (La/AC) and fluoride reaction
in order to establish optimum conditions for achieving high
sensitivity and reproducibility of measurements.
Photocolorimetric investigations were made in both the visible
and the ultraviolet region of the spectrum. Solutions of stan-
dard fluoride, alizarin-complexan, lanthan-nitrate, and acetate
buffer were prepared. Acetone, acetonitrile, methanol,
ethanol, propanol dioxane, and dimethylformamide were com-
pared for their effects on solution sensitivity. Of the tested
solvents, acetone was the most suitable; its optimum rate in
the final solution was 33%. Introduction of acetone cut down
the stabilizing time in the reaction of the La/AC solution with
the fluoride sample from 1 hr to 20 min, and sufficiently sta-
bilized the solution for 24 hrs or more. Difference in optical
density at 618 micron between the test solution and the cor-
responding blank appeared to be a maximum at pH 4.3. In the
ultraviolet region of the spectrum at 280 micron, methanol,
ethanol, propanol, and dimethylformamide were utilized
because of the high absorbance of acetone. As a result, the
sensitivity in the ultraviolet region was more than 50% higher
than the sensitivity in the visible region. Except for sulfite, all
the ions investigated had approximately the same effect on the
density of the test solution in both the visible and the ul-
tra violet region. The diverse interference of sulfite was
eliminated by its oxidation with hydrogen peroxide. The
diverse effect of total sulfates was eliminated by their
precipitation with benzidinhydrochloride. Aluminum ion was
successfully eliminated by kationite. The ratio of lanthanum
(III) to alizarin-complexan solutions, the rate of buffer, the
type and the amount of the organic solvent and the pH value
have considerable effect on the sensitivity of the method. The
optimum values of these factors are in some cases dependent
upon each other and on the fluoride concentration. (Author ab-
stract modified)

MONITORING IN AIR POLLUTION CONTROL. Preprint,
New Hampshire Univ., Durham and Air Pollution Control As-
soc., Pittsburgh, Pa., 14p. 1971. 9 refs. (Presented at the Air
Pollution Sampling Seminar, Windsor, Conn., Oct. 27, 1971.)
The impact of the 1970 Clean Air Act on air monitoring should
increase the demand for source and ambient air sampling
equipment by 500 to 700% in the 25-year period from 1975 to
2000. During this period, additional personnel, technicians, and
instrumentation personnel will have to be added to the staff of
governmental agencies and industrial firms. Because of the
enormity of the task and the lowering of emission and air
quality standards, more refined and less costly equipment for
monitoring particulates, sulfur dioxide, nitrogen oxides, carbon
oxides, mercury, hydrocarbons, chlorine, metals, hydrogen
sulfide, hydrogen fluoride, fluorides, oxidants, odors, and
other pollutants will also have to be developed. In addition,
remote units for industrial monitoring and unitized equipment,

C. MEASUREMENT METHODS

205

such as portable gas chromatographs, will also be in demand in the near future. Ambient and source sampling methods include colorimetry, coulometry, conductivity, infrared spectrometry, flame ionization detection, and Orsat analysis. The development and operation of a monitoring network is outlined.

RAPID METHODS FOR THE DETERMINATION OF NOX-
IOUS SUBSTANCES IN THE AIR. (Bystryye Melody
Opredeleniya Vrednykh Veshchestv Vozdukhe). p. 9-10, 17-41,
47-59, 62-70, 80-97, 182-186, 253-254, 1962. 22 refs. Translated
from Russian. Foreign Technology Div., Wright-Patterson AFB,
Ohio, Translation Div. 103p., April 8, 1971. NTIS, DDC: AD
726795

One of the most important aspects for safeguarding human health is the monitoring of the air in the plant, shop, or work environment. Rapid methods for determining a large number of substances which have a toxic effect upon the human organism are described. Sampling methods, method of preparing mixtures of toxic substances with air, calibration methods, and analytical procedures for the determination of oxides of nitrogen, hydrogen sulfide, sulfur dioxide, hydrogen cyanide, hydrogen fluoride, fluorine, and chlorine are included. Samplers include aspirators, absorption devices, and diffusion bottles. Colorimetry is the major analytical method discussed.

Rechenberg, W.
RAPID DETERMINATION OF FLUORIDE IN RAW
MATERIALS, CLINKERS AND DUST IN CEMENT MANU-
FACTURE. (Schnellbestimmung von Fluorid in Rohstoffen,
Klinkern und Staeben der Zementherstellung). Text in Ger-
man. Zement-Kalk-Gips (Wiesbaden), 25(9):410-416, 1972. 25
refs.

At least 90% of the fluoride entering the cement kiln with the raw material leaves the kiln with the clinker. The rest is found in the dust in the form of solid calcium fluoride; the waste gases contain no gaseous fluorides. For better knowledge of the cycles of volatile matter in the cement kiln, an accurate determination is necessary of the fluoride content in silicates, for example in the raw material, the fuel, the cement clinker, and the dust. A modified method was developed to decompose and separate the fluoride in the silicates so it can be determined photometrically. During decomposition with alkalis, 0.1 to 1.0 g of the substance is treated with 4 g of lithium tetraborate by heating at 1000 C in a gold-platinum crucible for 10 minutes. After cooling, the tablet formed as a result of this decomposing conversion process is completely dissolved from the crucible. The tablet is transferred to the distilling flask of a Seel apparatus and decomposed with superheated water vapor in the presence of 20 ml of 60% perchloric acid and 0.7 g of silicagel. A distillation time of 20 minutes is sufficient to liberate 40 to 240 micrograms of fluoride from its compounds and distill it quantitatively into the receiver. The most favorable pH value for the formation of the color complex in the presence of tetraborate is 4.3 ± 0.05 . The method has no systematic error and possesses excellent correlation of extinction and concentration with a correlation coefficient equal to 0.999. The fluoride in raw meals, clinkers, and dusts in cement manufacture in a concentration of around 0.03% (by weight) can be determined with a repetition scatter of .0002% (by weight), while corresponding figures for concentrations of around 0.07% and 0.25% are 0.0004% and 0.004% (by weight), respectively. With this method it is possible to carry out 20 fluoride determinations in 2 days.

DETERMINATION OF HYDROFLUORIC ACID IN THE AIR.

(Opredeleniye ftoristogo vodoroda v atmosferenom vozdukhe).
Text in Russian. Tr. Glav. Geofiz. Observ. (Leningrad), no.
254:172-177, 1971. 11 refs.

A colorimetric method for the determination of hydrofluoric acid in the air is described. Sampling is done by means of Richter type absorber equipped with filter, containing 5 ml of twice-distilled water, at a rate of 2-3 l/min over 20 min. The liquid sample thus obtained is combined with zirconium nitrate dissolved in 3.5n-hydrochloric acid. Xylene orange is added after 30 min, and the optic density is determined by means of photoelectric colorimeter after 3-5 min against a calibration curve obtained for a standard series containing 0.125, 0.25, 0.5, 1.0, 2.0, 4.0, 6.0, 8.0, and 10.0 micrograms of F per 5 ml. The sensitivity of the method for a sampling rate of 3 l/min and a sampling duration of 20 min is at 0.002 mg/cu m. The error is + or - 6%. While sulfate concentrations occurring in the air do not interfere with the determination, aluminum ion concentrations of 2 micrograms/ml or more cause interference.

METHODS AND TOOLS FOR THE MEASUREMENT OF
HYDROGEN FLUORIDE AND CHLORINE GASES. (Fukka
suiso gasu, enso gasu no sokuteiho to kiki). Text in Japanese.
PPM (Japan), 3(11):41-47, Nov. 1972.

The basic methods of hydrogen fluoride analysis include the weight method, the titration method, the absorption spectrometry method, the filter paper fluorescence method, and the ion electrode method. Presently, colorimetry and ion electrode methods are employed in domestically manufactured apparatus. The alkaline filter paper collection method, alizarin complexion method, and Zr-ECR automatic analyzer are explained. The method of concentration, sampling tips such as care against evaporation and splash losses, tearing of filter paper, or dust in the tube, are given. For measuring chlorine gas, orthotolidine chlorine solution is used. Currently commercially available apparatus using orthotolidine colorimetry are discussed with a diagram.

Hamamoto, H., S. Hattori, H. Kono, and A. Kanazawa
MICRO-MEASUREMENT OF ATMOSPHERIC FLUORINE
BY ALKALI FILTER PAPERS. (Arukari roshiho ni yoru taikichu fusso no biryo sokuteiho). Text in Japanese. Nippon Koshu Eisei Zasshi (Japan. J. Public Health), 19(10):421, Oct. 1972. (Presented at the Japan Society of Public Health, General Meeting, 31st. Sapporo, Japan, Oct. 25-27, 1972.)
The litmus paper and alkali filter paper methods can be used to measure fluorine concentrations. However, these methods usually require a lot of time and material. Alkali filter papers and positive ion exchange resins were tested to enhance knowledge of convenient testing methods. Alkali concentrations of 10, 20, and 30% were set up, fluorine was added, and the infrared-120 absorption was measured before and after disposition. The reduction of absorption prior to disposition was due to pH and carbonate. The infrared-120 disposition figure was similar to that obtained by a medium heating disposition. The infrared-120 disposition method is extremely simple and can be used for a number of pollutants. Interference from strong winds and humidity was avoided by putting alkali filter papers around a cylinder with a 10-centimeter circumference.

TEMPORARY PRECEDURAL DIRECTIVES FOR DETERMINING THE CONTENT OF POLLUTANTS IN THE ATMOSPHERE. (Vremennyye metodicheskiye ukazaniya po opredeleniyu sodержaniya primesey v atmosfere). Hydrometeorological Service of the USSR, Moscow, 1971. 6 refs. Translated from Russian. 120p.
Systematic and efficient air pollution monitoring must include, along with air sampling and analysis for atmospheric pollutants, meteorological observations. Various techniques for air pollution monitoring and meteorological observations are reviewed. Sampling methods are reviewed for sulfur dioxide, hydrogen sulfide, carbon disulfide, nitrogen dioxide, phenol, hydrogen fluoride, chlorine, dust, soot, and carbon monoxide. Laboratory techniques, calibration, instrumentation, reagent preparation, and sample analysis are examined for photocolometric analysis (spectrophotometry and colorimetry). Equipment and techniques for measurements of wind speed and direction, air temperature, and humidity; criteria for determinations of weather characteristics (sky cover, haze, mist, rain, snow, fogs, and solar radiation); plume characteristics; and recording methods are also reviewed.

Sakai, Kaoru
ANALYTICAL APPARATUS AND MEASUREMENT TECHNIQUES FOR TOXIC GASES. (1). (Yugai gasu no bunseki sochi to sokutei gijutsu (1)). Text in Japanese. Kankyo Sozo (Environ. Creation), 2(10):38-44, Oct. 1972.
For measuring sulfur dioxide, a sampling method using a filter and a trap, an analytical apparatus using electroconductivity, a flame photometric detector, a non-dispersive infrared gas analyzer, and gas chromatography used in combination with a flame photometric detector are explained with illustrations. For measuring hydrogen sulfide and bad odors containing sulfur, gas chromatography and flame photometry are used in

combination. Fluorides and hydrogen fluoride are sampled in a sampling tube heated to 140 C to prevent condensation of test gas. A lanthanum-alizarin solution is used for analysis. A newly developed two wavelength spectrometer has a sensitivity hundred of times higher than previous analyzers. For measuring chlorine, orthotolidine colorimetry and a detector method are used according to the Japanese Industrial Standard. However, using any method, low concentrations of less than several ppm cannot be determined. For measuring hydrogen chloride, the Japanese Industrial Standard designates the thiocyanic acid secondary mercury method, the silver nitrate method, the neutralization method, and the continuous analysis method. The first is the most dependable, but is subject to the interference of halogen compounds and cyanides. Therefore, the electroconductivity method, although it does not give good repeatability, cannot be ignored.

MEASUREMENT OF GASEOUS AND PARTICULATE

CHLORIDE IN THE ATMOSPHERE. (Taiki-chu gasujo oyobi

ryushijo enkabutsu sokutei). Text in Japanese. Japan Society of Air Pollution, Proc. Symp. Japan Soc. Air Pollut., 13th, 1972, p. 113. (Nov. 7-9, Paper 68.)

The separation measurement method of particulates and gaseous compounds (hydrogen chloride mainly) was somewhat improved. The collection rate of gas by filter paper stays at 95% at 26 l/min whether the paper is soaked in a sodium carbonate solution of 5% or of 1%. Therefore, a filter paper soaked in sodium carbonate can be used for simultaneous capturing of hydrogen fluoride and HCl. The collection rate of a millipore LSWP 04700 filter was examined, using polystyrene particles of 0.365 micron diameter. The capturing rate was 99.9995% at 00 flow rate of 10 l/min. Sodium chloride was extracted from the filter paper using nitric acid of various concentrations; extraction was disrupted when the concentration was more than 1N. The improved method of collection and measurement is the use of two filters, one a millipore SLWP filter and the other a filter soaked in 1% sodium carbonate solution and dried. After filtering the gas for 2-4 hr at 20 l/min, the SLWP filter is soaked in scalding 0.5 N nitric acid, and the sodium carbonate filter is soaked in scalding water. Extracts are measured by the thiocyanic acid mercury method.

American Industrial Hygiene Assoc., Analytical Chemistry Committee

ABSTRACTS OF INTERSOCIETY COMMITTEE METHODS FOR AMBIENT AIR SAMPLING AND ANALYSIS: REPORT

I. Am. Ind. Hyg. Assoc. J., 33(4):269-278, April 1972. 13 refs.

Tentative methods for air sampling and analysis of various pollutants are presented including references, method of collection, principle of analysis, interferences, sensitivity, and reagents and equipment needed. Particulates containing arsenic can be collected on membrane or glass fiber filters and analyzed by colorimetry with a spectrophotometer. Gaseous chlorides are collected by frittered glass absorbers or impingers; particulate chloride is collected by filtration, impingement, or electrostatic precipitation. Chloride can then be

<xref image="2000WVFQ.TIF|V3|2006:09:28:01:28:12.00|118744|0"> image: </xref>

C. MEASUREMENT METHODS

207

analyzed by titration with ir . ? c nitrate solution using diphenyl carbazoneebromphe. i > lue as the indicator. Fluorides can be collected by dry collectors such as membrane or fiber filters or by wet collectors such as dilute alkaline solution or distilled water. Then fluorides can be manually determined by direct titration or spectrophotometry. The semiautomatic method relies on colorimetry. Three collection methods are used for nitrogen dioxide ? bubbler, glass syringe, and evacuated bottle methods; NO₂ is analyzed by spectrophotometry or colorimetry using azo dyes. Total nitrogen oxides can be collected in flasks or bottles and determined by oxidation to nitrate which is reacted to phenoldisulfonic acid and by measuring the light absorption of the product. Bags are used to collect oxidants such as ozone which are determined by iodimetry. Grab samples of hydrocarbons can be analyzed by gas chromatography using a flame ionization detector and a chromatographic column. Polynuclear hydrocarbons, collected on glass fiber filters using a high-volume air sampler, are analyzed by benzene extraction and column chromatography separation followed by spectrophotometry or by cyclohexane extraction and column chromatographic separation followed by spectrophotometric and fluorimetric analysis. Benzo(a)pyrene analysis consists of collection on a hi-vol, micro-, or membrane filter and analysis by microanalysis with a spectrophotofluorimeter or a filter fluorimeter, by chromatographic analysis with chromatographic separation and fluorescence analysis, or by spectrophotometric analysis.

Gilbert, Traugott

THE MONITORING OF INDUSTRIAL EMISSIONS. (Die Ueberwachung industrieller Emissionen). Text in German. Tech. Ueberwach. (Duesseldorf), 13(7/8):247-250, 1972.

Continuous monitoring is used for the measurement of particulates and sulfur dioxide. Boiler furnaces operated with solid or liquid fuels and with a heat production of more than 100 Gcal/hr are monitored continuously, as are cement plants. In the near future, iron and steel plants also will have to be continuously monitored. A brief description of sampling methods such as photometry, colorimetry, gas chromatography, and mass spectrometry is given. Measurements of gaseous and particulate emissions were taken in various plants. The hydrocarbon concentration from a naphthalene factory was to 1.0 to 5.0 g/cu m, and in anthracene melting plants 2.0 to 15.) g/cu m. In the waste gas of brick kilns the gaseous fluorine compounds reached concentrations of 180 mg/cu m. The West German Federal Ministry of the Interior authorized two units for the continuous measurement of SO₂ in waste gases of boiler furnaces (100 Gcal/hr), the Uras I and II. For the continuous measurement of dust emissions, the smoke density measuring units RM 3 and D-R/110 have been authorized.

SAMPLING AND MEASUREMENTS OF EMISSION. Preprint, Norwegian Society of Professional Engineers, Oslo, 22p., 1972. 3 refs. (Presented at the International Symposium on the Fluoride Problem in the Aluminum Industry, May 24-26, 1972.)

Equipment designed to sample hydrofluoric acid and solid fluorides in gases at primary aluminum smelters is described, as well as optimum selection of sampling sites, sampling duration, and sampling frequency for fluoride measurements. A sampler was tested in a laboratory; it was composed of a spray arrester designed to separate droplets larger than 50 micron, a cyclone to reduce the loading on the filter during long periods of sampling uncleaned gases, membrane type acrylonitril-polyvinyl chloride filters with a pore size of 1.2 micron, a temperature sensor, a gas drier and condensate collector to be used in cold weather, and sieve-tray gas absorbers with 5% monobasic potassium carbonate. Sampling outlay for

a plant with 168 closed prebake 150 kA pots is described. Emissions from each of the three sections and the performance of the scrubbers were checked monthly by sampling ventilation air in one fan and uncleaned and cleaned pot exhaust, simultaneously. Gaseous and solid fluorides were sampled separately. Uncleaned pot exhaust was sampled in the center of horizontal ducts ahead of the scrubbers. Ventilation air was sampled below the fans to avoid segregation of solids due to centrifugal forces. Since emission of fluorides varies during the day, although not significantly, duration of sampling should be 24 hours. The annual average emission can be measured fairly accurately by sampling six sections four times a year.

Shirasawa, Tadao

HARMFUL GAS MEASURING EQUIPMENT. (Yugai gasu sokutei kiki ni tsuite). Text in Japanese. Netsu Kauri to Kogai (Heat Management Public Nuisance), 25(2):77-83, Feb. 1973. Measurement methods as described in Japanese Industrial Standards are discussed for sulfur oxides, nitrogen oxides, chlorine, hydrogen chloride, fluorine compounds, and hydrogen fluoride. Dust concentrations and lead and cadmium content in dust should be analyzed by polarography. Sulfur oxides are measured by electroconductivity (suitable for concentrations up to 10,000 ppm). Ultraviolet spectrometry can also be used to measure SO₂ up to 10,000 ppm. The Saltzman method and chemiluminescence can be used to measure nitrogen oxides. Ultraviolet spectrometry is suitable for nitric oxide up to 1000 ppm concentration.

49752

Japan Environmental Agency

INSTRUCTIONS FOR AIR QUALITY MEASUREMENTS AND OTHER ENVIRONMENTAL INVESTIGATIONS. (Kankyo taiki chosa sokutei hoho nado shishin). Text in Japanese. 58p., Aug. 1972.

Instructions for sampling and measuring methods of air pollutants are given. Sulfur oxides in the air are collected in a 0.006% hydrogen peroxide aqueous solution having a sulfuric acid concentration of .0001 N, and the concentration is measured by the conductivity method. Carbon monoxide and hydrocarbons are collected using a Mylar bag and are determined by infrared spectrometry and flame ionization, respectively. Airborne soot, and particulates including sulfate ion, nitrate ion, organic compounds, and metals are collected by a high-volume or low-volume sampler. Sulfate and nitrate are determined by the spectrophotometric method. Organic compounds are determined by the gravimetric method, and metals are determined by the atomic absorption method. Gaseous and granular fluorides are collected and separated by two-stage filters, a millipore filter, and a millipore filter impregnated with 1% sodium carbonate; they are determined by the fluoride ion electrode method or colorimetric method. Nitrogen oxides are collected in an absorbing solution prepared by dissolving 5 g of sulfanilic acid and 140 g of glacial acetic acid in 900 ml of water and adding to it 20 ml of 0.1% aqueous solution of N-(1-naphthyl)-ethylenediamine hydrochloride followed by dilution with water to 1 l and by determination by the colorimetric method.

Sira Inst., Chislehurst (England), Market Research Section
POLLUTION AND ITS CONTROL: THE ROLE OF INSTRUMENTATION TO 1980. A STUDY OF THE UK SITUATION.
Rept. SUN 9501842-2-5, 140p., 1971. 40 refs.

The form and nature of monitoring requirements with respect to air and water pollution and present and future demand in the field are reviewed. Pollutants and their sources, instrument applications, and technological developments are examined. The markets for pollution monitoring devices were calculated, including the trends of use of smokemeters, light interference instruments, and opacity measurement devices for smoke monitoring; titration techniques, gauges, and lead dioxide candles for sulfur dioxide determination; nondispersive infrared methods for the determination of SO₂, carbon dioxide, carbon monoxide, and hydrocarbons; carbon monoxide monitors with thermal detection; chemiluminescence techniques for nitrogen oxides; and flame ionization detectors for hydrocarbons. The more recent developments include an automatic continuous recording meter based on the chemical reduction of SO₂, laser-Raman devices for CO, NO_x, and SO₂; correlation spectrophotometers for NO_x; fluoride monitors; odorimeters for atmospheric measurements; flame photometric detectors for SO₂, ozone measurement techniques based on chemiluminescence; and techniques for monitoring lead compounds in car exhaust.

Zurlo, Nicola

TECHNICAL CONSIDERATIONS ON THE ANALYTICAL METHODS INCLUDED IN THE REGULATION TO BE APPLIED BY THE INDUSTRY ACCORDING TO LAW NO. 615.

(Considerazioni tecniche sui metodi di analisi del regolamento di applicazione per l'industria della legge 615). Text in Italian. *Chim. Ind. (Milan)*, 54(9):801-804, Sept. 1972. (Presented at the Giornate della Chimica, 23rd Convegno, Milan, Italy, April 19-20, 1972.)

The antismog law No. 615 stipulates maximal permissible concentrations for all major industrial pollutants at 2 levels, i.e., 30-minute median concentrations for nine substances, and 24-hour median concentrations which are 3-4 times lower than the 30-minute concentrations. The median annual concentration is 15-20 times lower than the 24-hour concentration. Only the more precise and generally used measurement methods are permissible and these are stipulated in the regulation. Particulates are determined gravimetrically by a 5 cm membrane filter where a major source of error is the variation in the weight of the filter. Free silica is analyzed by the same method as inert dusts, but it is complex and subject to errors. The colorimetric method is prescribed for sulfur dioxide. If this method yields equal or a little lower values than the analysis of SO₂ and sulfur trioxide combined then the presence of sulfates can be excluded. If the difference is large then it can be due to sulfate or to free sulfuric acid which must be determined. Nitrogen oxides are determined by the Saltzman method; for 14-hour median levels absorption with soda and subsequent colorimetry is prescribed. The methods leave much to be desired and all that can be done is to follow scrupulously the prescribed procedure. Chlorine is determined by the orthotoluidine method, hydrogen chloride by the sulfocyanide reaction, hydrofluoric acid by colorimetry with a zirconium alizarin indicator or by a specific electrode, sulfuric acid by the methylene blue method or by a specific electrode, lead by colorimetry or by atomic absorption, carbon monoxide by the infrared method or by the iodine pentoxide method.

HARMFUL GAS MEASURING APPARATUS (2). (Yugai gasu sokutei kiki ni (suite. (2))). Text in Japanese. Netsu Kanri to Kogai (Heat Management Public Nuisance), 25(3):51-58, March 1973.

The measurement method for chlorine consists of colorimetric determination using an orthotolidine solution. Another method uses ultraviolet rays for chlorine determination. Hydrogen chloride can be determined by electroconductivity or by colorimetry using a ferric sulfate ammonium and thiocyanate mercuric salt and photocells. Fluorine compounds can be determined by colorimetry and ion electrodes. These methods are continuous, automatic methods which are easy to maintain and control.

Giever, Paul M.

ALL ABOUT TAPE SAMPLERS. Pollut. Eng., 5(2):38-40, Feb. 1973.

Automated filter tape air samplers are sensitive, timer-controlled, portable instruments that operate with a very high degree of repeatability. They can sample or monitor all types of particulate matter and certain gaseous pollutants in ambient air. Designed to collect cyclical samples of polluted atmosphere, and to operate unattended for extended time intervals, these tape instruments perform widely varied indoor and outdoor air sampling applications. When used outdoors, the instruments should be suitably enclosed for weather protection and to discourage tampering. Tape instruments have been adapted to sample hydrogen sulfide and fluoride gases in the parts per billion range. Tape instruments have visually demonstrated the performance of a dust collecting system by taking simultaneous air samples on both sides of the collector unit. Particle samples collected on tapes may be evaluated by two different techniques. One uses light transmitted through the sample spot, and the other uses light reflected from the spot. In both techniques, the degree of soiling by particulate matter is determined by comparing the light reading of a sample spot (from 0 to 100% light transmission or reflectance) with a reading of 100% transmission or reflectance taken from the clean tape sections adjacent to the sample spot. Tape instruments are not suitable for air evaluations based on volumetric or mass measurements, such as the measurement of a certain weight of particulate matter in a specific volume of air.

Sugano, Saburo

AN ANALYTICAL METHOD FOR POLLUTION AND ITS PROBLEMS. (Kogai bunsekiho to sono mondaiten). Text in Japanese. Preprint, Japan Society of Analytical Chemistry, Tokyo, 45p., 1973. (Presented at the Japan Society of Analytical Chemistry, Symposium on Pollution and Analytical Chemistry, 7th, Tokyo, Japan, March 16, 1973, Paper 3.)

Several analytical methods have been revised to make them simpler and more correct. The revised analytical methods are being tested in water and air analyses. Total mercury in water can be analyzed by an atomic absorption spectrophotometer. The reductive vaporization method, alkyl mercury method, and gas chromatography method are mentioned. Cadmium, lead, copper, zinc, iron, manganese, and nickel can be determined in water or particulate matter by an atomic absorption spectrophotometer. Chromium can be determined by triocetylamine-MIBK extraction an atomic spectrophotometer. Arsenic and cyanides can be determined by the silver diethyldithio-carbamate method. Fluorine and nitrogen can be determined by an ion electrode method. The 4-aminoantipyrine method is used to determine phenol. Total nitrogen compounds and nitrates can be determined by the nitric acid ion electrode method. Nitric oxide in air can be determined by the Saltzman or phenoldisulfonic acid methods.

METHODS FOR THE DETERMINATION OF FLUORINE IONS IN AIR AND WATER. (O metodakh opredeleniya ftoriona v vozdukh i vode). Text in Russian. Gigiena i Sank., no. 4:65-67, 1973. 11 refs.

> /enty five different photocolometric methods for the determination of fluorine ions in air, water, and other media were 'i -ted for their specificity, accuracy, and reproducibility. Three methods using the respective reagents zirconium enochrome cyanine; zirconium complex of 4-sulfophenylazo-

1,8 dioxynaphthalene-3,6-disulfonic acid; and cerium alizarine complex, were retained as the ones satisfying the above criteria best. Wharton's method using a zirconium complex of 4-sulfophenylazo-1,8-dioxynaphthalene-3,6-disulfonic acid was modified by reduction of the chelate concentration and by addition of thiourea. The cerium alizarine complex method was modified to improve solubility. All three reagents were specific for fluorine even in the presence of several other ions in concentrations of 100 to 10,000 micrograms. The zirconium complex method was more specific than the zirconium eriochrome cyanine and the cerium alizarine complex methods. The zirconium complex and the zirconium eriochrome cyanine methods are suitable for the determination of fluoride dusts and aerosols in the air. An air sample volume of 15-20 l is taken at a rate of 2 l/min for the determination of hydrofluoric acid concentrations. In winter, as well as for the determination of fluorides and fluorine, the Yarovskaya absorber with silicage! Js used.

Warner, Theodore B. and David J. Bressan
DIRECT MEASUREMENT OF LESS THAN 1 PART-PER-BILLION FLUORIDE IN RAIN, FOG, AND AEROSOLS WITH AN ION-SELECTIVE ELECTRODE. Anal. Chim. Acta, 63(1): 165-173, Jan. 1973. 21 refs.

A potentiometric method for the determination of fluoride in rain, snow, fog, and aerosols in samples containing as little as 0.28 ppb was developed using a lanthanum fluoride electrode. The method involves little sample handling, takes 15-22 min for a determination, and can be extended over eight decades of concentrations. Probable uncertainty ranges from 10-20% near 0.28 ppb to 3-6% above 100 ppb. (Author summary modified)

Cross, Frank L., Jr. and Howard F. Schiff
MONITORING AIR POLLUTION. Plant Eng., 27(6):94-96, March 22, 1973.

The major goals for air pollution monitoring and various analytical and measuring techniques are reviewed. Most of the current monitoring effort is for particulates, sulfur dioxide, nitrogen oxides, hydrocarbons, carbon monoxide, and photochemical oxidants. The recommended sampling and analytical procedures include colorimetry, coulometry, conductometry, and chemiluminescence analysis for SO₂; colorimetry and electrochemical methods for NO_x; continuous sampling, non-dispersive infrared analysis, and flame ionization detection for CO; chemiluminescence techniques and colorimetry for ozone; high-volume sampling for particulates; and gas chromatography, colorimetry, and flameless atomic absorption for hydrocarbons, fluoride, and mercury, respectively. Chlorine, metal, hydrogen chloride, and hydrogen sulfide methods are mentioned. Costs are cited.

COLORIMETRIC METHOD OF DETERMINATION OF FLUORINE IN ATMOSPHERIC AIR. (Kolorymetryczna metoda oznaczania fluoru w powietrzu atmosferycznym). Text in Polish. Roczniki Panstwowego Zakladu Higii., 34(1): 109-114, 1973. 35 refs.

<xref image="2000WVFT.TIF|V3|2006:09:28:01:28:22.00|115026|0"> image: </xref>

The methods of fluorine determination in atmospheric air are described. A number of modifications of the colorimetric methods of fluorine determination of Belcher, Leonard, and West are mentioned. The technique of fluorine determination in atmospheric air using alizarin and lanthanum salts in a modification is described in detail. The optical density is read on the spectrophotometer with 620 nm wavelength. The detection threshold of this method is 0.5 micrograms in a 5 ml sample; this enables the detection of 8 micrograms/cu m using 60 l test air. The sensibility of the method can be increased by measuring the absorbance on the spectrophotometer using 281 nm wavelength.

Rooth, R., O. K. Bockman, K. O. Hagen, and A. Tokerud
MEASUREMENT OF FLUORINE EMISSION FROM ALUMINUM SMELTERS--A NEW AND MORE CORRECT METHOD. Preprint, American Inst. of Mining, Metallurgical, and Petroleum Engineers, New York, Metallurgical Society, p. 327-340, 1973. 1 ref. (Presented at the American Institute of Mining, Metallurgical, and Petroleum Engineers, Metallurgical Society, 1973, Paper A73-23.)

Most methods for sampling the fluoride content of fumes from aluminum smelters are unsatisfactory since the sampling trains are not equipped to collect submicron particulate fluorides. Improved sampling equipment has the ability to determine separately gaseous fluorine, coarse particulate fluorides, and fine particulate fluorides. In addition, particle size distribution can be evaluated. The sampling train for gas and dust includes a replaceable probe nozzle, a heating and cooling device, two cyclones for the collection of coarse particulates, a cellulose nitrate filter for collection of fine particulates, and absorption bottles for hydrofluoric acid. After sampling, concentrations are determined through weighing and analyses in the laboratory. In addition to the probe nozzle, cyclones, and filter, the equipment for particle size distribution includes a miniature electrostatic precipitator on which submicron dust is deposited. Collecting electrodes provide direct introduction into scanning or electron microscopes. The equipment is valuable for predicting the factors that affect wet scrubber performance. A correlation between scrubber pressure loss, cleaning efficiency for total fluorides, and raw gas composition is presented.

Giang, Benjamin Yunwen
DEVELOPMENT OF A GAS CHROMATOGRAPHIC DETECTOR SELECTIVE FOR FLUORINE-, CHLORINE-, AND SULFUR-CONTAINING COMPOUNDS, USING ION SELECTIVE ELECTRODES. California Univ., Davis., Dept. of Agricultural Chemistry, Thesis (Ph.D.), Ann Arbor, Mich., Univ. Microfilms, Inc., 1972, 139p. 141 refs.

A highly selective potentiometric gas chromatographic detection system for the analysis of fluorine-, chlorine-, and sulfur-containing compounds was developed and tested. The essential units include a common flow-through unit equipped with an ion selective sensing electrode and a reference electrode located slightly downstream. The design and operation variables are examined. The system was tested with aqueous standard solutions and gas samples. The minimum detectable amounts were about 3.4 micrograms of fluorine for each compound, 135 ng of chlorine, and about 1.0 ng of sulfur. The application of the system to the detection of pesticide residues was investigated.

VDI (Verein Deutscher Ingenieure), Duesseldorf (West Germany), Kommission Reinhaltung der Luft
INSTRUCTION FOR EMISSION MEASUREMENTS FOR WASTE INCINERATORS WITH THROUGHPUT CAPACITIES UP TO 1500 KG/HR. (Anleitung fuer Emissionsmessungen an Abfallverbrennungsanlagen mit Durchsatzleistungen bis zu

1500 kg/h). Text in German. VDI (Ver. Deut. Ingr.) Richtlinien, no. 2301:1-2, Sept. 1971.

Instructions for emission measurements of waste incinerators with throughput capacities of up to 1500 kg/hr are presented. Emission measurements should be performed during normal operation. Odor tests, as well as carbon monoxide, sulfur dioxide, hydrochloric acid, and hydrofluoric acid concentration measurements should be conducted in the gas duct. At least six measurements of a duration of 10 min, spread over 2 hr, are necessary for continuously charged incinerators. The dust content is determined by measuring a filter inserted in a partial flow, and by ignoring precipitated acid compounds. The waste gas temperature and composition should be continuously recorded. The waste gas plume is evaluated against the Ringelmann gray wedge. Bacharach soot indices should be determined at a point before the inlet of cooling air.

Lehmden, Darryl J. von, Robert H. Jungers, and Robert E. Lee, Jr.

THE DETERMINATION OF TRACE ELEMENTS IN COAL, FLY ASH, FUEL OIL AND GASOLINE. PART I: A PRELIMINARY COMPARISON OF SELECTED ANALYTICAL TECHNIQUES. Preprint, American Chemical Society 19p., 1973. 8 refs. (Presented at the American Chemical Society Meeting, Symposium Analytical Methods Applied to Air Pollution Measurements, Dallas, Tex., April 1973.)

As part of a program to monitor trace elements in fuels and related atmospheric emissions, nine laboratories determined the concentrations of 28 elements in the same fuel and fly ash matrices. Among the elements studied were mercury, beryllium, lead, cadmium, arsenic, vanadium, manganese, chromium, and fluorine. The analytical methods used included neutron activation analysis, atomic absorption, spark source mass spectrometry, optical emission spectrometry, anodic stripping voltammetry, and x-ray fluorescence. At least eight trace elements in coal, fly ash, and residual fuel oil and three trace elements in gasoline were reported in concentrations varying by more than one order of magnitude. This wide range in reported results indicates that different sample preparation and analytical techniques can lead to erroneous conclusions and points out the need for developing standard reference materials certified in trace elements which can be used for analytical methods evaluation and quality control. Ohkita, Toshiichi

DETERMINATION OF FLUORIDES IN EMISSION SOURCES
AND IN THE ATMOSPHERE, AND THEIR PROBLEMS.

(Endoo haigasu-chu oyobi taiki-chu no fukkabutsu no bunseki to niondaiten). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 9(4):359-365, April 1973.

The measurement of fluorides in emission sources and in the atmosphere is described including sampling tube, absorbing solution, filter, analytical methods and instruments, and problems. The use of stainless steel and copper tubes in the sampling of fluorides is not recommended because of the reaction of hydrogen fluoride with these metals. A teflon tube is very useful. The correct selection of a dust filter is very important in obtaining correct data. The continuous automatic measurement of hydrogen fluoride in stack gas with a selective electrode and colorimetry was investigated. The determination of HF is attainable with an absorbing efficiency of almost 100%, even though the gas flow rate is 24 l/min.

53987

Ivie, James O.

GASEOUS FLUORIDE SAMPLING ON INDUSTRIAL

STACKS. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 20p., 1973. 3 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 66th, Chicago, Ill., June 24-28, 1973, Paper 73-171.)

A stack sampling design that eliminates the loss of hydrogen fluoride in sampling lines by using an absorber system in the stack is described. The absorbing solution is pumped into the stack where it enters with the gas sample into the line running to the sensor. The HF is absorbed in the first few inches and is carried to the liquid air separator in the liquid where the sensing cell then measures the HF present. A temperature drop on leaving the stack and high humidity in the stack do not affect the results. The modified coulometric method provides for specific sensing of HF on five full scale ranges between 1/2 ppm to 800 ppm. Response time is 1 min. Fifteen mm is required for stable values after a step change while recovery time takes 30 mm. (Author conclusions modified)

Committee D-22 on Sampling and Analysis of Atmospheres

STANDARD METHOD OF TEST FOR INORGANIC

FLUORIDE IN THE ATMOSPHERE. Book ASTM Stand.,

1971:371-380, 1971. 8 refs.

A method for analyzing various types of atmospheric samples for total fluoride ion in the range from 0.005 to 10 mg is presented. It is intended primarily for inorganic fluorides and is not applicable to certain organic fluoride compounds. Too much acid in the distillate, residual amounts of fluoride in the distillation flasks, sulfuric acid, large amounts of aluminum or silicon, borates, phosphates, sulfates, nitrates, peroxides, sulfides, and sulfites interfere with the procedure and/or results. Reagents are calcium oxide, chloroacetate buffer solution, hydrochloric acid, hydrogen peroxide, perchloric acid, phenolphthalein solution, silver perchlorate solution, sodium alizarin monosulfonate solution, sodium fluoride, sodium hydroxide, sodium hydroxide solution, thorium nitrate, and thorium nitrate solution. Sampling procedures are given for gaseous inorganic fluorides, inorganic fluoride particles in the absence of gaseous fluorides, mists containing inorganic fluorides, and mixtures of gaseous and particulate inorganic fluorides. Preparation of the sample for distillation is

discussed, along with distillation of the fluoride, titration of the fluoride, and calculation of the fluoride ion content of the total distillate.

Habel, Karl

PRESENT STATE OF THE MEASURING TECHNIQUE FOR THE DETERMINATION OF THE FLUORINE CONTENT IN IMMISSIONS AND EMISSIONS. (Derzeitiger Stand der Meßtechnik zur Bestimmung des Fluorgehaltes in Immissionen und Emissionen). Text in German. Arch. Eisenhüttenw., 44(9):697-702, Sept. 1973. 7 refs.

The difficulties encountered in the separation of gaseous and solid fluorine compounds are described. If precise data can be given on the concentrations, reasonable predictions will only be possible. The same criteria must be valid for emission ground level emission (immission) measurements because of their close relationship. Methods which yield optimum measurement results corresponding to the actual state of engineering should be examined. The experimental investigations revealed that a reliable procedure for the exact separation of gaseous and solid fluorine compounds is not yet available. A solution would be possible, if binding definitions for the limitation between gaseous and solid fluorine compounds are given and accepted. A procedure could be suggested for emission measurements enabling the determination of gaseous fluorine compounds with an exactness of 10 to 15%. The solid fluorine compounds can be determined on the basis of an exact determination of dust. (Author summary modified)

CONTINUOUS MONITORING OF FLUORIDE EMISSION. (Kontinuierliche Messung von Fluoremissionen). Text in German. Ziegelind. (Weisbaden), 1973:356-359, Nov. 1973. 5 refs. An instrument which records the concentration of gaseous fluoride compounds in flue gases was developed and tested for the monitoring of F emissions and control of the emission reduction process. The mode of operation of the instrument is described. Following activated carbon filtration of the flue gas specimen, the F compounds are absorbed into a buffer solution. The F ion content of the solution is measured by means of an ion-sensitive electrode. The F content of the flue gas is shown on a logarithmic scale. A report is given of the operation. <xref image="2000WVfV.TIF|V3|2006:09:28:01:28:30.00|115667|0"> image: </xref>

ing experience gained with the instrument at two brickworks. In the case of the first, an examination was made of the influence of a fuel oil additive on the F emissions, and in the second, the effectiveness of lime injection was studied.

Hermann, Peter

COMPARISON OF FLUORINE CONCENTRATION MEASUREMENT METHODS. (Vergleich von Messverfahren der Fluor-Immissionsmessungen). Text in German. Proc. Int. Clean Air Congr., 3rd, Duesseldorf, West Germany, 1973, p. C60-C62. 10 refs.

Sampling and analysis of gaseous and particulate fluorine compounds is described. Gaseous fluorine compounds were absorbed in quartz tubes filled with carbonate-coated silver balls. The absorbed fluorine compounds were then analyzed by means of fluorine-sensitive electrodes in semi-automatic operation. Particulate matter containing fluorine compounds was separated in an electrostatic precipitator with 10 kV potential that was heated at 80-100 C to prevent adsorption of gaseous fluorine compounds. All surfaces contacting gases were gold-plated. High separation efficiency up to 3000 l/h capacity was determined. The fluorine concentration readings were lower when an electrostatic precipitator was used than when Hertzt pot only was applied.

DETERMINATION OF FLUORINE COMPOUNDS IN THE AIR. (Oznaczenie zwiaskow fluoru w powietrzu). Text in Polish. Med. Pracy, 23(6):585-594, 1972. 26 refs.

A selective absorption colorimetric method for the determination of hydrogen fluoride, inorganic fluorides, and fluorosilicates in the air is presented. The method consists of passing air through a membrane filter and then through a sodium hydroxide solution and determining the fluorides colorimetrically in a reaction with zirconium oxychloride (ZrOCl₂) and sodium para-sulfophenylazochromotrope. Microdiffusion is used to eliminate cations interfering with the determination. Routine laboratory tests of the method were performed, and recovery of fluoride was almost 100%.

A SYSTEM OF CUMULATIVE DETERMINATION OF AIR POLLUTANTS IN AREA SURVEYS. Proc. Int. Clean Air Congr., 3rd, Duesseldorf, West Germany, 1973, p. C130-C132. 10 refs.

A system for the cumulative determination of air pollutants in area surveys is described. The purpose of the system is to obtain only average and relative data about the pollutants from a great number of sampling sites within a grid. Distances between sampling sites is about 1 km, and the number of sampling sites can reach a hundred or more. Corrections are made after the initial period of measurements by installing additional cumulative test devices in locations with a high gradient of contaminant concentration and removing some devices from places of uniform pollution level. Sulfur dioxide measurements are made by the corrosion-weight loss method which compares favorably with the use of potassium carbonate impregnated filter papers. The same papers can be used for determination of nitrogen dioxide and fluorides. Carbon monoxide is measured with 1% lead chloride impregnated filter paper strips. Accumulation of organic contaminants is performed by gas chromatography column packing materials.

Epstein, B. D.

ELECTROCHEMICAL METHODS OF POLLUTION ANALYSIS. In: Electrochemistry of Cleaner Environments. John O M. Bockris (ed.), New York, Plenum Press, 1972, Chapt. 6, p. 165-206. 162 refs.

Electrochemical analysis techniques for water and air pollution monitoring of ozone, oxides of nitrogen, sulfur oxides, carbon monoxide, and fluorides and fluorine are reviewed. The biggest shortcoming of redox electrochemical techniques, voltammetry, amperometry, and coulometry, is the requirement of extensive sample pretreatment in the form of reagent addition and deoxygenation. Sometimes this drawback can be eliminated by continual reuse or regeneration of reagents or by self-contained generation of hydrogen to be used for deoxygenation. Specificity in the case of selective ion electrodes is not always dependable, and there are additional effects from complexation and ionic strength that obscure the analysis. Electrochemical techniques, though admirable under laboratory conditions, appear to be a long way from on-line analysis.

THE PROBLEM OF RECOGNIZING AND DEMARCATING

FUME DAMAGE ON AERIAL PHOTOS. (Zur Frage der er-

kennung und abgrenzung von Rauchschaden aus Luftbildern).

Text in German. Mitt. Forst Bundesvers., no. 97:295-305, 1972.

(Presented at the International Symposium of Forest Fume

Damage Experts, 7th, Essen, West Germany, Sept. 7-11, 1970.)

Aerial photographic investigations of sulfur dioxide and hydrogen fluoride polluted forests in Germany indicate that color photos were more easily interpreted than black and white photos, and that false color photos were usually better than normal color photos. Damage symptoms invisible in the field remained invisible on the photos as well, and systematic morphological structure intensified the effects of damage such as foliage discoloration or defoliation, while variable habit makes interpretation more difficult. The basic element in the interpretation of forest damage is the individual tree crown, the size of which determines the photo scale. Photo quality, tree species, picture scale, and type and concentration of pollutant make it possible to rank individual crowns into three to five damage classes, although direct determination of the cause of damage is seldom possible. Particularly favorable conditions for photography make it possible to distinguish between old and fresh damage on Ektrachrome Infrared film. With regard to the spruce stands under investigation, there was a relative increase in damage towards the center of the pollution zone, and younger stands generally exhibited less damage than older stands. No demonstrable influence of slope direction was found on the degree of damage, although damage increases with increasing altitude. Pinus strobus stands exhibited the worst damage and fewer differences due to terrain.

POSSIBILITIES AND PROBLEMS OF AUTOMATIC MEASUREMENTS OF ENVIRONMENTAL CHEMICALS. In: Environmental Quality and Safety: Chemistry, Toxicology and Technology. Frederick Coulston and Friedhelm Korte (eds.), Vol. 1, New York, Academic Press, Inc., 1972. p. 189-209. 43 refs.

The parameters for air and water quality, the establishment of air and water quality criteria, and the efforts made in the USA and Japan for monitoring concentrations of a number of compounds in these media, are discussed. Efficient automatic monitoring systems (including systems for sampling, treatment, detection and determination, and data processing) for important pollutants in air and water are described in detail. The air concentrations of sulfur dioxide, nitric oxide, nitrogen dioxide, carbon monoxide, total oxidants, total hydrocarbons, hydrogen sulfide, hydrogen fluoride, and dust or air particulates have been continuously monitored. Colorimetry, conductimetry, coulometry, non-dispersive infrared spectrometry, gas chromatography, flame ionization detectors, and ion-electrode methods are discussed.

Ihida, Mutsumi and Teruaki Ishii
DETERMINATION OF FLUORIDE IN STEELMAKING SLAG AND DUST BY ION-SELECTIVE-ELECTRODE METHOD.

(Ion sentaku denkyokuho ni joru seiko suragu oyobi baijinrui no fusso no teiryō). Text in Japanese. Nippon Kokan Giho (Tokyo), no. 60:55-60, 1973. 9 refs.

Spectrophotometric methods have been used for the determination of fluoride in steelmaking slag and dust for pollution control purposes. But these methods require sophisticated analytical techniques and operations. Ion-selective electrodes are therefore being tested. In spite of many applications of these electrodes to rivers and waste water, there have been only a few applications of them to slag and dust analyses. Electrical conditions to be satisfied by the measuring instrument, the method of dissolving the sample, the effect of pH and ion interference, and the establishment of a favorable analytical procedure permitting simple and rapid measurement at high accuracy were studied. The sample was weighed and fused with sodium peroxide in a nickle crucible. The fused matter was dissolved in water. After the precipitation of hydroxide, part of the solution was taken into a 100 ml beaker, and buffer solution was added to this portion to regulated pH. The volume of the portion was then adjusted to 100 ml, and the electrodes were dipped into it for the measurement of elec-

tromotive force. The amount of fluoride was read out from a calibration curve.

Kaaijk, J.

POTENTIOMETRIC METHOD FOR THE DETERMINATION OF AIR POLLUTION BY FLUORIDES. (Une méthode potentiométrique pour déterminer la pollution fluorée de l'atmosphère). Text in French. Inst. Natl. Rech. Chim. Appl., Dixième Colloq. Atmos. Pollués, Proc., Paris, France, 1972, 13p. 4 refs. (May 3-5.)

Sampling techniques and potentiometric methods for determination of fluorine compound concentrations in the air are described. A variation of an Adams sampler with dripping capillary, and buffer solution composed of sodium carbonate, citric acid, and sodium CDTA at pH 5.5 are used for the absorption and concentration of the fluorine compounds. To obtain good separation of gaseous from particulate fluorine compounds, particles larger than 1 micron are captured before reaching the sampler. The fluorine concentration is determined by means of a fluorine-specific electrode which measures potential difference against a calomel reference electrode in the presence of fluorine ions. By replacing the buffer solution every 24 hr, it is possible to measure fluorine ion concentrations in a range of 0.05-15 micrograms/cu m.

PRESENT STATE AND FUTURE PROBLEMS OF POLLUTION MEASURING INSTRUMENTS. (Kogai keisokuki no genjo to kongo no kadai). Text in Japanese. Sangyo to Kankyo (Ind. Environ.), 3(4):24-29, April 1974.

Problems concerning automatic pollution measuring instruments are discussed. Air pollution measuring instruments can be qualitatively classified into three groups. The first group is measuring instruments which are commercially available and provide a high degree of accuracy but require some improvements to reduce frequency of maintenance. This group includes the carbon monoxide analyzer, sulfur dioxide analyzer, and hydrocarbon analyzer. The second group is new to the

<xref image="2000WVFX.TIF|V3|2006:09:28:01:28:36.00|115003|0"> image: </xref>

market and requires more improvement in both accuracy and maintenance. It includes the nitrogen oxides analyzer, dust meter, chlorine analyzer, hydrogen fluoride analyzer, and hydrogen sulfide analyzer. The third group consists of those instruments that must still be developed, and includes a dust meter for emission sources and an odor densitometer. The CO analyzer, the SO₂ analyzer for measurement at emission source, the sulfur oxides analyzer for measurement of environmental concentration, the NO_x analyzer for measurement at emission source, and the HC analyzer for measurement of environmental concentration are discussed at length.

EVALUATION AND COMPARISON OF THREE ATMOSPHERIC FLUORIDE MONITORS UNDER FIELD CONDITIONS. Atmos. Environ., 8(2):159-166, Feb. 1974. 15 refs.

Atmospheric fluoride levels were monitored at up to 22 stations in the vicinity of an alumina reduction plant by bicarbonate coated tube samplers, by a dual paper tape sampler, and by limed filter papers as part of a field evaluation and comparison of the three fluoride monitors. The bicarbonate tube sampler allowed classification of fluoride emissions by physical state; total atmospheric fluoride in the vicinity of the plant was 13% in gaseous form, 64% in particulate form, and 23% in gaseous form sorbed on aerosols. The dual tape sampler showed the same separation characteristics for gaseous an/particulate fluorides but was incapable of distinguishing between free gaseous fluoride and that sorbed on aerosols. A significant correlation appeared to exist between fluoride accumulation by limed filter papers and total gaseous fluoride content on an annual basis, confirming the fact that limed filter papers are good indicators for free gaseous fluoride. The limed filters were, however, rather insensitive to the particulate component. (Author summary modified)

Sholtes, Robert S., E. H. Meadows, Jr., and J. B. Koogler

EVALUATION AND MODIFICATION OF FLUORINE SAMPLING AND ANALYTICAL METHODS. Environmental Science and Engineering, Inc., Gainesville, Fla., Environmental Protection Agency Contract 68-02-0600, Program Element JA1010, EPA-650/2-73-007, 125p., Oct. 1973. 27 refs. NTIS: PB-230954/AS

Three fluoride sampling and analytical methods were evaluated and modified. The sampling methods are the Arthur D. Little method, the C. E. Decker method (EPA), and the Florida method. With care in placement of thy probes and operation of the train, the EPA F method can give results on comparative tests that are within 5%. Data collected using the three EPA F trains simultaneously at field sites indicated that variation between EPA trains can be as good as 5% and as poor as 24%. In the concentration range of 10-100 ppni F, the average collection efficiency of the EPA train using water was 58% and using 0.1 N sodium hydroxide it was 77%. However, for two runs at about 100 ppm F, the collection efficiency of a similar train was 90% in the range of 0-4000 ppm. Statistical analysis of the data indicated no significant difference between

water and NaOH as absorbing reagents; nor did analysis reveal differences in collection efficiency at different flow rates. Statistical analysis comparing the results of the Florida and EPA train indicated no significant difference between the two methods at the 99% confidence level. (Author conclusions modified)

Israel, Gerhard W.

A FIELD STUDY OF THE CORRELATION OF STATIC
LIME PAPER SAMPLER WITH FORAGE AND CATTLE

URINE. Atmos. Environ., 8(2):167-181, Feb. 1974. 30 refs.

A fluoride monitoring program was conducted by 22 monitoring stations located within a 7 km radius of an alumina reduction plant in order to examine the use of limed filter papers as a tool for estimating the accumulation of fluorides in the food chain of foraging animals and for indicating the fluoride exposure of cattle. The mean fluoride level in the excretion of cattle herds was predicted from limed paper measurements with a standard deviation of + or - 3 ppm, sufficient accuracy for estimating the chronic exposure of cattle to subacute fluoride levels; additional calculations showed the possibility of predicting average urinary fluoride level of single samples from three month average lime paper concentrations with a standard deviation of plus or minus 5 ppm. Assuming that the lime papers and the forage both absorbed mainly free gaseous fluorides, the correlation found between fluoride levels in forage and limed paper values should be generally valid in terms of a forage-lime paper conversion factor developed for the location monitored.

MEASUREMENT OF TOXIC GASES. (Yagai gasu no skoutei).

Text in Japanese. Kagaku Kojo (Chem. Factory), 18(4):27-30, April 1974.

The toxic gases discussed here are sulfur oxides, nitrogen oxides, fluorides, chlorine and hydrogen chloride. Sampling methods, sampling equipment, and analysis methods are described. The analysis methods include: iodimetric, arsenazo, chloranyl acid barium, electroconductivity, and infrared gas analysis for sulfur oxides; chemical PDS (phenoldisulfonic), nitric acid ion electrode, zinc reduction (NEDA naphthyl ethylene diamine method), chemiluminescence, infrared absorption and ultraviolet absorption, and constant potential electrolysis for nitrogen oxides; lanthanum-alizarin complexon method photometry for fluorides; orthotridine method for chlorine, and thiocyanide mercury and silver nitrate methods for hydrogen chloride.

C. MEASUREMENT METHODS

215

One or more components of a gas mixture are separate rapidly, selectively, and efficiently without the need for dilution, by passage through a bed of carrier material such as alumina, coated with a layer of 0.5-5 (1-2) molecules of a reagent which absorbs these components. The resulting complex is heated above the decomposition point to free the absorbed gases. Recommended absorption layer compounds are carbonates of sodium, potassium, lithium, calcium, cadmium, or barium for carbon dioxide; nicotinic acid or dimethylglyoxime for oxygen; iron(II) salts for nitric oxide; copper(II)-ammonium salts for carbon dioxide; sulfates of potassium, sodium, lithium, cadmium, or silver, or phenol, hydroquinone, or pyrogallol for sulfur dioxide, silicon tetrafluoride, hydrogen fluoride, hydrogen sulfide, or aromatic hydrocarbons.

DEVELOPMENT OF METHODS FOR SAMPLING AND ANALYSIS OF PARTICULATE AND GASEOUS FLUORIDES

FROM STATIONARY SOURCES. FINAL REPORT. Little

(Arthur D.), Inc., Cambridge, Mass., Environmental Protection Agency Contract 68-02-0099, Rept. EPA-R2-72-126, Rept. 73757, 133p., Nov. 1972. 54 refs. NTIS: PB 213-313

The development of tentative procedures for sampling and analysis of fluorides emitted from various processes within the primary aluminum, iron and steel, phosphate rock processing, and glass manufacturing industries is reported. In most cases, the distinction is made between gaseous, insoluble particulate, and soluble particulate fluoride species. Stack emissions from most of the processes that were considered can be sampled in a manner that separates the particulate from the gaseous species. For the tentatively recommended procedure, the particulate is collected by means of a filter or electrostatic precipitator heated above the water dewpoint with gaseous fluorides subsequently collected in a series of water impingers maintained at room temperature. Some very wet process streams, such as for the production of diammonium phosphate, include considerable water entrainment, precluding a particulate collector. In this case, the particulate is collected in the impingers and soluble particulate fluoride cannot be distinguished from gaseous fluorides. Chemical analysis procedures have been developed which emphasize procedural simplicity but which also provide reliable and reproducible results. The fluoride-specific ion electrode has been found to be the most suitable approach for measurement of fluoride concentration. Direct measurements on impinger solutions after appropriate buffering appears feasible in many cases. Otherwise, fusion and distillation procedures are required to assure solubility and separation from interfering species. (Author summary)

Harmsen, Hans

SEVENTY YEARS OF AIR MONITORING AND CLEAN AIR

MAINTENANCE AT BAYER AG. (70 Jahre Luftueberwachung

und Luftreinhaftung bei der Bayer AG). Text in German. Umwelthygiene, 25(2):37-39, Feb. 1974.

The history and the current practice of air pollution monitoring and clean air maintenance at the Bayer AG are described. Continuous sulfur dioxide concentration measurements have been conducted since 1954 by high-sensitivity automatic instruments. An automatic air quality monitoring network with 13 sampling stations and over 40 recording instruments in the Leverkusen area continuously measures the concentrations of such air pollutants as SO₂, hydrogen sulfide, carbon monoxide, nitrous gases, carbon dioxide, hydrocarbons, and chlorine. Routine laboratory measurements of the phenol, aldehyde, aromatic amine, chloride, fluoride, and organic carbon are conducted. Visible emissions are monitored by closed-circuit television, and pollutant concentrations on the lee side of the emission sources are measured by a laboratory van. The

switch from coal to fuel oil and natural gas, the use of filters, and the introduction of the Bayer double-contact sulfur acid production process have resulted in considerable reduction of the pollutant emissions for the last few years.

Organisation for Economic Co-operation and Development,
Air Management Research Group
SAMPLING AND ANALYTICAL TECHNIQUES. In: Air
Management Problems and Related Technical Studies, p. 53-69,
93-95, 1972. 41 refs.

Present measurement capabilities are reviewed for those air pollutants specified to be of priority interest in respect to both effects and abatement. Gaps in measurement capabilities are indicated and future research program recommended. The pollutants discussed include: asbestos-no sampling problems since adequate organic membrane filters are available; carbon monoxide?no measurement problems for concentration normally found in urban atmospheres; fluorides?no continuous method for routine measurement, not possible to distinguish between gaseous, particulate, and organic fluorides; heavy metals and other elements-number of methods available, but costly and time consuming; organic lead (fuel additive)? methods available for separating and identifying total organic lead; non-metallic organic compounds-no routine methodology developed; nitrogen oxides-no direct methods for nitric oxide, Saltzman method for nitrogen monoxide and nitrogen dioxide; oxidants and ozone- routine methods available for ozone, but not for other oxidants; sulfur compounds?adequate measurement methods available or being developed; odors-not studied in detail; pesticides?need for a total system of sampling and analysis.

MEASUREMENT OF ATMOSPHERE. (Taiki no sokutei). Text
in Japanese. Kankyo Joho Kagaku (Environ. Inf. Sci.), 2(4):48-
52, Dec. 1973.

Methods of measurement and analysis of such pollutants and sulfur oxides, aerosol, carbon monoxide, nitrogen dioxide and oxidant have been formulated since 1969, and are mostly described by Japan Industrial Standards, such as JIS Z 8808, which is briefly explained. For sulfur oxides, JIS K 0103, and for its gas volume, JIS Z 8808 are applied. For sulfur content in petroleum fuel, the radio isotope method, JIS K 2273, JIS K 2547, JIS K 2541, or JIS K 2263, are applied. For dust, JIS Z 8808, for cadmium and its compounds and lead and its compounds, JIS K 0097, and for sample collection, JIS Z 8808 3 and 6 applied. For chlorine, JIS K 0106 (O-lysine method) and JIS K 0106 (continuous analysis method) are applied. For hydrogen chloride, JIS K 0107, and for fluorine, hydrogen fluoride, silicon fluoride, JIS K 0105, and for nitrogen oxides, JIS K 0104 are applied. For measurement of dust, JIS Z 8808, for carbon monoxide, JIS D 1030, for hydrocarbon, JIS D 1030, for lead compounds, the atom light absorption method and polarograph method, for nitrogen oxides, JIS K 0104, and for particles, JIS D 8804 are applied. In measuring automobile exhaust, JIS K 0099 is applied for ammonium, JIS K 0105 for hydrogen fluoride, JIS K 0109 for hydrogen cyanide, and JIS K 0098 for carbon monoxide. Methods of analyzing sulfur oxides, such as the neutralization method, iodine titration method, chloranil acid barium method, solution conductivity

<xref image="2000WVFZ.TIF|V3|2006:09:28:01:28:44.00|126769|0"> image: </xref>

ratio method, infrared gas analysis method, and detector tube method, are compared. For aerosol, JIS Z 8813 and the volume air sampler method are applied.

FLAME SPECTROMETRIC F ANALYSES BY MEANS OF

THE SRF-BANDS. (Flamitienspektrometrische F-Analysen mit Hilfe der SrF-Banden). Text in German. Fresenius Z. Anal. Chem., 269(4):260-267, 1974. 10 refs.

By nebulizing strontium salts (nitrates, for example) and introducing the aerosol into a flame, strontium fluoride bands are observed if fluorine compounds are nebulized simultaneously. These SrF-bands are useful for F analysis. The best flame for this purpose is the turbulent hydrogen-oxygen flame in contrast to experience in F-sensitive flame detectors for gas chromatography. The most suitable SrF band is the band at 580 nm. The detection limit is 9.2 micrograms F. The precision is + or - 1.6%. The dynamic range is more than one power of ten. Interfering influences from sodium and phosphorus are discussed in detail along with possibilities for overcoming them.

DETERMINATION OF FLUORIDE IN BIOLOGICAL SAM-

PLES BY NONFUSION DISTILLATION AND ION SELEC-

TIVE MEMBRANE ELECTRODE METHOD. (Shokubutsu

taichu fusso no jinsoku bunsekiho ni tsuite). Text in Japanese.

Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 8(3):266, Oct. 1973. 1 ret. (Presented at the Japan. Society of Air Pollution, Annual Meeting, 14th, Fukushima, Japan, Nov. 6-8, 1973, Paper 2.)

To quickly measure the fluoride pollution from a fertilizer plant and a tile manufacturing plant which is absorbed from the air into plants, a nonfusion distillation method was used. The F content in plant leaves was determined and the values were compared with those of Association of Official Agricultural Chemists method and the ion-electrode method. The test material was ashed, perchloric acid and silver perchlorate were added, and reflux analysis was done at 140 C. The ashes were distilled and the extract was measured by colorimetry. The best recovery rate was obtained with the reflux time of 3 hr. By this method, the recovery rate was 93.8%, by the AOAC method about 90%, and the measurements were approximately the same. When using ion selective membrane electrode method, the results were similar to the colorimetry values. The nonfusion distillation method proved to be simple and accurate.

Tepper, L. B.

ANALYTICAL CONSIDERATION. In: Metallic Contaminants

and Human Health. D. H. K. Lee (ed.), New York, Academic, 1972, Chapt. 10, p. 229-241.

The analysis of environmental metals is discussed and some specific techniques are presented. Airborne metals are almost always particulate rather than gaseous. Particulates can be collected on a filter medium through which air is drawn by a pump. Particulates can also be separated from the air by impingement in a liquid-filled collector or by precipitation of charged particles in electrostatic fields. Organolead or mercury compounds which exist as volatile non-particulate material may be extracted from the air by adsorption on charcoal or by direct reaction with a specific chemical reagent. Laboratory procedures for analysis include wet chemical and instrumental methods. Wet chemical methods are based upon the development of a color, the intensity of which is measurable and related to the amount of the metal being assayed. Instrumental methods of analysis include spectrophotometry and spectroscopy. Preferred analytical techniques and standard values

are given for arsenic, beryllium, cadmium, chromium, fluoride, lead, manganese, mercury, nickel, and vanadium.

COLORIMETRIC ANALYZERS. (Kolorimetrie). Text in German. In: Elektrische Messgeraete fuer den Umweltschutz. Fachverband Messtechnik und Prozessautomatisierung im Zentralverband der Elektrotechnischen Industrie, Frankfurt, West Germany, 1973, p. 9-11, 21, 37.

The principle of the colorimetric analysis of gaseous pollutants, and commercially available colorimetric analyzers are described. The gas to be analyzed is contacted with a reagent solution for a certain time so that averaged concentration values are obtained. Colorimetric measurement is also possible by photoelectric comparison of color spots obtained on a reagent-soaked ribbon with a standard color. The Braun and Luebbe B and L-Imcometer is suitable for the measurement of the 30-min-concentrations of sulfur dioxide, nitrogen oxides, and oxidants by modified West-Gaeke and Saltzman methods. The measuring ranges are 0-0.25 ppm and 0-1.4 ppm for SO₂, 0-0.2 ppm and 0-0.55 ppm for nitrogen dioxide, and 0-0.15 ppm and 0-0.3 ppm for chlorine. The MONOCOLOR colorimetric gas trace analyzer by Maihak uses reagent-soaked paper ribbon for the measurement of hydrogen sulfide, hydrofluoric acid, hydrochloric acid, phosgene and toxic gases in a concentration range of 0-0.2 ppm. The concentration is determined by measuring the difference in the brightness of the colored spot and of a non-exposed standard.

61995

POTENTIOMETRIC ANALYZERS. (Potentiometrie). Text in German. In: Elektrische Messgeraete fuer den Umweltschutz. Fachverband Messtechnik und Prozessautomatisierung im Zentralverband der Elektrotechnischen Industrie, Frankfurt, West Germany, 1973, p. 9-11, 21.

The principle of the potentiometric measurement of gaseous air pollutant concentrations, and commercially available potentiometric analyzers are described. The B and L-Sensimeter by Braun and Luebbe, developed for hydrochloric acid and hydrofluoric acid emission concentration measurement in the respective ranges of 20-2000 mg/N cu m and 0.2-20 mg/N cu m, uses buffer solution for the absorption of the test gas, and thermostated measuring cell with ion-sensitive electrodes.

RECORDING STACK MONITORING FOR THE CONTROL OF ENVIRONMENTAL PROTECTION MEASURES AND THE ECONOMIC CONDUCTION OF COMBUSTION

PROCESSES. (Registrierende Schornsteinueberwachung zur Kontrolle des Umweltschutzes und des wirtschaftlichen Verhaltens von Verbrennungsprozessen). Text in German. Wasser Luft Betrieb, 18(4):212-217, 1974. 16 refs.

Methods for the measurements of the oxides of nitrogen, hydrogen, chloride, and fluoride are discussed in detail and a brief review of the methods available for the measurement of carbon monoxide, sulfur dioxide, and sulfur trioxide emissions

<xref image="2000WVG0.TIF|V3|2006:09:28:01:28:48.00|114453|0"> image: </xref>

is given. The discussion of the NO_x measurement methods is preceded by a review of the development of these components in industrial combustion processes. For the measurement of the oxides of nitrogen, the chemiluminescence method and the absorption methods in the infrared and ultraviolet range are described. For the measurement of HCl and HF emissions, samples are taken behind the electrostatic precipitator. The analyzer for these pollutants consists of an ion sensitive electrode. For the recording measurement of CO₂ and SO₂, a number of primarily physically operative analyzers in the IR and UV range are available. Also analyzers with chemical auxiliary reactions are used. The most difficult problem encountered at the measurement of SO₂ is posed by sampling. Here the conversion of the SO₂ present in the flue gas to SO₃ through the material of the sampling of the sampling probe or the reaction of SO₃ with the sampling probe or with dust must be taken into account. The sample flow is taken from the probe at a temperature above 450 C, filtered, and passed over heated pipes (200 C) to the analyzer. Of the familiar SO₃ measuring methods such as dew point determination; measurement of the film-forming speed; scrubbing with isopropanol and subsequent photometry or conductivity measurement; and SO₃ reaction with condensed water vapor, the two methods mentioned last have been in practical use for a longer period of time.

Moser, E.

MEASURING INSTRUMENTS FOR DETERMINATION OF FLUORIDE EMISSIONS. Fluoride, S(2):84-85, April 1972. (Presented at the International Society of Fluoride Research, The Hague, Netherlands, Oct. 24-27, 1971.)

Damage from gaseous fluorides such as hydrogen fluoride differs from that due to particulate fluoride. In evaluating fluoride damage to plants, the fluoride content of dust is relatively insignificant. In animals, fluoride absorption depends largely upon the solubility of the compound. An instrument is described for separating particulates from gaseous fluoride for use in determining the relative effects of the two types of fluoride. The instrument consists of a heated membrane filter. The sample is heated to avoid condensation of HF. The HF is absorbed either by an impinger or by an absorption tube with sodium hydroxide-loaded silver balls or bead spheres. The tested volume of air is about 2 cu m/hr. The method gives reproducible results. (Author abstract modified)

Imagami, Kazunari

SELECTION OF MEASURING APPARATUS FOR AIR POLLUTANTS (2). (Taiki osen busshitsu no sokuteiki no sentei). Text in Japanese. Kogyo Kanctsu (Ind. Heating), 11(2):82-8S, March 1974. 1 ref.

Measuring apparatus for analyzing air pollutants such as cadmium, lead, chlorine, hydrogen chloride, fluorine, hydrogen fluoride, hydrogen silicofluoride, nitrogen oxides, and other harmful substances are described. For heavy metals such as cadmium and lead, there are three methods, atomic absorption spectrophotometry, spectrometry, and polarography, each of which is accepted widely; atomic absorption spectrophotometry has, however, been most widely used. Emission spectrometry, X-ray fluorimetry, radiochemical analyzers, recently have attracted attention. Chlorine present in flue gas is mostly analyzed by the orthotolidine method in Japan, and hydrogen chloride is determined by the mercury thiocyanate method which is suitable for samples with a hydrogen chloride concentration of 2 to 40 ppm in cases where 40 l of sample gas are available and the effect of halide and cyanide is negligible. For fluorides in flue gas, spectrometry using a lanthanum-alizarin complex is adopted. Determination of nitrogen oxides in flue gas is done by the phenoldisulfonic acid method which

is suitable for concentrations of about 10 to 20 ppm. The present general trend is toward using the PDS method, Rapid PDS method, chemiluminescence, and electrochemical methods.

Thomas, Josephus, Jr. and Harold J. Gluskoter
DETERMINATION OF FLUORIDE IN COAL WITH THE
FLUORIDE ION-SELECTIVE ELECTRODE. Anal. Chem.,
46(9):1321-1323, Aug. 1974. 10 refs.

A fluoride ion-selective electrode method is described for the determination of F in coal. Coal samples are decomposed in a combustion bomb, the pH of the bomb contents is adjusted, and the solution is buffered prior to the determination of the fluoride concentration with the F ion-selective electrode. Analysis is by the addition method in which the change of potential resulting from the addition of a known volume of standard F solution to the initial test solution is used to determine the fluoride concentration of the initial solution. The technique is superior to direct potentiometry as problems resulting from interferences, complexation, and ionic strength variations are virtually eliminated. Analytical data are presented for coal samples decomposed by the bomb combustion method and by alkali fusion as well as for fluoride determinations of coal samples with test solutions at different pH values.

PROTECTION OF THE AIR BASIN FROM POLLUTION
AND AUTOMATION OF THE SANITARY-CHEMICAL CON-
TROL OF THE ATMOSPHERE. (Zakhyst povitrjanoho basejnu
vid zabrudnennja i avtotnatyzacija sanitarno-khimichnoho kon-
trolju atmosfery). Vestn. Akad. Nauk SSSR, no. 8:90-99, 1973.
Translated from Russian, 18p.

A review is presented on the development of automated equipment in the Soviet Union for the detection and monitoring of air pollutants and for the interpretation of air pollution and meteorological data. Automatic gas analyzers are described for the detection of such pollutants as sulfur dioxide, hydrogen sulfide, ozone, acetone chlorine, nitrogen oxides, sulfurous anhydride, ammonia, amines, carbon monoxide, carbon dioxide, various hydrocarbon volatiles, alcohols, halogenated hydrocarbons, phosgene, carbon disulfide, formaldehyde, fluorine compounds, and total oxidants. Equipment is also being developed for the automatic measurement of particulates. Telemetry systems are used to connect various measurement stations with a center for collection and interpretation of air pollution and meteorological data.

ERECTION OF AN AUTOMATIC EMISSION MEASURING
GRID. (Aufbau eines automatischen Immissionsmessnetzes). Text
in German. Siemens Z., 48(8):525-532, 1974. 25 refs.

The structure, hardware, and software of an automatic air quality monitoring network is described. The smallest independent unit of the network is constituted by the data recording unit integrating up to four pollutant analyzers together with the necessary sampling and calibration units and up to four instruments for the recording of meteorological parameters. One or more of such data recording units can be accommodated in

<xref image="2000WVG1.TIF|V3|2006:09:28:01:28:52.00|120810|0"> image: </xref>

one sampling station which is in turn connected to regional subcenters via remote control units. Apart from automatic operation, the individual data recording units can be also controlled manually. Final data processing is done in a computer center. The data recording centers are suitable for the concentration measurement of such air pollutants as sulfur dioxide, hydrogen sulfide, nitric oxide, nitrogen dioxide, total nitrogen oxides, carbon monoxide, carbon dioxide, ammonia, hydrochloric acid, chlorine, hydrofluoric acid, ozone, oxidants, and hydrocarbons.

66606

Birkle, M.

SETUP OF AN AUTOMATIC AIR POLLUTION MONITORING NETWORK. (Aufbau eines automatischen Immissionsmessnetzes). Test in German. Siemens. Z., 48(8):52S-S32, 1974. 25 refs.

The structure and functioning of automatic air pollution monitoring networks are described. Automatic monitoring networks are usually composed of measuring units which constitute the basic units of the system and which may include up to four pollutant analyzers complete with the corresponding calibration units, as well as up to four recording units for meteorological parameters. One or more of such measuring units together form one sampling station, and the sampling stations in their turn are connected to, and controlled by, regional sub-centers including process computers and remote control units. The measurement data received and reduced by the regional sub-center is transmitted to the computer center for processing, statistical evaluation, and warning initiation. The air pollutants to be monitored are selected from among the compounds sulfur dioxide, hydrogen sulfide, nitric oxide, nitrogen dioxide, total nitrogen oxides, carbon monoxide, carbon dioxide, ammonia, hydrochloric acid, chlorine, hydrofluoric acid, ozone, oxidants, total hydrocarbons, and dust. The SO₂ and ozone concentrations can be used as leading pollutants for smog alarm.

ANALYTICAL TECHNIQUES IN AIR POLLUTION. In: Air

Pollution and Industry, R. D. Ross (ed.), New York, Van Nostrand Reinhold Co., 1972, Chapt. 5, p. 248-280. 30 refs.

A review is presented on techniques for the sampling and analysis of air pollutants. The most common reaction for the noninstrumental detection of gaseous air pollutants is the colorimetric change which can be measured either visually or with a spectrometer. Dry chemical tests using indicating papers and tubes provide simple and rapid checks and are useful when the danger of toxic gases are present. The basic unit of the wet chemical air pollutant test is the absorption apparatus which may be either of the impinger type or the fritted glass scrubber, with the absorbed pollutants being subjected most often to colorimetric tests. The most basic form of instrumental techniques is also based on absorption, though in an automated manner, with the measurement often being done by a built-in colorimeter or conductivity cell. Such instruments are often used for monitoring sulfur dioxide, nitrogen oxides, ozone, chlorine, oxidants, cyanides, and sometimes carbon dioxide. Fluorides are better detected with fluorescence techniques as are nitrogen oxides. Hydrocarbons can be detected over a wide concentration range with a flame ionization detector. Air pollution instruments based on infrared spectrophotometry can be used for the measurement of CO₂, carbon monoxide, SO₂, O₃, acetylene, ethylene, methane, ammonia, and peroxy nitrates. Ultraviolet methods can be used for nitrogen dioxide, SO₂, O₃, and hydrocarbons. The gas chromatograph is one of the most versatile air pollution instruments and is able to separate complex mixtures. The mass spectrometer is capable of identifying small amounts of materials. Several instrumental techniques are also available

for organic and inorganic particulate analysis. Odor threshold determinations can only be made by using the average reaction of a group of people.

ANALYSIS FOR AEROTOXICANTS. CRC Critical Rev. Anal.

Chem., 1(3):275-333, Nov. 1970. 565 refs.

Analytical methods are reviewed for a variety of aerotox-
icants. Toxic compounds considered include: carcinogenic
poly nuclear hydrocarbons (arenes, aza arenes, and imino
arenes); cocarcinogens such as certain alkanes and phenols;
poly nuclear anticarcinogens; respiratory irritants such as
benzene, acetyl peroxide, formic acid, 2-methylbutene-2, 2-
methylpentane, peracetic acid, and propylene oxide; allergens
of the protein and glycoprotein type, including pollens; coaller-
gens and antiallergens; mutagenic and/or carcinogenic alkylat-
ing agents; lachrymators such as formaldehyde, acrolein, and
peroxyacyl nitrates; and phytotoxicants such as ethylene, sul-
fur dioxide, ozone, oxidants, and fluorides. Analytical
methods cited include: electrochemical techniques, chromatog-
raphy, colorimetry, spectrophotometry. fluorescence
techniques, various spectrometric methods including mass
spectrometry, and histamine bioassay techniques (for allergens).

PRESENT STATE OF THE MEASURING TECHNIQUE FOR

THE DETERMINATION OF THE FLUORINE CONTENT IN

IMMISSIONS AND EMISSIONS. (Derzeitiger Stand der Mess-
technik zur Bestimmung des Fluorgehaltes in Immissionen und
Emissionen). Text in German. Arch. Eisenhuettenw., 44(9):6p.,
Sept. 1973. 7 refs.

The present state of measuring techniques for the determina-
tion of the fluorine content in immissions and emissions is
reviewed. Topics covered include: the calculation of the
characteristic immission data, comparison of different immis-
sion measuring procedures, problems in the separation of gase-
ous and solid fluorine compounds in immission and emission
measurements, and the assessment of test results. Although a
reliable procedure for the exact separation of gaseous and
solid fluorine compounds is not yet available, a solution ap-
pears possible if binding definitions for the limitation between
gaseous and solid fluorine compounds are given and accepted.
A procedure is possible for emission measurements enabling
the determination of gaseous fluorine compounds with an ex-
actness of 10-15%; solid fluorine compounds can be deter-
mined on the basis of an exact determination of dust.

SOURCE SAMPLING FOR FLUORIDE EMISSIONS FROM

ALUMINUM, STEEL AND PHOSPHATE PRODUCTION

PLANTS: A STATE-OF-THE-ART REPORT. Health Lab. Sci.,

11(4):354-359, Oct. 1974. 9 refs.

The state-of-the-art of source sampling for gaseous and par-
ticulate fluoride emissions from aluminum and steel plants and

<xref image="2000WVG2.TIF|V3|2006:09:28:01:28:56.00|119867|0"> image: </xref>

phosphate production facilities is reviewed. Participate collectors employed for separation of gaseous and paniculate fluorides in dry emission streams from primary aluminum and steel plants include electrostatic precipitators and high-efficiency filters. Some of the paniculate is generally collected on the walls of the sampling probe. Insufficient data exist for demonstrating the effectiveness of in-stack filters for reducing the amount of paniculate in the probe. All sampling trains employ impingers to collect gaseous fluorides, and differences in collection efficiency using water versus dilute caustic appear negligible. There is no provision for conducting a separation of gaseous and water soluble paniculate fluorides in the case of wet streams from phosphate rock processing operations. The apparatus generally used for sampling stack emission is the same as for the dry stream industries, except for elimination of the paniculate collector. The tendency of hydrogen fluoride to react with paniculate matter on filters can be minimized in some cases by converting the HF to silicon tetrafluoride with a heated glass probe. The SiF₄ is then collected in the impingers, hydrolyzed with dilute alkali, and analyzed by an appropriate method.

RAPID QUANTITATIVE ANALYSIS OF FLUORINE IN
PLANT. PART 2. (Shokubutsutai chu fusso no jinsoku teiryō ni
tsuite dai ni ho). Text in Japanese. Miyagiken Kogai Gijutsu
Senta Hokoku (Miyagi Prefect. Pollut. Contr. Tech. Center
Rep.), no. 2:37-40, April 1974. 4 refs.

An ion selective electrode microanalytical method of determination of fluorine contained in plants was investigated. The sample plant was washed and dried in a vacuum dryer at 80 C for 4 hrs, and 5 g of the crushed sample was taken into a 300 ml flask and was carbonized with 0.5 g of quartz sand, 0.4 ml of perchloric acid, and 0.2 g of silver perchlorate at 130 C by 3 hr of reflux. By steam distillation, 200 ml of aqueous solution was obtained, of which 10 ml was mixed with 20 ml of TISAB (a buffer solution to adjust total ion strength). The electrostatic potential of the sample was measured 5 min later and fluorine concentration was determined by comparison with the calibration curve. It was found from the comparison of the results obtained by the present ion electrode method and the Alfusone colorimetric method that both methods gave the same results. Disturbance by metal ions on determination of fluorine concentration was checked. Addition of 0.1 and 1 mol of ferric ion to aqueous solution containing 0.5 ppm fluorine lowered apparent fluorine concentration by 15 and 70% respectively. Chlorine ion lowered the apparent fluorine concentration by 15% while other ions did not disturb the determination. The fluoride ion electrode method can be used as a practically useful microanalytical method for fluoride ion.

DETERMINATION OF TRACE AMOUNTS OF FLUORINE
BY NUCLEAR INELASTIC SCATTERING. Missouri Univ.,
Columbia, Trace Subst. Environ. Health, Proc. Univ. Mo. Annu.
Conf., 7th, Columbia, Mo., 1974, p. 313-321. 23 refs.

The detection of inelastic scattering of energetic protons to the first (110 keV) and second (197 keV) excited states of fluorine (19) is a sensitive tool for detecting trace amounts of fluorine in a large variety of environmental and biological samples. Gamma rays following inelastic excitation of fluorine nuclei are observed with a lithium-drifted germanium detector of 1.8 keV resolution. With the method, the minimum detectable amount is approximately 10 ng, assuming a 15 minute irradiation of the sample with a 4.8 MeV proton beam of current density of 0.5 microA/sq cm. Obvious improvements in experimental parameters such as detector geometry and shielding

and the use of a low-volume, high resolution detector could improve this result by a factor of 10. Results of some investigations are presented, and applications of the method are discussed. The method is useful to determine fluorine in coal, teeth, water, vegetation, and other environmental samples. The advantages of the technique are that minimal sample preparation is required and that very small amounts of material may be analyzed. (Author abstract modified)

THE STATE-WIDE AIR QUALITY MONITORING SYSTEM

IN BAVARIA. (Das lughygiensche Lan-

desueberwachungssystem Bayern (LUEB)). Text in German.

Gesundh.-Ingr., 95(10):297-301, 1974.

The air quality monitoring grid which existed in Bavaria was only partially automated. It comprised 27 measuring stations taking emission measurements of sulfur dioxide and partially also of carbon monoxide and the oxides of nitrogen. This measurement grid is now being expanded to a total number of eighty measuring stations and one data processing and evaluating station. In a first expansion phase 14 stations and a computer center will be added for operation in July 1974. The total system shall be completed by 1977. Costs are estimated to reach \$5 million. In its final version the system will measure 24 parameters, the pollutants SO₂, hydrogen sulfide, CO, nitric oxide, nitrogen dioxide, hydrocarbons, hydrogen chloride, hydrogen fluoride, ozone, the dust concentration and dust fall, meteorological parameters such as wind direction and velocity, air temperature, humidity, pressure, global radiation, precipitation with pH value, noise, radioactivity, electrostatic field, and short-term pressure fluctuations.

AN ASSESSMENT OF INSTRUMENTATION AND MONI-

TORING NEEDS FOR SIGNIFICANT AIR POLLUTANTS RE-

MITTED BY AIR FORCE OPERATIONS AND RECOMMEN-

DATIONS FOR FUTURE RESEARCH ON ANALYSIS OF

POLLUTANTS. Monsanto Research Corp., Dayton, Ohio, Air

Force Contract F33615-72-C-1304, Program Element 70230407,

Rept. ARL 74-0015, 184p., Feb. 1974. 372 refs. NTIS, DDC: AD

778938

Air pollution monitoring needs of the Air Force are considered in terms of presently used instrumentation and the development of new techniques to meet specific requirements. Recommendations regarding instrument development are given for the following areas of pollution monitoring: volatile aircraft emissions (carbon monoxide, nitrogen oxides, hydrocarbons, exhaust odors); particulate aircraft emissions (particle size distribution, smoke number, mass emission, optical transmission); emissions related to missile storage facilities and missile test and launching sites (hydrogen chloride, hydrogen fluoride, hydrazine, nitrogen oxides); metallic element emission sources; herbicide incineration emissions; and ambient air measurements. General recommendations are given for areas where fundamental research is vitally important.

MECHANICAL ANALYSIS METHOD FOR AIR POLLU-

TANTS AND ITS TREND. (Taiki osen busshitsuo no kiki bunseki hoho to doko). Text in Japanese. Sangyo Kogai (Ind. Public Nuisance), 10(9): 1-3, Sept. 1974. 8 refs.

The Agency of Industrial Science and Technology, Department of Equipment Standards has sponsored for the last 4 yr, with an annual budget of approximately \$50,000, research on various types of continuous analysis equipment to be utilized by the Japanese Industrial Standards. The research had been conducted by the Industrial Pollution Control Association and various equipment manufacturers. This equipment includes continuous analyzers for sulfur oxides, carbon monoxide, nitrogen oxides, suspended particulates, stack gas SO_x, hydrocarbons in the air, chlorine, oxidant, hydrogen fluoride, bad odors (hydrogen sulfide, ammonia), stack gas NO_x, aldehydes, and hydrogen chloride. The first three have already been passed as JIS equipment, and the rest are under examination. Absorption spectrophotometry is widely used in Japan for single element measurement for its superior color selectivity. Electropotentiometry is used for NO_x and CO. The ion electrode method is under consideration for JIS for its superior selectivity for specific ions. Among the dry methods, non-dispersive infrared spectrometry is widely used; more recently, ultraviolet absorption spectrometry has been adopted for NO_x analysis. The acidic rain that created physical effects this year for the first time in Japan has occurred in Europe since 1958, and acid generating substance was added as an air pollutant at the ISO Geneva Conference in 1972. The titration analyzer using a pH meter (developed in France) is widely used to measure acidity.

DETERMINATION OF FLUORIDES IN THE ATMOSPHERE

(FINAL REPORT). (De bepaling van fluoriden in de atmosfeer (eindrapport)). Text in Dutch. TNO, Haag (Netherlands), Chemisch Lab., Rept. 1973-22, 22p., Nov. 1973. 3 refs. NTIS: N74-256S6

The further development and the resulting prototype of an automatic fluoride analyzer for continuous monitoring of atmospheric fluorides are described. It was possible to reduce the water loss due to evaporation during sampling by cooling the air to be released by means of Peltier coolers. For the measurement of the gaseous fluoride concentrations, particulate fluorides with aerodynamic diameters over 1 micron are separated by means of a miniature cyclone at an efficiency of 98%. The results of atmospheric fluoride measurements carried out with the automatic analyzer were in good agreement with those obtained by means of impregnated filters. Factors influencing the calibration curves, such as temperature and time, were studied.

RADKJ-RELEASE DETERMINATION OF HYDROGEN FLUORIDE IN AIR USING RADIOACTIVE KRYPTONATE OF SILICA. Radiochem. Radioanal. Lett. 13(3):199-205, 1973. 6 refs.

Radioactive kryptonate of silica is suggested for the determination of hydrogen fluoride concentration in air. Kryptonated discs of silica were allowed to react with different concentrations of HF in air. The results were linear within the 2-10 ppm concentration range, and were in fair agreement with theoretical assumptions. (Author abstract)

AN ATMOSPHERIC HYDROGEN FLUORIDE MONITOR.

Preprint, Chemical Lab. TNO, Rijswijk (Netherlands), 8p., 1970 (?). 3 refs.

A sampling and analytical technique for measuring hydrogen fluoride is described. Gaseous fluorides are separated from particulate matter in a miniature cyclone. The gaseous fluorides are collected in a buffer solution which circulates continuously in the measuring cell. A fluoride electrode and a reference electrode are fixed in the measuring cell. The fluoride electrode responds to free fluoride ions. The potential developed by the fluoride electrode against the reference electrode is a logarithmic function of the fluoride ion concentration in the solution, if the measurements are carried out in a buffer solution in order to avoid variations in the pH and the ionic strength in the solution and to unbind fluoride of complexing ions. The fluoride ion concentration is measured potentiometrically during the sampling period of 24 hr. In this way it is possible to determine 24-hour averages of the atmospheric HF concentration and within this period short-term averages can be measured. The monitor can measure HF concentrations in the range 0.05-15 micrograms/cu m. The calibration and testing of the device are described. The technique can be used to measure HF in stack gases by shortening the cycle period and can also measure sulfide, chloride, cyanide, and ammonia if a suitable ion selective electrode and sampling solution is used.

TRACE ANALYSIS IN SOURCE TESTING. California Air Resources Board; California Univ., Berkeley, Dept. of Mechanical Engineering; and California State Dept. of Public Health, Air and Industrial Hygiene Lab., Conf. Methods Air Pollut. Ind. Hyg. Studies, 13th, Berkeley, Calif., 1972, 8p. (Oct. 30-31.) To determine the environmental impact from trace element emissions, the trace element composition of fuels and particulates collected with the Environmental Protection Agency source sample train was determined. The simultaneous multi-element analyses most frequently used were optical emission spectrography, spark source mass spectrometry, and neutron activation. These techniques were supported by other trace analysis methods including anodic stripping voltametry, atomic absorption, conductometric titrations, ion specific electrode methods, and wet chemistry. The advantages and disadvantages of these methods, precision of data, and findings to date are summarized. Considerable information can be gained relatively inexpensively if the industrial feed material, such as ore or coal, is first analyzed before a source test is initiated. Such an analysis is helpful in determining the need or scope of a source test. More measurements are needed of the size distribution of particles in various sources, especially as a function of the trace element composition. The validity of the results is being tested by conducting interlaboratory comparisons on source emission samples. Valuable information is also gained on analytical methodology and equivalency where several techniques are used to analyze the samples. A recent example of this type of activity is illustrated by the determination of fluoride by four laboratories using four different techniques in measurement of the samples.

mochiiru endo haigasu-chu no fukkabutsu no sanpuringu ni Lsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 9(2):436, Nov. 1974. (Presented at the National Air Pollution Research Conference, 15th, Chiba, Japan, Nov. 6-8, 1974, Paper 287.)

A filter paper holder consisting of a heating thermocouple and two layers of filter paper, a teflon filter paper, and an alkaline filter paper, was used for fluoride sampling. The filter paper was pretreated with a 10% sodium carbonate solution and dried. The sampling velocity was 10 l/min, and the filter paper flow rate was 0.35 l/sq cm/min. The filter papers were then immersed in 25 ml of sodium citrate buffer solution for 30-60 min, and the fluoride was determined by a fluoride ion electrode. More than 99% of the fluoride was collected.

Pollution Atmospherique par Residus Organiques et Mineraux Grenoble (France), Study Group
SAMPLING AND ANALYTICAL METHODS FOR AIR POLLUTANTS. (Methodes de prelevement et d analyse de polluants atmospheriques). Text in French. Bull. Inform. Sci. Tech. Comm. Energ. At. (Fr.), no. 191:7-29, April 1974. 6 refs. Sampling and analytical methods for air pollutants are described. Gaseous air pollutants are most often sampled through bubblers with adequate absorbent liquid at efficiencies of up to 85%. Organic vapors can be concentrated on gas chromatographic columns under cryogenic conditions. Particulate matter can be separated on filters or by the electrostatic method. An automatic sequential sampler can separate gases and vapors either in a bubbler or on a column. Another dust sampler is able to sample dust quantities of up to 50 mg/day without granulometric separation, and with granulometric separation from 1 micron upward. Sulfur dioxide is determined by a spectrophotometric method, using West-Gaeke's reagent, while nitrogen oxides are determined by Saltzman's reagent. The methyl orange method used for the determination of chlorine has a sensitivity of 1 microgram/cu m. Hydrofluoric acid, and soluble chlorides can be determined by means of ion-specific electrodes at a sensitivity of 0.1 microgram/cu m. Organic vapors are determined best by a combination of a gas chromatograph and a mass spectrometer, using molecular sieves as an interface. Colorimeters for SO₂ and NO_x vapors, chemiluminescent instruments for ozone and nitrogen oxides, infrared analyzers for carbon monoxide, fluorescence and potentiometric analyzers for SO₂, and flame ionization detectors for hydrocarbons are commercially available.

Yamaki, Naomi
TECHNIQUES OF ATMOSPHERIC POLLUTION PREVENTION MEASUREMENT. (Taiki osen keisoku gijutsu). Text in Japanese. Sangyo Kogai Boshi Gijutsu (Ind. Pollut. Control Tech.), 1974:33-36, June 1974. Measurement methods for gaseous pollutants and suspended particulates are reviewed along with a discussion of the preparation of standard gases. Automatic methods for sulfur dioxide and nitrogen oxides are being developed. The Electrochemical Lab is studying the electromagnetic determination and identification of minor components of air using electron impact ionization. The Institute of Environmental Pollution and Resources is studying the measurement of hydrofluoric acid, hydrogen chloride, carbon monoxide, nitrogen oxides, and hydrogen cyanide. It was recently found that almost complete collection of mercaptan and sulfite is possible by the use of a large excess of silver nitrate and that with 6 N HCl decomposition of the collected substances is possible to the extent of 94-100% for mercaptans, 99-100% for monosulfite, and 98% for bisulfite. These findings are being applied to determination by combined chromatography-mass spectral analysis. Dilution methods for standard gases are discussed.

American Society for Testing and Materials, Philadelphia, Pa.
TENTATIVE METHOD OF ANALYSIS FOR FLUORIDE
CONTENT OF THE ATMOSPHERE AND PLANT TISSUES
(SEMIAUTOMATED METHOD). Book ASTM Stand., no.
26:754-767, 1974. 9 refs.

A semiautomated colorimetric procedure for the analysis of total fluoride in the atmosphere and other media (e.g., plant tissue) is described. The method incorporates microdistillation of the sample and may be applied to any fluoride-containing solution where standards of identical composition are carried through the same sample preparation procedures and are proven to provide quantitative recovery when analyzed by the semiautomated system. Atmospheric samples must be brought into solution and must fall within the calibration range of the instrument. Samples are analyzed sequentially with standard solution, which have a composition similar to the samples or with standards which provide the same recovery of fluoride. In either case, the method must be confirmed by a manual procedure. The semiautomated procedure involves pumping a sample slurry or solution and sulfuric acid into a polytetrafluoroethylene coil of a microdistillation device maintained at 170 C. A stream of air carries the acidified sample through the coil to a fractionation column. Fluoride and water vapor are condensed and pumped continuously from a distillate collector. Spent acid and solids are continuously removed as waste. Distillate is mixed continuously with a colorimetric reagent (alizarin fluorine blue-lanthanum) and passed through the flow cell of a recording colorimeter. The normal range of analysis is 0.1-4.0 micrograms F/ml. normal range of analysis is 0.1-4.0 micrograms F/ml.

American Society for Testing and Materials, Philadelphia, Pa.
TENTATIVE METHODS FOR ANALYSIS FOR FLUORIDE
CONTENT OF THE ATMOSPHERE AND PLANT TISSUES
(MANUAL PROCEDURES). Book ASTM Stand., no. 26:735-
753, 1974. 31 refs.

Titrimetric, spectrophotometric, and potentiometric methods for the manual determination of fluorides in the atmosphere and other media (e.g., plant tissue) are outlined. Direct titration of fluoride with standard thorium nitrate solution can accommodate from 10 to 0.05 mg of fluoride in the total sample. Back titration modifications can measure from 50 to about 5 micrograms fluoride in the total sample. Direct titration can also be used for the lower ranges if photometric end point detection is employed. For the spectrophotometric detection of fluoride, both Zirconium-Eriochrome Cyanine R and Zirconium-SPADNS reagents obey Beer's law over the range from 0.000-1.40 micrograms of fluoride/ml with a detection limit of 0.02 microgram/ml. A Lanthanum-Alizarin Complexone procedure for the lower range covers from 0.00 to 0.5 microgram of fluoride/ml with a detection limit of approximately 0.015 microgram/ml. The spectrophotometric methods are temperature sensitive, and absorbances must be read within + or - 2 C of the temperature at which the respective calibration curve is established. The potentiometric determination of fluoride (inorganic) is achieved by diluting the alkaline sample solution containing atmospheric fluoride 1 + or - with a combined buffer (ionic strength adjuster and complexing agent) ad-
<xref image="2000WVG5.TIF|V3|2006:09:28:01:29:06.00|123602|0"> image: </xref>

justed to pH 5.9-6.1 prior to analysis with a fluoride ion selective electrode. The potential corresponding to the fluoride ion concentration is measured in millivolts. The recommended range for analysis of air samples is between 0.1 and 10 micrograms/ml of fluoride in solution.

TENTATIVE METHOD FOR SEPARATION AND COLLEC-
TION OF PARTICULATE AND GASEOUS FLUORIDES IN
THE ATMOSPHERE (SODIUM BICARBONATE- COATED
GLASS TUBE AND A PARTICULATE FILTER METHOD).

Book ASTM Stand., no. 26:728-734, 1974. 6 refs.

A method for the separation and collection of paniculate and gaseous fluorides in the atmosphere is described. The method employs a sodium bicarbonate-coated glass tube and a membrane filter and is capable of collecting 2-500 micrograms of gaseous fluoride over a 12-hour sampling period at a sampling rate of 14.2 l/min (0.2-50 micrograms/cu m). The lower limit of detection is considered as twice the standard deviation of the monthly arithmetic mean blank value. The method involves removing gaseous fluorides from the air stream by reaction with sodium bicarbonate coated on the inside wall of a borosilicate glass tube. Paniculate fluorides are collected on a filter following the tube. The fluoride collected on the tube is eluted with water or buffer and analyzed for fluoride, and the particulates collected by the filter are eluted with acid and then analyzed for fluoride. The results are reported as micrograms of gaseous fluoride and micrograms of paniculate fluoride per cubic meter of air at 21 C and 760 torr pressure. Possible interferences include acid aerosols or gases which are capable of neutralizing or acidifying the bicarbonate coating and phosphates or metals such as aluminum which are capable of interfering with the subsequent analysis. Regarding the method's precision, the root mean square difference of duplicate bicarbonate-coated tubes within the range from 0.5- 3.3 micrograms fluoride/cu m is 0.051 microgram fluoride/cu m. Recovery of hydrogen fluoride is better than 95% for amounts of fluoride up to about 40 micrograms and for sampling periods of 15-120 min. Data on particulate fluoride are insufficient to establish recovery under field conditions.

71245

American Society for Testing and Materials, Philadelphia, Pa.
TENTATIVE METHOD FOR CONTINUOUS SEPARATION
AND COLLECTION OF PARTICULATE AND WATER-
SOLUBLE GASEOUS FLUORIDES IN THE ATMOSPHERE
(FILTER AND IMPINGER METHOD). Book ASTM Stand., no.

26:721-727, 1974. 6 refs.

A method for the continuous separation and collection of particulate and water-soluble gaseous fluorides in the atmosphere is described. The method utilizes a chemically treated filter and an impinger. Sampling rate may vary from 14.2 l/min for 24 hr to 28.3 l/min for 3 hr, depending on the atmospheric fluoride concentration. The procedure involves drawing air through an air inlet tube for passage through an acid-treated prefilter which removes particulates. The stream is then drawn through an impinger for the removal of water-soluble fluorides. The prefilter and impinger solutions are subsequently analyzed by potentiometric or photometric methods. Possible interferences include particulate metallic salts, phosphates, and metals such as aluminum. The precision and accuracy of the method are not yet established.

72015

American Society for Testing and Materials, Philadelphia, Pa.
TENTATIVE METHOD FOR AUTOMATED SEPARATION
AND COLLECTION OF PARTICULATE AND ACIDIC GASE-
OUS FLUORIDE IN THE ATMOSPHERE (DOUBLE PAPER
TAPE SAMPLER METHOD). Book ASTM Stand., no. 26: 715-

720, 1974. 14 refs.

A tentative method for the automated separation and collec-

tion of particulate and acidic gaseous fluoride in the atmosphere by means of a double paper tape sampler is described. Air is drawn through an air inlet tube and is first passed through an acid-treated prefilter paper tape to remove any particulates which may contain fluoride and then through an alkali-treated paper tape to remove acidic fluoride gases. Exhaust air is filtered through soda lime-glass wool, and the cleaned air is used to pressurize the front compartment to prevent fluoride contamination of the paper tapes from the ambient air. At the end of the preset sampling period (several minutes to 3 hr), the vacuum pump is automatically turned off, and the tapes are indexed. The paper tapes are removed from the sampler and analyzed by potentiometric or photometric methods. Possible interferences include: particulate metallic salts, acid aerosols or gases, and phosphates or metals such as aluminum. The relative standard deviation of hydrogen fluoride determination is about 16% for the 1-3 micrograms/cu m range and about 5% for the 12-45 micrograms/cu m range. Recoveries of hydrogen fluoride are better than 95% with amounts of fluorides of up to 40 micrograms and at sampling periods of 15-120 min. The precision and accuracy of particulate fluoride determinations are not yet established.

72017

Prinz, B.

APPROACHES AND RESULTS OF AN EFFECT MONITORING-PROGRAMME IN THE STATE NORDRHEIN

WESTPHALIA. World Meteorological Organization and World Health Organization, Geneva (Switzerland), World Meteorol. Organ./World Health Organ. Tech. Conf. Observ. Measurement Atmos. Pollut., Helsinki, Finland, 1973, p. 223-235. 1974. 10 refs. (July 30-Aug. 4, Paper 368.)

An effect monitoring program was conducted in Nordrhein Westphalia to measure the effect of pollutants on a set of indicators. Three groups of indicators were applied: effect observations by use of exposed lichens, wood, and metal patterns representing the biological and technical part of the environment; uptake of pollutants by the biosphere by use of standardized grass cultures; and uptake of pollutants by standardized materials by use of massflow proportional measuring devices. The mortality rate of the lichen area was determined in percent of the undamaged area at the beginning of the exposure. The mortality rates range from 0 to 38% comparable with 0% at a site in nonindustrial area and 84% at a site in Duisburg, both outside the surveyed region. Grass cultures were exposed under standardized conditions to sulfur, fluorine, chlorine, lead, zinc, and cadmium. All sites showed a considerable and widespread amount of S uptake. The correlation coefficients between S uptake and the uptake of the other five compounds reflect the emission situation in the area. The correlations and partial correlations between sulfur dioxide concentrations, IRMA-data (mass stream proportional uptake of a pollutant), and uptake of S by grass are more significant for the effect-related uptake by grass than the concentration values.

Dee, L. A., H. H. Martens, and J. T. Nakamura
EVALUATION OF SOLID SORBENTS FOR SAMPLING SO₂,
HCL, AND HF FROM STATIONARY SOURCES (FINAL RE-
PORT). United States Air Force, Edwards, Calif., Rocket
Propulsion Lab., Environmental Protection Agency Proj. EPA
000CX, Rept. AFRPL-TR-74-54, FY 73, lip., Aug. 1974. 6 refs.
NTIS, DDC: AD-784813

Various solid sorbents were evaluated for the sampling of sul-
fur dioxide, hydrogen chloride, hydrogen fluoride, and silicon
tetrafluoride from stationary sources. Lead oxide did not ab-
sorb HF or SiF₄, though it did appear to absorb HCl and SO₂
quantitatively; however, the problems associated with extrac-
tion and subsequent analysis of the corresponding anions are
insurmountable at present. Lithium carbonate is a useful sor-
bent for HCl and HF, though less complicated carbonate sor-
bents need to be first evaluated. Manganese dioxide also ab-
sorbs SO₂, but further efforts are needed to develop a more
specific trace sulfate determination method

ON THE HF GAS MONITOR BY FLUORIDE ELECTRODE.
(Ion denkyoku-ho ni yoru haigasuchu HF sokutei no tsuite).
Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollu-
tion), 9(2):437, Nov. 1974. (Presented at the National Air Pollu-
tion Research Conference, Chiba, Japan, Nov. 6-8, 1974, Paper
288.)

A hydrogen fluoride monitor having a glass absorption
chamber in which absorbent was sprayed into the sample gas
is described. A pH buffer for fluoride determination was sup-
plied as an absorbent at 1 ml/min, and a sample gas containing
HF was introduced at a flow rate of 4 l/min. The resulting ab-
sorbent was pumped to a detector cell, and the fluoride con-
centration was determined by the fluoride ion electrode
method. Results obtained from five samples of the same type
were compared to those obtained by chemical and lanthanum-
alizarin complexone (JIS K 0105) methods, and correlation
coefficients of 0.994-0.996 were obtained. The monitor was
usable in the ranges of 0-5 ppm and 0-2 ppm, and the standard
deviation was about + or - 3%.

DETERMINATION OF HYDROGEN FLUORIDE IN AT-
MOSPHERE. (Opredeleniye fluoristogo vodoroda v atmosfere s
otborom prob na tverdyi sorbent). Text in Russian. Tr, Gl.
Geofiz. Observ, no. 293:78-82, 1973. 9 refs.
A method for sampling gaseous hydrogen fluoride on solid sor-
bent for subsequent photometric determination by the attenua-
tion of the coloration of a zirconium-xyleneol range complex is
described. Glass granules of 1 to 2 mm in size, treated with
0.2% alcohol solution of potassium chloride, are used as solid
sorbent either in a wet or dry state. The rate of sampling
amounts to 3 l/min for up to 20 min for hydrogen fluoride con-
centrations not greater than 0.2 mg/cu m. The adsorbed
hydrogen fluoride is quantitatively desorbed by a small amount
of water. The solid sorbent is placed in a glass tube 5 mm in
diameter.

MEASUREMENT TECHNOLOGY AT AN OUTBREAKING
POINT OF AIR POLLUTION. (Hasseigen ni okeru sokutei
gijutsu). Text in Japanese. Preprint, Japan Society of Civil En-
gineering, p. 31-46, 1972. (Presented at the Japan Society of
Civil Engineering, Lecture Meeting, Tokyo, May 23-24, 1972.)
Measurement methods for determining the total emission of
gaseous pollutants from fixed sources are described. Total sul-
fur oxides are determined by the neutralization method, the

Arusenazo III method, and the barium chloranilate method. Waste gases containing nitrogen dioxide, hydrogen chloride and chlorine cannot be analyzed for their total SO_x by the neutralization method. Sulfur dioxide can be analyzed by using a sulfamate solution as the absorbent and titrating with iodine. Fluoride can be analyzed using the lanthanum-alizarin complexone method by measuring the absorbance of the resulting complex near 620 nm. Chlorine can be analyzed by passing the gas into ortho-tolidine solution which results in the formation of a yellow solution (absorbance near 435 nm). Hydrogen chloride can be analyzed by a spectrophotometric method (mercuric thiocyanate method) or a volumetric method (silver nitrate method and neutralization method). A correction is required if chlorine coexists. Total nitrogen oxides can be analyzed by the naphthylethylenediamine method. The continuous determination of the above substances by conductivity, infrared analysis, potentiometry, ultraviolet analysis, chemiluminescence, and gas chromatography is also briefly discussed

74234

Weinstem, L. H. and R. H. Mandl
THE SEPARATION AND COLLECTION OF GASEOUS AND PARTICULATE FLUORIDES. VDI (Ver. Deut. Ingr.) Ber., no. 164:53-70, 1971. 20 refs.

Laboratory and field tests of three methods for the separation and collection of gaseous and particulate fluorides were conducted. The three sampling procedures evaluated comprised: bicarbonate-coated tubes with citric acid-treated Acropor AN-800 membrane filters fitted to either the inlet or the outlet ends of the tubes, a double-tape sampler with a citric acid-treated Whatman No. 52 prefilter tape and a Whatman No. 4 alkali-treated tape, and duplicate filter holders each containing citric acid-treated Acropor AN-800 membrane as a prefilter and an alkali-treated Whatman No. 41 paper to collect gaseous fluoride. The results for gaseous fluoride collected by the three devices were reasonably close, although the tape sampler gave results considerably higher than the others on 3 days. The tape sampler also showed wide diurnal fluctuations in fluoride concentration which was highest during warm periods when fluoride desorbed from chamber surfaces. The bicarbonate-coated tubes were sensitive to humidity; moisture condensation resulted in partial or complete removal of the bicarbonate coating from the tubes.

CUMULATIVE MEASUREMENT OF SULFUR DIOXIDE
AND FLUORIDES IN AMBIENT AIR. (Kumulyativnoye
opredeleniye dnuokisi sery i ftoridov v atmosferom vozdukhe).
Text in Russian. Izv. Akad. Nauk Est. SSR, Khim. Geol.,
23(3):208-213, 1974. 17 rets.

A method for the cumulative sampling and determination of ambient sulfur dioxide and fluorides in a given sample is described. Sulfur dioxide and fluorides are sampled by means of potassium carbonate-impregnated filter papers exposed at 4 m altitude. Sulfates are determined by precipitation with benzidine hydrochloride and subsequent alkaline titration in the presence of phenolphthalein. Fluorides in the same sample are determined colorimetrically at 618 nm by means of a lanthanum alizarine complex.

ENVIRONMENTAL POLLUTION MONITORING SYSTEM.
(Kogai Kanshi taisei). Text in Japanese. In: Environmental
White Paper, 1974, p. 300-303, 1975.
For efficient air pollution control, the accurate and expeditious measurement of pollution is essential. In Shizuoka Prefecture, the concentrations of sulfur oxides, suspended particulates, oxidant, nitrogen oxides, hydrocarbons, carbon monoxide, hydrogen fluoride, and hydrogen sulfide have been constantly monitored. The list of automatic measurement instruments used as of Dec. 1973 includes 66 automatic SO_x analyzers, 26 NO_x analyzers, 5 HC analyzers, 7 CO analyzers, 10 HF analyzers, and 10 H₂S analyzers. Microanalyzers such as the X-ray microanalyzer for the measurement of micro-amounts of pollutants (such as polychlorinated biphenyls and data processing systems were acquired in 1973. A list of measurement instruments used as of Dec. 1973 for air, water, noise, vibration, and other pollution measurement is also given.

Inagaki, K.
AIR POLLUTION MEASUREMENT METHODS. (Taiki node
no sokutei ho). Text in Japanese. Kagaku Kojo (Chem. Factory),
19(8):24-34, Aug. 1975. 12 refs.
Sampling and measurement methods of air pollution are discussed. The JIS methods for the analysis of air pollutants (absorbent in parentheses) include: ammonia: titration and indophenol methods (0.5 W/V% boric acid); total sulfur oxides: neutralization (3% hydrogen peroxide) and arsenazo III methods (ammonium sulfamate + ammonium sulfate, pH 5.4); sulfur dioxide: iodine titration method (ammonium sulfamate + ammonium sulfate, pH 5.4); nitrogen oxides: naphthylethyleneamine method (0.1 N ammonia water); total NO_x: phenolsulfonic acid method (diluted sulfuric acid + H₂O₂); nitrogen dioxide: naphthylethyleneamine method (0.1 N sodium hydroxide); fluoride: lanthanide alizarin complexon and thorium nitrate-neothorin methods (0.1 N NaOH); chlorine: o-toluidine method (0.01 W/V% o-toluidine hydrochloric acid solution (pH 1.6)); HCl: mercuric thiocyanate, silver nitrate, and neutralization methods (0.1 N NaOH); hydrogen sulfide: iodine titration and methylene blue methods (zinc ammonium complex salt solution); and hydrogen cyanide: silver nitrate titration and pyridine-pyrazolone methods (2 W/V% NaOH). Infrared spectrometry is used for continuous analyses of SO₂, carbon monoxide,

nitrogen oxide and NH₃, while conductivity and spectrophotometric methods are used for continuous analyses of SO₂, chlorine gas, HCl, NH₃ and NO_x.

INFRARED GAS FILTER CORRELATION INSTRUMENT
FOR IN-SITU MEASUREMENT OF GASEOUS POLLUTANTS
(FINAL REPORT). Philco-Ford Corp., Newport Beach, Calif.,
Aeronutronic Div., Environmental Protection Agency Contract
68-02-0575, Program Element 1AA010, Work Unit 14, ROAP
26AAP, Rept. EPA-650/2-74-094, Rept. U6121, 64p., Dec. 1974.
15 refs. NTIS: PB 239467/AS

An infrared gas filter correlation instrument for measuring the concentrations of carbon monoxide, nitric oxide, sulfur dioxide, hydrogen chloride, and hydrogen fluoride in the effluent of stationary sources is described. An infrared beam is directed across the stack to a retroreflector and back so that the instantaneous average concentration is measured continuously without disturbing the constituents of the effluent. A small, removable, fixed-position grating monochromator acts as a unique optical filter that passes narrow spectral intervals that are centered at wavelengths where the gas to be detected absorbs. One grating monochromator is used for CO and NO, another for SO₂ and HCl, and a third for HF. The useful ranges of concentration times path length, in atm cm, over which the gas can be measured are: 0.005-0.04 for NO; 0.0013-0.15 for CO; 0.001-4.0 for SO₂; 0.0003-0.2 for HCl; and 0.0001-0.02 for HF. Discrimination against other gases in the effluent is excellent. Field tests of the instrument on the smokestack of a coal-burning power plant were satisfactory. Minor problems encountered included: the accumulation of dirt on the windows, binding of the window shutters, and difficulties in changing the detector without exposing it to the sunlight. (Author abstract modified)

ment IAG 215, Program Element 1AB013, ROAP 21ADD-BJ,
Rept. EPA-650/2-74-125, 208p., Dec. 1974. 772 refs. NTIS: PB
241991/AS

The capabilities and costs of various analytical methods for trace element determinations in fly ash, coal, oil, ores, minerals, metals, alloys, organometallics, incinerator particulates, slurry streams, and sedimentation process feeds are summarized. Analytical methods covered include nuclear activation, mass spectrometry, X-ray fluorescence, electron and ion microprobe spectrometry, atomic absorption spectrophotometry, emission spectrophotometry, polarography, and potentiometry. These methods are evaluated in terms of their capability for determining trace amounts (less than 100 ppm) of mercury, beryllium, cadmium, arsenic, vanadium, manganese, nickel, antimony, chromium, zinc, copper, lead, selenium, boron, fluorides, lithium, silver, tin, iron, strontium, sodium, potassium, calcium, silicon, magnesium, uranium, and thorium. A selected bibliography and a review of the Standard Reference Materials available for environmental analysis are also presented.

DETERMINATION OF VOLATILE FLUORIDES EMITTED

BY ALUMINUM PLANTS. In: Atmospheric Diffusion and Air

Pollution Problems, Voprosy atmosfernoj diffuzii i zagryaz-

neniya vozdukha, Leningrad, Gidrometeoizdat Press, 1974,

225p. 5 refs. Translated from Russian, 5p.

The efficiency of sorption tubes that trap silicon tetrafluoride and hydrogen fluoride for measurement was tested with a range of known concentrations, and at different rates of drawing air through the tubes. One tube containing a 1 ml layer of solid sorbent absorbed almost all the SiF₄ and HF at 10 l/min. A Richter device was used to measure fluorides that slipped through the tube. The influence of several atmospheric cations that enter the absorbing solution during measurement of the fluorides in the solution was also tested. No effect on the measurement of fluorides was found for a 100-fold excess of calcium, cadmium, lead, zinc, or chromium cations, or for a 10-fold excess of iron cations. Silicon tetrafluoride is emitted in significant quantities with HF in some industries. Its generation for lab study is complicated because it tends to hydrolyze and to be sorbed on glass. A device that solves this problem and is effective for generating microconcentrations of SiF₄ in air is described.

MEASURING TECHNIQUES FOR DETERMINATION OF

FLUORINE CONTENT OF AIR AND STACK GASES.

(Derzeitiger Stand der Messtechnik zur Bestimmung des

Fluorogehaltes in Inmissionen und Emissionen). Text in Ger-

man. Arch. Eisenhuettenw., 44(9):697-702, 1973. 7 refs.

Recent measuring techniques for and problems involved in the measurement of gaseous and particulate fluorine concentrations in the air and in stack gases are reviewed. It is possible to determine the total fluorine content in the air by sampling with impinger or sorption tube filled with sodium carbonate-coated silver spheres. These methods do not permit, however, the separation of gaseous and particulate fluorine. Gaseous fluorine can be sampled in such sorption tubes after the air is passed through a dust separator. Gaseous and particulate fluorine can be separated in a more or less satisfactory manner by the membrane filter method using a heated filter, combined with impinger or sorption tube. Filtration through silica wool is suitable for the sampling of gaseous fluorine compounds in stack gases in a concentration range of up to 200 mg/cu m. There is no reliable procedure for the exact separation of gaseous and solid fluorine compounds. Gaseous fluorine compounds can be determined at an accuracy of 10-15%, while solid fluorine compounds can be determined on the basis of the dust measurement.

SEMI-AUTOMATIC DETERMINATION OF THE FLUORINE

CONCENTRATION IN SAMPLES FROM GAS IMMISSION

MEASUREMENTS AND FROM PYROHYDROLYSIS OF

SOLID MATERIALS. (Halbautomatische Bestimmung des

Fluorgehaltes in Proben aus Gasemissionsmessungen und in

Feststoffaufschlüssen). Text in German. Staub, Reinhaltung

Luft, 35(8):298-302, Aug. 1975. 14 refs.

The fluoride contents of solutions received from emission measurement and from pyrohydrolysis of solid materials were determined by semiautomated analysis using three ion-specific electrodes. The time required is 18 min for each sample. The standard deviation is s equals 0.04 mg/l at fluoride concentrations of 1 to 2 mg/l and s equals 0.02 mg for a sample containing 0.05 to 1 mg fluoride. Interferences by aluminum and magnesium ions were not found at concentrations up to 1 mol/l. The detectable limit of the method is 1.7 times 10 to the -6th

power mol/l or 0.03 mg.

SIMPLIFIED COLORIMETRIC DETERMINATION OF
FLUORINE IN URINE AND PARTICULATE FLUORIDES IN
ATMOSPHERE BY MEANS OF DIRECT DIFFUSION.
(Chokusetsu kakusan ni yoru kichi ryushi jo fiikka- butsu
narabini nyo-chu fusso no kanben hishoku sokutei ho). Text in
Japanese. Tetsudo Rodo Kagaku (Science of Railroad Labor),
no. 28:65-71, 1974. 11 refs.
A simplified colorimetric method for the determination of
fluorine in urine is described. The mean recovery of fluoride
by the proposed method is 99.1% when fluorine is added to
the urine. The standard value of fluorine content in urine by
this method is 0.83 mg/l and 57.2 micrograms/hr. The upper
limit of the 95% region is 3.51 mg/l and 299.5 micrograms/hr.
This method is also successfully applied to the determination
of fluorides in the atmosphere after the collection of particu-
lates on a filter made of paper or glass fiber. In this case, the
use of a glass fiber hinders the diffusion of fluorine. However,
the accuracy of determination is not lost if a correction is
made by preparing a calibration curve. Examinations of urine
from workers at a factory where welding is done indicate safe
concentrations of fluorine in the welding area.

THE CHEMICAL ANALYSIS OF SMALL FLUORIDE CON-
TENTS IN SOLIDS AND IN CASE OF EMISSION MEASURE-
MENTS. (Zur chemischen Analyse geringer Fluorgehalte in
Feststoffen und bei Emissions-messungen). Text in German. Z.
Ziegel-, Steinzeug- Ind., vol. 4:142-145, 1975. 11 refs.
Fusion processes for the determination of small fluoride con-
tents in solids are compared. Alkaline oxidizing fusion with
subsequent distillation and the pyrohydrolytic fusion process
produce the same results. The photometric determination of
fluoride ions in distillates from these solid fusions is made
using alizarin complexon with a fluoride ion sensitive electrode
fitted into a semi-automatic type of equipment. Adsorption
solutions from emission measurements are similarly deter-
mined according to the two analytical processes. The equal
validity of the two methods of analysis is demonstrated by a
random sampling of 30 solutions. Detailed instructions are
given on the pyrohydrolytic fusion of solids and also on mea-
surement with fluoride ion sensitive electrodes, including semi-
automatic operation.

PAROM (Pollution Atmospherique par Residus Organiques et Mineraux) Study Group of C.E.N., Grenoble, France
METHODS OF SAMPLING AND ANALYSIS OF ATMOSPHERIC POLLUTANTS. (Methodes de prelevements et d'analyse de polluants atmospheriques). Text in French. Bull. Inform. Sci. Tech. Commis. Energ. At. (Fr.), no. 191:7-29, 1974. 6 refs.

Existing air pollutant sampling and analytical methods developed by PAROM, Grenoble, France, are described. Gaseous pollutants are sampled most commonly by bubbling them through a reagent or absorbent solution, while organic vapors are adsorbed on a chromatographic adsorbent layer at a very low temperature. Particulate matter is sampled by filtration or by electrostatic precipitation, the latter technique permitting non-destructive sampling and granulometric separation for analysis. Certain gaseous air pollutants, such as sulfur dioxide, nitrous gases, and chlorine are determined commonly by the spectrophotometric method, while hydrogen fluoride and soluble chlorides are determined by means of ion-specific electrodes. For the analysis of particulate matter, the organic fraction is extracted with solvents by ultrasonic technique, after which the organic fraction is separated by thin-layer or liquid chromatography for determination by a combination of gas chromatography and mass spectrometry, while the mineral fraction is analyzed by atomic absorption or X-ray fluorescence. Organic vapors are determined most efficiently by a combination of gas chromatography and mass spectrometry. An instrument for the field measurement of gaseous fluorine by means of an ion-specific electrode at a sensitivity of 0.1 microgram/cu m, and a similar instrument for chlorine determination at 1 microgram/cu m sensitivity have been developed.

DEVELOPMENT OF GAS-BLENDING SYSTEMS FOR CALIBRATION: APPLICATION TO HYDROGEN FLUORIDE, ARSINE AND PHOSGENE IN AIR. Am. Ind. Hyg. Assoc. J., 36(1):755-759, Oct. 1975. 9 refs.
Gas blending systems for calibrating analytical monitoring devices were developed and applied to hydrogen fluoride, arsine, and phosgene in air. A high concentration of the standardized gas mixture is dynamically diluted with air or nitrogen to obtain the desired concentration levels. The standardized gas mixtures are measured periodically to determine any changes with time in the concentrations. Gas mixtures prepared by dilution were measured and compared with values calculated from the gas blending data. Hydrogen fluoride in the standardized mixture and in the gas mixtures prepared by dilution was determined by potentiometry employing a fluoride ion specific electrode. Arsine and phosgene gas mixtures are determined by spectrophotometric methods. Phosgene in a standardized gas mixture is measured by coulometric titration at constant current. These gas mixtures are measured in the concentration ranges from 1-60 ppm for HF, from 0.02-0.2 ppm for arsine, and from 0.05-5.0 ppm for phosgene. These concentrations represent from 0.5 to 5 times the threshold limit value for these gases.

OPTICAL - ACOUSTIC DETECTION OF SMALL CONCENTRATIONS OF HYDROGEN FLUORIDE, NITRIC OXIDE AND CARBON DIOXIDE MOLECULES IN GASES BY IR-RADIATION WITH HYDROGEN FLUORIDE PULSED

LASER. (Optiko- akusticheskie detektirovanie malikh kont- centrtrcy molekul ftoristogo vodoroda, okisi azota i dnuokisi ugleroda v gasakh izlucheniem inipul snogo lazera na ftoristom vodorode). Text in Russian. Kvantovaya Elektron., no. 8:1805-1811, 1974. 11 refs.

Experimental results on detection of micro-concentrations of hydrogen fluoride, nitric oxide, and carbon dioxide molecules in air and in oxides are given. These results were obtained by an optical-acoustic method making use of a hydrogen fluoride pulsed laser. In the pulsed regime the laser gives substantially more energy than in the continuous regime. This property of the pulsed laser allows detection of the minimal concentration of impurity in the air (1 ppm). The system was absolutely calibrated on a standard mixture. The results on detection of HF, NO, and CO₂ molecules and relationships between energy and coefficient of absorption and between output signal and pressure of pure CO₂ are given. Continuously tunable lasers should be used to increase sensitivity and selectivity.

APPLICATION OF REMOTE MONITORING TECHNIQUES

IN AIR ENFORCEMENT. Preprint, Science Applications, Inc., La Jolla, Calif. 4p., 1975. (Presented at the Environmental Sensing and Assessment Conference, Las Vegas, Nev., Sept. 14-19, 1975.)

The application of remote measurement techniques to air enforcement monitoring is discussed. Several modes of remote detection can be employed in enforcement monitoring: direct observation of a plume by passive or active monitors, perimeter monitoring from van-based platforms or airborne platforms, and horizontal active long-path monitoring. Air pollutants that are amenable to remote monitoring in the immediate or near-term time frame include particulates, sulfur dioxide, nitrogen dioxide, carbon monoxide, light hydrocarbons, hydrogen chloride, hydrogen fluoride, ammonia, nitrogen oxides, hydrogen sulfide, nitric acid, ozone, and vinyl chloride. Remote monitoring in the long-term time frame shows potential for the measurement of heavy hydrocarbons, sulfur oxides, certain specific trace elements, and chlorinated hydrocarbons. The most promising laser systems for near-term operational use are differential absorption, lidar, and the laser Doppler velocimeter.

(CF2C12) shows two sharp spectral features at 921.9/cm and at 923.2/cm in addition to broad band absorption. The CF2C12 band occurs in a stratospheric window between minor absorption by HNO₃ and carbon dioxide bands. Nitric acid column density is shown to increase from the equator to high latitudes, with the latitudinal variation in the northern hemisphere differing from that in the southern hemisphere. Calculated absorption spectra for hydrogen chloride, ammonia and sulfur dioxide are presented and demonstrate the feasibility of using remote sensing for the detection of these compounds also.

CHEMICAL ANALYSIS AND ENVIRONMENTAL QUALITY.

Chem. Ind. (London), no. 19:814-820, Oct. 4, 1975. 44 refs.

The chemical analysis of the atmospheric environment is discussed. Field tests are available for specific industrial hazards designed to indicate levels of exposure approaching the threshold limit value. The threshold limit value in industrial situations for sulfur dioxide is 5 ppm by volume. Total sulfate is determined by the sensitive tetrachloromercurate method used for short period sampling. Rugged portable electro optic devices based on ultraviolet absorption are available for SO₂ estimations. Particulate material is collected in a standard deposit gauge. Separate measurements of combustible matter, ash, tar, and dissolved ions are made. Smoke is assessed as units of equivalent standard smoke using a reflectometer to measure the darkness of a stain collected on a filter. Other standard methods are available for the measurement of sulfuric acid, total sulfate, ammonium salts, sodium chloride, polycyclic aromatic hydrocarbons, trace metals, total fluoride, hydrogen sulfide, ammonia, nitrogen oxides, carbon monoxide, ozone, and methane.

DETECTION OF HALOGENS AND SULFUR BY MEANS OF

LASER MICROSPECTRAL ANALYSIS. (Rezo hakko-bunko

bunseki ni yoru harogen genso oyobi iou no kenshutsu). Text in

Japanese. Bunko Kenkyu (Res. Spectroscop.), 22(S):321, 1973,

The emission spectroscopy of fluorine, chlorine, bromine, iodine, and sulfur was studied using a Nd-doped glass laser and a ruby laser as the excitation source. The emission lines were photographically measured using high purity potassium fluoride, barium fluoride, lithium fluoride, potassium chloride, sodium chloride, potassium iodide, sodium iodide, thallium iodide, or sulfur powder; the spectral region measured was 2300 to 5000 Å. No emission could be detected when the laser was used as the only excitation method, however, with the addition of spark excitation using carbon electrodes, several emission lines of each element could be observed. The emission intensities increased under the discharge condition, producing a spherical spark plasma. The number of observed emission lines was small for fluorine and chlorine, however, many emission lines were detected for bromine, iodine, and sulfur. The emission intensity of fluorine and chlorine tended to be weaker than that of bromine, iodine, and sulfur. The width of the observed spectral lines for these elements was broader than for iron and silicon. The 0.6% thallium iodide in graphite powder could be detected.

Williams, David T. and Charles S. Palm

EVALUATION OF SECOND DERIVATIVE SPECTROSCOPY

FOR MONITORING TOXIC AIR POLLUTANTS (FINAL RE-

PORT). Florida Univ., Gainesville, Aerospace Medical Div.

Contract F41609-73-C-0011, Kept. SAM-TR-74-19, 124p., Sept.

1974. 21 refs. NTIS, DDC: AD/A-000 949

The feasibility of using second derivative absorption spectrometry to analyze toxic gases and vapors was investigated.

Test data from scans of 28 different substances are presented for the 2000 to 7000 A spectral region. Substances measured included acetone, ammonia, aniline, benzaldehyde, benzene, dimethylamine, formaldehyde, hydrazine, monomethylamine, nitric oxide, nitrogen dioxide (nitrogen tetroxide), oxygen, ozone, pyridine, sulfur dioxide, toluene, trimethylamine, unsym-dimethylhydrazine, (UDMH), xylene, carbon monoxide, chlorine, chlorine trifluoride, dry and wet diborane, ethyl nitrate, ethylene oxide, fluorine, and monomethylhydrazine (MMH). All but the last eight produced signatures which are quantified in tables of instrument sensitivity values. A special effort was expended in the study of the hydrazines. Hydrazine itself was found detectable in the pure form and via its air reaction product ammonia. Monomethylhydrazine is undetectable in the pure form, but it is readily detectable via reaction products with air; UDMH is detectable in pure form. The second derivative spectrometer is unlikely to be made hand portable because of the required high detection sensitivities. The design of a fixed base installation of somewhat higher sensitivity is relatively simple to produce. Theory and characteristics of a second derivative spectrometer are discussed. FLUORIDES AND HYDROGEN FLUORIDE IN AIR AND WATER. In: Manual of Analytical Methods for the Environmental Health Laboratory. Atomic Energy Commission Contract AT (29-1)-789, p. 23-25, June 1975. 2 refs. NTIS: SAND75-0014 A colorimetric method for the determination of fluorides and hydrogen fluoride in air and water is described. The method is based on the reaction between fluoride and a zirconium-dye lake. The color of the dye lake becomes progressively lighter as the amount of fluoride increases and can be measured at 570 nm. Interfering ions include: aluminum, chloride, iron, hexametaphosphate, phosphate, sulfate, and alkalinity as calcium carbonate. It is necessary to distill the water sample to remove most interferences. Since the interferences are neither linear nor additive, mathematical compensation can not be employed for corrections. The temperature of the samples and standards must be the same to obtain correct results.

MEASUREMENT AND AUTOMATIC CONTROL OF AFFI
POLLUTION. (Mesure et controle automatique de la pollution
atmospherique). Text in French. Sci. Munic. Rev. Eau,
(70(6):249-258, June 1975.

Systems and apparatus for manual and automatic sampling and
analysis of air pollutants, especially within air quality monitor-
ing networks, are described. An Air Quality Sampler
developed in the U. S. uses special plastic bags made of alu-
minum-coated Mylar or Tedlar for air sampling. The stan-
dardized strong acidity method is used for the determination
of sulfur dioxide in hydrogen peroxide solution of pH 4.5. This
method is equally applicable as a manual or automatic method.
When used as an automatic method, the solution pH value is
stabilized by the addition of sodium tetraborate. According to
a new manual method, sulfur dioxide, nitrogen dioxide,
hydrochloric acid, hydrogen sulfide, and fluorine are absorbed
on a dry absorbent impregnated with an adequate reagent.
Nitric oxide is determined by a preliminary oxidation to NO₂
in ultraviolet light. Nitrogen oxides can also be measured by
chemiluminescent method, especially by the oxidation of NO
into NO₂ by means of ozone. Sulfur dioxide can be measured
by automatic flame photometry.

MEASURING METHOD AND APPLIED EXAMPLES OF
HYDROGEN FLUORIDE AND HYDROGEN CHLORIDE
GASES. (Fukka suiso gasu, enkasuiso gasu no sokuteiho to
oyorei). Text in Japanese. PPM (Japan), 6(11):67-78, 1975. 3
refs.

Analytic methods for hydrogen fluoride gas from industries
such as aluminum refineries, superphosphate manufacturers,
ceramic industries and steel industries, and for hydrogen
chloride gas from waste incineration plants, amino-acid plants,
polyvinyl chloride manufacturers, metal pickling plants, and
general chemical plants are reviewed. The prevalent Lanthani-
um-Alizarine Complexion method (ALC method) and ion elec-
trode method for hydrogen fluoride, and various chemical
analytic methods and continuous analytic methods for
hydrogen chloride are discussed. An automatic analyzer for
monitoring concentrations of hydrogen fluoride, model GNE-
21 of the Denki Keiki Co., Ltd., is introduced and its design
structure and performance are discussed. A continuous
analyzer for hydrogen chloride, model GSF-11, by the same
company is introduced, and its analytic principle, design struc-
ture, analytic conditions, and the volume measured as com-
pared to the volume measured by chemical analytic methods
are discussed.

FLUORATED ATMOSPHERIC POLLUTION. (La pollution at-
mospherique fluoree). Text in French. Pollut. Atmos (Paris),
17(65):10-13, Jan.-March 1975.

Analytical methods currently used to identify and measure the
rate of atmospheric pollution by the fluorated by-products are
reviewed. Statistical methods express cumulative pollution
throughout a determined period through an impregnated sup-
port. The unit adopted is arbitrary (microgram/d sq m/day).
Dynamic methods measure a mean pollution (in microgram/cu
m) throughout the sampling period which can vary from a few
hours to a few days according to the intensity of the pollution.
There is no technique to separate with certainty gaseous
fluorated by-products (hydrogen fluoride) and particle
fluorides, whose size is usually submicronic.

Anderson, Paul L.

DEVELOPMENT OF A CENTRIFUGE FOR SOURCE SAM-

PLING TO DETERMINE PARTICLE SIZE DISTRIBUTION.

Environ. Sci. Technol., 10(2):145-150, Feb. 1976. 6 refs.

A small centrifuge source-aerosol sampler with a spectral calibration range of from 0.16-3 micron is described. The sampler includes multi-orifice cascade impactor plants ahead of the centrifuge to process coarse particulates. The centrifuge is thermally protected and small enough to be used for some in-stack sampling applications. The application of the sampler to the collection of aerosols before and after a fluid bed reactor baghouse on the experimental aluminum reduction cell is described. The fluid alumina bed appears to be an efficient collector of fine fume particles as well as hydrogen fluoride. Coarse fines (1-10 micron) predominately penetrate the baghouse as opposed to fines less than 1 micron in size. (Author abstract modified)

Ottaway, J. M. and D. C. Hough
CARBON FURNACE ATOMIC ABSORPTION ANALYSIS OF ATMOSPHERIC PARTICULATES. Proc. Anal. Div. Chem. Soc., 12(12):319-321, Dec. 1975. 1 ref.

A carbon furnace atomic absorption technique for the analysis of atmospheric particulates was developed and applied in a steelworks. Fifteen elements were monitored: arsenic, beryllium, cadmium, cobalt, chromium, copper, fluorine, mercury, manganese, molybdenum, nickel, lead, tin, vanadium, and zinc. The main sources of the dust emissions were the sinter plant, the open hearth steel making furnace, and the basic oxygen steel making furnaces. A high volume turbine blower mounted on the back of a van was used to collect the atmospheric particulate samples from various locations at the works. Particulates were collected from up to 17 cu m of air in 30 min and sample masses varying between 0.6 and 0.7 mg were collected on Whatman No. 41 filter papers. These were dissolved in nitric and perchloric acids. Acceptable results were obtained for Zn, Fe, Mn, Pb, and Cu.

GLASS FURNACE EMISSION TESTING FOR CONDENSABLE BATCH MATERIALS AND TRACE METALS. Preprint, Toledo Univ., Toledo, Ohio and George D. Clayton and Associates, Inc., Southfield, Mich., 26p., 1975. 11 rels. (Presented
<xref image="2000WVGC.TIF|V3|2006:09:28:01:29:28.00|110009|0"> image: </xref>

at the Engineering Foundation Conference, Evaluation of Air Pollution Emissions of Stationary Sources, Pacific Grove, Calif., March 31-April 4, 1975.)

Sampling and analytical methods that can be used to determine filterable and total fractions of boron, chlorides, fluorides, sulfur oxides, and trace metals in emissions from glass melting furnaces are reviewed. Considerations dealing with the selection of materials for nozzle and probe construction, the selection of filter media, probe decomposition and chemical corrosion, and the formation of glass deposits on the sampling nozzle under various environmental conditions are discussed. Analytical methods reviewed include: atomic absorption spectrometry, chemical methods, spectrophotometric methods, gravimetric procedures, emission spectrometry, flame photometry, and X-ray methods.

THE APPLICATION OF A MULTICHANNEL FIXED AND SEQUENTIAL SPECTROMETER SYSTEM TO THE ANALYSIS OF AIR POLLUTION PARTICULATE SAMPLES FROM

SOURCE EMISSIONS AND AMBIENT AIR. Preprint, Environmental Protection Agency, Research Triangle Park, N. C., Environmental Research Center, 10p., 1975. 2 refs.

A Siemens multichannel wavelength X-ray fluorescence spectrometer that is specially adapted to the needs of the Environmental Protection Agency for the rapid analysis of particulate samples is described. The system consists of 16 fixed-wavelength spectrometers which are optimized for 16 pre-selected elements and a computer operated scanning channel which is used to determine additional elements that might be desired on a given sample. A minicomputer operates the instrument and sample changer and also processes the data. The fixed monochromators in the spectrometer are capable of analyzing for chromium, lead, manganese, arsenic, mercury, bromine, phosphorus, silicon, cadmium, aluminum, sulfur, sodium, fluorine, magnesium, potassium, and chlorine. The detection limit for most elements is 30 nanograms/sq cm or less. The high resolution of the crystal spectrometers permits analyses of air pollution and source emission samples which contain several dozen elements over a wide range of concentrations. MODERN METHODS FOR AIR POLLUTION MONITORING.

Pure Appl. Chem., 44(3);519-534, 1975. 16 refs.

The monitoring of basic pollutants (sulfur oxides, nitrogen oxides, carbon monoxide, oxidants, hydrocarbons, and particulate matter) to determine the air quality of a certain area is described. Specific methods for monitoring sulfur oxides include: acidimetry, conductimetry, coulometry, potentiometry and coulometry, and flame photometry. Nitrogen oxides are measured using colorimetry, coulometry, chemiluminescence, and fluorescence. Oxidants are monitored using colorimetry, electrochemistry, chemiluminescence, and ultraviolet photometry. Methods for monitoring CO include: titrimetry, colorimetry, non-dispersive infrared analysis, catalytic analysis, electrolysis, and gas chromatography. Hydrocarbons are measured by hydrogen flame ionization detector, while some fluorides are determined by the classical colorimetric procedure. Mass measurements of particulates are made by weighing. The performance of air monitoring by static, mechanized, or automatic devices in point sensors and by remote and long path sensors is discussed. (Author abstract modified)

Baker, Bertsil B., Jr.

MEASURING TRACE IMPURITIES IN AIR BY INFRARED SPECTROSCOPY AT 20 METERS PATH AND 10 AT-

MOSPHERES PRESSURE. Am. Ind. Hyg. Assoc. J., 35(11):735-740, Nov. 1974. (Presented at the American Industrial Hygiene Conference, Minneapolis, Minn., June 1-6, 1975.) The measurement of trace impurities in air by infrared spectroscopy at 20 meters path and 10 atmospheres pressure is described. The use of a new type of drying device achieves considerable selectivity in the removal of water from ambient air. The sample is compressed to 10 atm, without the separation of liquid water that would otherwise occur. Use of the higher pressure in a 20 meter gas cell permits the infrared spectral detection of many compounds of lexicological interest in the 0.05 to 1 ppm range. These include the air pollutants carbon monoxide, sulfur dioxide, hydrogen sulfide, and carbon disulfide, and classes of pollutants such as chlorinated hydrocarbons, fluorinated hydrocarbons, acid fluorides, esters, aldehydes, ethers, ketones, nitriles, amines alcohols, and acids.

PROBLEM AND ITS SOLUTION IN SAMPLING BY THE
ATP METHOD. (ATP ho ni yoru sanpuringu no mondaiten to sono kairyo). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):287, 1975. (Presented at the National Air Pollution Research Conference, 16th, Niigata, Japan, Nov. 5-7, 1975, Paper 25.)

The loss of sodium fluoride from filter paper used in the adenosine triphosphate method was studied. Sodium fluoride was added to a filter paper to give 300 microgram fluoride, which was then exposed to the atmosphere for 1 month. At the end of the exposure, the fluoride remaining on the filter was 45 to 74% less than the initial amount. When 100 microgram fluoride was added to a filter paper, there was 4 to 47% less than the initial fluoride amount after 1 month exposure. The loss of fluoride compounds from the filter paper can be neglected during exposure. Three cylindrical filter papers were put together, and the lower two cylinders were wrapped with a vinyl cover, which was then exposed in the atmosphere near an aluminum refinery. After a 1-month exposure, the fluoride on each cylindrical filter paper was determined. The fluoride detected from the bottom cylinder was less than 20 microgram/50 sq cm paper/month. The middle cylinder had 38 to 78 microgram, and the top cylinder had 194 to 378 microgram. Thus, wrapping the filter paper with a vinyl cover prevented the loss of fluoride compounds.

The use of alkaline filter paper for the collection of fluoride compounds in flue gas was studied. Toyo filter paper No 51 A, 40 mm diameter, was treated with 1% sodium carbonate solution and dried. In a filter holder, two of the alkaline filter papers prepared were placed in series after a teflon filter to remove dust, then flue gas was sucked through the holder. The

<xref image="2000WVGD.TIF|V3|2006:09:28:01:29:32.00|117603|0"> image: </xref>

collection efficiency for fluoride compounds by two alkaline filter papers were more than 90%. The alkaline filter paper method was compared with the impinger method. Both methods were used to collect fluoride compounds from the same flue gas. The alkaline filter paper method collected more fluoride compounds than the impinger method. With the same flue gas flow rate of 1.7 l/min, the alkaline filter paper method gave 0.19 mg fluoride/N cu m, while the impinger method gave 0.12 mg/N cu m.

ANALYTICAL METHODS FOR SEPARATION OF FLUORIDE FROM FLUORIDE COMPLEX IN ATMOSPHERIC SAMPLES USING GEL-CHROMATOGRAPHY. (Taiki chu no fukkabutsu oyobi fusso-saku kagobutsu no gerukuromatogurapfi ni yoru bunri bunsekiho to sono oyo). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):306, 1975. (Presented at the National Air Pollution Research Conference, 16th, Niigata, Nov. 5-7, 1975, Paper 48.)

A separation method for fluoride ion compounds and hexafluorosilicate (IV) complex compounds by gel-chromatography was studied. The column materials examined were Sephadex-G10, ECTEOA, alumina, and an ion exchange resin. No separation could be obtained by the latter two column materials, but separation could be achieved by the former two. The fluoride ion compound in 0.05 N sodium chloride solution was not absorbed with Sephadex-G10 but the hexafluorosilicate complex compound in the same solution was absorbed with this column material and could be eluted with 0.5 N sodium chloride solution. The fluoride ion compound in water was not absorbed with ECTEOA but the hexafluorosilicate complex in the same solution was adsorbed with this column material and could be eluted with 0.05 N sodium chloride solution. The method was applied to analyze atmospheric fluoride compounds. Of the fluoride compounds, 1290 were fluoride ion and the remaining 88% were fluoride complex.

84213

Kobayashi, Yoshitaka, Masahiro Hori, and Akira Iino

MEASUREMENT OF TRACE FLUORIDE IN ATMOSPHERE BY THE ALKALINE FILTER PAPER METHOD. (Arukair roshiho ni yoru taikichu fukka luitsu no sokutei ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 10(4):304, 1975. (Presented at the National Air Pollution Research Conference, 16th, Niigata, Nov. 5-7, 1975, Paper 46.) An analytical technique for gaseous fluorides by the alkali filter method with the lanthanum alizarine complex method was studied. A filter paper was pre-treated with 30% potassium carbonate solution, on which fluoride was collected. The fluoride collected on the filter paper was heat-extracted with water and the measurement was done using the lanthanum-alizarine complex method. A linear fluoride calibration curve was obtained up to 2.0 microgram fluoride/ml from the pH 5 solution. No interference with the absorbance was observed for potassium ion, carbonate ion, chloride ion, nitrite ion, ferric oxide, 01 aluminum oxide. However, the presence of sulfate ion produced a suspension in the solution which increased the absorbance measured. This sulfate ion interference could be eliminated if the suspending compounds were removed by a centrifugal separation before the measurement of the absorbance. The technique was applied to measure the fluoride pollution in an industrial area. The filter paper was exposed for 1 month in the atmosphere, and the fluoride level was determined. Up to 20 microgram fluoride/day/100 sq cm was detected from the air. This analytical result agreed with the result obtained by a conventional method which was also used to measure the fluoride pollution at the area.

Ohmichi, Sadao and Hikotaro Ida
COLLECTION AND DETERMINATION OF GASEOUS AND
PARTICULATE FLUORIDES IN AMBIENT AIR. (Taikichu no
ryushijo, gasujo fukkabutsu no hoshu to bunsekiho). Text in
Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution),
10(4):305, 1975. (Presented at the National Air Pollution
Research Conference, 16th, Niigata, Nov. 5-7, 1975, Paper 47.)
The collection and analysis of gaseous fluoride compounds
was studied. The collection method studied was a filter paper
which was pre-treated with 1 to 10% sodium carbonate solu-
tion. The prepared filter paper was used to trap hydrogen
fluoride gas. The HE collected on the filter paper was ex-
tracted with water, and was measured by the ion electrode
method and the lanthanum-azanine complex method. The de-
tection limit of HE by both methods was 0.25 microliter HE.
The HE trapping efficiency of the filter papers treated with
1% and 2% sodium carbonate solution was 89.6 to 96.8% and
90.7 to 94.9%, respectively. When the filter paper was pre-
treated with more than the concentration of 5% sodium car-
bonate solution, it affected the absorbance in the lanthanum-
alazine complex method. When the filter paper was pre-
treated with 10% sodium formate instead of sodium carbonate,
it did not affect the absorbance; moreover, the filter paper
gave better HE trapping efficiency, ranging between 96.5 and
98.1%.

AMBIENT MONITORING OF FLUORIDES. Preprint, Air Pol-
lution Control Assoc., Pittsburgh, Pa., 12p., 1975. 6 refs.
(Presented at the Air Pollution Control Association Southern
Section Annual Meeting, 6th, Nashville, Tenn., Sept. 18-19,
1975.)

The development of a program for the ambient monitoring of
fluorides at a fiberglass facility is described. The program is
required to demonstrate compliance with Tennessee regula-
tions governing gaseous fluorides. Included in the program are
economic and technical factors: cost/benefit analysis; qualifi-
cations of personnel conducting the program, number and lo-
cation of monitoring stations; design of sampling stations;
number size, and frequency of samples to be taken; duration
of sampling program; and sampling and analytical procedures
used during the program

COLLECTION EFFICIENCY STUDY OF THE PROPOSED

METHOD 13 SAMPLING TRAIN (FINAL REPORT). Entropy

Environmentalists, Inc., Research Triangle Park, N. C., Environmental Protection Agency Contract 68-02-1792, Program Element 1AA010, Rept. EPA-600/2-75-052, 28p., Sept. 1975.

The collection efficiency of the proposed Method 13 sampling train and the accuracy and precision of the two Method 13 analytical techniques for determining fluorides were investigated. A collection efficiency of 99% for gaseous hydrogen fluoride was obtained for fluoride concentrations ranging from 6-118 ppm and at sampling rates of 3/4 and 1 cu ft/min. The fluoride specific ion electrode method of fluoride analysis was more accurate and precise than the Spadns Zirconium Lake colorimetric method, with the latter showing a positive bias. GUIDELINE ON MEASUREMENT METHODS OF ENVIRON-

MENTAL ATMOSPHERE. (Kankyo taiki chosa soutei hohoto

shishin). Text in Japanese. Kankochō Kogai Senmon Shiryo

(Public Nuisance Gaz.), 10(4): 33-53, July 1975.

A revised edition of the Guideline on measurement methods of environmental atmosphere was published in 1973. The 1974 edition gives improved methods based on further experience.

The committee to investigate measurement methods was established at the Environmental Protection Agency. Efforts have been made to unify analytical methods, but no completely satisfactory result has been reached. Therefore, at some research institutes which have had extensive experience in analysis, if it is not necessary to conform to the unified measurement methods described here. Methods, frequency, and period of sampling referred to are also only general standards, to be revised in accordance with the anticipated concentration in the atmosphere. The pollutants covered are sulfur dioxide, carbon monoxide, hydrocarbon, oxidant, ozone, dust, aerosol, fluorine (gaseous and particulates), nitrogen oxides, gaseous halogens, ammonia, mercury, cyanides, polychlorinated biphenyls, benzopyrene, hydrogen sulfide), and soot. General rules for measurement are also given. Reagents used must be better than Japanese Industrial Standard special class quality. Air volume is based upon 20 C. The error of flowmeters is around 2%

A FLUORIDE AIR POLLUTION MONITORING PROGRAMME. Preprint. (Presented at the 58th Annual Meeting, Air Pollution Control Association, Toronto, Canada, June 20-24, 1965, Paper 65-31.)

This report describes the fluoride monitoring programme that was developed in 1962 when cyanamid of Canada Limited constructed a granular phosphate plant at Niagara Falls, Canada. Article points out that an effective fluoride monitoring programme must have the following objectives: (1) Continuous monitoring of particulate and gaseous fluoride emitted to the atmosphere, (2) Vegetation and soil sampling for fluoride within a 5 mile radius of the source, (3) Observation of significant meteorological conditions, (4) Continuous monitoring of aqueous fluorides discharged from the plant, and (5) Personnel monitoring for fluoride.

FUME EXPOSURES FROM WELDING WITH LOW HYDROGEN ELECTRODES. Ann. Occupational Hyg. (London) 10 (2), 113-21 (Apr. 1967).

Studies were made of the exposures of arc welders using low hydrogen electrodes under a variety of welding conditions. The welding locations are described and classified according to the degree of confinement. Fluoride and total fume determinations were made on samples of welding fume collected beneath the welding handshield. The range of exposures was wide for each location and the median value was selected as a more representative value than the mean. Confined locations produced the highest total fume and fluoride concentrations. Total fume values in excess of 10 mg/cu.m. were found in 75 percent of samples from confined environments, 50 percent from enclosed and 27 percent from open. Fluoride concentrations in excess of 2.5 mg/cu.m. were recorded in 35 per cent of the samples from confined spaces and 13 per cent from each of the other environments. Time-weighted exposures ranged from 1.05 to 7.9 mg/cu.m. for total fume and 0.17 to 0.88 mg/cu.m. for fluoride. (Author summary modified)

ATMOSPHERIC POLLUTION BY FLUORINE COMPOUNDS IN THE NEIGHBORHOOD OF AN ALUMINUM PLANT.

(Zagryaznenie atmosfery soedineniyami flora v okrestnostyakh alyuminievogo zavoda.) Text in Russian. Gigiena i Sank.. 30(9), Sept. 1965. Engl. Transl. by Israel Program for Scientific Translations, Hyg. Sanit., 30(9):426-428, Sept. 1965. CFSTI: TT66-51033/3

The results of the determination of fluorine compounds in the atmosphere around an aluminum plant over a period of 6 years are given. The method used consisted of the titration of distilled samples with thorium nitrate, in the presence of the new metallochrome indicator Methylthymol Blue. Concentrations of fluorine compound in the atmosphere within a large radius of an aluminum plant varied from 0 to 1.15 mg/cu. m. The fallout from the atmosphere of solid fluorine compounds in the vicinity of the plant amounted to 4300 kg/cu.km. per year, which is almost 53 times the natural fallout of this substance over small populated areas. The area around the plant is excessively contaminated, with high fluorine concentrations in the soil, agricultural products, plants, animal surface waters, and other elements of the environment.

Public Health Service, Washington, D. C., National Center for Air Pollution Control

PARKERSBURG, WEST VIRGINIA, MARIETTA, OHIO AIR POLLUTION ABATEMENT ACTIVITY. 87p., March 1967.

((38)) refs.

An investigation of air pollution in the interstate area encompassing Mariette, Ohio, Parkersburg, West Virginia, and Vienna, West Virginia was conducted. The average concentrations of suspended particulates measured in the three major population centers was in excess of 150 micrograms per cubic meter with maximum daily values in excess of 500 micrograms per cubic meter. The average value for 2-hour sulfur dioxide measurements made at three locations was approximately 0.02 part per million parts of air. At the Vienna station, however, a daily average concentration of 0.10 part of sulfur dioxide per million parts of air was exceeded 3.4 percent of the time. Short-term concentrations approached one part sulfur dioxide per million parts of air at various times. Sensitive vegetation exposed in Vienna developed injury that was attributed to the synergistic action of ozone and sulfur dioxide in low-level combination. Damage to indigenous vegetation from sulfur dioxide and fluorides was also observed. Atmospheric corrosion of ferrous metals was not abnormally high. Tarnishing of silver plate indicated, however, that the presence of gaseous sulfides is consistent with reported complaints of odor nuisance. From an inventory of emissions of sulfur oxides and particulate pollutants it is estimated that more than 123,000,000 pounds of sulfur oxides and 25,000,000 pounds of particulate pollutants are emitted each year from sources in the survey area. Approximately 85 percent of the sulfur oxide and 55 percent of the particulate matter are emitted from sources in Ohio, and 15 percent of the sulfur oxides and 45 percent of the particulate matter from sources in West Virginia. Eight point sources account for almost 98 percent of the total sulfur oxides and 94 percent of total particulate emissions. Mathematical applications of diffusion theory were used to estimate the relative contributions of specific sources.

SULFATION AND CORROSION MEASUREMENTS IN A MARINE COASTAL CITY OF FLORIDA. In: Proceedings of the International Conference on Atmospheric Emissions from Sulfate Pulping, Sanibel Island, Fla., April 28, 1966. E. R. Hendrickson (ed), Sponsored by: Public Health Service, National Council for Stream Improvement, and University of Florida. DeLand, Fla., E. O. Painter Printing Co., ((1966)), p. 354-357
<xref image="2000WVGG.TIF|V3|2006:09:28:01:29:40.00|102102|0"> image: </xref>

D. AIR QUALITY MEASUREMENTS

233

As part of a comprehensive survey in a Marine coastal city in Florida, measurements were made of corrosion rates and sulfation rates. The location of pulp mills, power plants and static sampling stations are shown on a map. Sampling stations were located throughout the entire area of 15 miles by 15 miles. At each station, sulfation, dustfall, fluoride by lime paper, and corrosion were monitored. All stations were changed once a month. A 1000-foot television tower was located at the center of the grid. Sulfation was measured by the lead dioxide-candle method. The units which were used for expressing sulfation rate were micrograms of SO₃ per square centimeter per day. Corrosion measurements were made using carbon-steel plates which were cleaned, dried and weighed, and exposed for the 30-day period. Following exposure each plate again was cleaned and reweighed. The unit of measurement for corrosion rate was milligrams of metal oxidized per square centimeter per month. In order to determine the effect of marine environment on corrosion rate, a separate series of sampling stations was located on a line through the television tower beginning at the beach front and running into town. At the waterfront 15 miles from the center of town, the corrosion rate was very high but moving back from the beach, rates dropped off rapidly to a background level. The highest corrosion rates were noticed north of the T. V. tower area, in the center of the industrial area. The corrosion rate with vertical distance was also measured at the T. V. tower. These data indicate that the plumes from both the power plants and pulp mills have a corrosive influence. The background corrosion rate in this community is rather high as would be expected in a coastal city.

LONG-DURATION FLUORINE STUDIES IN AN INDUSTRIAL

CONCENTRATION AREA. Staub (English translation), 28(1): 17-24, Jan. 1968. 10 refs. CFSTI: TT 68-50448/1

Continuous measurements over large spaces were carried out in industrial areas to determine the fluorine content of air near Duisburg, Germany. The air samples were taken by means of apparatus which operated continuously under any weather conditions. Altogether 1,339 individual values were used for the determination. The mean value of all measurements was 1.3 micrograms F/cu m air and thus by two to three powers of ten below the Maximum Allowable Concentration value. No indications were found as to continuous or temporary fluorine emission sources (Author's summary, modified)

13838

Macuch, P., E. Hluchan, J. Mayer, and E. Able

AIR POLLUTION BY FLUORIDE COMPOUNDS NEAR AN ALUMINUM FACTORY. Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 2(1):28-32, Jan. 1969.

From 1958 to 1965, contamination near an aluminum factory in the vicinity of Bratislava, Czechoslovakia, averaged 0.14 mg F/cu cm. This average represents a fivefold increase above the maximum allowable concentration of 0.03 mg F/cu cm. The gaseous fluorides HF and SiF₄ constitute 39% of the fluid values in the air near the plant as compared to 61% solids, namely CaF₂, NaF, and AlF₃. The proportion varies with the distance from the factory: at an area 8 to 9 km from the factory, 15% solid and 85% gaseous F compounds were present in the atmosphere. The relative increase in gaseous compounds is apparently due to sedimentation of the solid F compounds near the factory. Values of the yearly F fallout in the contaminated area were 44 to 7337 kg sq km. F values obtained for soil in the area of the factory were 135 mg/100 g (1350). This is 4 to 7 times higher than the usual F content of soil. Grass near the factory contained F values as high as 133 mg/100 g dry substances. While running surface waters showed only slightly increased F levels, standing surface

waters contained as much as 10.9 mg/l. Determination of F fallout and of F content in plants and biological materials is the best means of assessing long term effects of fluoride emissions. Meteorological influences appear to be less significant in evaluating F damage. The composition of soil, the presence of F dust on plants, and the F content of flowing and ground waters are of little use in determining F damage to human, plant, and animal life.

Hluchan, E., J. Mayer, and E. Abel
AMBIENT POLLUTION FROM FLUORINE COMPOUNDS IN
THE NEIGHBORHOOD OF AN ALUMINUM FACTORY.

(Inquinamento ambientale da compost! del fluoro nelle vicinanze di una fabbrica di alluminio). Text in Italian. Med. Lavoro (Milan), 59(S):370-375, 1968.

Measurements conducted from 1958 to 1965 show that fluoride emissions from an aluminum factory near Bratislava ranged from 3.6 to 4.2 tons per day. In the zone surrounding the factory, the total concentration of fluoride in the air averaged 0.14 mg/cu m, five times the amount of the maximum allowable concentration. The gaseous fluorides HF and SiF₄ constituted 39% of the total fluorides in this area, and the particulate fluorides CaF₂, NaF, and AlF₃ about 61%. At a distance of about 8 to 9 km, the gaseous forms were 85% of the total, and the particulates only 15%. Values up to 135 mg F/100 g were found in the soil near the factory. Grass in this area had a fluorine content as high as 135 mg/100 g dry weight. Drinking water in the area was relatively unaffected, but the pollution of marsh and stagnant waters averaged 10.9 mg/liter. The high environmental F concentrations were reflected in animals: ashes from the bones of sparrows and frogs caught near the factory contained, respectively, from 101.3 to 352.7 and 85.2 to 788 mg/100 g. The following measures are proposed to protect the health of the inhabitants of the region: limitations on the food products grown even in the least contaminated zones and on the number of persons allowed to settle in the area, clinical control of the exposed population, and a plan of development for the entire region. These measures should be implemented by technological steps to reduce the pollution caused by the factory.

Monk, Jozsef
MEASUREMENT OF AIR POLLUTION IN HUNGARIAN INDUSTRIAL CENTERS. (A levego szennyezettsegenek merteke ipari telepuleseinken). Text in Hungarian. Magy. Tud. Akad. Orvosi Tud. Oszt. Kozlemen., 18(3/4):417-424, 1967.

Budapest has by far the most serious air pollution problems of any Hungarian industrial center as shown by large scale measurements over a 10-15 year period. Data is presented in the form of 7 tables, compiled both by the author and by other Hungarian authors, based on studies of air pollution in Hungarian metropolitan areas. Eleven such areas, including Budapest, almost consistently show values in excess of the legally permissible limits of dust, carbon particles, and sulfur dioxide. In some of these communities, there are also excesses of such dangerous substances as chromium, phenol, beryllium, copper, silicon, and manganese. In the industrial sectors of the big cities, in addition to soot, dust, and sulfur compounds resulting chiefly from some type of combustion, one also finds a noticeable content of ammonia, the nitrogen oxides, chlorine gas, and organic chlorine compounds such as chlorphenol. The

<xref image="2000WVGH.TIF|V3|2006:09:28:01:29:44.00|126252|0"> image: </xref>

stench of some of these organic compounds, particularly the chlorinated hydrocarbons, is noticeable as much as 15-20 kilometers away. Measurements of fluorine pollution in the vicinity of the Varpalata aluminum plant gave concentrations of 0.097 mg of fluorine per cu meter at 2 km distance from the plant, and 0.67 mg at a distance of 20 meters. The permissible limit is 0.01.

17642

Tomson, N. M., Z. V. Dubrovina, and E. N. Bondareva
SANITIZATION OF ATMOSPHERIC AIR POLLUTED BY AN
ALUMINUM PLANT DISCHARGES. U.S.S.R. Literature on
Air Pollution and Related Occupational Diseases, vol. 8:136-140,
1963. (B. S. Levine, ed.) CFSTI: 63-11570

Air in the vicinity of a plant where aluminum oxide is electrolyzed on carbon electrodes was analyzed for dust content, fluorides, sulfur dioxide, and tars. Dust settling at 500 meters from the plant accumulated to 63 g/sq m in 30 days; at 1000 meters, to 200 g/sq m; and at 2000 meters, to 50 g/sq m. Sulfur dioxide concentrations of 6.0 mg/cu m in the plant's sanitary clearance zone were 12 times in excess of the 0.03 mg/cu m allowable limit and hydrogen fluorides were 68 times in excess of the allowable 0.3 mg/cu m limit. At 2000 meters, the concentration of tarry substances was 100-200 mg/cu m. In neighboring residences, sulfur dioxide concentrations were almost identical with those outdoors, while fluoride concentrations were even greater. Forty-one percent of the patients from the village where the plant was located had active tuberculosis or were carriers of tubercle bacilli. It is proposed that the pollutant discharge be reduced by the use of tall stacks, fluoride trapping devices, and more suitable electrodes.

Yunghans, Roland S. and Thomas B. McMullen
AMBIENT AIR FLUORIDE CONCENTRATIONS IN THE
UNITED STATES. Preprint, Public Health Service, Cincinnati,
Ohio, National Air Pollution Control Administration, 18p., Aug.
1969. 8 refs.

The total water soluble fluoride concentration was determined in samples of suspended particulate matter collected through an air surveillance network in 1966 and 1967. A fluoride-selective electrode method was used which is suitable for analyzing a large number of samples. Results of analyzing over 5400 samples from urban stations, and over 1400 samples from nonurban stations are summarized. Eighty-seven percent of all measurements at urban stations showed concentrations below 0.05 micrograms/cu m, the threshold of detectability. Thirteen measurements (0.2% of urban samples) exceeded 1.00 micrograms/cu m; the maximum was 1.89 micrograms/cu m. Ninety-seven percent of all measurements at nonurban stations showed no detectable amounts of fluoride. Three nonurban samples (0.2%) contained fluoride concentrations exceeding 0.10 micrograms/cu m; the maximum was 0.16 micrograms/cu m. The maximum fluoride levels found were well below most of the published standards for a 24-hour average concentration of soluble fluoride, as HF (10 micrograms/cu m in the U. S. S. R. and Czechoslovakia; 7 micrograms/cu m in Montana; 5 micrograms/cu m, in Pennsylvania; and 3.3, 1.61 and 0.8 micrograms/cu m in industrial, urban, and rural areas of New York State). No geographic patterns were evident, nor did the data cover a long enough period to reveal trends. Generally it can be said that airborne water soluble fluoride concentrations are not approaching the currently acknowledged thresholds that would cause concern for human well-being. INVESTIGATION OF AIR POLLUTION IN THE CITY OF
MILAN. PART VI. PRESENCE AND BEHAVIOR IN THE
CITY. (Indagini sull'inquinamento atmosferico della citta di
Milano. Nota VI. Presenza e comportamento nell'atmosfera ur-
bana). Text in Italian. Nuovi Ann. Igiene Microbiol. (Rome),

vol. 9:31-36, Jan./Feb. 1958. 13 refs.

Some results of an air quality measurement program, begun in 1956 in Milan to determine such pollutants as carbon monoxide, carbon dioxide, hydrogen sulfide, chlorine, fluorine, ammonia, nitrogen oxides, and particulates, are reported. Carbon monoxide levels in the areas of heaviest traffic did not exceed 62 ppm. Hydrogen sulfide, chlorine, and fluorine do not occur in the central zones of the city, although fluorine is present in the neighborhood of an enamel-varnish factory. High concentrations of CO₂ occurred in both residential and industrial areas. Concentrations of ammonia and nitrogen oxides did not exceed 0.72 and 0.05 ppm, respectively.

19145

TNO, Delft (The Netherlands), Research Inst. for Public Health Engineering
ATMOSPHERIC POLLUTION. ANNUAL REPORT, p. 15-23, 1968.

Air quality measurements conducted in The Netherlands in 1968 focused on the area between Rotterdam and the North Sea, the area between the Hook of Holland and The Hague, The Hague, Delft, Zuid Holland, north-eastern Groningen, the North Sea Canal, and the Sloe area. Most of these areas are highly urbanized and characterized by concentrations of several industries. In addition to simple measurements made with deposit gauges and Liege spheres, measurements were made to determine concentrations of sulfur dioxide, hydrogen fluoride, standard smoke, and carcinogenic substances. For SO₂ and smoke measurements, many stations employed a new fourfold, automatic absorption apparatus. Other new gas detection apparatus, and new analytical methods, are reviewed. In general, the measured concentrations were not alarming, but in many cases it is thought desirable to continue measurements.

Koehler, Albert and Walter Fleck
CONCENTRATION OF GASEOUS AIR POLLUTANTS IN POLLUTED AND 'CLEAN' ZONES. Staub (English translation from German of: Staub, Reinhaltung Luft), 29(12):21-26, Dec. 1969. 4 refs.

The concentration of gaseous air pollutants in polluted and clean zones was measured in 1967 and 1968. Carbon dioxide was measured by an infrared analyzer, total sulfur concentration by the water wash-bottle method, nitrogen dioxide by the Saltzman method, and fluorine by the standard impinger and colorimetric methods. In addition, the concentrations of suspended matter, dust precipitation, radioactivity, and biological objects were also determined. An analysis of the annual and daily variations shows distinct differences between the polluted and clean zones. The concentrations of sulfur compounds and nitrogen dioxide are 10 to 15 times higher in the polluted zones than in the clean zones. The CO₂ concentration, which is largely controlled by natural phenomena, is up to 20 ppm higher in polluted zones than in clean zones.

AIR POLLUTION IN THE CITY OF BOLZANO. PART H:

RESULTS AND REFLECTIONS ON FOUR YEARS OF STU-

DIES. (L inquinamento atmosferico della citta di Bolzano. Nota II: Risultati e considerazioni di un quadriennio di Ricerche).

Text in Italian. Ann. Sanita Pubblica (Rome), 30(S):795-831,

1969. 110 refs.

Air pollution studies in the city of Bolzano were begun in 1963 and interrupted at the end of 1964, at which time a city ordinance required the installation of smoke purifiers in home heating plants. Studies were resumed in September 1965 and terminated in the spring of 1967. At 6 sampling stations, the pH of rainwater was determined, as well as the presence of dust, calcium, magnesium, chloride, fluoride, sulfate ions, sulfur dioxide, chlorine gas, iron, fluorine gas, and aluminum; dust was additionally analyzed according to size of particulates. Meteorological conditions were also observed. Comparing the two periods of study, insoluble tarry substances notably decreased after the installation of smoke purifiers, while the content of insoluble inorganic pollutants increased, particularly at two stations. Chloride ion content was higher in the summer. Taking account of seasonal variations, the sulfur dioxide content was clearly reduced during the second period of study. In comparison with other cities, the residential areas of Bolzano showed better air quality than such areas in Melbourne, Naples, Modena, and London, while the industrial zone was about comparable to that of such large industrial complexes as Nagoya, Muenster, Mestre-Marghera, and Pittsburgh. Neither the industrial nor the residential zones gave values that exceeded the acceptable limits.

AIR POLLUTION TEST PROGRAM IN BERLIN. (Luftunter-

suchungsprogramm in Berlin. Text in German. Schriftenreihe

Ver. Wasser Boden Lufthyg. (Berlin), no. 33:19-24, 1970. 19

refs.

On August 1, 1968, six automatic testing devices for sulfur dioxide were installed in 6 different locations of West Berlin and the readings were transmitted by telephone to a central recording station. Subsequently the testing program was enlarged by the continuous testing of carbon monoxide, carbon dioxide, dust, and hydrocarbon levels in one location, by intermittent SO₂ level tests in 82 other localities, by intermittent testing of fluorine, chlorine, and ammonia levels in one station, and of dust in 2 stations and 2 other localities. Wind velocity and wind direction were measured in 1 station in addition to the meteorological data available from the Meteorological Institute of the Free University of West Berlin. The SO₂ emission recorded equalled or exceeded the SO₂ concentration measured in similar programs in other West German cities which is explained by the widespread use of sulfur-rich brown coal from deposits in central Germany by Berliners. Under adverse weather conditions, CO levels in sections with little traffic were as high as in streets with heavy traffic. The highest median half-hour levels exceeded 20 ppm CO. In remote sections of the city, emission fluctuations are influenced by meteorological factors much stronger than in heavy traffic areas. During the period from August to January, CO emission exceeded by from 50-97.5% that measured during the period February-July.

THE CORRELATION BETWEEN SULFUR DIOXIDE AND

FLUORIDE EMISSION. (Untersuchungen ueber die Korrela-

tion zwischen Schwefeldioxid- und fluorid-Iminissionen). Text in

German. Schriftenreihe Ver. Wasser Boden Lufthyg. (Berlin),

no. 33:25-28, 1970. 11 refs.

The existence of a correlation between the emission of sulfur

dioxide and of fluorides was studied from analytical data collected over 12 month periods in Berlin, in Mannheim-Ludwigshafen, and around Cologne. Fluorides were determined by the impinger method; SO₂, by an automatic testing device or manually by the silica gel method. The median correlation coefficients calculated for Berlin for periods of 1 month exceeded the value plus or minus 0.27 only once (February 1969, r equalled 0.71). This low correlation also emerged from calculations for the other two areas under study. The exceptionally single high coefficient must be considered accidental. In none of the three areas did the results of correlation analysis indicate the existence of a linear relationship between SO₂ and fluoride emissions. No conclusions can be drawn from SO₂ measurement on simultaneous fluoride emission as in the case of CO measurements where a correlation was found to exist with hydrocarbon and lead emissions.

AIR POLLUTION AND RESIDENTIAL AREAS-RELATIONSHIP BETWEEN AIR POLLUTION AND TOWN PLANNING.

World Health Organization, Copenhagen (Denmark), Regional Office for Europe, Proc. Conf. Public Health Aspects Air Pollution Europe, Milan, Italy, 1957, p. 218-235. 6 refs. (Nov. 6-14.)

In the early stages of research on the degree of pollution and its distribution in Padua and Venice, a method of measurement based on instantaneous sample collections was adopted. Samples were taken in such a way that deposit meters and peroxide cylinders were always placed downwind. Thus, it was possible to gather data indicating the maximum concentration of polluting substances in the wind stream, irrespective of difficulties caused by variations in or turbulence of atmospheric currents. A total of 803 analyses for sulfur dioxide, nitrogen dioxide, and elemental fluorine have been performed to date for Padua. The results are presented in tabular form and the distribution of the pollutants shown on a map. The implication of the results for town planning is noted.

ATMOSPHERIC POLLUTION IN THE PONDEROSA PINE

BLIGHT AREA. Ind. Eng. Chem., 44(6):1356-1365, May-Aug.

1952. 13 refs. (Presented at the American Chemical Society Meeting, 119th, Cleveland, Ohio.)

The ponderosa pine trees in the industrialized area north of Spokane, Wash., have exhibited a characteristic reddening of the needles since 1943, known locally as 'ponderosa pine blight.' The blighted area now embraces approximately 50 square miles, and the trees within a 3-square mile area near the center are dead. As a portion of a comprehensive investigation, the concentrations of gaseous fluorine and sulfur compounds in the air during the growing season of 1950 have been determined through operation of twelve air-sampling stations and a mobile air-analysis laboratory. Analysis of rain-water samples obtained during each rainy period throughout October and November 1950 at 82 locations established the

<xref image="2000WVGJ.TIF|V3|2006:09:28:01:29:52.00|120256|0"> image: </xref>

points of origin of the contaminants and the extent of their dispersion. Meteorological and topographical conditions in the ponderosa pine blight area, which control the dispersion of pollutants and explain the damage and pollutant concentration patterns, are discussed. Concentrations of gaseous fluorine compounds in the atmosphere of the area will serve as a guide in controlled fumigation of ponderosa pine. (Author abstract)

Cholark, J., L. J. Schafer, and R. F. Hoffer
RESULTS OF A FIVE-YEAR INVESTIGATION OF AIR POLLUTION IN CINCINNATI. Arch. Ind. Hyg. Occupational Med., Vol. 6:314-325, 1952. 3 refs. (Presented at the American Industrial Hygiene Association, Air Pollution Division, Annual Meeting, 13th, Cincinnati, Ohio, April 24, 1952.)
The results of an air quality investigation in Cincinnati, Ohio are presented. Samples were taken at 18 sites, several times monthly for a period of five years. At each of the stations, samples of suspended matter were collected by an electrostatic precipitator and were analyzed several ways to determine the composition of the particulate matter suspended in the atmosphere. Compounds identified included various metals, sulfur dioxide, fluorides, chlorides, carbon monoxide, carbon dioxide, aldehydes, nitrates, and ammonia. In addition, measurements of odors and dust fall are reported. Relationships between pollutant concentration and traffic density, season, and meteorological conditions are discussed. Plans for the continuation of the monitoring network are described.

Valach, Roman
FLUORIDES AND CHLORIDES IN PRECIPITATION SAMPLES IN BOHEMIA. (Fluoride und Chloride in Niederschlaegen von Boehmen). Text in German. Stud. Geophys. Geod., vol. 11:241-251, 1967. 33 refs.
Analysis of results of fluoride and chloride content determinations in precipitation samples in Bohemia disclosed that, in samples containing ash, the halogens came mostly from the ash while in samples that contained little or no ash the halogens came from the atmosphere. The atmospheric levels of F and Cl were unaffected by the intensity of coal combustion and it is doubtful that industrial emission is the principal source of Cl and of F in precipitation. These findings seem to confirm the hypothesis that both Cl and F in the atmosphere are mainly of volcanic origin and originate from exhalations of highly hygroscopic chlorides and fluorides. Hydrofluoric acid forms heavy fogs with humidity which can be observed in the north Bohemian coal basin where the coal is rich in F. The Cl/F ratio in precipitation was found to be approximately 10, the same ratio in volcanic gases in approx. 6.

MacIntire, W. H., L. J. Hardin, and Winnifred Hester
MEASUREMENT OF ATMOSPHERIC FLUORINE.
ANALYSES OF RAIN WATERS AND SPANISH MOSS EXPOSURES. Ind. Eng. Chem., 44(6):1365-1370, June 1952. 6 refs. (Presented at the American Chemical Society, Wilson Dam Section and the Southern Association of Science and Industry, Inc., Southwide Meeting, Wilson Dam, Ala., Oct. 18-20, 1951.)
Rainfall collections at six points were analyzed to measure the periodic washdowns of fluorine from the atmosphere in relation to the locations of operations that emit fluorine effluents, and charges of Spanish moss were exposed to measure progressive intake of fluorine from the atmosphere. Longer intervals between rainfall caused higher concentrations of fluorine at the several locations. Proximities of samplings to sources of emissions were reflected by higher concentrations of fluorine in rain waters. Exposures of Spanish moss acquired substantial progressive enhancements in fluorine uptake at points near those where fluorine emissions occurred. The findings demonstrate that these two feasible and economical

procedures can be implemented in parallel to establish whether a particular locale is subject to atmospheric pollution and the degree of pollution. Through integration with meteorological records, the determined occurrences of fluorine in the rain waters might indicate the origins of the contaminative effluents. (Author abstract)

Thompson, Richard J., Thomas B. McMullen, and George B. Morgan

FLUORIDE CONCENTRATIONS IN THE AMBIENT AIR.

Preprint, Air Pollution Control Association, New York City, 14p., 1970. 15 refs. (Presented at the Air Pollution Control Association, Annual Meeting 63rd, St. Louis, Mo., June 14-18, 1970.)

Data are reported for ambient atmospheric concentrations of water-soluble fluorides determined in samples of suspended particulate matter collected from rural and urban sites on glass-fiber filters by the National Air Surveillance Network. Data for over 12,000 samples collected in 1966, 1967, and 1968 are examined to give an estimation of current air quality with respect to fluoride content. Samples were extracted with pure boiling water and the fluoride concentration of the extracts measured using a fluoride-ion selective electrode. The data were tabulated on an annual basis; a table is presented summarizing the results, which show that the fluoride content in the majority of the samples is below the minimum detectable amount of 0.05 micrograms F/cu m. It is concluded that only in rare instances would the fluoride concentrations at the sites sampled be in excess of published standards, and that airborne fluoride does not prevail in the general environment at concentrations anywhere approaching the currently acknowledged thresholds endangering human safety. It is also noted, however, that the urban sites in this network represent center-city business environments, and that the findings do not refute results of special investigations near major sources of fluorides that clearly document excessive levels and adverse effects on vegetation and livestock. McHenry, Charles R. and Hoyt Charles

MONITORING OF FLUORIDE CONTENT OF AIR, WATER,

AND VEGETATION. Air Pollution Control Assoc. J., 11(2):66-70, Feb. 1961. (Presented at the Air Pollution Control Assoc. Annu. Meet., 53rd, Cincinnati, Ohio, May 22-26, 1960.)

The phosphate fertilizer industry is one of several industries that emits gaseous fluorides from certain manufacturing processes. There are nine major companies located in the Polk County, Fla. area engaged in the manufacture of various phosphate fertilizers. American Cyanamid Co. was one of the last companies in the area to build a triple superphosphate manufacturing plant. These types of plants emit gaseous fluorides in the forms of silicon fluoride and hydrogen fluoride as a by-product. In order to reduce emission of gaseous fluoride to a minimum, certain control measures were incorporated in the blueprint specifications of the new processing plant. A five-year air pollution study was started in 1956 to measure the effectiveness of the built-in control devices. The study, still in progress, includes: continuous monitoring air and

<xref image="2000WVGK.TIF|V3|2006:09:28:01:29:54.00|120393|0"> image: </xref>

D. AIR QUALITY MEASUREMENTS

237

water sampling studies, vegetation surveys, and a meteorological monitoring program. Results of the study have been used to determine a fluoride emission rate for the plant that will be consistent with the air pollution laws of the state of Florida and the maintenance of desirable conditions around the plant site. Additional control equipment is presently being installed to accomplish this objective. To date, American Cyanamid Co. has spent 1.4 million dollars in the study to set plant operating standards and for pollution control equipment. The air pollution monitoring program has been an indispensable tool in defining the extent of the problem at Brewster and in determining necessary control measures for maximum production without air pollution. 25093

Quellmalz, Eberhard

RESULTS OF FLUORINE MEASUREMENTS. (Ergebnisse von Fluormessungen). Text in German. Staub, Reinhaltung Luft, 30(7):292-294, July 1970.

Fluorine emissions involving three glass works, one fluorine minerals processing plant, one clay works, one electric metal smelting plant, and one brick factory were measured. The emission of one glass factory was 15 to 60 mg F/cu m, the emission at a distance of 80 m from the source 100 microgram F/cu m. Pine needles at a distance of 400 m turned brown as a result. The emission levels of the plant processing fluorides fluctuated between 2.6 and 7.8 microgram F/cu m at a downwind distance of 100 to 300 m. A brick factory processing fluorine-rich clay which was put into operation recently in a wooded area severely damaged trees in the surrounding woods. The emission was between 50 and 70 mg F/cu m, the median emission level 50 m downwind was 4.5 microgram F/cu m. The emission measurements undertaken at other factories yielded comparable results. The median fluorine emission level measured at the periphery of the city of Karlsruhe where no fluorine generating industry was located within a radius of several miles was around 0.6 microgram F/cu m which was obviously due to the effect of the city.

Gilbert T.

PROTECTION OF ENVIRONMENT. (Nachbarschutz). Text in German. Rheinisch-Westfälischer Technischer Überwachungsverein c. V. Jahresbericht, 1969:57-66. 16 refs.

Methods and results of several hundred ambient concentration and emission determinations of sulfur dioxide, fluorine, chlorine, ammonia, carbon monoxide, hydrogen sulfide, nitrogen oxides and of hydrocarbons emitted by a variety of industrial enterprises and shops undertaken in 1969 in the State of Nordrhein-Westfalen are tabulated and analyzed as are 469 expert opinions concerning pollution rendered as part of a certification procedure of new enterprises from all industrial fields. Procedural and instrumental changes designed to improve on present practices as they result from the analysis are proposed. These involve emission measurement of boiler plants, dust emission by large boiler furnaces, the operation of refuse incinerators, the supervision of steam and hot water boiler plants, exhaust gases from combustion engines and errors in pollution measuring instruments (Diesel-engine smoke). Noise pollution measurements issued from 65 different sources undertaken during 1969 are tabulated and recommendations designed to reduce the noise level are submitted. Decrees, norms and guidelines concerning pollution promulgated during 1969 in the state of Nordrhein-Westfalen are listed.

Niigata Prefectural Government

REPORT ON AIR POLLUTION STUDY, NAOETSU REGION.

Naoetsu chiiki no taiki osen chosa hokokusho. Text in Japanese. 104p., March 1970.

From August 1967 through October 1969, a study on air pollution was undertaken in the Naoetsu region, Niigata Prefecture. Sulfur oxides were measured by the PbO2 and the electroconductivity methods. At the same time, the pararosaniline method was partly applied in order to measure merely sulfur dioxide. Suspended particulate matters and dust fall were respectively measured by the British standard suspended particle matter meter and the high volume air sampler. The alkali filter paper method and lime filter paper method (LTP method) were applied in the measurement of fluorides. Sulfur oxides recorded 0.26 mg SO3/100 sq cm PbO2 in 1967; in general, it is increasing yearly. In reference to the seasons, in some places the level increased in spring and summer and decreased in autumn and winter; the contrary occurred in other places. In two or three places around the industrial area, a comparatively high level of concentration was detected, but the pollution was slight. Suspended particulate matter recorded 11.4 t/sq km/month in 1967 and is gradually increasing; however, the level was about that of a medium industrial city. The level of drifting dust was generally high; attention must be given to the sectional pollution. As to fluoride sectional pollution was recognized. The problem of the content of sulfur and fluorine in the test plants still needs further study; however, the result of the analysis of fluorine content briefly coincides with the other results on air pollution studies. This report includes preparatory study on the effect of air pollution upon plants in Naoetsu region. As a result, suppression of growth and abnormal leaves in the plants in Hinode town and Fukuhashi in Naoetsu city were recognized as notable.

CHATTANOOGA, TENNESSEE - ROSSVILLE, GEORGIA
INTERSTATE AIR QUALITY STUDY 1967-1968. National Air
Pollution Control Administration, Durham, N. C., Div. of
Abatement, NAPCA Pub.-APTD-0583, 120p., Oct. 1970. 25 refs.
NTIS: PB 195145

Results are presented for an air quality survey conducted in the Chattanooga, Tennessee - Rossville, Georgia interstate area from October 1967 through April 1969. The survey included air quality measurements, meteorological measurements, vegetation effects measurements, material effects studies, and an emissions inventory. The climatology of the area was found to be characterized by light average wind speeds, topographically confined flow, and frequent inversion conditions ? factors associated with poor pollutant dispersion. A suspended particulate problem exists in the area, with maximum concentrations in the downtown Chattanooga-Rossville valley and the Volunteer Army Ammunitions Plant (VAAP), where nitrogen oxide concentrations are also extremely high. Sulfur dioxide concentrations are lower than national standards; oxidant, hydrocarbon, and carbon monoxide levels are comparable to national levels. At study sites where selected vegetation was exposed, damage attributable to nitrogen dioxide, ozone, peroxyacetyl nitrate, sulfur dioxide, hydrogen fluoride, and an interaction of low concentrations of these and other pollutants developed. Vegetation at the VAAP revealed damage characteristic of overexposure to nitrogen dioxide, sulfur dioxide, and acid mist. Steel and zinc corrosion rates at one VAAP site are excessive, as are dye-fading rates in the

<xref image="2000WVGL.TIF|V3|2006:09:28:01:29:58.00|119795|0"> image: </xref>

area of the plant. Silver tarnishing, the index of sulfide gas pollution; occurs at all locations in the area, but values do not exceed the National Interstate Surveillance Project upper quartile. Quantities of pollutants emitted in Hamilton County, Tennessee and Walker and Catoosa Counties, Georgia in 1968 are summarized, as is the percent contribution of all pollutants by source category. Industrial process losses are probably the most important source, followed by mobile sources and stationary fuel combustion.

26702

Bay Area Air Pollution Control District, San Francisco, Calif.
AIR POLLUTION AND THE SAN FRANCISCO BAY AREA.

29p., Nov. 1970.

Air pollution emissions in the Bay Area are presented for 1969 by source category. The Bay Area Air Pollution Control District is comprised of six counties, Alameda, Contra Costa, Marin, San Francisco, San Mateo, and Santa Clara. It is governed by a twelve man Board of Directors, with each county represented by two members, which has the power to develop and enforce regulations for the control of air pollution in the District. To advise the Board and the staff, there is a 20-man Advisory Council, appointed by the Board. Members of the Advisory Council represent special interest groups and must include representatives of colleges or universities, health agencies, agriculture, industry, community planning, transportation, professional engineers, contractors, architects and organized labor. An important feature of the District is its Hearing Board, which makes findings of fact and can issue orders of abatement. The Bay Area Air Pollution Control District operates on a performance standard basis rather than on a permit system. Regulations have been adopted to control open burning, emissions of particulates and dense plumes, hydrocarbons and sulfur dioxide emissions, as well as reactive organic compounds. A Combined Pollutant Index was established in 1968 and includes oxidants, carbon monoxide, nitrogen dioxide, and particulates. The enforcement division comprises thirty-eight inspectors, as well as an engineering section and source testing groups. The technical division embraces the laboratory, air monitoring, data analysis and meteorology, and library sections. Examples of particulate matter are indicated, and visibility reduction is mentioned. Important gaseous emissions include carbon monoxide, sulfur oxides, hydrogen sulfide, fluoride, oxides of nitrogen, and organic compounds. Photochemical smog is mentioned, as well as meteorological factors and topography. Health effects, plant damage, and material deterioration are also reviewed. Government agencies and air quality standards are discussed.

27254

Kumamoto Prefectural Government (Japan), Public Nuisance
Section

REPORT OF INVESTIGATION OF THE AIR AND NOISES.

(V): JANUARY, 1969 - MARCH, 1970. (Taiki, soon chosa hokoku sho. Dai V ho. (Showa 44 nen 1 gatsu - Showa 45 nen 3 gatsu)). Text in Japanese. 212p., May 1970.

Investigations of air pollution, meteorology, and environmental pollution were carried out at Kumamoto, Arao, Udo, Yatsushiro, Taura-cho, and Minamata of Kumamoto Prefecture from January 1969 to March 1970; the results are reported. The average annual amounts of dust fall are within a 5.15 - 12.34 t/sq km/month level (by the deposit gauge method) and it is decreasing in all cities with every year. Among the contents of dust fall nitrate (-) was frequent in the cities where they use coal for fuel and sulfate (-2), chlorine (-), and calcium (+2) in the cities where there were carbide or chemical factories. Concentrations of sulfur dioxide (by the PbO₂ method) are increasing in all cities; the highest value of the average annual concentrations was 0.94 mg/100 sq cm/day at Arao and the lowest was 0.23 mg/100 sq cm/day at Taura. There was about 33% increase in general compared with those of the previous

year. The results of automatic measurements of SO₂ and floating dust at Arao and Yatsushiro revealed that the average annual values were 2.60 ppm at Arao and 0.86 ppm at Yatsushiro; the average annual index of the degree of pollution by floating dust was 12.5% and 4.29%, respectively. Measurement of concentration of fluorine in falling dust and in indicator plants has been carried out since June 1969 in order to perform examinations before the establishment of a factory for electrolysis of aluminum at Arao. Carbon monoxide, nitric oxide, nitrogen dioxide, and the amount of floating dust and its contents were measured in order to investigate the effects of automobile traffic volume and automobile exhaust gases.

Schedling, J. A.

THE MEASURING AND ANALYSIS OF ATMOSPHERIC POLLUTION. (Ueber Messungen und Analysen von Luftverunreinigungen). Text in German. Arch. Hyg., 154(4):349-357, 1970. 5 rcfs.

The tendency prevails not to limit the measuring of atmospheric pollution to the determination of a single pollutant like to sulfur dioxide because the assumption that the level of an indicator substance is a characteristic measure of the sum of all pollutants is valid only to a limited extent, if at all. Five hundred dust fall measurements performed over a period of two years (1962-1963) in a center city site in Vienna and 2000 dust fall measurements performed in 1965 and 1966 and continued at the same site in 1969 by means of a dust collection filter device at 1 and 9 m above ground were evaluated and the levels of lead, of benzopyrene and of fluorine compounds were determined. Lead compounds were determined polarographically, benzopyrene, spectrometrically; and fluorine compounds, by means of an ion-sensitive electrode. The present air pollution monitoring program in the city of Vienna will have to be extended to include nitrogen oxides and hydrocarbons and later also asbestos dust and oxidants. The pollution levels will have to be evaluated on the basis of internationally agreed air quality criteria not only for their immediate toxicity but for their hygienic implications in the overall pollution picture as seen by the WHO

28188

Huffstutler, K. K

FLUORIDE CONCENTRATIONS IN VARIOUS RECEPTORS NEAR PHOSPHATE INDUSTRIES. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 17p., 1970. (Presented at the Air Pollution Control Association, Annual Meeting, 63rd, St. Louis, Mo., June 14-18, 1970, Paper 70-153.)

Within Polk, Hillsborough, and Manatee Counties in west central Florida are located 17 phosphate fertilizer and related phosphate product manufacturing plants, 13 of them enclosed within seven and a half mile radius in Polk County. In 1965 an emission limit regulation was adopted limiting each company to 0.6 lb fluoride per ton of P₂O₅ manufactured in any one 24-hr period prior to May 1, 1964, allowing one year for compliance. Total industry emissions dropped from 11,700 lb per day in 1965 to 2700 lb in 1969. Samplin data show a related decrease in ground level concentrations. On the basis of data collected in a pasture grass sampling program started in 1963, a 40 or 45 ppm 'iso-fluor' was drawn representing the average annual at each station, in order to measure affected areas and

239

to define land ownership and use patterns. Measurements of fluoride accumulation in citrus leaves did not demonstrate correlation with ambient air fluoride levels; however, in a preliminary test of root uptake of fluoride, a citrus tree receiving gyp pond water showed an increase in fluoride content double that of a control tree.

SAMPLING AND ANALYZING OF FLUORIDES. PART I.

(Hasseigen kojo ni okeru fukkabutsu no sanpuringuho oyobi hunsekiho ni (suite. Dai-1-po). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), S(1):89, 1970. (Proceedings of the Japan Society of Air Pollution, Annual Meeting, 11th, 1970.)

On the assumption that the present JIS method of measuring fluorides as gases alone is inadequate for determining total fluorides emitted to the atmosphere in industrial areas, the following experiment was conducted. Fluoride gases as well as particulates were collected inside and outside plants by dust tubes with copper wool and polyethylene impingers. The items sampled were gases and mists under 20 micron and those particulates over 20 micron. The hydrogen fluoride values measured are tabulated. They indicate that a substantial amount of HF is also contained in particulates. Total fluoride was 2.30 to 6.53 HF ppm in one factory and 24.80 to 30.60 HF ppm in a second factory, B. In the area of the second factory, values were 325 to 351 ppb.

DESCRIPTION OF THE 'SCHAUINSLAND' STATION, GERMANY, AS AN EXAMPLE OF A PILOT STATION. In:

Research Facilities, Necessary to Adequately Support Measurement of Low Levels of Pollutants and Follow Their Trends. Organization for Economic Co-operation and Development, Paris (France), Chapt. 2, p. 9-28, Sept. 22, 1970.

Mans are being made to create a world network of background and pollution measurement stations in which a regional or national network is associated with a central laboratory, called a pilot station. The Schaumsland pilot station is one of a network of seven supporting stations in West Germany. Its tasks are to coordinate the measurement methods, measuring equipment, and working programs of the network, to calibrate measurement methods, to examine limitations of the methods in use, and to develop and test new measurement methods. To obtain samples in unpolluted air, the measurement and testing station is located in open countryside. Methods and instruments used for measuring dust fallout and concentrations of suspended matter, sulfur oxides, nitrogen dioxide, nitrous oxide, and fluorine compounds in the atmosphere are described. Other tasks undertaken include examination of condensation nuclei and recording of atmospheric electrical components. Biological materials, such as pollens and spores, are sampled continuously in a Burkard trap. Meteorological parameters are measured and recorded. Development work in progress includes an investigation of the use of a fluorine-specific electrode under low concentration conditions, automatic recording methods for measuring sulfur oxides and NO₂ concentrations, and testing of a calibration procedure which uses a gas mixing pump. The personnel of the station consists of a scientific director and five technicians. Equipment for research and development cost approximately \$10,563, routine work equipment cost \$51,098, and basic equipment for the laboratory, workshop, office and recreation rooms, office equipment, and miscellaneous items totalled \$30,750. Operating costs for one-year are estimated at \$140,228.

Davis, K. A.

ENVIRONMENTAL MONITORING SUMMARY FOR THE
PADUCAH PLANT FOR 1970. Union Carbide Corp., Paducah,
Ky., Paducah Gaseous Diffusion Plant, AEC Contract W-740S-
eng-26, Rept. KY-629, 9p., April 1, 1971. NITS: KY-629
Several factors are routinely checked at the Paducah Gaseous
Diffusion Plant including uranium fluorides, nitrates, hex-
avalent chromium, pH, alpha and beta activity, and
background gamma radiation. Air and water samples are taken
continuously in the vicinity of the plant, samples of the Ohio
river are collected monthly; and vegetation samples are taken
bimonthly. Air samples are collected through a membrane
filter for particulate matter and through a scrubber for
fluorides. Vegetation is dried and then pulverized for fluoride
analysis. In 1970, alpha activity averaged 0.04 pCi/cu m; beta
activity averaged 0.04 of the Radioactivity Concentration
Guide; gaseous fluoride averaged 0.45 ppb, 42rf less than
1969; fluorides in grass were of a 25 ppm concentration on site
and below that off-site (a safe concentration for grazing
animals). The water mixed with alkaline wastes became
neutralized so that no significant difference in the concentra-
tions of fluorides, chromates, uranium, pH, or radioactivity
was found below the mouth of the drainage creeks from that
upstream from the Paducah plant. Ground water was also sam-
pled.

MEETING OF THE COORDINATING COMMITTEE ON AIR
POLLUTION IN SOUTH HOLLAND (NETHERLANDS).
(Coördinatiecommissie meting luchtverontreiniging in Zuid-Hol-
land). Text in Dutch. 19p., 1968.
The coordinating committee on air pollution in South Holland
(the province of the Netherlands which includes Rotterdam
and The Hague) was activated March 15, 1967 by the Queen's
Commissioner. It has no formal membership list and is not in-
corporated. Its primary purpose is the measurement of air pol-
lution. As of September 1968, an inventory of air pollution
measuring stations in South Holland chose 57 stations for the
measurement of sulfur dioxide, 44 for the collection of
precipitation, five for smoke sampling, three for nitrogen diox-
ide, and two for hydrogen fluoride. The values obtained from
SO₂ measurements during the summer of 1966 are plotted on a
map of South Holland in the form of isonitrogen lines, while dust
fall data are plotted in the form of iso-dust fall lines, ex-
pressed in tons/sq km of land area. The South Holland data is
also compared with measurements in four areas of Great
Britain, and in terms of permissible limits established in vari-
ous other countries, including Russia, Germany, Poland,
Sweden, and the LISA

REPORT OF A SURVEY ON ENVIRONMENTAL QUALITY
IN THE DISTRICTS UNDER POLLUTION CONTROL PRO-
GRAM. (Kogai boshi keikaku sakutei chiiki kankyo chosa
hokokusho). Text in Japanese. 136p., March 1969.
Air pollution, water pollution, offensive odors, and noise in
the Chiba/Ichihara, Yokkaichi, and Mi/ushirna districts were
surveyed in 1968. Average daily sulfur dioxide concentrations
were 0.02 ppm in the Chiba/Ichihara district and 0.01-0.05 ppm
<xref image="2000WVGN.TIF|V3|2006:09:28:01:30:04.00|110101|0"> image: </xref>

in the Yokkaichi district. Values measured at 28 points in the latter district varied according to direction, wind velocity, and geographical conditions. The mean value of suspended dusts in the Chiba/Ichihara district was 151.6 microgram/cu m, but values as high as 256-1649 microgram/cu m were measured in Yokkaichi. Here iron contents of 105.8 microgram/cu m and 334.0 microgram/cu m were found. Organic sulfur compounds such as dimethyl sulfide (1.0 ppb) and isopropyl mercaptan (3.5 ppb) were also detected in Yokkaichi City. Nitrogen oxides and hydrogen chloride values in the Chiba/Ichihara district were 0.003-0.025 ppm and 0.01-0.06 ppm, respectively. Fluorine compounds were not detected. Maximum chlorine, formaldehyde, and hydrogen sulfide concentrations of 0.07, 0.057, and 0.005 ppm, respectively, were measured in the summer. In the Mizushima district, two methods were applied to determine offensive odors from petroleum complexes: odometry and gas chromatography. With the latter measuring 0.006-0.012 ppm of ethyl acetate. The gas was irritative with a sour and sweet odor. Biological oxygen demand measurements and analysis of bottom soil in Yokkaichi harbor, and 0.20-1.28 milligram/dry kg of mercury in bottom soil of the drainage at a chemical factory in the Mizushima district. Noise levels in residential areas were below or only a little higher than the standard, but noise levels along heavily travelled roads were significantly high.

SOME RESULTS OF AIR HYGIENE RESEARCH IN THE
GERMAN DEMOCRATIC REPUBLIC AND THEIR PRACTICAL
APPLICATION. (Ueber einige Ergebnissc der Lufthy-
gienischen Forschung in der DDR und ihre Anwendung in der
Praix). Text in German. Z. Ges. Hyg. Ihre Grenzgebiete (Ber-
lin), 17(6):396-399, June 1971. 23 refs.
East Germany is gradually establishing an emissions-monitor-
ing system. Emission measurements were taken in Berlin,
Halle, Magdeburg, Schwerin, and in the Erz Mountains. Sulfur
dioxide and dust were identified as the major air pollutants;
hydrogen chloride, hydrogen sulfide, chlorine, HCOH,
fluorine, arsenic, lead, carbon monoxide, and polycyclic and
other hydrocarbons were present to a lesser extent. Several
measurements showed high nitrogen dioxide levels in some but
not all areas of the country. In the center of East Berlin,
monthly average values were 0.007-0.032 NO₂ mg/cu m. Com-
parative measurements with continuous monitors indicated a
close relationship between SO₂ and dust concentrations. A
90% value of the sum frequency of 0.28 mg/cu m and 0.19
mg/cu m was calculated for dust and SO₂, respectively. The
high dust and SO₂ concentrations found in East Germany are
due to the fact that 89.29% of power plants are still fired with
soft coal. Based on comparison of death certificates for a rural
area and an industrial area, mortality rates due to respiratory
disease and heart ailments are higher in the latter area:
478/1000 for women and 5.78/1000 for men. For the rural
area, the respective rates are only 3.6/1000 and 3.85/1000.

AIR POLLUTION IN THE VICINITY OF THE POWER
PLANT ON NOVEMBER 7 AND OF THE ALUMINUM
WORKS AT VARPALOTA. (A levego szennyezettsege a
November 7. Hoeromu es a Varpalotai aluminiumkoho kor-
nyezeteben). Text in Hungarian. Idojaras (Budapest), no 6:344-
351, 1967. 12 refs.
Air quality measurements were made showing that emissions
from an aluminum plant at Varpalota and an adjacent power
plant are detectable at a distance of 1.5 to 2 km, and are stron-
gest in the southerly direction. In the eastern part of the re-
gion, south of the aluminum works, conditions are much
worse than in the western part due to the presence of sulfur

dioxide, dust, and fluorine, and to prevailing wind conditions. The amount of bituminous matter, 3,4-benzopyrene, and fluorine in the dust found on the vegetation in this region was measured. The fluorine content in the dry matter of the plants was also determined. The amount of 3,4-benzopyrene, caused by the tar vapors emitted from the aluminum works, was significantly higher in the dust adhering to the plants than in that collected in housing districts. Approximately 19.4 mg benzopyrene/sq m of plant surface was found; fluorine content was 6.9 mg/sq m of leaf surface. The average fluorine content of the dry matter of plants was 67.5 mg. The fluorine content is significantly higher than the normal value of 1 mg.

Hendrickson, E. R.

AIR SAMPLING AND QUANTITY MEASUREMENT. In: Air

Pollution. Arthur C. Stern (ed.), Vol. 2, 2nd ed., New York, Academic Press, 1968, Chapt. 16, p. 3-52. 64 refs.

Devices and techniques for determining the concentration of pollutants in the atmosphere are important to establish hazardous levels in the environment, to determine the efficacy of ameliorative measures, and to appraise contamination from a process or source. Problems encountered in sampling may include sample size, sampling rate, duration of sampling, collection limitations, analytical limitations, alteration of constituents, storage effects, accuracy and precision requirements, collecting versus recording samplers, units of expression, and computation of the results. Common equipment needs are vacuum sources, metering devices, and supplementary devices such as a timer. Sampling of aerosol contaminants may be done by filtration, impingement, sedimentation, electrostatic precipitation and, centrifugal methods. Techniques for sampling gaseous contaminants discussed are adsorption, absorption, freezeout, and grab sampling. Simplified techniques for sulfur dioxide, gaseous fluoride, hydrogen sulfide, and ozone are presented. Types of recording instrumentation and the principles of measurement are briefly described.

USE OF ACTIVATION ANALYSIS TO DETERMINE THE CHEMICAL COMPOSITION AND ORIGIN OF PARTICULATES COLLECTED IN THE MARINE ATMOSPHERE. In-

ternational Atomic Energy Agency, Vienna (Austria), Nucl. Tech. Environ. Pollut. Proc. Synip., Salzburg (Austria), 1970. p. 159-168. 26 refs. (Oct. 26-30, Paper IAEA-SM-142a/6.)

Pollution of the marine atmosphere is steadily increasing, as indicated by increased lead concentrations in polar ice samples and ocean surface waters, by the observance of pesticides transported with wind-blown dust over the Atlantic and Indian Oceans, and by a general increase in ambient aerosol concentrations probably of man-made origin. The use of neutron activation, photon activation, and proton activation analysis has been investigated to determine the elements boron, fluorine, sodium, sulfur, chlorine, potassium, calcium, manganese, bromine, strontium, and iodine in particulate samples from the marine atmosphere. Methods were developed for collecting airborne particulates on ships and aircraft and at shore stations. Appropriate sample preparation procedures were developed for the different types of activation analysis. The

D. AIR QUALITY MEASUREMENTS

241

implication for pollution studies is that, by determining elemental ratios such as F/Cl, Na/Cl, Na/K, Ca/S, and Mn/Cl, one can determine whether an aerosol is of natural origin or of man-made origin. Samples taken along the Atlantic coast of the U. S. show the influence of polluted continental air masses in near-shore region; influx of African dust was found in the middle of the Atlantic, and pure marine aerosols were analyzed in Hawaii. SULFUR HEXAFLUORIDE: ATMOSPHERIC BACKGROUND

CONCENTRATIONS. PRELIMINARY RESULTS. In:

Radiological Physics Division Annual Report. Environmental Studies. Argonne National Lab., 111., Radiological Physics Div., p. 110-120, 1970. 4 refs. NTIS: ANL-7760, Part III

Over 100 air samples were collected in Chicago urban and suburban areas and at the Argonne National Laboratory and analyzed for atmospheric sulfur hexafluoride backgrounds. Sampling times were about five seconds for samples collected in evacuated one liter cylinders and 24 hours for samples collected in 12 liter plastic bags. Samples were analyzed with a gas chromatograph and a nickel(63) electron capture detector. Sulfur hexafluoride concentrations ranged from less than detectable (two picoliters/liter) to greater than 500 picoliters/liter. The highest values were found in five-second samples collected at Argonne, which has several known sources of SF₆. However, a number of the Chicago samples also showed detectable SF₆ concentrations. (Author abstract modified)

Fuji City Citizens Committee for Environmental Pollution Control (Japan)

REPORT OF THE SURVEY ON PUBLIC NUISANCE IN FUJI

AREA (1). (Fuji chiki kogai chosasho, dai 1-pen). Text in Japanese. SSp., Sept. 1969.

Pollution in the Fuji industrial area includes detailed data on climatic characteristics, the mechanism and the state of air pollution in the area centered around Motoyoshihara Junior High School, comparison with Yokkaichi city, bad odor and noise, sources of odor emission, a survey of respiratory diseases in the area, results of questionnaires, water pollution of the sea and rivers, influence of pollution on plants and agricultural produce, and the state of pollution in the neighboring Fujikawa township. Fuji Municipal Motoyoshihara Junior High School is located in the most polluted area in the entire Fuji industrial complex; situated on a sand dune near the shore of Suruga Bay, it is flanked by four large plants on the west and 10 on the north. The sulfur dioxide counts go up characteristically with north-northwest winds; with 5 m/sec winds, it can go above 0.1 ppm. The average SO₂ count from five months in 1968 was 0.093 ppm. The pollution sources include Kraft pulp mills, cellophane plants, chemical factories, Tagonoura port dredgers, aluminum electrolysis plants, fertilizer plants, and automobile exhaust gas. In the neighboring Kanbara township, there is also a light metal company. Pollutants are soot and other particulates (lime, mirabilite), sulfur dioxide, hydrogen sulfide and other sulfides, hydrogen fluoride, chlorine gas and chlorides, nitrogen compounds, and dusts. According to the investigation in April 1968, the total heavy oil consumption in Fuji city was 2,240 kl/day; black liquor, 2,750 kl/day; coal, 23 t/day; coke, 5 t/day; and wood, 16 t/day. The calculated total sulfur dioxide emissions was 130 t/day from heavy oil and 49 t/day from black liquor. According to an investigation by the Fuji Medical Association between Nov. 1967 and Oct. 1968, bronchitis and asthma cases in the polluted areas were 2.5 times as many as those in nonpolluted areas, and cases of asthmatic bronchitis in the former were four times as many as those in the latter. The ratio of asthmatic children in polluted and nonpolluted areas was 37:18; the number of absences,

131:27, and average absence per child, 3.63:1.49.

33309

Lindberg, Walter

ATMOSPHERIC POLLUTION PROBLEMS IN NORWAY. National Society for Clean Air, London (England), Intern. Clean Air Conf. Proc., London, England, 1959, p. 21-22. 4 refs. (Oct. 20-23.)

In the past, air pollution in Norway was not a serious problem and only caused rare effects on human health, such as manganese pneumonias. Recently, air pollution from the aluminum industry has led to grass pollution with fluorides and resulting fluorosis in cattle. Public interest has led to the creation of a committee on air pollution to investigate prevention and to recommend abatement laws and regulations. Although air pollution in Norway is not as serious as in other countries, it is a considerable nuisance. The most serious problems are caused by the location of industry in deep valleys on the coast. A dust fall survey in Oslo showed 20 to 55 per cent of the average values found in London. The amount of dust and ash decreased in December and increased in April, when the snow melted, leaving the sand and gravel exposed. Since 1958, air pollution has been measured at 11 sites by smoke filters (reflectometer readings), volumetric sulfur dioxide apparatus (titration of total acidity following absorption in peroxide solution), and tarry matter fluorescence measurements. The pollution varied markedly in the winter due to high fuel consumption for domestic heating. Also, pollutants accumulated during the winter in calm weather and with inverse vertical temperature gradient. The use of hydroelectric power should reduce pollution.

33425

Tebbens, Bernard D.

GASEOUS POLLUTANTS IN THE AIR. In: Air Pollution. Arthur C. Stern (ed.), Vol. 1, 2nd ed., New York, Academic Press, 1968, Chapt. 2, p. 23-46. 45 refs.

Gaseous pollutants that may be present in the air are described, and the expression of gas concentration, the importance of averaging the time on air quality data, the components of normal air, and the effect of water vapor from air pollution standpoint are discussed. Carbon dioxide concentration has been suggested as an index of the total amount of combustion and natural ventilation in an urban environment, but the CO₂ level in any area where vegetation is plentiful has typical diurnal and seasonal variations. Carbon monoxide, emitted by internal combustion engines, is found in the greatest concentrations where traffic is heaviest. The lack of information of CO concentrations stems from its lack of effect on any of the human senses. Hydrocarbons are also present in the atmosphere, including oxygenated hydrocarbons such as the aldehydes. Sulfur dioxide is more prevalent in the air than sulfur trioxide, while hydrogen sulfide is an occasional air pollutant, known for its unpleasant odor. Mercaptans are among the odorous gaseous by-products of the kraft pulping industry. Continuous monitoring has shown that nitrogen dioxide predominates during nighttime, while during the day NO and nitrogen dioxide may be equally abundant. The recognition of peroxyacetyl nitrate as a serious phytotoxicant has stimulated intensive study, employing very sensitive chromatographic procedures for identification and quantitation of PAN. The presence of ozone, oxidants, and fluorides in the atmosphere is briefly discussed.

Hyogo Prefecture (Japan), Dept. of Living

PUBLIC NUISANCE IN HYOGO PREFECTURE. (Hyogo-ken no kogai). Text in Japanese. 197p., Nov. 1970.

The degree of air pollution in most cities in Hyogo Prefecture has stayed on the same level or increased slightly in recent years, except for Himeji and Akashi cities. Prevalent pollutants in Hyogo cities are carbon monoxide, nitrogen oxides, hydrocarbons, and oxidants created by the photochemical reactions of these material. Standard permissible and actual counts of sulfur oxides, CO, NO, NO₂, suspended and settling particulates, lead, and fluoride, compounds are presented in description, tables, and graphs. Average amounts of settling particulates in Hyogo Prefecture run between 5.30 t to 14.52 t/k sq m/month; the highest figure is for Amagasaki city. Kobe city is the next most polluted; measurements at four locations all indicate more than 10 t/month average. The annual average for Kobe in 1967 was 12.78 t; in 1968, 12.54 t and in 1969, 12.87 t. At the highest point in an industrial area of Kobe, settling particulate averaged as high as 17.95 t/month. The annual average of sulfur oxides in Amagasaki in 1968 was 0.083 ppm/hr and in 1969, 0.084 ppm, representing a much higher figure than the maximum permissible amount of 0.05 ppm. Carbon monoxide concentration is 5.0-9.0 ppm/day in Kobe, 2.7-5.8 ppm in Himeji, and 2.3-6.8 ppm in Itami. Monthly averages of NO concentration in Kobe are 80-142 ppb and of NO₂, 33-37 ppb. Figures in Himeji, Kakogawa, and Itami are much lower than those of Kobe. Western Hyogo around Akashi, Kakogawa, and Himeji are relatively unpolluted. The Himeji area has especially shown a marked improvement since dust collectors were installed in electric furnaces of iron foundries in 1967. The annual average of settling particulates of 11.12 t/k sq m/month in 1966 decreased to 7.92 in 1967, 6.54 in 1968, and 5.64 in 1969.

33858

Heaney, Robert J.

DISTRIBUTION OF TRACE ELEMENTS IN THE VICINITY OF AN INTEGRATED PRIMARY COPPER PRODUCTION

FACILITY. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 31p., 1971. 4 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 64th, Atlantic City, N. J., June 27-July 2, 1971.)

A comprehensive air surveillance network has been established near an integrated primary copper production facility to gather air quality data related to its emissions and those of other potential sources. The results from this sampling network are analyzed. Several types of air samplers were used in the study. Fluoride concentrations were monitored using calcium oxide or calcium formate-impregnated filter papers. Sulfur oxides were sampled with the lead peroxide-coated cylinder method. Dust was monitored using high volume and low volume filter samplers for suspended dust, and dust fall jars or adhesive papers for settling dust. Data from these samplers were analyzed in several ways: on a 10-year statistical basis to establish averages, ranges, and long-term trends and annual variations; on an average monthly basis to determine seasonal variations; and on a statistical basis to determine the approximate lognormality of the data. The data analysis indicates slight decreasing trends for copper and sulfur oxides and significant decreases for fluorides. Review of the monthly data shows the gaseous constituents, sulfur oxides and fluorides, are more subject to seasonal meteorological variations than the particulate constituents. There was an inverse relationship between suspended and settling dust, with the former being higher during the windier months and the latter during the more stable inversion months. Clear relationships were shown for concentrations of various constituents with distance from known sources. The analysis of statistical distributions showed that both gaseous and particulate matter-related constituents are approximately log-nor-

mally distributed. (Author abstract modified)

Dimitriev, M. T.

A STUDY OF ATMOSPHERIC POLLUTIONS AND PHYSICOCHEMICAL PROCESSES PREVAILING IN THE ATMOSPHERE OF THE DDR. (leucheniye atmosferykh zagryazneniy i fizikokhimiicheskikh protsessov, proiskhozhayashchikh v atmosfere nom vozdukh GDR). Text in Russian. *Gigiena i Sank.*, 36(7):84-87. 1971.

The main trends in the assessment and control of air quality in the Deutsche Demokratische Republic are reviewed. Sulfur dioxide, sulfur trioxide, sulfuric acid, hydrogen sulfide, nitrogen dioxide, ozone, carbon monoxide, chlorine, hydrogen fluoride, tetraethyl lead, benzo(3-4)pyrene, dust and soot levels constitute the main pollutants measured during continuous monitoring. The SO₂ concentrations range from 0.03 mg/cu m, in the summer, to 0.32 mg/cu m in winter in the city of Berlin; these fluctuations are due to domestic heating. Automotive exhaust gases constitute the main source for NO₂ pollution which reaches 0.5 mg/cu m during the morning and evening peak traffic hours. There are 16 stations for systematic monitoring of atmospheric ozone, SO₂, dust, and radioactivity. Maximum ozone levels occur during May and June along with other peak photooxidant concentrations related to air pollution. Photochemical generation of ozone, formaldehyde, and other photochemical oxidants in the polluted air constitute an important research area. The popularity of the two-stroke vehicle in the DDR increases the amount of pollutants due to exhaust gas. Thus, benzo(3,4)pyrene and formaldehyde are 30 to 50 and three to five times higher, respectively, than emissions from four stroke vehicles. The exhaust gases from two-stroke vehicles contain 50 mg/cu m lead and the air in the urban areas contains 0.3 to 0.5 microgram/cu m Pb in the DDR. Dust levels vary from 0.1 to 3.0 g/sq m in the cleanest rural areas to between 25 and 120 g/sq m in the industrial areas, with an average of 13 g/sq m in Berlin. Interactions between aerosols and the solubility of these carcinogens in blood serum constitute another area of air pollution research in the DDR. The main research institutes are indicated.

35764

PUBLIC NUISANCE WHITE PAPER, 1971. (Kogai hakusho, Showa 46 nendo ban). Text in Japanese. 483p., July 10, 1971. The state of air pollution in Japan is surveyed with respect to statistical data on concentrations of sulfur oxides, carbon monoxide, nitrogen oxides, suspended and settling particulates, and specific toxic materials (hydrogen fluorides and hydrogen cyanides). Local conditions are discussed with emphasis on areas with complex and acute air pollution problems, such as the Tokyo-Yokohama and Osaka-Amagasaki areas; specific industrial developments, e.g., Fuji, South Nagoya, Yokkaichi, North Kyushu, and Omuta; and areas where pollution is rapidly increasing due to the development of large-scale industrial complexes, such as Tomakomai, Kashima, Chiba-Ichihara-Kimizu, Mizushima, and Oita. Damages caused by air pollution and effects on human health and agricultural and forestry produce are discussed. Governmental means of control, the nation-wide network of pollutant measuring devices, and local and regional surveillance systems are reviewed. The policy on desulfurization and acquisition of

Tairafune, K., A. Sato, W. Nakano, and M. Takahashi
INVESTIGATION ON THE AIR POLLUTION IN MIVAKO
DISTRICT. (Kwateken Miyako chiku no taiki osen ni (suite).
Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 6(1): 191, 1971. (Presented at the National Council Meeting of Air Pollution Studies, 12th, Nagoya, Japan, Oct. 27-29, 1971.)

The concentrations of sulfur dioxide, nitric oxide, nitrogen dioxide, hydrogen fluoride, suspended particulate matter, and its metal components (cadmium, manganese, copper, and lead) were measured at six locations in Miyako City for seven days in Aug. 1970. The maximum SO₂ concentration was 0.095 ppm, however, 98% of the measured value was less than 0.05 ppm. The mean NO and NO₂ concentration was 0.01 ppm except at one location, which was presumably attributable to the effect of wind direction. The mean HF concentration was 1.6 ppb, and the mean concentrations of metallic components were (in micrograms (cu m): Cd, 0.11-0.15; Mn, 0.11-1.11; Cu, 0.10-0.84 Pb, 0.06-0.93.

37473

Waldbott, G. L.
AIRBORNE FLUORIDE IN THE LAKE ST. CLAIR-DETROIT
RIVER AREAS. Fluoride, 4(2):93-96, April 1971. 6 refs.
A study of air pollution in the Lake St. Clair-Detroit River area was undertaken by a special board at the request of the International Joint Commission representing the governments of Canada and the United States. Of the 80 sampling stations set up, five monitored airborne fluorides - two in the Port Huron/Sarna area and three in the Detroit/Windsor area. The maximum recorded F(-) values ranged from 1.3 ppb in Port Huron/Sarnia samplings to 2.9 ppb at Grosse Isle, Michigan. In comparison, the highest level obtained by the National Air Sampling Network in 1966 and 1967 was 2.4 ppb. Gladioli planted at five locations had F(-) levels of 25-50 ppm. Tip and margin burns occurred within five weeks after the gladioli were planted. Before these findings can be applied to the evaluation of the health effects of F(-) on humans, consideration should be given to such variables as duration and continuity of sampling, height of sampling stations and their distance from emitting sources, and F(-) levels in soil and edibles. Hokkaido Prefectural Government (Japan), Dept. of Hygiene
REPORT ON RESULTS OF INVESTIGATION AND ESTIMATION OF AIR POLLUTION. REPORT 7. (Hokkaido no taiki osen chosa sokutei kekka hokoku. Dai 7 ho). Text in Japanese. 25p., Feb. 1971.
The survey results of air pollution for 1969 in main cities in Hokkaido (Muroran, Asahigawa, Kusniro, Obihiro, and Tomakomai) are indicated, and a trend of pollution in each city is summarized. The estimation results are shown by monthly averages of each estimated spot in each city for amount of falling dust and soot, concentration of sulfur oxides by the lead dioxide and conductivity methods, concentrations of floating dust and soot by the filter paper method and concentration of hydrofluoride by the alkali filter paper method; a wind distribution chart is also given. Asahigawa, Kusniro, and Obihiro constitute an urban pollution type and the source of pollution was considered to be heating systems in winter; Muroran and Tomakomai constitute an industrial pollution type and the source was a factory. The extent of the pollution was

on the same level in falling dust and soot; the concentration of sulfur dioxide has increased in Asahigawa and Kushiro.

Mathe, Peter

MUCH INDUSTRY AND LITTLE AIR. (Viel Industrie und wenig Luft). Text in German. Technische Umweltmag., no. 1:16-19, Feb. 1972.

Because of heavy industrialization, the Duisburg area already has a high background concentration of pollutants. Unfortunately a new industrial center is planned in the recreational area in the Northeast of Duisburg. In a residential area in the city the following pollutant concentrations were measured during the growing seasons of 1968 and 1969: fluorides had a diurnal average of more than 2 micrograms and a daily maximum concentration of more than 12 micrograms/cu m air, the chloride concentrations were 67 and 695 micrograms/cu m air, the sulfur dioxide concentrations were 130 and 244 micrograms/cu m. During 5.3 to 15.5% of the measuring time a concentration of 400 micrograms SO₂/cu m was exceeded, during 2 to 4% of the measuring time of a concentration of 750 micrograms SO₂/cu m air was exceeded. Standard deciduous trees showed clear to heavy injuries. The mortality rate was high. The green belt used as a recreational area by city residents shall now be destroyed by two large power plants, one aluminum plant, and one petrochemical plant.

EVALUATION OF GASEOUS CONTAMINATION IN THE ELECTROLYSIS SHOPS OF THE BRATSK ALUMINUM PLANT. (Operativnaya otsenka zagazovannosti tsekha elektroliza na BrAZe). Text in Russian. Tsventn. Metal., no. 10:45-47, Oct. 1971.

The quality of the technological equipment was studied, and the contributions of human carelessness to air pollution were analyzed. Based on the weekly surveys of electrolyzers, burners, and exhaust fans, contribution indices were established for the different equipment and stages of technology. The number of non-hermetic electrolyzers was regularly determined. As a result of the steps taken, the number on non-hermetic electrolyzers dropped from 32.3% in Sept. 1969 to 15% in Feb. 1970. General improvement in air quality was reached, with concentrations below the threshold. Hydrofluoric acid and fluoride concentrations of 0.27 mg/cu m and 0.42 mg/cu m, respectively, were measured in Feb. 1970, against the maximum allowable values of 0.8 mg/cu m and 1 mg/cu m. In addition, drastic drop in the volume of atmospheric emissions was obtained.

Yamaguchi Prefecture (Japan), Research Inst. of Health; Yamaguchi Prefecture (Japan), Section of Environmental Hygiene; Yamaguchi Prefecture (Japan), Section of Public Nuisance; and Kuga Health Center (Japan)
RESULT OF AIR POLLUTION RESEARCH AROUND B
TREATMENT AND DISPOSAL PLANT FOR INDUSTRIAL
WASTES. (B sangyohaikibutsu shoriijo shuhen no taiki osen chosa seiseki ni tsuite). Text in Japanese. Yamaguchi-ken Eisei Kenkyusho Nenpo (Ann. Rept. Yamaguchi Prefect. Res. Inst. Health, vol. 13:78-79, 1971.

<xref image="2000WVGR.TIF|V3|2006:09:28:01:30:18.00|115044|0"> image: </xref>

The industrial wastes of the B treatment and disposal plant of Kumate-cho consist of the last disposal substances from an oil refinery, an oil chemical factory, and other chemical factories. The research was carried out at four spots of the area on the 11th and 12th of Dec. 1970. A sequential air sampler was used to measure sulfur dioxide every hour. Nitric oxide, nitrogen dioxide, ammonia, and chlorine were measured every two hours, and fluorine and SO₂ were measured every three hours. The SO₂ concentrations averaged 71.6 ppm at the outlet of chimneys, and 2.06 ppm at the outlet of a gas and vapor separator. Most SO₂ was exhausted from the chimney (averaged 0.005-0.006 ppm) (the highest concentration being 0.029 ppm) at the spot 40-100 m distant from the incinerator. Among nitrogen oxides concentrations, NO averaged 0.032-0.019 ppm, and NO₂ was 0.033-0.031 ppm. As for NH₃, Cl, F, and sulfate, 0.005 ppm of chlorine was determined and others were not found.

39054

Shimizu Municipal Office (Japan)
SURVEY REPORT ON ENVIRONMENTAL CONDITIONS
(CONCERNING ATMOSPHERE). (Kankyo joken chosa hokoku
(Taiki kankei)). Text in Japanese. Kept., 4-(1), 21p. March 1972.

The air pollution survey of Shimizu City, Shizuoka Prefecture has been going on since Sept. 1967. This report primarily deals with the survey results for Sept. 1970 through Aug. 1971 and briefly discusses on the trend for the past 4 yrs. Air pollutants centering around sulfur oxides are measured at 31 selected spots in the city. Settling dusts, sulfur oxides, and fluorides are measured. The results are broken down by the measuring spot, method, month, and season. Heavy oil fuel consumption as well as weather conditions during the period are also discussed. The FY 1970 heavy oil consumption is estimated at 585,000 kl, of which about 440,000 kl (76%) was consumed in Miho District and 100,000 kl (16%) in or about the municipal office area. The most prevailing wind was NE (18%), followed by NNE (14%), and ENE and SW, 6% each as in the preceding year. The year had 36 rainy days with rainfall amounting to 1,730.8 mm, compared with 1,015 mm in the previous year. The precipitating dust was 6.3 tons/sq m/mo in average at Shimizu Municipal Office, 7.0 t at the Miho Fire Station, and 6.1 t at the Sodeshi Citizens Hall, all indicating a decrease by 10-25% from the previous year. Results obtained by lead dioxide method indicated that the high-concentration pollution zones (12 mg sulfur trioxide/100 sq cm PbO₂/day) observed in the previous year disappeared this fiscal year while the medium-concentration pollution (1.0 mg SO₃/100 sq cm PbO₂/day) expanded to engulf more areas. The annual average for 10 spots in Shimizu municipal area was 0.82 mg SO₃/100 sq cm PbO₂/day indicating a decrease from the previous year's 0.95 mg. Pollution with fluoride has been negligible with no notable change again this year. As to the 4-year trend of the pollutants, both the soluble and insoluble content of the precipitating dust decreased each year, while the pH value fluctuated with the highest recorded early in 1970. The 0.5-1.0 mg SO₃/100 sq cm PbO₂/day zone is expanding while the 1.5-2.0 mg zone remains the same or decreases.

Bourbon, P.
ANALYTICAL PROBLEMS POSED BY POLLUTION BY
FLUORINE COMPOUNDS. (Probleme analytique du dosage de
1 ion fluor). Text in French. National Society for Clean Air,
London (England), Intern. Clean Air Congr. Proc., London, En-
gland, 1966, p. 174-176. (Oct. 4-7, Paper VI/6.)
Analytical problems from fluoride pollution are discussed; a
critical analysis of air sampling methods is made. Discussions
are illustrated by determinations carried out at 20 sampling lo-
cations situated at a 20 km radius around an aluminum factory
of one of the Pyrenean valleys in France. Sampling methods

focus the utilization of an impinger which is a modification of the Greenberg-Smith device and which allows accumulation of fluorine ions 70 ml of 0.1 N sodium hydroxide solutions with no dust or hydrogen fluoride interference. Determinations of F ion were made monthly. Fluorine containing dusts were determined at a 1.0 km radius around the factory whereby separation from hydrogen fluoride was carried out with Millipore filters (0.8 micron pores). These filters were utilized when sampling was made in dry weather conditions and heated air flows (80 C) were bubbled into NaOH- containing impingers. The amounts of HF carried along did not exceed 5.0% of the total amount of fluorine thus trapped. Additional information was obtained from F ion determinations carried out on rain water samples at the 20 pluviometer network installed at a 10 km radius around the factory. Determinations made once monthly according to the Spanos-Zirconium method showed only the presence of ionisable fluorine in the rain water. Of the thoroughly described sample preparation and analytical methods the Lanthane-Alizarine-complexone spectrophotometric procedure was the best one for below 10 micrograms F ion in 50 ml aliquots. Average values (from 100 samples) showed F ion from hf to be 57% and F ion from dust to constitute 47%. The dust composition included coke, tar, aluminum trioxide (50-60% of the dust weight), sodium carbonate and sodium sulfate (traces), and fluorine compounds. Fluorine pollution ranged from 0-3.0 micrograms/cu m referred to as F ion. Amounts below the 1.0 micrograms/cu m level were the most frequent. Extreme values of 10 - 20 micrograms/cu m were found incidentally in the immediate vicinity of the plant under inversions.

Sadtler (Sameul P.) and Son, Inc., Philadelphia, Pa.
SMOKE IN THE CUYAHOVA VALLEY OF CLEVELAND.
42p., 1950. 4 refs.

The air quality of the Cuyahoga Valley of Cleveland, Ohio was measured to determine the general atmospheric conditions with respect to smoke, dust, and fumes and to assess the extent of air pollution damage to health, plant life, and property. Qualitative analyses of the air determined various proportions of metal compounds, metal oxides, fluorides, hydrogen sulfide, phenols, silica, sulfur dioxide, hydrofluoric acid, sulfur compounds, nitrogen oxides, hydrocarbons, and heavy oils. Smoke shade was measured using the Ringelmann chart; visibility, dustfall, and haze were also monitored. The major sources within the area include blast furnaces, steel industries, coke works, sintering plants, open hearth furnaces, iron foundries, and electric furnaces. Various control methods are suggested.

AIR POLLUTION IN THE CITY OF MILAN. OBSERVATIONS ON AN INVESTIGATION CARRIED OUT BETWEEN OCT. 1969 AND JUNE 1970 AND OCT. 1970 AND MAY 1971.

(L inquinamento atmosferico della citta di Milano. Osservazioni su un indagine svolta nel periodo ottobre 1969 - Giugno e Ottobre 1970 - Maggio 1971). Text in Italian. Riv. Combust. (Milan), 26(1):22-3S, Jan. 1972. 9 refs.

The contribution of heating to the air pollution in the city of Milan was studied between Oct. and June 1969-1970 and Oct.

<xref image="2000WVGS.TIF|V3|2006:09:28:01:30:22.00|122962|0"> image: </xref>

D. AIR QUALITY MEASUREMENTS

245

and May 1970-1971 and related to the local meteorology and to the utilized fuel. Milan is a city characterized by large levels of atmospheric humidity and very scarce winds, reaching a maximum of six km/hr speeds. Domestic heating represents one of the main pollution sources in Milan, utilizing fuel oils with a 2.8% sulfur content or solid fuels such as coal, coke, and anthracite with a level of volatile compounds below 13%. Other pollutant sources contributing to the atmospheric quality of the city are metallurgical industries, emitting metal oxides, lead and zinc compounds, sulfur dioxide, and chlorine and fluorine compounds; petroleum processing emitting sulfur compounds, hydrocarbons, and particles; rubber processing industries, emitting sulfur and nitrogen oxides, and carbon monoxide. The program for air quality studies herein described includes the installation of five monitoring stations in different areas of the city. The facilities operate continuously for 8 days at a time, taking samples twice a day for 6 hr periods from 6 through 12 am and from 3 through 9 pm. Analytical determinations include gravimetric dust measurement, and their qualitative and quantitative composition study by means of X-ray fluorescence spectrometry, atomic absorption, and neutron activation techniques and total acidity expressed in SO₂ and measured according to a British standard method. The variation in these two parameters related to temperatures and relative humidity if represented graphically. Peak values are usually reached during the December and January months, which coincide with the most persistent thermal inversion seasons and decrease gradually from February through May. Cessation of heating leads to decreases in atmospheric SO₂ from 0.54 ppm (Dec. 1969) to 0.02 ppm (June 1970). Dust decreases represent minor contrasts indicating the involvement of other important sources: automotive traffic, industries. The severe air pollution conditions during the winter season are attributed to the fuel factor and may be improved once the law regarding this subject is put into practice.

41979

Ibaragi Prefecture (Japan), Environmental Pollution Research Center
ANNUAL REPORT OF THE ENVIRONMENTAL POLLUTION RESEARCH CENTER OF IBARAKI-KEN NO. 3.
(Ibaraki-ken kogai gijutsu sent; nenpo). Text in Japanese. 162p., Aug. 1970.

Air pollution, noise and water quality in Ibaragi are discussed. Falling dust, sulfur oxides, and meteorological observation in Hitachi and Kashima areas are given. Waste gas of factories in 16 areas of Ibaragi Prefecture and odor in Kashima area are mentioned. Automobile exhaust gases in five cities whose street traffic is comparatively heavy was measured. Dust fall near a cement factory was heavy and the concentration of sulfur dioxide in the basin of the River Miyata was as high as in the preceding year. There was a large amount of dust fall in the Kashima area. This was caused by the sand dune zone around the area and the effect of various construction works in Kashima. The amount of smoke from some factories where several complaints were reported was over the emission standard of environmental pollution control regulations in Ibaragi Prefecture. Hydrogen sulfide, ammonia, SO₂, methyl mercaptan, and hydrogen fluoride were the cause of odor. The concentration of carbon monoxide and the amount of lead in automobile exhaust was low in every area, compared with the degree of pollution in the main cities. Water quality of different rivers and drainage of factory sewage were surveyed and reported.

Katz, Morris
THE ATMOSPHERIC POLLUTION PROBLEM IN CANADA.
Chem. Can., 4(8):2S-32, Aug. 1952. 67 refs.

In Canada, as in other countries, huge economic losses have been sustained by the unrestricted emission of excessive

smoke, toxic gases, and particulate effluents from combustion, metallurgical, and other industrial operations. In agricultural and forest areas, extensive damage has been caused by the liberation of excessive quantities of sulfur dioxide, fluorine compounds, arsenical dust, and other effluents. In urban areas, the economic effects are evident in accelerated corrosion of metals, deterioration of stonework and other building materials, plant and household equipment, soiling and injury to textiles and other fabrics, and excessive laundry bills. The Trial smelter case and a current problem of urban pollution involving industrial wastes and smoke from vessel traffic in the Detroit River area are discussed. Other problems considered involve the nickel smelting district of Sudbury and the gold mining and smelting district of Yellowknife. Urban air pollution, sulfur dioxide pollution, and the distribution of particulate contaminants are considered, including the effects of air pollution on vegetation and human health. High stacks and meteorologic control are mentioned, as well as the removal and recovery of effluents. Emission standards are discussed.

Garber, K.

AIR POLLUTION IN THE INDUSTRIAL SECTION OF HAMBURG AND ITS EFFECT ON VEGETATION. (Die Luftverreinigung im Hamburger Industriegebiet und ihre Auswirkung auf die Vegetation). Jahresber. Staatinst. Angeu. Bot., Hamburg, vol. 83/84:158-173, 1966. 19 refs. Translated from German, 26p.

Three-year tests were conducted in the industrial section of Hamburg to ascertain the amount of atmospheric pollutants and their effect on vegetation. In addition, the results from other institutes were evaluated. The highest sulfur dioxide average values were .4-.5 rng SO₂/cu m from a SW and WSW direction. The effect of emissions on vegetation was determined by means of plant tests in containers with uniform soil compared to control tests in nonindustrial areas. Chemical analyses showed test plants in industrial areas had sulfate contents 10 times as high as in nonindustrial areas while chloride and fluorine contents were only twice or three times as high. Kagawa Prefecture (Japan)

INVESTIGATION OF ATMOSPHERIC AIR IN SAKAIDE

AND MARUGAME AREAS. (Sakaide, Marugame chiku kankyo

taiki chosa hokokusho). Text in Japanese. 127p., March 1972.

Measurements of meteorological conditions and atmospheric contaminants were carried out during the period from Nov 6-13, 1971 in order to grasp the quality, quantity, and extent of air pollution in Sakaide and Marugame areas of Kagawa Prefecture and to obtain the data necessary for preventive measures. Meteorological studies were undertaken by recording wind vanes and anemographs at five spots. Oxides of sulfur were measured by sequential air samplers at 12 measuring spots around factory districts, and the collected gas was analyzed by the P-rosanilin method. Suspended particulates were continuously collected by high volume air samplers at 12 measuring spots for 7 days, and the quantity of suspended particulates, benzene soluble matter, water soluble matter, sul-

<xref image="2000WVGT.TIF|V3|2006:09:28:01:30:24.00|119952|0"> image: </xref>

246

func and nitric acid radicals, and metallic elements were analyzed. Oxides of nitrogen were measured by air samplers at six spots around the factory district for 8 hours a day for 7 days, and analyzed by means of the Saltzman method. Fluorine compounds were measured by low volume air samplers and the alkali filter paper method at five spots around the factories for 8 hours a day for 7 days. The amount and method of fuel consumption in industries were also examined.

44267

Tomakomai City Government (Japan) and Tomakomai Health Center (Japan)

ACTUAL SITUATIONS OF POLLUTION IN TOMAKOMAI

CITY. (Tomakomai-shi ni okeru kogai chosa no genkyo (Showa-45-ncn 1-gatsu - 12-gatsu)). Text in Japanese. 44p., March 1971. The monthly amounts of dust fall, suspended dust, sulfur oxides by the lead dioxide method and by the electroconductivity method, fluorides by the alkaline filter method, water quality, and noise in Tomakomai City in 1970 were investigated. The concentrations of sulfur oxides were higher than those of the previous year at two spots in the city. Moreover, more than 0.2 ppm occurred for 7 hours among 4385 total hours at one spot; and 15 hours among 5412 total hours at the other. The increasing tendency of high concentrations of noxious gases in coastal industrial regions was also found. Water in Tomakomai Harbor is of good quality. Wind and other meteorological factors were also measured. Nitrogen dioxide and nitric oxide values are given.

44799

Graefe, Kurt

AIR POLLUTION MONITORING METHODS AND DETERMINATION OF AIR POLLUTANT-INDUCED EFFECTS.

(Methoden der Luftüberwachung und der Wirkungsbestimmung von atmosphärischen Schadstoffen). Text in German. *Städtehygiene (Uelzen/Hamburg)*, 21(8):190-192, Aug. 1970. Air pollution monitoring methods as applied in West Germany, and studies on the effects of air pollutants are reviewed. Automatic multi-component monitoring with regard to carbon monoxide, carbon dioxide, sulfur dioxide, hydrogen sulfide, nitrogen oxides, hydrocarbons, chlorine, aerosols, wind velocity and direction, and vertical temperature distribution are being carried out in Leverkusen. Measurements in the equatorial regions of the Atlantic revealed a slight increase in the CO₂ concentrations, and CO contents of 0.08-0.20 ppm. Forest damages due to aerosols were determined in coastal areas. Precipitation pH values of 4-5 and DDT concentrations of 1-3 g/cu km in air were measured in Germany. Sulfur dioxide measurements at different altitudes in Munich revealed a maximum of 0.6 mg/cu m at 50 m height. Continuous measurements of SO₂, CO, CO₂, hydrocarbons, dust, wind speed and direction, as well as intermittent recordings of fluorides, chlorides, and ammonia are being run in Berlin. The SO₂, CO₂, and dust concentration variations showed good correlation. The use of automatic program control and data processing by means of on-line computer is being considered. Studies of air pollutant-induced effects will center on SO₂, nitrogen dioxide, and respirable dust. Grass is regarded as an outstanding indicator plant.

47976

Ministry of International Trade and Industry (Japan)

A REPORT ON THE SURVEY OF THE ENVIRONMENTAL

CONDITIONS OF THE CHIBA INDUSTRIAL AREA. (Chiba

chiku konbinato kankyo hozen chosa hokokusho). Text in Japanese. 60p., Dec. 1972.

The air pollution conditions are improving gradually in the Chiba area. The averages of sulfur dioxide concentration in 1971 at 31 locations ranged from 0.035 ppm to 0.016 ppm, which was within the environmental standard. These results were brought about by the promotion of collectivization of

stacks and high stacks, and the use of low sulfur fuels. Settling particle measurements at seven locations between 1969 and 1971 decreased gradually, especially at the most heavily polluted district in 1969, which dropped from 24.47 t/sq km/mo to 16.18 t/sq km/mo. Suspended particulates have not shown much improvement according to the measurements at seven locations. The morbidity of respiratory diseases of inhabitants were investigated in 1971 by the BMRC questionnaire, and a high morbidity rate was reported. In May 1972, detailed health examinations were initiated in heavily polluted areas; a city ordinance was issued on a relief program of health damages caused by air pollution. As of Aug. 10, out of 183 examinees (the total number to be examined: 753), 98 persons were diagnosed as patients, in the ratio of 37 chronic bronchitis, 45 bronchial asthma, seven asthmatic bronchitis, and nine emphysema cases. As for the damages on agricultural produce, fluoride damages on rice plants have been reported in July 1969 and 1970.

Silicon tetrafluoride (SiF₄) and Hydrogen fluoride (HF) were determined in 349 and 347 air samples, respectively, taken in four locations of the Dimitrograd city area with a superphosphate and a cement producing industry. Samples were collected 5 days each month between March and November of 1970. Of 347 samples, 19.2% had an average of 0.011 to 0.013 mg HF/cu m exceeding by four times the maximum allowable concentration (MAC) value of 0.02 mg/cu m. Highest HF concentrations reaching 0.058-0.081 mg/cu m were found at locations closest to the superphosphate plant. Of the 349 air samples, 3.4% exceeded the SiF₄ MAC of 0.02 mg/cu m and maximum figures ranged from 0.036 to 0.053 mg SiF₄/cu m, while average values of 0.008 mg SiF₄/cu m were found, generally. Urinary excretion of fluorine compounds in highschool students 12 to 14 years old exceeded 60 micrograms % in fluorine levels in 32% of the Dimitrovgrad city group, compared to an age-related group of children from Sofia with 42.8 micrograms % fluorine excretion

ENVIRONMENTAL POLLUTION BY FLUORINE IN THE
TOMAKOMAI DISTRICT. (Tomakoamai-chiku ni okeru fusso
no kankyo osen ni (suite). Text in Japanese. Nippon Koshu Eisei
Zasshi (Japan. J. Public Health), 19(10):422, Oct. 1972.
(Presented at the Japan Society of Public Health, General Meeting, 31st, Sapporo, Japan, Oct. 25-27, 1972.)

In the Tomakomai region, fluorine compounds have appeared as atmospheric pollutants since aluminum refining and phosphate fertilizer manufacturing have begun. The ocean wind, from spring through summer, causes mobile inversion layers and occurrences of its typical smog. Fifteen measuring spots have been set within 7 km of the source. Measurements were made the first week of every month. Average values of these spots for 1971 and curved lines representing their

<xref image="2000WVGU.TIF|V3|2006:09:28:01:30:28.00|116105|0"> image: </xref>

D. AIR QUALITY MEASUREMENTS

247

equivalent intensities are shown. The value within 1 km of the source is as high as 20 to 30 times the minimum value. All measured spots located NNE from the source and their year round averages are correlated. More than 91% of the polluted substances fall within 3 km of the source. Sulfur dioxide in April and fluorine in May and June had their peak values. At spots within 2 km from the source, where the fluorine concentration was over 10 micrograms/100 sq cm, plant damage occurred.

A REPORT ON A SURVEY OF AIR POLLUTION IN THE

EHIME PREFECTURE, REPORT NO. 1. (Ehime-ken taiki osen

gaikyo hokoku, daiippo). Text in Japanese. 68p., Feb. 1972.

Results of air pollution measurements in various areas are given. The measurements of sulfur oxides, airborne particulate, hydrogen fluoride, nitrogen oxides, and oxidants were performed by conductivity and lead dioxide, light scattering, fluoride ion activity, colorimetry, and spectrophotometric methods, respectively. The condition of sulfur oxides pollution was classified into five degrees from under 1.0 mg SO₃/day/100 sq cm PbO₂ to above 4.0 mg SO₃/day/100 sq cm PbO₂. All locations except the industrial areas showed first to second degree SO_x pollution. The SO_x concentration in the industrial area was higher than the environmental standard value, but there was a decreasing tendency. The HF concentration in an aluminum refinery area was about 0.5 ppb/mo. The particulate concentration from the major cities in this area was below average compared to the major cities in other areas.

49118

Kagawa Prefecture (Japan)

THE RESULTS OF 1972 INVESTIGATIONS OF AIR POLLUTION AND WATER POLLUTION IN KAGAWA PREFECTURE.

(Kagawa-ken) (Showa 47-nendo taiki osen, Suishitsu odaku chosa kekka). Text in Japanese. 59p., Dec. 1972.

Measurements were conducted for sulfur oxides concentrations at seven locations by the electric conductivity method and 45 locations by the lead dioxide method, for particulate concentrations at IS locations by deposit gauges; and for fluorides concentrations at five locations. The sulfur oxides concentrations measured by the PbO₂ method were classified into five degrees - from under 1.0 mg/100 cu m/day as slight pollution to over mg/100 cu m/day as severe pollution. The SO_x concentrations measured by the conductivity method were all below the environmental standards. Among the 45 locations at which SO_x concentrations were measured by the PbO₂ method, only three locations had SO_x concentrations slightly over 1.0 mg/100 cu m/day. Only one location had a particulate concentration over 10 tons/sq km mo. The hydrogen fluoride concentrations were also below the threshold values which would cause damage to plants.

49260

Nakagawa, Yoshihiro and Kokei Takata

ATMOSPHERIC FLUORIDE POLLUTION AROUND STEEL

WORKS AND FERTILIZER PLANTS. (Seitetsu kojo oyobi

seihi kojo shuhen chiku ni okeru fusso kagobutsu ni yoru taiki osen). Text in Japanese. Japan Society of Air Pollution, Proc. Symp. Japan Soc. Air Pollut., 13th, 1972, p. 189. 2 refs. (Nov.

7-9, Paper 144.)

As a simple method of estimating the degree of pollution, the water soluble fluoride content in suspended particulates were measured. Environments of a steelworks and a fertilizer plant were examined. The relationship between fluoride level and

other pollutants was also examined. Hi-vol and low-vol samplers with glass fiber filters were used for sampling. The measurements were analyzed by a comparison with a fluorine ion calibration line. An ion strength adjustment buffer solution was used to give ion strength and to eliminate interference by ferrous aluminum. Of the 11 measuring points at the ironworks, the maximum concentrations were 464.5 micrograms/cu m of suspended particulates and 1.012 micrograms/cu m of soluble fluorides. Averages were 194.6 and 0.273 micrograms. Correlations among suspended particulates were: dusts 0.428, manganese 0.686, zinc 0.586, iron 0.563, lead 0.526, and cadmium 0.449. The highest amount of suspended particulates in the environment of the fertilizer plant was 184.8 micrograms/cu m, and fluorides 0.438 microgram/cu m; averages were 112.3 and 0.118. Significant correlations (1%) were recognized between fluorides and all other elements in the surroundings of the ironworks: but only 1% correlation between dusts and fluorides and y/c correlation between cadmium and calcium were recognized near the fertilizer plant.

49860

International Joint Commission, Ottawa (Ontario), St. Clair-Detroit Air Pollution Board

JOINT AIR POLLUTION STUDY OF ST. CLAIR-DETROIT RIVER AREAS FOR INTERNATIONAL JOINT COMMISSION. CANADA AND THE UNITED STATES. APTD-1305, 266p., Jan. 1971. 43 refs. NTIS: PB 212635

An air pollution emission and air quality inventory was conducted in the Port Huron-Sarnia and Detroit-Windsor areas of the United States-Canada borders. Data were collected on particulates, sulfur dioxide, hydrocarbons, dust fall, odors, fluorides, carbon monoxide, hydrogen sulfide, nitrogen oxides, and oxidants; trace metal concentrations in particulate matter; meteorological factors; seasonal variations; emission sources; and effects on vegetation and materials. Dispersion models were used to calculate pollutant transboundary flow and local pollution. Costs were calculated for implementing remedial measures. Based on the data, a transboundary flow was determined across both the St. Clair and Detroit River international boundaries. Transboundary and local pollution both exceeded the level that is detrimental to the health, safety, and general welfare of citizens and to property. An emission inventory was conducted on fuel combustion, refuse disposal, solvent losses, and point sources. Control methods and equipment are described for boilers, steel mills, cement plants, lime plants, fertilizer plants, grain handling, sugar companies, petroleum refineries, chemical plants, automobiles, power plants, and grey-iron foundries.

AIR QUALITY DATA FOR 1968, FROM THE NATIONAL AIR SURVEILLANCE NETWORKS AND CONTRIBUTING STATE AND LOCAL NETWORKS. Pub-APTD-0978, 240p., Aug. 1972. 1 ref. NTIS: PB 213830

Air quality data for 1968 collected throughout the United States by the National Air Surveillance Network are presented. Data includes measurements of benzene-soluble organic fractions, including benzo(a)pyrene; inorganic nonmetallic ions, including ammonium, nitrates, sulfates, and fluorides; suspended particulate matter; metallic components of air samples including antimony, beryllium, bismuth, cadmium,

<xref image="2000WGV.TIF|V3|2006:09:28:01:30:32.00|119362|0"> image: </xref>

chromium, cobalt, copper, iron, lead, manganese, molybdenum, nickel, tin, titanium, vanadium, and zinc; soiling index; and gaseous pollutants, including carbon monoxide, nitric oxide, nitrogen dioxide, sulfur dioxide, total hydrocarbons, and total oxidants. Data are tabulated for urban and nonurban sites. Laboratory methodology and instrumentation are reviewed.

Kitagawa, Y., T. Maeda, A. Furukawa, H. Ryomi, and M. Ito
ENVIRONMENTAL ATMOSPHERE SURVEY RESULT OF
UBE-ONODA AREA. (Ube-Onoda chiku kankyo taiki chosa
seiseki ni tsuite). Text in Japanese. Yamaguchi-ken Eisei Ken-
kyusho Nenpo (Ann. Rept. Yamaguchi Prefect. Res. Inst.
Health), no. 14:65-71, Aug. 1972.

Sulfur dioxide, hydrogen fluoride, nitric oxide, nitrogen dioxide, and aerosols were measured in Aug. 1971 at two industrial areas of Ube and Onoda. Sulfur dioxide in Ube averaged 0.034 ppm downwind of industrial plants. The maximum concentration was 0.161 ppm. In Onoda, the area affected by cement and sulfuric acid factories had a 0.040 ppm SO₂ concentration. The maximum concentration was 0.164 ppm. The NO and NO₂ concentrations were higher downwind of factories, but not as conspicuously as in the case of SO₂, perhaps due to automobiles. No correlation between SO₂ and the nitrogen oxides was found. The NO_x concentrations were higher in the afternoon than morning; NO₂ reached 0.03 ppm between 1 and 4 pm. Hydrogen fluoride was higher when the measured area was downwind of industries; the daily average was 0.006 ppm. Average aerosol concentration at Ube, which has large-scale cement, iron, and fertilizer plants, was 88 micrograms/cu m, ranging from 51 to 126 micrograms. Onoda had an average of 187 micrograms/cu m, ranging from 103-266 micrograms. There was no significant correlation between SO₂ and aerosol. Sulfate and nitrate were also measured.

RESULTS OF SPECIAL CHEMICAL INVESTIGATIONS OF
THE AIR IN THE UNTERMAIN REGION. In: Lufthygienisch-
meteorologische Modelluntersuchung in der Region Untermain.
4. Arbeitsbericht. Regionale Planungsgemeinschaft Untermain
Frankfurt am Main (West Germany), p. 61-75, Oct. 1972.

The average and maximum sulfur dioxide, nitrogen dioxide, phenol, fluoride, dust, lead, chloride, and formaldehyde concentrations for April 1971 to March 1972 are listed in a table for the untermain region around Frankfurt. The measurements were taken at 43 sites. The average concentrations of pollutants at the sampling sites are represented graphically on maps. Eight tables contain the frequency distribution of all measured values of the individual substances for various concentration categories. Another table shows the average values of pollutant concentrations for each day. The following peak average values per day were found: sulfur dioxide 222 micrograms/cu m, nitrogen dioxide 122 micrograms/cu m, phenols 13 micrograms/cu m, fluoride 2.23, formaldehyde 25, chlorides 57, dust 620, and lead 5.18 micrograms/cu m. In the winter months October the concentrations of sulfur dioxide, phenol, dust, and lead were higher than the concentrations of sulfur dioxide, phenol, dust, and lead were higher than the concentrations in the summer months. For nitrogen dioxide and formaldehyde it was the other way around. No points of especially high concentration could be found for phenols, fluorides, or formaldehyde. For chlorides, nitrogen dioxide, and sulfur dioxide the highest concentrations occurred in the city of Frankfurt.

INVESTIGATION OF DUST FALL. (Koba baijin chosa ni
tsuite). Text in Japanese. Nara-ken Eisei Kenkyusho Nenpo (An-
nu. Rep. Nara Prefect. Inst. Pub. Health), no. 6:136-141, Feb.

1973. 5 refs.

Dust fall was measured at five spots in Nara Prefecture for a month. Dust averaged 5.42 t/sq km/mo at one slightly contaminated spot. Dust fall was 4 t/sq km/mo at the other four spots, which is light contamination. Dust was generally acidic. Sulfuric acid, hydrochloric acid, hydrofluoric acid, and nitric acid, occurred in rainwater.

Mizutani, Hiroo, Akio Kamiya, and Toyomasa Kato
SOME CONSTITUENTS OF AIR BORNE PARTICULATES IN
NAGOYA SOUTHERN INDUSTRIAL AREA. (Nagoya-shi
nanbu kogyo chiiki ni okeru taikichu fuyu funjin-chu no kagaku-
teki seibun ni tsuite). Text in Japanese. Nagoya-shi Kogai Ken-
kyushoho (Rep. Environ. Pollut. Res. Inst., City Nagoya), no.
1:15-18, Nov. 1972. 4 refs.

Suspended dust, heavy metals, tars, and water-soluble dust content were measured in Nagoya city from March 11 to 22, 1972 at two locations in the center of the industrial area and one location in Minami Ward. Dust was collected with a hi-vol air sampler; heavy metals in the dust were extracted and analyzed by atomic absorption spectrophotometry. Tar was extracted with acetone; water-soluble constituents were extracted with distilled water to analyze sulfates, nitrates, fluorides, and chlorides. The highest dust concentration was 1078.3 micrograms/cu m in the industrial area. Heavy metals included iron, manganese, copper, lead, and cadmium. The nitrate concentration was about half the sulfate concentration at both measuring stations in the industrial area.

Yunghans, R. S. and T. B. McMullen
FLUORIDE CONCENTRATIONS FOUND IN NASN SAM-
PLES OF SUSPENDED PARTICLES. Fluoride, 3(3): 143-152,
July 1970. 8 refs.

Samples of suspended particles collected at various urban sites in the National Air Sampling Network were analyzed for contents of the fluoride ion. Of the over 7700 measurements, 87% were at fluoride concentrations below 0.05 micrograms/cu m, i.e., the threshold of detectability; 0.2% exceeded 1.00 micrograms/cu m, with 1.89 micrograms/cu m as the maximum; and 0.2% exceeded 0.10 micrograms/cu m. Ninety-seven percent showed no detectable amounts of the fluoride ion. The maximum levels were well below most of the published standards for a 24-hour average concentration. (Author summary modified)

Davison, A. W., A. W. Rand, and W. E. Belts
MEASUREMENT OF ATMOSPHERIC FLUORIDE CONCENTRATIONS IN URBAN AREAS. Environ. Pollut., S(1):23-33, 1973. 14 refs.

Coal and shale are recognized sources of fluoride pollution in Great Britain, but little is known about ground level concentrations in coal-burning areas. A high-volume sampler powered by a portable generator was tested and used to measure fluorides in local mining villages. Modal concentrations were less than 0.05 and about 0.3 micrograms/fluorine/cu m at rural and urban sites, respectively. Concentrations were locally very high near burning pit heaps. Partition of the fluoride using a citric acid impregnated pre-filter showed that most was in a gaseous and therefore phytotoxic form. It is suggested that fluoride concentrations from burning coal could be sufficiently high to damage sensitive plants and could contribute to fluorosis. (Author abstract modified)

REGIONAL POLLUTION BY EMITTED GASES OF ALUMINUM REFINERY. (Aruminyumu seiren kojo haigasu ni yoru chiiki osen). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 9(4):347-351, April 1973. 6 refs.

An aluminum refinery in Japan yields 1,900,000 tons of products a year and emits fluoride compounds. It is located in a long narrow valley with largely southerly winds. Fluorides were measured in red pine leaves and in the ambient air. The leaves were dried, ashed, and analyzed by spectrophotometry. The area to the east of the refinery had an air fluoride content of 20-30 micrograms; the area to the north had 70-80 micrograms of fluoride in the air. The winter had values three or four times larger than the summer. The fluoride content in pine leaves 1 km from the refinery was 150-300 ppm. The northern area had slightly larger values than the southern areas. Plants growing in the northern area had greater damage than those in the southern area.

Fukushima Prefecture (Japan), Office for Environmental Pollution Regulation
PRESENT SITUATION AND CONTERPLAN FOR ATMOSPHERIC POLLUTION IN FUKUSHIMA PREFECTURE. (Fukushima-ken no taiki osen no genjo to taisaku). Text in Japanese. Taiki Osen Nyusu (Air Pollution News), no. 78:2-8, Sept. 1973.

The Iwaki district, comprised of factories, chemical plants, fish processing plants, and power plants, was examined. Falling smoke dust, sulfur oxides, and acidic substances were monitored. Sulfur oxides decreased in 1965-1967, increased to peak in 1969, and are decreasing again. Higher pollution appeared near the plants, during spring to autumn, and on windy days. During 1972, seven out of 21 sites were above the maximum allowable concentrations. In the Onahama district, faulty land developments cause problems for living and industry. In the Aizu district, a smelting plant is the only emission source. Cadmium pollution and SO₂ emissions are high, but are being improved. Dust and fluoride pollution exist in the Koriyama and Kitagawa districts. A power plant is under construction in the Soso district.

Office of Air and Water Programs, Research Triangle Park, N. C., Office of Air Quality Planning and Standards
AIR QUALITY DATA FOR NONMETALLIC INORGANIC IONS 1969 AND 1970 FROM THE NATIONAL SURVEILLANCE NETWORKS. APTD-1466, 79p., June 1973. 3 refs.
NTIS: PB 223630

Paniculate pollutant data gathered during 1969 and 1970 by the cooperating stations of the National Air Surveillance Networks provide the basis for listing the urban and nonurban concentrations of four nonmetallic inorganic ions: ammonium, fluoride, nitrate, and sulfate. Laboratory methodology for each nonmetallic inorganic constituent is described. The data for ammonium, nitrate, and sulfate are presented as cumulative frequency distributions. Because there were no nonurban fluoride measurements above the detectable concentration, the table showing nonurban concentrations of fluoride is abbreviated. (Author abstract modified)

PORTSMOUTH GASEOUS DIFFUSION PLANT: ENVIRONMENTAL MONITORING REPORT - 1972. In: Environmental Monitoring At Major U. S. Atomic Energy Commission Contractor Sites Calendar Year 1972. Goodyear Atomic Corp., Piketon, Ohio, Atomic Energy Commission Contract AT-(33-2)-1, Rept. GAT-740, TR-021973-SAJ, p. 957-974, Feb. 28, 1973. 4 refs.
NTIS: WASH 1259

Environmental monitoring data of both radioactive and non-radioactive pollutants are presented for the Portsmouth Gaseous Diffusion Plant located in Pike County, Ohio for the year 1972. The principal process in the plant is the separation of uranium isotopes through gaseous diffusion. Maximum concentrations of alpha and beta-gamma activity in the air were only 10.1 and 0.5%, respectively, of the applicable radioactivity concentration guides. Average ambient air concentrations for fluorides were no higher than 2.6 ppb. Annual average sulfur dioxide concentrations were all below the national secondary air quality standard, 60 micrograms/cu m. Concentrations for paniculate matter ranged from 6.7-733 micrograms/cu m, and the annual geometric mean for the year was 145 micrograms/cu m. The paniculate samples were collected only directly downwind from the steam plant; thus, the exceeding of the 60 micrograms/cu m standard was not surprising since it did not truly represent an average.

Union Carbide Corp., Oak Ridge, Term., Nuclear Div.
ENVIRONMENTAL MONITORING REPORT: UNITED STATES ATOMIC ENERGY COMMISSION OAK RIDGE FACILITIES, CALENDAR YEAR 1972. In: Environmental Monitoring At Major U. S. Atomic Energy Commission Contractor Sites, Calendar Year 1972. Rept. UCC-ND-244, p. 889-929, March 26, 1973. 9 refs. NTIS: WASH 1259
Environmental monitoring data are presented for the Atomic Energy Commission's Oak Ridge Reservation which includes facilities involved in nuclear research, the enrichment of uranium hexafluoride in the uranium-235 isotope, and weapon production and support activities consisting of the production
<xref image="2000WVGX.TIF|V3|2006:09:28:01:30:38.00|115253|0"> image: </xref>

and recovery of compounds and the fabrication of metal materials. Data on the concentrations of radioactive materials in air of the surrounding areas indicated an average gross beta radioactivity from particulates in the air of 0.08% of the applicable concentration guide specified in the AEC Manual, Appendix 0524. The average gross alpha concentrations were 0.13% or less than the concentration guide for natural uranium, and the average concentration of (131)iodine measured by a perimeter air monitoring system was less than 0.01% of the inhalation concentration guide for individuals in uncontrolled areas. Average concentrations for fluorides, reactive sulfur, dust fall, and suspended particulates did not exceed the applicable standards.

Union Carbide Corp., Oak Ridge, Tenn., Nuclear Div.
 ENVIRONMENTAL MONITORING REPORT: UNITED STATES ATOMIC ENERGY COMMISSION PADUCAH GASEOUS DIFFUSION PLANT, CALENDAR YEAR 1972. In: Environmental Monitoring At Major U. S. Atomic Energy Commission Contractor Sites, Calendar Year 1972. Rept. UCC-ND-245, UC11, p. 931-955, 1973. 6 refs. NTIS: WASH 1259
 Environmental monitoring data are presented for the Paducah Gaseous Diffusion Plant located in McCracken County, Kentucky for the year 1972. The plant is engaged in operations involving uranium enrichment cascade with associated uranium hexafluoride manufacturing. Air analyses for alpha and beta radioactivity averaged less than 1% of the applicable Radioactivity Concentration Guide for all off-site sampling stations. Air and grass off-site analyses for fluorides met the Kentucky air quality requirements. Data was also collected for water and soil samples.

Environmental Protection Agency, Research Triangle Park, N. C., Air Pollution Control Office
 MOUNT STORM, WEST VIRGINIA-GORMAN, MARYLAND, AND LUKE, MARYLAND-KEYSER, WEST VIRGINIA, AIR POLLUTION ABATEMENT ACTIVITY. (PRE-CONFERENCE INVESTIGATIONS). APTD-0656, 133p., April 1971. 63 refs.
 An air pollution investigation was conducted in the Mt. Storm, W. Va.-Gorman, Md., and Luke, Md.-Keyser, W. Va. areas in 1969 and 1970. The major problem in the Mt. Storm-Gorman area is air pollution related damage to commercial Christmas tree growing operations. Air quality measurements were made for sulfur dioxide, nitrogen dioxides, oxidants, particulate matter, and fluorides. A review of the vegetation damage (discoloration, browning of needles, tip burns, poor foliage) suggest that SO₂, ozone, and settling particulates are of primary concern. The major sources of SO₂ and particulate matter are the Mt. Storm Power Plant and the Westvaco pulp mill. There are three power plants outside the area that could have an appreciable affect on air quality. The relatively high O₃ source is not established. The air pollution problems in the Luke and Keyser area are caused by particulate matter and noxious sulfur gases released from industrial plants. A pulp and paper mill operated by the Westvaco Corp. is the primary source of air pollutants. A control program will not be achieved until 1975 or 1976. A number of smaller sources include a coal washing plant, a charcoal plant, and a gob pile. Additional information for both areas include: history of problem, Federal abatement activity, geography, climatology, and air pollution meteorology.

Lee, Robert E., Jr., Jim Caldwell, Gerald G. Akland, and Robert Fankhauser
 THE DISTRIBUTION AND TRANSPORT OF AIRBORNE PARTICULATE MATTER AND INORGANIC COMPONENTS IN GREAT BRITAIN. Preprint, Environmental Protection Agency, Research Triangle Park, N. C., National Environmental Research Center, 30p., 1973 (?). 14 refs.

Daily measurements of total suspended particulate matter, sulfate, nitrate, ammonium, and fluoride components were made during the heating and nonheating season at six primary and five secondary sites in Great Britain. Samples were collected with high volume air samplers operating for 24-hour periods. The degree of association between the inorganic components were markedly influenced by the total suspended particulate concentration, and a strong relationship was found between sulfate and ammonium concentrations at the primary sites. Wind direction was the most important factor in the particulate concentration levels in Great Britain; and during stagnation conditions or when the wind was predominantly from an easterly or southern direction, i.e., from the northern European continent, particulate levels were highest. Particulate levels were the lowest when the wind was predominantly from a westerly direction, i.e., the Atlantic Ocean. The particle sizes of the total suspended particulates and aerosol components appeared to be sufficiently small to account for their long-distance transport from sources outside of Great Britain. (Author abstract modified)

CONCENTRATION OF FLUORIDE IN THE AIR OF VARIOUS COMMUNITDES IN JAPAN. (Honpo kakuchi ni okeru taikichu fukkabutsu nodo ni tsuite). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 8(3):496, Oct. 1973. (Presented at the Japan Society of Air Pollution, Annual Meeting, 14th, Fukushima, Japan, Nov. 6-8, 1973, Paper 226.) The gaseous fluoride, and water soluble and nonsoluble fluoride particle concentrations in the atmosphere were measured separately at 30 locations including Osaka, Kawasaki, Yokohama, aluminum refining industry areas, ceramic industry areas, ceramic industry areas, ironwork areas, regional industry areas, and commercial areas. Millipore filters and sodium carbonate soaked filters were used for sampling the atmosphere. Gaseous fluoride was extracted by warm water from the treated filter; particles were extracted by warm water; nonsoluble particles were measured by burning the filter after the solubles were extracted and distillating it by sulfuric acid steam. Fluorine ion electrodes were used for quantitation. The measurements in the neighborhoods of aluminum refining industries ranged from 0.03 to 4.02 micrograms F/cu m in total amount, with rather high ratios of soluble particles. In ceramic industrial areas, the total fluorides ranged from 0.05 to 2.16 micrograms/ F/cu m, and the ratio of gaseous fluoride was overwhelmingly high.

D. AIR QUALITY MEASUREMENTS

251

As a preliminary study for an estimation for the proposed industrial site east of the present Tomakomai industrial belt, where annual production of one million tons of aluminum is expected, the extent of the present fluorid pollution was investigated. The F content in the air was measured by the Hokkaido Government using alkaline filter paper, and the F content in plants was studied in red clover collected in July, August, and September of 1971 and 1972. The fluoride content in clover and the distance and direction from the emission sources showed direct linear relationships. The measurements by alkaline filter paper and the fluoride content in clovers agreed well, and the correlation was 0.981. Southeastern and southwestern winds dominate in summer in the area and fluorides disperse inland; seasonally it coincides with the period of plant growth. High F contents in plants extended 6 km to north and 2 km to east and west from the emission source.

SPECIAL STUDIES IN AIR CHEMISTRY. (Bericht ueber spezielle luftchemische Untersuchungen im Raum Untermain in der Zeit von April bis Juni 1971). Text in German. Regionale Planungsgemeinschaft Untermain, 4th Frankfurt am Main (West Germany), Lufthyg.-Meteorol. Modelluntersuch. Reg. Untermain, Frankfurt am Main, West Germany, 1971, p. 36-39. (Nov. 4-5.)

The layout and preliminary results of air pollutant concentration measurements performed in the Lower Main region from April until June 1971 within an air hygienic and meteorologic model study of that region are presented. Three test stations with automatic air sampling for 1 hr each at 15-hour intervals by means of impingers for chloride, fluoride, and phenol concentration measurements, and three laboratory vans for one random sampling per month at each of the 43 sampling sites were used for the air pollutant measurements. Dust and lead concentration measurements were done in samples collected at 3 to 5 sampling sites for one sample within 3 to 5 hr. The sampling sites were arranged radially with Frankfurt am Main as a center, at increasing distances from the center city to the periphery of the investigation area. The average concentrations of sulfur dioxide, nitrogen dioxide, phenol, fluoride, formaldehyde, chloride, dust, and lead concentrations, obtained at the different sampling sites, were in the respective ranges of 30-126, 14-80, 2-5, 0.7-3.6, 4-33 and 4-93 micrograms/cu m, 0.18-0.23 mg/cu m, and 1.19-1.47 micrograms/cu m, respective-

STUDIES ON FLUOP \E. (Fusso ni kansuru kenkyu). Text in Japanese. Kankyo Hoken Reporto (Environ. Health Rept.), no. 26:77-81, Nov. 1973.

The procedure and results of an analysis of airborne fluorine compounds are reported. These are caught with two different kinds of filters and are classified into gaseous fluorine compounds, soluble panaculate fluorine compounds, and insoluble panaculate fluorine compounds. These are dissolved in suitable solvents and the eluted solutions are analyzed by the ion electrode method. The limit of this analysis is 0.02 microgram/cu m for gaseous fluorine and 0.01 microgram/cu m for panaculate fluorine. Analyses have been made in Kawasaki City, Yokohama City, Niigata Prefecture, Gifu Prefecture, Osaka Prefecture, Matsuyama City, Sakaide City, Yatsudo City, and Kamaishi City.

THE DETERMINATION OF TRACE METALS AND
FLUORIDE IN MINERALOGICAL AND BIOLOGICAL SAM-
PLES FROM THE MARINE ENVIRONMENT. J. Radioanal.
Chem., 19(2):373-381, 1974. 10 refs.

Neutron activation analysis was used to measure trace metals

in dust collected over the Atlantic Ocean, and photon activation analysis was used to measure fluoride in the dust. Mercury WPS also analyzed by neutron activation, but in a slightly different way. The results are presented for samples from the Atlantic, the Caribbean, the Greenland Sea, the Pacific, and near the east coast of the U. S. Results agreed well with those done by other methods. The composition of the dust was close to the composition of average crustal rocks, thus agreeing with the contention that most dusts were from the continents or from volcanic eruptions. Instrumental neutron activation analysis of mercury presented some difficult problems. Despite the uncertainty of a 30% error, it was apparent that mercury concentrations in atmospheric dust exceeded those found in average crustal rocks (0.08 ppm) by about two orders of magnitude. The levels of fluoride lent additional support to the dust's continental origin, since fluoride content exceeded that of sea salt in air by a factor of more than 10. Mercury uptake by marine algae was also studied. In the radiotracer experiments, neutron activation analysis was used to determine the mercury content of the algae. The research methodology, results, and problems of the study are described. The amounts of mercury determined ranged from 10 to 40 micrograms.

Lahmann, E.

AIR QUALITY MEASUREMENTS OF THE INSTITUTE FOR WATER-, SOIL-AND AIRHYGIENE. In: Air Hygienic Meteorological Model Studies of the Lower Main Region. Report 5. Regional Planning Assoc., Lower Main Region, Frankfurt am Main (West Germany), p. 100-115, June 1974. At three measurement stations in the center of Frankfurt, in the east of Frankfurt, and in Hattersheim air was drawn for one hour through an impinger and the concentration of chloride, fluorides and phenols determined. For measurements of the dust concentration high volume samplers were used. The lead analyses of the dust were carried out by atomic absorption spectrometry. In addition the sulfur dioxide and oxides of nitrogen concentrations were determined in random samples. In the year 1972/73 the maximum daily average of SO₂ was 201, of nitrogen dioxide 81, of phenol 13, of fluoride 0.98, of formaldehyde 23 of chloride 30, of dust 730, and of lead 7.51 micrograms/cu m. The annual average concentration of SO₂ was 71, of NO₂ 48, of phenol 6, of fluoride 0.45, of formaldehyde 5, of chloride 16, of dust 220, and of lead 7.51 micrograms/cu m. The emissions measured in 1972/73 were in most cases lower than during the previous year. This is true for both the annual averages and the maximum daily averages. Of the pollutants, only SO₂ was clearly higher in the center of Frankfurt than at the other stations. Formaldehyde exceeded, in two instances, the existing long-term maximum allowable emission concentration of 30 micrograms/cu m.

THE EFFECTS OF THE STEEL INDUSTRY ON ATMOSPHERIC POLLUTION IN THE CLEVELAND AREA.

Ind. Hyg. Newsl., 11(2):22-23, Feb. 1951.

Dust and gaseous pollutants in the air over Cleveland were measured during a steel strike in 1949 when the plants were

<xref image="2000WVGZ.TIF|V3|2006:09:28:01:30:46.00|120434|0"> image: </xref>

closed and after the plants reopened to determine the effects of the steel industry on pollution. The monitoring program is reviewed including sampling methods, sampling procedures, and results. Sulfur dioxide concentrations during the steel strike ranged from 0 to 0.389, but one sample was 0.290-0.389 ppm in the southern area of the valley. After the strike, the range was 0-0.489, and only one sample was in the range of 0.390-0.489 ppm in the northern area of the valley. Mean SO₂ concentrations during the strike and poststrike periods were, respectively 0.034 and 0.050 ppm. Fluorides during the strike were 0-50 micrograms; after the strike the range was the same. The mean fluoride concentrations, respectively, were 11.59 and 11.12 micrograms/cu m. While these contaminants did not seem to have been affected much by the absence or the presence of steel-making activities, there was an appreciable effect on soiling caused by dust. The overall soiling range during the poststrike period was roughly 50% greater than during the strike.

DETERMINATION OF GASEOUS AND PARTICULATE CHLORIDE AND FLUORIDE IN THE ATMOSPHERE. Atmos. Environ., 8(9):927-936, Sept. 1974. 22 refs.

The measurement of gaseous and particulate chloride and fluoride in the atmosphere was accomplished using a combination of a Millipore filter and a sodium carbonate impregnated filter. The sampling flow rate was about 20 l/min, and the Millipore pre-filter was heated during the sampling. Hydrogen chloride and hydrogen fluoride were collected by a filter impregnated with 1% sodium carbonate and particulate and gaseous components of chlorides and fluorides were separated by aerosol filters in laboratory tests. The impregnated filter was also tested in a field study of gaseous and particulate chlorides and fluorides in Japan and Manila. The gaseous chloride concentration was high at the coast and on mountains, but the sources of the gaseous chloride concentration was obscure. The significance of sea salts, volcanoes, and man-made sources varied from place to place. Samplings of fluoride revealed that near and in an aluminum refining plant, the percentage of particulate component was higher than that of the gaseous component. (Author abstract modified)

Hokkaido Government (Japan), Dept. of Health
REPORT ON THE AIR POLLUTION INVESTIGATION AND MEASUREMENT IN HOKKAIDO, REPORT NO. 10. (Hokkaido no taiki osen chosa sokutei kekka hokoku). Text in Japanese. 385p., Nov. 1973.

The air pollution measurements in five cities in Hokkaido are presented in tables. The measurements in Sapporo are not included in this report, but the reason is not given. Settling particles by deposit gauges were monitored at eight locations in Muroran, nine in Tomakomai, six in Asahigawa, three in Obihiro, and five in Kushiro. Fluoride was measured by alkaline filter paper at 13 locations in Tomakomai. Sulfur oxides are measured by lead dioxide at eight locations in Muroran, 25 in Tomakomai, 11 in Asahigawa, three in Obihiro, and five in Kushiro; sulfur dioxide is measured also by electroconductivity at four locations in Muroran, five in Tomakomai, one each in Asahigawa and Obihiro, and two in Kushiro. The measurements for 1972 are presented in tables and printouts. The PbO₂ monthly averages of SO_x in Muroran ranged from 0.3 to 1 mg/day/100 sq cm. The highest measurements were 1.4 mg in April and December at two different locations. The Tomakomai averages were from 0.11 to 58 mg/day/100 sq cm; the three other cities ran about the same figures. The fluoride pollution in Tomakomai was 0.11 microgram to 8.72 microgram/day/100 sq cm. The highest single average was 25.76 microgram/day 100 sq cm in August at one location, which

also had a high figure of 23.91 micrograms in July, but as low as 0.61 micrograms in November. The reason is not clear. The most polluted city by settling particulates was Muroran, where in winter months, the dust accumulations were 99.8 tons or 100.8 jns/sq km/month.

Heaney, Robert J.

DISTRIBUTION OF TRACE ELEMENTS IN THE VICINITY
OF AN INTEGRATED PRIMARY COPPER PRODUCTION

FACILITY. Preprint, Air Pollution Control Assoc., Pittsburgh, Pa., 31p., 1971. 4 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 64th, Atlantic City, N. J., June 27-July 2, 1971, Paper 71-135.)

Sulfur oxide and particulate composition data are presented from air quality monitoring activities in the vicinity of an integrated primary copper production facility during the period 1959-1970. The average long term sulfur oxide concentrations ranged from 0.30-0.58 mg sulfur trioxide/day/sq dm. Suspended particulate levels of lead and copper ranged from 0.2-3.2 and from 0.3-0.8 micrograms/cu m, respectively. Settleable particulates ranged from 5-26 tons/sq mi/month and contained zinc, molybdenum, and selenium. Fluorides were also measured and showed significant decreases as compared to slight decreases for copper and sulfur oxides. Sulfur oxides and fluorides were much more subject to seasonal meteorological variations than particulate material constituents. An inverse relationship was observed between suspended particulates and settleable dust, with the former being higher during the windier months and the latter during the more stable inversion months. Concentrations were clearly related to distance from the source, and analysis of statistical distributions showed that both gaseous and particulate matter-related constituents were approximately log-normally distributed.

STUDIES ON AIR POLLUTION BY FLUORINATED COM-
POUNDS (13): ON ATMOSPHERIC CONCENTRATIONS OF
FLUORIDES IN VARIOUS PARTS OF THE COUNTRY. (Fuk-
kabutsu ni yoru taiki osen ni kansuru kenkyu (dai-13-ho):

Honpo kakuchi ni okeru taikichu fukkabutsu nodo ni (suite).
Text in Japanese. Preprint, Japanese Society of Public Health,
Fukushima, p. 416, 1974. (Presented at the Japanese Society of
Public Health Annual Meeting, 33rd, Fukushima, Japan, Oct.
16-18, 1974, Paper 546.)

Fluoride concentrations were measured at a total of 52 sites, including residential areas and industrial areas. Near aluminum and steel factories and phosphate fertilizer plants, fluorides were mostly present as water-soluble particles. Near ceramic industries, gaseous fluorides were predominantly present. In metropolitan residential areas, fluorides were generally present in concentrations not exceeding 0.2 micrograms F/cu m. With some pollution sources it becomes necessary to measure water-soluble fluoride particulate concentrations in addition to atmospheric fluoride particulate determination as hydrogen fluoride in order to obtain the precise total fluoride pollution concentrations.

Sapporo District Meteorological Observatory (Japan),
Tomakomai Weather Station

THE STATE OF AIR POLLUTION IN TOMAKOMAI.

(Tomakomai ni okeru taiki osen no genjo). Text in Japanese.
Sapporo Kanki Kishodai Gijutsu Jiho (Sapporo Dist. Meteorol.
Observ. Tech. Bull.), no. 82:27-40, March 1974.

The paper and lumber industries in Tomakomai city developed rapidly as a new industrial area after the completion of new harbor in 1963. The air pollution measurements initiated in 1963 are now monitored at the Pollution Control Center established in 1973. The data obtained at 26 measuring points in the city were compiled and analyzed. The yearly average settling particulate was 11.2 tons/k sq m/mo in 1972, and the data compiled since 1963 showed a decreasing trend. Within a 1.5 km radius of Ohji Paper Mill, the sulfur dioxide concentration was as high as 0.5 mg/100 cu cm/day. The relationships between the SO₂ concentration and meteorological factors were analyzed. The average fluorine gas concentration was 81.2 micrograms/100 cu cm/mo, however, the concentration reached as high as 150-270 micrograms/100 cu cm/mo in the vicinity of an aluminum refinery and fertilizer plant.

Cross, Frank L., Jr.

FLUORIDE EMISSIONS FROM PHOSPHATE PROCESSING

PLANTS. Air Pollution Control Assoc., Pittsburgh, Pa., Southern Section and Technical Council, Control Technol., Agric. Air Pollut., Memphis, Tenn., 1974, p. 159-165. 4 refs. (March 18-19.)

Results from field monitoring activities in the vicinity of a phosphate fertilizer plant are reported. Plant dumps some 2000 tons/day of gypsum waste into a settling pond from which fluorides are released into the atmosphere. Maximum fluoride concentrations of 32,000 micrograms were observed at a distance of 1500 ft from the pond, with the concentration dropping sharply to 3000 micrograms at a distance of 2700 ft. Analyses of citrus leaves within 0.2 mi of the plant revealed levels up to 550 ppm in old leaves and up to 150 ppm in young leaves. Levels of 75 ppm were found in young leaves 0.5 mi from the phosphate plant; this concentration appears useful as an indicator of air pollution capable of reducing citrus yield. Measurements at the surface of the pond demonstrated fluoride emissions of up to 0.16 lb/acre/day. At least 26 lb of fluoride/day were emitted from the 160-acre gypsum pond.

AIR POLLUTION BY FLUORIDE OF OMACHI DISTRICT,

REPORT 2. (Nagano-ken Omachi chiiki no ikeru fukkabutsu ni yoru taiki osen ni tsuite, dai 2-ho). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 9(2):542, Nov. 1974.

(Presented at the National Air Pollution Research Conference, 15th, Chiba, Japan, Nov. 6-8, 1974, Paper 390.)

The content of fluorine in rainfall and soil was measured in the Omachi area, Nagano Prefecture, where a fluorine pollution source exists. The fluorine concentration in soil increased linearly with the increase in soil particle size. The monthly transition of fluorine level was also studied, and the fluorine level in the winter was higher than that in the summer.

71362

Ando, Asahiro, Kenichiro Terai, and Yoshikazu Nasu

AIR POLLUTION BY FLUORIDE IN TOMAKOMAI, HOK-

KAIDO PART 2. (Hokkaido Tomakomai chiku ni okeru fukkabutsu osen ni tsuite, dai 2-ho). Text in Japanese. Taiki Osen Kenkyu (J. Japan. Soc. Air Pollution), 9(2):543, Nov. 1974.

(Presented at the National Air Pollution Research Conference, 15th, Chiba, Japan, Nov. 6-8, 1974, Paper 391.)

The atmospheric fluorine level in the Tomakomai area was analyzed for contents of gaseous fluoride compounds, and

water soluble and water insoluble fluorine particulates using a dry separatory collection technique. The sample was collected at two locations near a fluorine pollution source. The average composition of atmospheric fluorine compounds was 10% gaseous fluoride compounds, 60-70% water soluble, and 20-30% water insoluble fluorine particulates. The average total fluorine concentration in the atmosphere was about 0.8 micrograms/cu m. The conventional fluorine autoanalyzer detected only 10% of total fluorine in air, because the teflon filter inside the analyzer excluded fluorine particulate.

73286

Schaetzle, P.

AIR POLLUTION IN SWITZERLAND. (Die Luftverunreinigung in der Schweiz). Text in German. Gesundheitstech., 8(11):278-281, 1974.

Results of air quality measurements taken in various parts of Switzerland since 1967 are reported. In the Swiss Kanton Bas-selland the sulfur dioxide concentration of the atmosphere has been measured since 1967 at 15 points according to the method by Liesegang. For the first time since 1967, the atmospheric SO2 pollution dropped significantly in 1973. It rose from 4.2 mg SO2/100 hr in 1967 to 6.3 mg SO2/100 hr in 1972 and dropped to 5.4 mg SO2/100 hr in 1973. The highest monthly average was measured in MuttENZ (0.04 mg/cu m in July and 0.18 mg/cu m in January). Dust measurements according to Bergerhoff were likewise taken at 15 measuring points. The lead content was determined in the collected dust. The highest lead concentrations were found near busy streets and in the vicinity of the lead working industry. In 1973 fluoride measurements in the vicinity of brick kilns were taken for the first time. The annual average dust concentrations ranged from 91.7 mg dust/sq m/day to 165.6 mg dust/sq m/day. The dense traffic through Brugg in Switzerland has lead to intolerable carbon monoxide, hydrocarbon, dust, and oxides of nitrogen concentrations. The 12-hour maximum allowable immission value of 9 ppm is exceeded most of the time from 6 am to 10 pm.

Ehime Prefectural Government (Japan), Div. of Life and Environment, Section of Environmental Pollution

ENVIRONMENTAL POLLUTION IN EHIME PREFECTURE

IN 1974: PRESENT SITUATION OF AIR POLLUTION.

(Ehime no kogai: Taiki osen no genkyo). Text in Japanese, p. 5-40, 1974.

The present status of air pollution in Ehime Prefecture is reviewed. Data on emission quantity (5759.2 cu m/h), maximum one-hour value (0.08-0.45 ppm), and daily average (0.033-0.13 ppm) of sulfur oxides concentrations are compiled and analyzed in reference to regional characteristics. Data on falling particulates (2-23 ton/sq km/mo) and suspended particulate (yearly average 0.02-0.07 mg/cu m) concentrations and hydrogen fluoride concentration (maximum daily average 0.6-7.1 ppb) are also given. Meteorological conditions associated with high oxidant concentration are described. The oxidant
<xref image="2000WVH1.TIF|V3|2006:09:28:01:30:52.00|115592|0"> image: </xref>

concentration on days when smog forecasts or warnings were issued and diurnal variation in oxidant concentration are given and analyzed in relation to meteorological conditions. The pollution caused by automobile traffic was investigated by measuring carbon monoxide and suspended particulate concentration and analyzed in relation to wind direction, wind velocity, and traffic volume. Regional characteristics of SO_x and suspended particulate pollution are also analyzed.

Shizuoka Prefectural Government (Japan)
AIR POLLUTION. (Taiki osen). Text in Japanese. In: Shizuoka Prefectural Environmental White Paper, 1974. p. 15-68, 1975. Sulfur dioxide concentrations measured at 20 locations in the Fuji area during 1973 ranged from 0.008 ppm at Shibakawa-cho to 0.047 ppm at Imaizumi. The concentrations measured at 16 locations in the Shizuoka-Shimizu area ranged from 0.013 ppm at Ryunan to 0.034 ppm at Shimizu. The concentrations measured at 12 locations in the Numazu-Mishima area ranged from 0.017 ppm at Tokukura to 0.029 ppm at Nagaizumi. The concentrations measured at eight locations in the Hamamatsu area ranged from 0.019 ppm to 0.51 ppm. The yearly average nitrogen dioxide concentrations measured at 10 locations ranged from 0.018 ppm at Banda and Hakoue to 0.043 ppm at Shizuoka. The yearly average airborne particulate concentrations measured at 33 locations ranged from 0.010 mg/cu m to 0.104 mg/cu m. The average hydrogen fluoride concentrations measured at 10 locations ranged from 0.1 ppb to 0.4 ppb.

76890

Kanagawa Prefectural Environmental Center (Japan)
VARIATION OF ATMOSPHERIC HEAVY METAL CONCENTRATION IN KANAGAWA PREFECTURE. (Kanagawa-ken ni okeru taikichi jukinzoku nodonada no henka). Text in Japanese. Kanagawa-ken Taiki Osen Chosa Kenkyu Hokoku (Tech. Rept. Air Pollution Yokohama-Kawasaki Ind. Area), no. 17:29-48, Feb. 1975.

In Kanagawa Prefecture, the atmospheric concentrations of heavy metals were measured at 15 locations once a month for 3 yr from 1971 to 1973. The data compiled were analyzed in terms of the regional average of the entire period and the average of the entire region on each measurement date. The average atmospheric concentrations (microgram/cu m) of the entire period were 0.005-0.042 for cadmium, 0.20-0.89 for lead, 0.060-0.36 for manganese, 0.016-0.526 for nickel, 2.7-7.7 for iron, 0.001-0.018 for chromium, 0.001-0.017 for cyan, 0.07-0.42 for fluorine, and 141-259 for suspended particulates. The concentrations at ground level and building tops were compared, and correlation coefficients obtained were 0.90 for Cd, 0.77 for Pb, 0.87 for Mn, 0.82 for Ni, 0.73 for Fe, 0.80 for Cr, 0.73 for cyan, 0.66 for F, and 0.81 for suspended particulates. The correlation coefficients between Mn and Fe concentrations were in the range of 0.35-0.95.

Takahashi, R. and T. Watanabe
ON THE RESULT OF MONITORING OF BIFLUORIDE IN KANABARA AREA IN 1972. (Showa 47 nendo Kanbara chiku fussoka suiso kanshi kekka ni tsuite). Text in Japanese. Shizuoka-Ken Kogai Boshi Senta Nenpo (Bull. Environ. Pollut. Contr. Res. Center Shizuoka Prefect.), no. 2:92-95, 1972. Hydrogen fluoride gas emitted from the Kanbara Plant, Nippon Light Metal Company is damaging agricultural products such as tangerines. Monitoring of the HF concentration in the atmosphere was conducted at nine locations, and accumulated HF was measured at 38 locations. The rain water pH soluble fluorine, and dust were measured at five locations. The accumulation of fluorine in tangerine leaves was measured at 14 locations. Wind direction and velocity were measured at two spots. During 1972, HF pollution decreased by 22%, and the fluorine concentration in tangerine leaves decreased by about

14%. More than 1.5 km from the pollution source the HF concentration in the area was 5 micrograms/100 sq cm/day. The fluorine content of tangerine leaves (new leaves, collected in October) was approximately 100 ppm. The correlation between the amount of fluorine contained in tangerine leaves collected in October and the results of HF measurements indicated that the fluorine in the leaves was mostly due to HF in the atmosphere. Although fluorine ion dissolved in rain water, it did not affect the pH. About thirteen times as much fluorine ion was detected at areas near the pollution source as compared to those more distant from the source.

Hosokawa, Y., S. Izumi, M. Chinda, T. Seki, T. Nanta, and H. Ohno

ON THE FLUORIDE CONTAMINATION AT HACHINOHE

AREA. (Hachinohe chiku ni okeru fukkabutsu osen ni tsuite).

Text in Japanese. Aomori-ken Kogai Senta Shoho (Rept. Environ. Pollut. Control Cent., Aomori Prefect.), no. 1:60-64, Feb. 1975.

Toyo number 526 filter papers treated with 30% sodium carbonate solution were used to collect fluorides in the air at 22 locations throughout the city and number 51A papers treated with 1% Na₂CO₃ were fixed in a multi-stage low-volume sampler to collect fluorides in the flue gas from polluting sources. The average fluoride concentration in August 1974 ranged from non-detectable at the Musu primary school to 60 micro g/100 sq cm/month at Miyazaki-taku. The average concentration in September ranged from non-detectable at 6 locations to 183 micro g/100 sq cm/month at Miyazaki-taku, that in October from non-detectable at 5 locations to 98 micro g/100 sq cm/month at the second fish market and that in November from non-detectable at 6 locations to 1974 micro g/100 sq cm/month at the Second Fish Market. The fluoride concentration at the polluting sources ranged from non-detectable in the flue gas of the electric furnace at Hachinohe Steel Works to 5.9 mg/N cu m in the flue gas of an electric furnace at the Taiheyo Metal Company.

Tochigi Research Inst. for Environmental Pollution, Dept. of Air Quality and Noise

SURVEY RESULTS FOR ATMOSPHERIC POLLUTANTS.

(Taikichi ni okeru osen busshitsu no chosa kekka ni tsuite). Text in Japanese. Tochigi-ken Kogai Kenkyusho Nenpo, (Annu. Rep. Tochigi Prefect. Res. Inst. Environ. Pollut., no. 1:78-90, Jan. 1975.

Atmospheric pollutants (sulfur oxides; automotive emissions; hydrogen fluoride) were measured during 1971-1973, at various locations in Tochigi Prefecture, Japan. Concentrations of sulfur oxides were highest (0.033-0.087 ppm, 24-hr average values) in Ashio City, where copper mines are located. Elsewhere in the prefecture, SO_x concentrations ranged from 0.002-0.014 ppm, at 20 locations. Automotive emissions (carbon monoxide, nitrogen oxides) were measured at 11 major intersections in the prefecture. From 1971 to 1973, some decrease was seen in the 8-hr average values of CO (4.4-10.7 ppm, 1971; 2.3-7.4 ppm, 1973). Average 24-hr values of nitrogen dioxide increased yearly from 1971 to 1973 (0.025-0.040 ppm, 1971; 0.033-0.076 ppm, 1973). Average 24-hr values

<xref image="2000VW2.TIF|V3|2006:09:28:01:30:56.00|113695|0"> image: </xref>

D. AIR QUALITY MEASUREMENTS

255

of nitrogen monoxide ranged from 0.040-0.138 ppm in 1973. Traffic volume concentrations of airborne dust, lead, vanadium, and aldehyde were measured at 6 urban intersections in 1973. Types of vehicles were not differentiated. For an 8-hr sampling time, the number of vehicles ranged from 1154 to 3166. Ranges of pollutant concentrations were: dust, 0.26-0.96 mg/cu m; lead, 0.76-1.59 micrograms/cu m; vanadium, 0.09-0.14 micrograms/cu m; aldehyde, 0.01-0.05 ppm. In 1973, at 6 locations, 24-hr average values of HF ranged from 0.22-2.73 ppb, with measured values ranging from 0.14-7.15 ppb. There was no clear correlation between HF and plant damage.

THE MEASUREMENT OF AIR POLLUTION. (Ilman saaste-analyysi- mittauksia). Text in Finnish. Kemia-Kemi, no. 6:340-341, 1974. 2 refs.

In those areas where industrial and urban development is greatest, pollution is usually heaviest. In West Germany the quantities of the following impurities emitted into the air in 1969 were as follows: carbon monoxide, 8/Mton; dusts, 4 Mton; Sulfur dioxide, 4 Mton; nitrogen oxides, 2 Mton; hydrocarbons, 2 Mton. There were 2 Mton of fluorides, hydrogen chloride, and strong-smelling substances combined. Fifty-six percent of this was caused by traffic, 18% by energy production, 17% by industry and 9% by households. Measurement stations are generally situated near large industrial and urban centers. When the information from a large area is collected for further analysis there are several advantages. Planning of new industrial sites and traffic routes is improved, smog warnings can be issued when critical levels are reached and polluting industries can be located. The state of Baden-Wurttemberg in West Germany is installing a network of measuring stations. Siemens, Inc. is supplying the analyzers, information transfer machinery and process computers. The industrial and urban density is light in Finland and a network of this kind is not yet a timely issue.

78954

Hokkaido Prefectural Government Office, Dept. of Life Environment

PRESENT SITUATION OF AIR POLLUTION IN HOKKAIDO. (Hokkaido no Taiki osen jokyo). Text in Japanese. 548p., Jan. 1975.

Results of air pollution measurements in 1973 at more than 20 locations in Hokkaido are tabulated. Sulfur dioxide and sulfur oxides were analyzed by conductivity and lead dioxide methods, respectively; airborne aparticulates by a light scattering method; nitrogen oxides and oxidants by a spectrophotometric method, hydrogen fluoride by specific ion electrode, and dust was by deposit gauge. The average SO₂ concentrations ranged from 0.008 ppm at Utonai to 0.025 ppm at Shinnittetsu Gymnasium at Muroran. The average airborne particulates concentrations ranged from 0.02 mg/cu m at 9 locations (out of 14) to 0.08 mg/cu m at Tokura store at Obihiro. The average NO_x concentrations ranged from 0.017 ppm at Akino, a semi-industrial area, to 0.11 ppm at Living Yasumoto, a commercial area. The average oxidants and HF concentrations at Akino were 0.028 ppm and 0.1 ppb, respectively. The highest average dust concentration was 52.3 t/sq km/mo at Shinittetsu Gymnasium. The highest average SO_x concentration was 0.85 SO₃ mg/day/100 sq cm at Yusaicho in Muroran city.

79343

Kumamoto Prefectural Government (Japan)

PRESENT SITUATION AND CONTROL OF AIR POLLUTION. (Taiki osen no genjo to taisaku). Text in Japanese. In: Environmental White Paper in 1974, p. 11-32, June 1975.

In Kumamoto prefecture, sulfur oxides and suspended particulates are two major air pollutants, and pollution problems by

hydrogen fluoride and hydrogen chloride are observed locally. The SO_x concentration and suspended particulates measured since 1964 showed a generally decreasing trend after 1970. Data on SO_x concentration measured in Arao, Yashiro, Minamata, Kumamoto and Uto cities are compiled and analyzed. The yearly average SO_x concentrations(ppm) for 1972 and 1973 were 0.020-0.027 in Arao, 0.017-0.019 in Yashiro, 0.014-0.021 in Minamata and 0.021-0.026 in Kumamoto. Suspended particulate concentrations (yearly average of 1972 and 1973) were 0.025-0.059 in Arao, 0.025-0.056 in Kumamoto, 0.046-0.081 in Yashiro and 0.047-0.081 in Minamata. Amounts of sedimented dust (ton/sq km/month) measured in 1973 were 5.55 in Arao, 4.8 in Kumamoto, 5.62 in Yashiro and 5.84 in Minamata. In Arao city, the HF concentration was measured by the ion electrode method, and the yearly average HF concentration was 0.18-0.24 ppb.

Fukuoka Prefectural Environmental Pollution Center
INVESTIGATIONS OF AIR POLLUTION. (Taiki Osen Kan-
kei). Text in Japanese. In: Annual Report of Fukuoka Environ-
mental Research Center (1973), p. 30-34, 1975.

The following studies were made in 1973: the effect of com-
bined pollutants on humans; gaseous air pollution in Fukuoka;
the distribution of air pollutants; air pollution of underground
arcades; air pollution in Karita, Ikuhashi, and Mizumaki; dust
pollution in the Tagawa area and in Omuta city; the effects of
fluorine in the Omuta and Orano area; and damage to vegeta-
tion by fluorine. Fukuoka Prefecture had higher concentrations
of sulfur oxides, nitric oxide, nitrogen dioxide, and dust com-
pared to the national average, but lower cadmium, manganese,
lead, and iron. The investigation of dust pollution in the
Tagawa area was conducted to prove that the source of en-
vironmental pollution in this area is a cement plant. The in-
vestigation found large amounts of heavy metals such as cad-
mium, copper, zinc, and manganese in airborne dust and dust
deposits in the Tagawa area.

Ebisawa, E.
SUMMARY OF AIR POLLUTION SURVEY. (Taiki osen chosa
no gaiyo). Text in Japanese. Ibaraki-ken Kogai Gijutsu Senta
Nenpo (Annu. Rept. Environ. Pollut. Res. Center, Ibaraki
Pref.), no. 7:17-19, Oct. 1975.

An air pollution survey in Ibaraki Prefecture is summarized.
There were 22 monitoring stations for sulfur dioxide and air-
borne particulates, and 16 stations for nitrogen oxides and oxi-
dant measurements. Photochemical smog emergency warnings
were issued 34 times, while forecasts of photochemical smog
emergency were issued 71 times. Seventeen complaints claim-
ing oxidant damage were filed. The damage to morning glory
by photochemical smogs and the damage to plant leaves by
fluorides were investigated. Visible damage to plant leaves was
observed at some places near an aluminum treatment factory,
and 95 ppm to 48 ppm fluoride was detected. Damage to the
morning glory was observed at Kashima City and Mito City

E. ATMOSPHERIC INTERACTION

02325

K. D. Hage, N. E. Bowne, and G. R. Hilst.

PRELIMINARY ESTIMATES OF ENVIRONMENTAL EXPOSURE FOR FUEL AND EXHAUST PRODUCTS. VOLUME I.

Travelers Research Center, Inc., Hartford, Conn. (Rept. CR-61056). Jan. 1965. 158 pp. NASA: CR-61056

A preliminary mathematical model that attempts to describe the transport and growth of a gas or vapor cloud released from a quasi-instantaneous volume source in low-level shearing wind flow was formulated and programmed for use on a digital computer. Computations of smoothed peak concentrations and total dosages were performed for plane polar grid points within a 90 degree sector at ground level from the source to distances of about 15 km. The computations were performed for specified initial conditions believed to be representative of test firing exhaust releases of hydrogen fluoride and pipeline spill releases of liquid fluorine at Marshall Space Flight Center, Huntsville, Alabama. An experimental program has been presented for MSEC with three alternatives of complexity and cost which lead to different solutions for the problem of atmospheric diffusion in the Huntsville area. The basic experimental design is the same for all programs, i.e., use of an aerosol tracer to measure diffusion of material and resultant surface concentrations. As the complexity and costs increase so does the understanding of the diffusion processes. The design anticipates a curvature in the trajectory of material released from the static test area in a wind flow that would result in material reaching Huntsville. A thorough mathematical analysis of the statistical diffusion model was prepared to ensure the sampling density would be satisfactory but not excessive. Provisions were made for determining peak concentration.

METEOROLOGICAL CONSIDERATIONS IN THE HANDLING

OF A MIXTURE OF LIQUID FLUORINE AND LIQUID OXYGEN.

Weather Bureau, Washington, D. C., Spaceflight

Meteorology Group. Oct. 15, 1964. 47 pp.

Fluorine is a highly toxic and corrosive gas, the safe handling of which requires the utmost care. HF is considerably less toxic than F₂, but is very corrosive. Optimum weather conditions for the diffusion of FLOX are difficult to define. If it is assumed that the cloud will conform to the characteristics of a ground level release, then the following weather conditions would provide optimum release conditions: (1) Unstable atmosphere; (2) Variable winds blowing away from populated areas and preferably offshore; (3) Rain. If a catastrophic spill occurs, it is likely that the resulting cloud, or fireball, would assume the characteristics of an elevated, instantaneous release. This would occur because the high temperatures of reaction with H₂ and the buoyancy of HF would displace the cloud upwards at a rapid rate, penetrating and temporarily destroying any low-level inversion. Under these circumstances optimum weather conditions would be: (1) Stability in the lower levels; (2) Offshore winds; (3) High moisture content from surface to pollutant level. In the mean these conditions are more likely during the nighttime hours in the months of December through March. From April through November low-

level winds are predominantly onshore and during the summer months atmospheric instability is strongest and is of longest duration. The climatology presented here suggests a location for FLOX storage facilities that is isolated from populated areas, orchards or costly structures, particularly in the northwest and southeast quadrants. In general, these are the directions of the prevailing winds and the strongest winds. Fog and low ceilings occur most frequently with winds from the northwest quadrant.

Centre Departemental d'Etude des Pollutions Atmospheriques, Paris, Section Sante et Meteo.

A DAY OF POLLUTION IN THE LACQ REGION. (Journee de pollutin vecue dans la region de Lacq). Text in French. Pollut. Atmos. (Paris), 11(Special):36-40, Feb. 1969.

Observations and measurements of pollution are reported for the period from Oct. 4 to 5, 1968, in the 15 km-wide valley of the Gave de Pau. On the night of Oct. 4, a 4-day old descending inversion reached an 11-degree amplitude with a 700-m thickness. Early morning pollution was near zero, but as the fog cleared and wind conditions of less than 1 knot prevailed, pollution indices rose greatly. Later in the day the wind rose, and in the absence of any inversion, pollution dropped by a factor of 10. A gas desulfurization plant in the valley emits 500 to 1000 tons of sulfur dioxide daily. Measurements made by absorption of acid gases in glycerinated 0.5 NaOH, in hydrogen peroxide solution, or in glycerinated zinc acetate gave qualitatively similar results. Emissions were from a 104-m high chimney, but maximum ground level pollution was found 5 km from the chimney, a distance about 40 times the theoretical chimney height, i.e., the plume height above the chimney. Another source of pollution in the valley is an aluminum extraction plant which employs the Soderberg process and emits 150 kg per day of fluoride ions. Measurement by exposure of lime-impregnated papers, with colorimetric estimating techniques, correlated in 70% of the cases with direct absorption on fiberglass, and was reproducible to better than 10%. Decrease of pollution with distance was found to be exponential, with the worst pollution occurring within 2 km of the plant.

ATMOSPHERIC FLUORINE COMPOUNDS AS INDICATORS
OF AIR MOVEMENTS. *Nature* (London), 230(5293):379, April
9, 1971. 2 refs.

Preliminary measurements are reported for atmospheric concentration of sulfur hexafluoride and trichlorofluoromethane and atmospheric turbidity in southwest Ireland during July and August 1970. The contaminants were measured with a gas chromatograph with an electron capture detector, the turbidity with a sun photometer. High concentrations of CCl_3F and SF_6 and appreciably increased turbidity are noted to be associated with easterly winds from continental Europe. These observations lend support to the proposal that CCl_3F and SF_6 can be used as indicators of air masses recently polluted by industrial pollutants.

AIR SURVEYS LINKED WITH MATHEMATICAL MODEL
TO PROTECT ENVIRONMENT. *Water Pollution Control*
(Toronto), 109(5):S9-61, May 1971. 4 refs.

Data from long-term air measurements were used to develop atmospheric dispersion equations describing ground-level concentrations of fluorides from the gypsum ponds and the diammonium phosphate stack of fertilizer complex and fluoride plus sulfur dioxide concentrations from a neighboring power plant stack. With the equations it was possible to simulate mathematically any combination of circumstances affecting the fertilizer plant emissions and to determine appropriate pollution control measures. On the basis of the study, it was decided to install a venturi scrubber in the diammonium phosphate stack and to create a buffer zone around the gypsum plant.

ATMOSPHERIC REACTIONS AND SCAVENGING
PROCESSES. In: *Air Pollution* Arthur C. Stern (ed.), Vol. 1,
2nd ed., New York, Academic Press, 1968, Chapt. 6, p. 149-186.
77 refs.

Atmospheric influences can change air pollutants. Through turbulence and diffusion, substances released at ground level will eventually be exposed to conditions in the upper atmosphere and become accessible to high energy photons which break up even the most stable molecules. Ozone reacts with nitrogen to form several oxides. The energy requirements, light source, reactions, free radical formation, and chain reactions in photochemical and photosensitized reactions are discussed. Heterogeneous reactions may also take place on the surfaces of various solid and liquid particles. Again, light can play an important role. Mathematical simulations of atmospheric dispersion of stack gases can be used to predict atmospheric concentrations. Inorganic pollutants include sulfur oxides and nitrogen oxides. Organic pollutants are formed in photochemical smog. The process and symptoms of photochemical smog are given including data for downtown Los Angeles. Spectrograms have been used to determine the chemical nature of smog. Eye irritation is a function of hydrocarbons and nitrogen oxides. Photochemical reactions can also cause rubber cracking. The chain reactions in photochemical smog are quite complex. Suggested photooxidation mechanisms involving branching chains and the reaction of oxygen atoms with olefins are also given. Scavenging foreign material from the atmosphere consists of deposition and conversion to normal atmospheric constituents. Most of the sulfur contaminants are emitted in the form of gaseous sulfur dioxide, some of which oxidizes to sulfur trioxide which then reacts with water vapor to form sulfuric acid. Hydrogen fluoride, hydrogen sulfide, ammonia, carbon dioxide, carbon monoxide, nitrogen ox-

ide, fly ash, and particulates are also pollutants. The washout mechanism is effective in removing some particles.

TRACE ELEMENTS IN ATMOSPHERIC PRECIPITATION
AROUND THE OTKAZNOE RESERVOIR. (Mikroelementy v
atmosferykh osakdakh rayona Otkaznenskogo vodok-
hranilishcha). Text in Russian. *Gidrokhim. Materialy*, vol.
49:74-79, 1969. 15 refs.

The amounts of 17 trace elements introduced into Otkaznoe water reservoir with atmospheric precipitation were analyzed in a one year study. Boron, fluorine, bromine, and iodine in atmospheric precipitation were determined by chemical analysis; those of vanadium, manganese, cobalt, nickel, copper, molybdenum, silver, tin, lead, iron, aluminum, bismuth, and titanium were determined spectroscopically. The elements Co, Mo, Ag, Sn, Pb, and Bi were not found in atmospheric precipitation. The content of other elements was higher in comparison with other areas. This is explained as depending on the character of climatic conditions of the area, i.e., dry and windy climate and poor coverage by plants, which cause increased dustiness of the atmosphere.

CHEMICAL PROCESSES AT THE AIR-SEA INTERFACE:
THE BEHAVIOR OF FLUORINE. *J. Geophys. Res.*, 76(3):736-
741, Jan. 20, 1971. 14 refs.

Ion fractionation between fluorine and chlorine at the air-sea interface was investigated. Radiochemical experiments showed a decrease in the F/Cl ratio for laboratory aerosols produced from sea water. Marine aerosols showed an increase in the F/Cl ratio with a possible contribution from airborne dust contamination. Jet drops in the laboratory and naturally occurring marine jet drops showed little to no change. Radiochemical tracers also showed that drying of sea water droplets sometimes increased the F/Cl ratio of the salt residue, whereas acidification of the sea water always caused the residue to have a decreased ratio. The observed complex chemical behavior of fluoride in air-sea interactions suggests the necessity of taking new approaches in the laboratory and in field experiments. (Author abstract modified)

Hollinden, A. B.
METEOROLOGICAL SITING FOR TOXIC FUEL TESTING.
Preprint, American Meteorological Society, Boston, Mass., and
American Inst. of Aeronautics and Astronautics, New York, p.
458-461, 1970. (Presented at the National Conference on
Aerospace Meteorology, 4th, Las Vegas, Nev., May 4-7, 1970.)
Different sites in the Gypsum Canyon, Calif., were considered
as storing and testing grounds for such toxic propellants as
nitrogen dioxide, uns-dimethylhydrazine, hydrazine, pen-
taborane, and fluorine. The distribution downward of the toxic
material depends on the mean wind flow pattern and the diffu-
sive action caused by atmospheric turbulence. Tests were car-
ried out to obtain details of flow in the canyon. Gypsum
Canyon is a north-south canyon located in a desert region.
Prevailing synoptic situation throughout the year involved
<xref image="2000WVH5.TIF|V3|2006:09:28:01:31:04.00|115181|0"> image: </xref>

weak pressure gradients, and local circulation predominated. On a typical sunny day the wind in the main canyon blew up the canyon at speeds from 3 knots at 9:30 am to 6-7 knots at 12:30 pm, at which time it became variable. A sudden surge of down-canyon wind then occurred and the winds gradually weakened but remained southerly 6-7 knots until 4 or 5 pm. This wind reversal had little or no effect on the circulations in the side canyons. Five of the sites considered were located, respectively, on the small center ridge, the north slope of side-valley, the east side of side-valley entrance, a side-canyon, and a sharp ridge 75 feet higher than the main canyon floor. Classifications of each with respect to meteorological conditions are included.

ENVIRONMENTAL POLLUTION AND THE USE OF RI
(RADIOACTIVE ISOTOPE). (Kankyo osen to RI riyo no gen-
jo). Text in Japanese. Genshiroyoku Kogyo, 17(8):5-8, Aug.
1971. 6 refs.

Tracer studies of gas dispersion patterns and chemical reactions using isotope ratios are discussed. Isotope ratios in sulfur are extremely different according to the conditions of accumulation and compaction of natural resources. Using this fact, a method of tracing dispersions of flue gases by identification of the S isotope ratio which is different from S in the air was developed. Sampling of sulfur dioxide is taken by a glass fiber preliminary filter and a cellulose filter with SO₂ absorbent. The preliminary filter collects soot and SO₃, and the second filter recovers SO₂. After a chemical treatment, a quantitative analyzer measures the S isotope ratio; SF(6), emitted artificially from the flue with SO₂, is measured by gas chromatography. Both data are compared, and the dispersion pattern and SO₂ oxidation and reduction are determined. The method of tracing in a more difficult, complex environment is also given. Other radiation applied apparatus such as Sr (90) ozone counter and an Egg shell thickness gage are described. Application of radio-release and chemical substitution using kryptonate, developed by Schleck, and quantitative determinations of SO₂ gas, fluoride, oxygen residue, chromium oxide ion, and vanadium hydroxide by various isotopes are briefly discussed.

FLUORINE WASTE GASES IN THE SURROUNDING ATMOSPHERE OF YUGOSLAV FACTORIES. (Otpadni plinovi fluora u okolisnoj atmosferi nasih tvornica). Text in Serbo-Croatian. Vet. Arh., 40(3/4):61-77, 1970. 20 refs.

The transport of fluorines in Yugoslav areas threatened with outbreaks of fluorosis and the concentrations of fluorine in the electrolysis rooms and the atmospheres of aluminum factories were investigated with respect to direction, range, and speed of dispersion and relation to the hydrometeorologic characteristics of the area. In the electrolysis rooms, monitored in three factories, average annual fluoride concentrations were 4.6, 5.6, and 3.6 mg/cu m. The concentration in the surrounding atmosphere, determined by analysis of the precipitation, was 0.4 mg/1 annually. Fluorides moved in the direction of the prevailing winds to a defined distance and then decreased again. The annual average concentrations for all six measurement locations ranged from 1.04 to 0.14 mg/1.

Hendrickson, E. R.
DISPERSION AND EFFECTS OF AIR BORNE FLUORIDES
IN CENTRAL FLORIDA. J. Air Pollution Control Assoc.,
11(5):220-225, 232. May 1961. 14 refs. (Presented at the Air Pollution Control Association, Annual Meeting, 53rd, Cincinnati, Ohio, May 22-26, 1960.)

Citrus groves, winter truck crops, and commercial gladioli in a 100-sq-mile area of central Florida all show evidence of

damage by airborne gaseous fluorides. Sources of the fluorides are phosphate rock drying and grinding plants, superphosphate and elemental phosphorus plants, and a defluorinating plant. The dispersion of the gaseous fluorides is tracked by a network of static sampling stations using filter papers treated with calcium formate solution (sulfur dioxide is also measured, by the lead peroxide candle method). During the sampling period, records are also obtained of wind direction and velocity and vertical temperatures in the area. When analysis is complete, concentrations are plotted on maps for each month at each sampling station. From this information isopleths are drawn in the light of wind roses for that particular month. With this technique, it is possible to determine the extent of pollution from several sources, to compare one area with another, and to evaluate monthly changes in exposure at single stations.

FLUORINE WASTE GASES IN THE SURROUNDING ATMOSPHERE OF YUGOSLAV FACTORIES. (Otpadni plinovi fluora u okolisnoj atmosferi nasih tvornica). Text in Serbo-Croatian. Vet. Arh., 40(3-4):61-77, 1970. 20 refs.
The dispersion of fluorides was investigated in three areas of Yugoslavia jeopardized by fluorosis: Kidricevo, Lozovac, and Razine. Fluorides were measured in both aluminum electrolysis rooms and the open atmosphere to determine the direction and extent of their dispersion. The annual average levels in the electrolysis rooms were 4.6 mg/cu m at Kidricevo; 5.6 mg/cu m at Lozovac; and 3.6 mg/cu m at Razine. In the Ptuj field (Kidricevo), the average annual amount of fluoride in precipitation was 0.4 mg/l at six locations representing various directions and distances from the source of contamination. The annual average amount of fluorides for all six locations was 1.04-0.14 mg/l. The fluoride-containing waste gases moved in the direction of prevailing winds to a definite distance, after which the concentrations decreased.

Bartels, Otto G.
AN ESTIMATE OF VOLCANIC CONTRIBUTIONS TO THE ATMOSPHERE AND VOLCANIC GASES AND SUBLIMATES AS THE SOURCE OF THE RADIOISOTOPES BE(10), S(35), P(32) AND NA(22). Health Phys., 22(4):387-392, April 1972. 30 refs.
Utilizing new data on the presence of a sulfate aerosol layer in the stratosphere, an analysis is made of the source of excess sulfate in precipitation. Data are presented against the hypothesis of appreciable escape to the atmosphere of hydrogen sulfide produced on the continental shelves. Calculated volcanic contributions to the atmosphere in metric tons/yr are chlorine-7.6 million, sulfur-17 million, fluorine-7.3 million, boron-73,000, sodium-6 million, potassium-2.3 million, and calcium-7.2 million. The calculations support Conway's hypothesis of volcanic water and the volcanic chloride origin of the ocean. The points of weakness in the spallation hypothesis of atmospheric radioisotopes are presented. A table

GEOCHEMICAL ASPECTS OF INORGANIC AEROSOLS

NEAR THE OCEAN-ATMOSPHERE INTERFACE. Am. Chem.

Soc., Div. Water, Air Waste Chem. Gen. Paper, n(2):156-158, Sept. 1971. 14 refs.

Aerosol samples collected over the oceans near the air-sea interface were analyzed. Efforts were directed toward the determination of metals such as sodium, magnesium, aluminum, titanium, vanadium, manganese, scandium, iron, cobalt, antimony, cerium, and europium by neutron activation analysis, and of fluorine and chlorine by photon activation. Atomic absorption spectroscopy was used to determine sodium, potassium, iron, and manganese. The fluoride ion-specific electrode was used to determine fluoride in seawater, sea spray, and rainwater. Comparison of the elemental ratios for Ce/Fe, Sc/Fe, Co/Fe, and Eu/Fe with those of other investigators showed good agreement. Comparison of results obtained from the Indian Ocean for Al/Fe and Mn/Fe with the present results for same elemental ratios over the Atlantic agree satisfactorily. Comparison of these results with average elemental ratios found in seawater and in crustal rocks shows that the source of the trace metals is the continents rather than the ocean. The elemental ratios for Sc/F, Fe/F, Na/F, and Ti/F differ by several orders of magnitude for seawater and average crustal rocks. These ratios were determined in Atlantic aerosols and indicate that the continents are the source of these trace metals. Fluoride concentrations are an excellent indicator of a marine aerosol. The results for inland rain compare well with the same elemental ratios determined over land in aerosols near the east coast of the U. S. In coastal areas aerosols rapidly change to continental characteristics.

INFRARED DETECTION OF HF TRACER GAS IN INERT

AND COMBUSTING FLOWS. Preprint, American Inst. of

Aeronautics and Astronautics, New York, 17p., 1972. 26 refs.

(Presented at the American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 10th, San Diego, Calif., Jan. 17-19, 1972, Paper 72-70.)

A noninterfering diagnostic technique that employs monomeric hydrogen fluoride as a passive tracer gas was developed. Infrared absorption by HF is used to infer turbulent mixing rates in inert and combusting flows. Data are presented on the turbulent diffusion of HF seeded streams of air, heated air, hydrogen, and carbon dioxide into an outer coaxial air stream. Combustion of acetylene and air in a free jet configuration was also investigated with the HF tracer. In most of these flow situations, the HF exhibited apparent rotational nonequilibrium. Development of the experimental technique and methods for data acquisition and analysis are discussed. (Author abstract modified)

Auermann, E., W. Fojt, and J. Janetzky
COMPARISON OF MEASURED AND CALCULATED
FLUORINE EMISSION CONCENTRATIONS. (Vergleich
gemessener und berechneter Fluor-Emissionen). Text in
German. Z. Ges. Hyg. Ihre Grenzgebiete (Berlin), 18(6):414-418,
June 1972. 5 refs.

The fluorine emissions of a source were measured at the stack and six measuring stations erected in all directions at distances of 200 to 650 m. For the emission measurements, samples were taken with a platinum probe. For the determination of the fluorine the method by Megregian was slightly modified and applied. The measuring accuracy was + or - 15%. For determination of the emission concentrations, the air samples were drawn with a speed of 6 l/min through a heavily diluted sodium hydroxide solution (n/500). The concentration was determined by colorimetry. The temperatures at the measuring sites were between 6 and 8 C and 4 and 5 C. The winds from southwest to west had an average velocity of 4 m/sec 2 m above the ground. With the aid of the formulas by Bosanquet and Pearson, the fluorine concentrations were calculated and compared with the measured results. A good agreement between the two results was achieved. The background concentration was between 2 and 9 micrograms/cu m. Maximum concentrations (4.0, 9.0 and 5.3 micrograms/cu m) were measured in a distance of 290 m at an average wind speed of 6 m/sec. The emission concentrations were 45, 62, and 103 mg/cu m.

Sueda, Shintaro, Kenichi Shimohara, Yukio Eguchi, Nobuyasu Shigemori, and Takashi Akiyama
FLUORIDE AND SULFATE CONCENTRATION IN THE ATMOSPHERE OF KITA-KYUSHU CITY. (Kita-Kyushu shi ni okeru taiki-chu fusso oyobi ryusankon no bunpu). Text in Japanese. Japan Society of Air Pollution, Proc. Symp. Japan Soc. Air Pollut., 13th, 1972, p. 187. (Nov. 7-9, Paper 142.)
Thirty-two monitoring stations were installed in Kita-Kyushu in June 1971, and the measurements of fluorides and sulfates, and the distribution changes were observed. Settling particles and rain water collected in deposit gauges were filtered, and the solution was distilled. The lanthanum-alizarin-complexion method was used for fluorides and nephelometry was used for sulfate determinations. Sulfur dioxide measurements were taken by the lead dioxide method. The sulfate distribution was high along the Dokai Bay and agreed with the distribution pattern of SO₂ gas. Fluorides showed a similar distribution pattern, but the concentration was especially high in the Kokura industrial area. In northern Moji, sulfate was low but fluoride concentration was high. Sulfate concentration was high in June and February and low in July, August, and Oct. The SO₂ fluctuations were similar. Fluoride count was low only in Oct.

AIR POLLUTION BY FLUORIDE IN THE OMACHI DISTRICT.
(Nagano-ken Omachi chiku ni okeru fukkabutsu ni yoru taiki osen ni tsuite). Text in Japanese. Japan Society of Air Pollution, Proc. Symp. Japan Soc. Air Pollut., 13th 1972, p. 188. (Nov. 7-9, Paper 143.)

Fluoride near an aluminum refining factory was measured by the LTP method, and the fluoride accumulation in red pine needles was used as an index for pollution. The monitoring stations were installed at 15 locations covering 5 km east to west and 10 km south to north surrounding the aluminum plant. The fluoride accumulation was checked monthly from May 1971 to April 1972. One-year-old red pine needles were collected, and F content was determined by the photometric method. In the north-south directions, approximately 750 micrograms/100 sq m/mo was accumulated at 400 m from the plant and 250 micrograms at 800 m. The accumulations were only 20-30 micrograms in the east-west directions. In the south, seasonal fluctuations were great; they were 80-100 micrograms/mo in the summer, but the amount was four or five times greater in the winter. Near the plant, the F accumulation in pine needles was 200-300 ppm. In the leeward side, even at distances of 15,000 to 20,000 m, 20 to 30 ppm F were found. In this area, the wind was predominantly northerly and pollution extended to the south. There was a high correlation (0.977) between yearly accumulation of F and the F content in pine needles.

TESTING AN AREA SOURCE MODEL THROUGH APPLICATION TO AN ISOLATED AREA SOURCE AND SIMULTANEOUS CONCENTRATION MEASUREMENTS.

(Ueberpruefung eines Vielquellenmodells durch Anwendung an einem isolierten Flaechenemittenten und parallele Immissionsmessungen). Text in German. VDI (Ver. Deut. Ingr.) Ber., no. 200:189-198, 1973. 6 refs.

A multi-source model was used to analyze the fluoride concentration in the vicinity of an aluminum plant. The set of emitters consisted of two furnace halls, each 560 m long and 16 m high, and a chimney 130 m high. Concentrations were calculated for selected meteorological conditions and for a 5 by 5 sq km grid with a spacing of 200 m. The calculated results were compared with measured concentrations. Using mobile measuring devices, measurements were taken in the plume from the set of emitters. Up to 20 instrument mobile stations were used simultaneously. Comparisons between calculated and measured results were obtained at 30-minute intervals and for 86 sets of conditions. The results are explained and interpreted.

Jansen, P., S. Jordan, and W. Schikarski

COMPARATIVE MODEL THEORY OF THE ATMOSPHERIC

POLLUTANT LOAD CAUSED BY POWER PLANTS. (Ver-

gleichende Modeltheorie der atmosphärischen Schadstoffbelastungen durch Kraftwerke). Text in German. Inst. Natl. Rech. Chim. Appl., Dixieme Colloq. Atmos. Polluees, Proc., Paris, France, 1972, 10p. 32 refs. (May 3-5.)

A model theory of the air pollutant loads caused by conventional and nuclear power plants, and future development of the pollutant loads on the basis of the expected energy production and of the maximum allowable ground level concentrations is presented. The pollutants concerned are sulfur dioxide, nitrogen oxides, dust, and fluorine compounds as well as xenon-113 and krypton-85. The specific SO₂, dust, nitrogen oxide, and fluorine emissions from coal are 6.0-7.7; 1.4-2.7; 1.4-4.6, and 0.05-0.11 g/per kWh. The corresponding values for oil are 7.4 g of SO₂, 0.7 g of dust, 1.5-3.4 g of nitrogen oxides, and 0.004 g of fluorine per kWh. Natural gas produces 0.002 g

of SO₂, and 07-3.1 g of nitrogen oxides per kWh. The hold time of air pollutants in the atmosphere is dependent of their concentrations, high concentrations corresponding to short decay times. The hold time of SO₂, dust, nitrogen oxides, and fluorine in the atmosphere is 1-6 days, 3-7 days, 1-3 days, and 3-7 days, respectively. The average yearly ground level concentration of SO₂ and nitrogen dioxide in polluted areas is 150 micrograms/cu m and 50 micrograms/cu m. Nuclear energy is about 1000 times less polluting than either coal or fuel oil, while natural gas is about 100 times better than the fossil fuels. The energy generation facilities operating currently are susceptible to creating considerable pollution even under normal meteorological conditions, while concentrations exceeding the maximum allowable levels by two orders of magnitude occur during inversions.

Kovygin, G. F

CERTAIN PROBLEMS OF SUBSTANTIATING THE PERMISSIBLE DENSITIES OF SURFACE CONTAMINATION WITH BERYLLIUM. (Nekotoryye voprosy obosnovaniya dopustimyykh plotnostey zagryazneniya noverkhnostey berillyem). Text in Russian. *Gigiena i Sanit.*, no. 2:43-45, 1974. 1 ref. The permissible density of surface contamination by beryllium was studied with respect to the redispersion of the surface contaminant and to the resulting in-the-air concentration of beryllium. Ammonium fluoroberyllate and metallic beryllium dust with a particle size of 50 micron, a fan providing for an air velocity of 1.8 m/sec were used for the experiments. Inverse correlation between the redispersion index; i.e., the ratio of the in-the-air aerosol concentration to the surface density of contamination, and the surface density of contamination was established. The correlation coefficient decreased with increasing air velocity. The maximum allowable surface contaminations that cause no aerosol contamination exceeding the maximum allowable beryllium concentration were 0.9 and 0.7 mg/sq m for ammonium fluoroberyllate and metallic beryllium without air movement, and 0.4 and 0.2 mg/sq m at 1.8 m/sec air velocity.

Goddard, A. J. H., R. E. Holmes, and H. Apsimon

COMPUTATION AND MAPPING OF THE DISPERSION AND HERBAGE UPTAKE OF GASEOUS EFFLUENTS FROM INDUSTRIAL PLANTS. *Society of Engineering Science, Pollut. Eng. Sci. Solutions, Proc. Int. Meet. Soc. Eng. Sci.*, 1st, Tel Aviv, Israel, 1972, p. 548-563, 1973. 16 refs. (June 12-17.) Computer routines which enable rapid computation of air contamination downwind from complex release patterns are described. Routines exist whereby isopleths of ground level air concentration averaged over varying time intervals are automatically plotted for rapid appraisal. In addition, integrated air concentrations can be predicted for specified locations, such as air sampling stations, and these results printed out. Further routines compute the levels of contamination within plant and animal species as a function of time during the exposure. As an example of the application of some of the routines, the release of fluorides from aluminum smelting is discussed. The significance of aluminum smelting in the United Kingdom and emissions from the notional smelter are described. The relative significance of air and pasture contamination with fluorides, <xref image="2000WVH8.TIF|V3|2006:09:28:01:31:14.00|120020|0"> image: </xref>

E. ATMOSPHERIC INTERACTION

261

human and animal toxicity, and plant toxicity are reviewed. Calculation of dispersion, computer mapping of concentrations of fluoride at ground level, and calculation of time-dependent herbage levels are discussed for the example of fluorides released from an aluminum notional smelter. The numerical results illustrate the application of this ecosystem pollution program to the initial analytical stages of this type of environmental study. The program provides rapid and readily comprehensible predictions of air and herbage contamination. By virtue of the low cost of operation, computations can be made to relate herbage monitoring and district air sampling results to specific variables such as significant changes in weather, seasonal changes in herbage growth rates, and changes in the release pattern of fluorides from the plant.

Israel, G. W.

DEPOSITION VELOCITY OF GASEOUS FLUORIDES ON ALFALFA. Atmos. Environ., 8(12): 1329-1330, Dec. 1974. 6 refs.

Fumigation of alfalfa and orchard grass with constant hydrogen fluoride levels for more than 16 days yielded a deposition velocity of 16 mm/sec as compared with an estimated deposition velocity for field crops of alfalfa and orchard grass of 31 + or - 16 mm/sec. The estimated average fluoride accumulation coefficient for field crops was about twice that derived from the fumigation studies, though the reason for the discrepancy was not established. The deposition velocity values for alfalfa were about 3-6 times higher than published deposition velocity values for sulfur dioxide on grass. This difference may be partially due to the relatively large leaf surface area of alfalfa per unit area of ground and the vertical spacing of the leaves. Assuming that atmospheric fluorides are admitted by the plant mainly through the leaves and that the effective fluoride absorption area is 5 sq in of leaf surface per sq m of ground surface, the alfalfa deposition velocity is similar to SO₂ deposition velocities reported for grassland

I.andsberg, H H.

THK DEFINITION AND DETERMINATION OF CLIMATIC CHANGES, FLUCTUATIONS AND OUTLOOKS. Preprint, Maryland Univ., College Park, 19p., 1975. 36 refs. (Presented at the Atmospheric Quality and Climatic Change Symposium. Chapel Hill, N. C., March 21, 1975.)

The nature and nomenclature of various types of climatic change are discussed, with particular reference to anthropogenic climatic alterations. Urbanization with its associated heat island effect is responsible for alterations in temperature, humidity, and rainfall on a local scale, while industrialization produces regional changes in climate. An increase in carbon dioxide production on a global scale as well as an attendant increase in temperature result from the burning of fossil fuels as well as from urbanization and industrialization. Global effects involving ozone reduction and increased ultraviolet radiation result from aircraft flying in the stratosphere and from the release of man-made chemical compounds containing chlorine and fluorine. The possibility exists that certain elements of air pollution, if continued beyond a presently as yet unknown critical limit, might induce irreversible processes such as polar ice melting or ice extension.

Schneider, T , N. D. van Egmond, H. J. van de Wiel, A. C. Posthumus, M. van Leeuwen, P. Steenbergen, J. van Straaten AIR POLLUTION CASE STUDY OF THE SOUTH HOLLAND REGION - FIRST PHASE (1973). National Institute of Public Health, Bilthoven (Holland), 105p., 1973 (?). Air quality and meteorological parameters were measured in South Holland during 1973, with special emphasis on the components of photochemical smog. At Vlaardigen, the highest

concentrations of most pollutants, especially acetylene, were found during the morning on days when atmospheric conditions were unstable. Winds from the north caused higher concentrations of the acetylene from traffic emissions. Winds from the southwest were accompanied by maximal concentrations of nitrogen dioxide, isobutane, butane, and propane, indicating that these pollutants originate at some distance from the measuring point. Higher concentrations of nitric oxide and ethene were found at very low wind velocities. The NO:NO₂ ratio diminished with higher wind velocity for winds from all directions except the south-southeast. For higher wind velocities from this direction, a relatively high NO concentration was found, which might have come from a nitrogen oxides source at some distance from the station. Highest NO concentrations were found near highways. Data from mobile measurement units indicate that ground level concentrations of NO and NO₂ in Vlaardingen originated from the Rijnmond industrial region 50% of the time; these pollutants can be traced to that source only 25-30% of the time in the Rotterdam-Schiedam region. Measured sulfuric acid concentrations were low. The small stinging nettle proves more sensitive than lettuce or grass to the effects of peroxyacetyl nitrate in the Westland region, and is a suitable plant indicator; tobacco was especially sensitive to ozone; and gladiolus and freesia were damage-sensitive to hydrogen fluoride. Hourly pollution measurements arranged in score diagrams facilitated the analysis of the interaction of pollutants with meteorological variables.

STRATOSPHERIC CONCENTRATIONS OF SF₆ AND CCL₃F.

In: Health and Safety Laboratory Environmental Quarterly. Energy Research and Development Administration, New York, Health and Safety Lab., p. I-97-I-123, July J975. 18 refs. NTIS: HASL-294

Because of the chemical inertness of freon-11 and sulfur hexafluoride in the environment, their concentrations in the stratosphere were measured as part of a study of global atmospheric diffusion. Compressed air samples were recovered from the stratosphere by aircraft. The SF₆ and freon were concentrated and determined by gas chromatography. The stratospheric concentrations of freon and SF₆ are given. The two trace gases behave similarly in the stratosphere. Although the Northern Hemisphere is the primary source of these gases, the similarity of their hemispheric distributions suggests a rapid interhemispheric exchange. The SF₆ results are important because they demonstrate that halocarbons other than the freons have penetrated the stratosphere. The trace gas concentrations decrease with increasing altitude above the tropopause. Freon and SF₆ concentrations in the stratosphere have spatial and seasonal distributions which are similar to lead 210 distributions from radon emanation at the earth's surface. An atmospheric box model is developed which indicates from the observed inventories that the photolytic half life of a freon 11 molecule in the stratosphere is 2 to 4 yr and the total atmospheric half life is 12 to 24 yr. Brown, R. M., R. N. Dietz, and E. A. Cote
THE USE OF SULFUR HEXAFLUORIDE IN ATMOSPHERIC
TRANSPORT AND DIFFUSION STUDIES. J. Geophys. Res.,
80(24):3393-3398, Aug. 20, 1975. 9 refs.

The use of sulfur hexafluoride as a tracer in atmospheric transport and diffusion studies is discussed. Airborne and ground level concentration measurements using specially designed chromatographs were made. They illustrate the potential use of the method in tracking plumes from short or tall stacks and its ability to isolate and detect concentrations from a particular site. Meteorological input and other pertinent input information are used in a computer programmed model to compare measured versus calculated diffusion parameters. A measure of the standard deviation of the wind direction at plume height produces the best fit to the measured concentrations. The model is being developed to predict diffusion patterns and the concentrations from single and multiple source stacks. (Author conclusions modified)

THE TERRIGENOUS DUST CONTRIBUTION TO FLUORIDE
AND IODIDE IN ATMOSPHERIC PRECIPITATION. J. Rech.
Atmospheriques, 8(3-4): 689-697, July-Dec. 1974. 31 refs.
(Presented at the International Symposium on the Chemistry of
Sea/Air Particulate Exchange Processes, Nice, France, Oct. 4-10,
1973.)

The terrigenous dust contribution to levels of fluoride and iodide in atmospheric precipitation is discussed. Fluoride and iodide have higher ratios to chloride in atmospheric precipitation than in seawater. While experimental evidence exists to propose a marine origin for the excess iodide, recent analyses indicate that fluoride is depleted in marine aerosols. This suggests a non-marine origin for the excess fluoride and airborne terrigenous dust is proposed as an alternative source. It is calculated that terrigenous dust, transported through the troposphere, does not account for more than 2% of the iodide and 4% of the fluoride in atmospheric precipitation. Unless injections from anthropogenic and volcanic activities are underestimated or other major sources exist, the oceans are the primary source of atmospheric iodide and fluoride and large positive enrichment occurs in the sea to air transport of these elements. Duuren, H. van, G. D. Knjt, and A. J Elshout
SULFUR HEXAFLUORIDE AS A TRACER FOR THE STUDY
OF THE DISPERSION OF AIR POLLUTANTS EMITTED
FROM PUNCTIFORM SOURCES. (Zwavelhexafluoride als
tracer voor de verspreiding van luchverontreinigende componenten vanuit puntbronnen). Text in Dutch. Elektrotechniek,
53(3): 135-143, March 1975. 20 refs.

The use of sulfur hexafluoride as a tracer in the study of the dispersion and conversion of air pollutants from point sources was investigated. The accuracy, defined as the variation coefficient $v \leq 100\%$, of the determination of SF₆ concentrations in the atmosphere is 20%. This is better than the accuracy that is obtained when the concentrations are calculated as in the case of dispersion from high sources. The degree of conversion of components such as sulfur dioxide, nitric oxide, and nitrogen dioxide in stack plumes is investigated.

Galbally, Ian E.
GAS TRANSFER NEAR THE EARTH'S SURFACE. Advan.
Geophys., vol. 188:329-339, 1974. 20 refs.
A mathematical method for relating gas uptake and adsorption at the earth's surface to the gas concentration in the air above the surface and the wind speed is derived. The resistance to gas transfer of the viscous layer at the surface-air interface and gas transfer in the turbulent constant flux layer are also

examined. Gas uptake parameters are tabulated for hydrogen fluoride, iodine, chlorine, sulfur dioxide, nitrogen dioxide, ozone, nitric oxide, and carbon monoxide. Guidelines for estimating gas uptake at land surfaces are also presented.

THE ELIMINATION OF HF FROM 'HOT' FLUORINATED ETHANES. AN ESTIMATION OF THE ACTIVATION ENERGIES AND RATE PARAMETERS. J. Phys. Chem. 69, (11) 3898-3905, Nov. 1965

The classical Rice-Ramsperger-Kassel theory of unimolecular reactions is shown to give a quantitative description of the decomposition of a 'hot' molecule of CH₂FCH₂F. The analysis also makes possible an estimate of the activation energy for the elimination of HF from this molecule within narrow limits: CH₂FCH₂F yields CH₂ equal CFH plus HF; Fact equal 62 plus or minus 3 kcal./mole; delta E_{298K}. equal 8 kcal./mole. From the theory one predicts the observed reductions in the rate of the elimination reactions for the series of 'hot' molecules C₂H₆-xF_x as x is increased. A similar analysis gives a theoretical explanation of the observed pressure dependence of the rates of stabilization of the 'hot' molecules (CH₂Cl. CH₂Cl), (CH₂Cl.CHC₁₂), and (CHC₁₂.CHC₁₂). A quantum modification of the classical Rice-Ramsperger-Kassel theory was found necessary when the magnitude of the unfixed internal energy approaches the size of a quantum of vibrational energy. This approximation of the classical theory predicted the correct rate of elimination of a Cl atom from the hot radical (CHC₁₂.CHC₁₂) which at the transition state had only 2 kcal./mole of unfixed energy. In these calculations the carbon-carbon bond energy in ethane was assumed to be invariant upon the replacement of hydrogen by halogen atoms (Author abstract)

PHOTOLYTIC PROCESSES IN PERFLUOROCYCLOBUTANONE VAPOR. J. PHYS. CHEM. 70, (4) 1235-43, APR. 1966. CFSTI, DDC AD 635437

The photolysis of perfluorocyclobutanone in the vapor phase at 3130, 3340, 3660, and 4047 Å has been investigated. Fluorescence and decomposition yields have been determined at the four wavelengths and the effects of pressure and temperature upon them studied. Two modes of decomposition occur at the shortest wavelengths and at high temperatures, one producing carbon monoxide and perfluorocyclopropane, the other producing tetrafluoroethylene. A mechanism is proposed which explains the results, and rate constants for reactions are determined. Results indicate that about 7 kcal/mole excess vibrational energy can be removed from the excited ketone by each collision with an unexcited ketone molecule (Author abstract)

PHOTOOXIDATION OF PERFLUOROETHYL IODIDE AND PERFLUORO-N-PROPYL IODIDE. Aerospace Corp., El Segundo, Calif., Lab. Operations. Apr. 1966. 11 pp. DDC: AD 483914

Perfluoroethyl iodide and perfluoro-n-propyl iodide were photolyzed in the presence of oxygen. In both cases, the major product is CF₂O. In the C₂F₅I system, it is produced with a quantum yield of about 2.0. CF₃CFO is also produced, but is 100 times less important. With HI present, the oxidation is drastically modified, and the RO₂ intermediate must live at least 10 to the 7th sec. (Author abstract)

ESTIMATED ACTIVATION ENERGIES FOR THE FOUR-CENTER ADDITION REACTION OF H₂, HX, AND X₂ TO ACETYLENES. J. Phys. Chem. 70, (10) 3336-8, Oct. 1966

The application of an electrostatic model to predict the activation energy of the four-center addition reactions of acetylene

is discussed. The transition state is considered an intimate semi-ion pair with an equivalent charge separation of plus or minus formal charge. The energy of activation can be equated to the electrostatic energy of interaction of point dipoles. Values obtained for the reacting substances (acetylene, methyl acetylenes, hydrogen halides, hydrogen, fluorine, chlorine, bromine, iodine) are tabulated. The activation energy for the molecular addition to acetylenes is about 1.5 kcal/mole smaller than that for the corresponding olefin.

INFRARED SPECTRA OF ISOTOPIC NITRYL HALIDES.
Spectrochim. Acta 23A, 237-48, 1967.
The infrared spectra of nitrogen-14 and 15 isotopic species of nitryl chloride and fluoride were examined in the vapor and solid states. Assignments of two fundamentals in both halides were changed from those proposed by earlier investigators. A band at 1/460 cm reported earlier for the fluoride was shown to originate from an impurity. Thermodynamic functions and new sets of force constants from both the valence and the Drey-Bradley force fields were calculated. (Author abstract)

METHOD OF DISPENSING VOLATILE FLUORIDES IN
PORTABLE GREENHOUSES. Agr. Food Chem., 5(11):852-854,
Nov. 1957. (Presented at American Chemical Society, National
Meeting, 130th, Division of Analytical Chemistry, Atlantic City,
N. J., Sept. 1956.)

Equipment and procedures are described for producing nearly
constant concentrations of fluosilicic or hydrofluoric acid in
fumigating greenhouses ranging from less than one to several
hundred parts per billion. The method makes use of diluted
solutions (0.01 to 4%) of these acids which are atomized by an
air pressure of 10 to 20 pounds per square inch through a
platinum nozzle. The atomized droplets are then passed
through an electrically heated tube (150 C) where they are
changed to the gaseous state before delivery to the air stream
entering the fumigating greenhouses. Given concentrations of
volatile fluorides can be maintained nearly constant in the
greenhouses for as long as 5 weeks. The functioning of the ap-
paratus is not affected by changes in temperature, and 3 liters
of solution are sufficient for 12 days of uninterrupted fumiga-
tion. (Author abstract)

Derner, Harold A.
SEMIAUTOMATED DETERMINATION OF FLUORIDE IN
URINE. Am. Ind. Hyg. Assoc. J., 28(4):357-362, July-Aug. 1967.
10 refs.

A procedure was developed, using the Technicon Au-
toAnalyzer, for the determination of fluoride in urine, which
does not require ashing or fusion of the sample. The only in-
terference encountered was chloride ion, which was easily
removed by the addition of silver perchlorate to the acidified
sample. Samples ranging down to 0.01 ppm F can be accurate-
ly analyzed at a rate of 10 to 15 per hour. Twenty milliliters of
urine are made slightly acidic with perchloric acid in a 25-ml
volumetric flask, chloride is precipitated by the addition of ex-
cess silver perchlorate solution, a portion of the sample is fil-
tered, and the filtrate is analyzed by the AutoAnalyzer. The
accuracy and precision of the procedure are reported, and the
results obtained on the semiautomated method are compared
with results obtained by using the manual Willard- Winter
distillation (Author's summary)

Sanderson, R. T.
MULTIPLE AND SINGLE BOND ENERGIES IN INORGANIC
MOLECULES. J. Inorg. Nucl. Chem., 30(2):375-393, Feb. 1968.
7 refs.

The new method of calculating bond energies recently re-
ported (R. T. Sanderson, J. Inorg. Nucl. Chem., vol. 28:1553,
1966) has now been extended to include multiple bonds. For
carbon-carbon double and triple bonds the energy is 1.50 and
1.75 times the single bond energy when corrected for the mul-
tiple bond length. These multiplicity factors are used to calcu-
late the single bond energies for nitrogen and oxygen that
would correspond to the experimental bond lengths and dis-
sociation energies of N₂ and O₂. Three different single bond
energy contributions each for nitrogen and oxygen are thus
determined, and estimates are made for similar values for
fluorine, phosphorus, sulfur, chlorine, bromine, and iodine.
The possible significance of such values is discussed in terms
of bond energy calculations for 141 gaseous molecules, based
on a consideration of the effect of lone pair electrons in bond
weakening. Calculated bond energies for CO, CO₂, NO, NO₂,
and other compounds are in excellent agreement with the ex-
perimental values. (Author's abstract modified)

SOLUBILITY OF HYDROGEN FLUORIDE IN MOLTEN

FLUORIDES. I. IN MIXTURES OF NaF-ZrF₄. J. Phys.

Chem., 63(12):1999-2002, Dec. 1959. 25 refs.

Because of their value in nuclear fuel element reprocessing and their use as fuel for experimental nuclear reactors, mixtures of NaF and ZrF₄ were chosen to investigate the solubilities of hydrogen fluoride at pressures from 0.5 to 3 atm and from 550 to 800 deg. The solubility of HF in all mixtures studied follows Henry's law and, in contrast to the behavior of noble gases in similar solvents, decreases with increasing temperature. As the mole percent of NaF in the solvent is increased from 45 to 80.5, solubility increases approximately tenfold. The enthalpy of solution, like the solubility, is dependent on the solvent composition. The values of entropies of solution are all negative and change only 1 e. u. over the range of solvent compositions investigated. The observed strong dependence of HF solubility on solvent composition may be related to the relatively high stability of NaF-HF compounds.

INFLUENCE OF THE ASHING METHOD ON THE RESULTS

OF FLUORINE DETERMINATIONS. Staub (English transla-

tion from German of: Staub, Reinhaltung Luft), 28(12):25-27,

Dec. 1968. 6 refs.

Errors in fluorine determinations of biological samples occur when ashing of samples is carried out in a muffle furnace. The analytic results are distorted because the furnace always contains relative high quantities of fluorine. At 450 C up to 40% F is simulated; at 550 C up to 10% F is simulated. For the investigation of samples which only contain a small amount of fluorine and to which CaO must be added before incineration, it is absolutely necessary to use a gas-tight muffle furnace lined with platinum plates. A furnace with nickel plate lining may be used in most cases for other vegetable samples and for hard tissues.

THE SOLUBILITIES OF HF AND DF IN MOLTEN

FLUORIDES. Oak Ridge National Laboratory, Oak Ridge,

Tenn., CONF-660907-1, Rept. ORNL-P-2202, 17p., June 27,

1966. 7 refs.

The solubilities of HF and DF in molten LiF-BeF₂ (66-34 mole % LiF) were determined over the temperature range 500-700 C and at solute gas pressures between 1 and 2 atm. Using previously established experimental methods, the solubilities of both gases were found to obey Henry's Law. The Henry's Law constants, $K(H)$ (0.001 moles HF/mole melt-atm) for HF and DF respectively at 500, 600 and 700 C were approximately 3.37, 2.96, 2.16, 1.83, 1.51, and 1.25. The values given were obtained by a linear least squares fit of the experimental data as in $K(H)$ vs. $1/T$ and the uncertainties are at the 95% confidence interval. The heat of solution, obtained from the least squares evaluation were approximately 5.98 and -6.43 kcal/mole for HF and DF respectively. The comparison of heat of solution for HF in this melt composition with those obtained previously in melts ranging from 54 to 89 mole % LiF in BeF₂ reveals linear dependence of heat of solution on the mole fraction of LiF above and below 67% with a maximum at

<xref image="2000WVHC.TIF|V3|2006:09:28:01:31:24.00|112406|0"> image: </xref>

67% LiF. Interpretation of the isotope effect is made by comparison of the difference in the entropies of solution between DF and HF with the difference in the calculated values of the entropies of the two gases at 600 C. (Author abstract modified) 15927

ACOUSTIC COAGULATION OF MIST CONTAINING

FLUORINE COMPOUNDS. J. Appl. Chem. USSR (English

translation from Russian oi: Zh. Prikl. Khimi.), 41(111:2494-2499, Dec. 1968. 4 refs.

The efficiency of acoustic coagulation of aerosols containing fluorine compounds has been previously studied by chemical determinations of fluoride contents before and after coagulation. In the present study, efficiency of sonic treatment was assessed by ultramicroscopic determinations of particle numbers per unit aerosol volume (number concentration) and both ultramicroscopic and photomicrographic determinations of particle size distribution. Determinations of particle number concentrations was made before and after acoustic coagulation of waste gas aerosols from a superphosphate granulation plant. The results show that the number of particles decreases by a factor of 100-1000 as the result of acoustic treatment for 3-5 sec. The results of determinations of particle size distribution before and after acoustic treatment are presented in the form of histograms and distribution curves. The form of the histograms suggest a Gamma-distribution. With the industrial mist, the number of particles deposited per unit area decreased by a factor of 125 after acoustic treatment for 1.5 sec, while the average diameter increased from 2.5 to 18.7 micron. Before treatment, 88% of the particles were in the 1-4 micron size range. Acoustic treatment shifts the distribution center to the right and increases the variance. Similar results were obtained from photomicrographs of mists deposited on greased glasses.

DISSOCIATION OF GASEOUS COMPOUNDS BY ELECTRICALLY

INDUCED GLOWING. (Zerlegung gasfoermiger Verbindungen durch elektrisches Gluehen). Text in German. Ann.

Chem. Pharm., 113(2):129-150, 1860. 4 refs.

Gases and vapors of liquids with low boiling points were exposed to powerful sparking as produced by the Ruhmkoff induction coil, to glowing platinum and iron wires, and to the high temperature of the flame arc, and the dissociation was observed. The induction coil is best suited for dissociation of ammonia; all the other methods take too long. Dissociation of C₂H₅N begins immediately, but it is never complete. Dissociation of C₆H₉N and of C₄H₇N is slow and incomplete. Iron wires dissociated C₂N completely but slowly, the flame arc is much faster. The induction coil is least suitable. Nitric oxide is dissociated rapidly by a glowing iron spiral and by the flame arc, and slowly by the induction coil. The dissociation is not complete. Similar results are obtained with NO₂. None of the methods work with dry CO. Reduction of CO₂ is slow with both the flame arc and the induction coil. The dissociation of CS₂, C₂H₄, C₄H₄, SO₂, HS, PH₃, C₁H and SiF₁₂ was observed in like manner, and the efficiency of each method was stated.

THE KINETICS OF THERMAL REACTION BETWEEN

F₂SO₃ AND NITROGEN DIOXIDE. (Die Kinetik der thermischen Reaktion zwischen Fluorfluorsulfonat (F₂SO₃) und Stickstoffdioxid). Text in German. Z Physik. Chem. Neue Folge (Frankfurt), 62(1-4): 159-167, 1968. 4 refs. AD 686588

The reverse of the kinetics of thermal reaction between fluorosulfonate and 2 nitrogen dioxide yields nitrogen tetroxide; was studied between -10 C and +10 C in an aluminum vessel. The reaction is homogeneous and is influenced by

neither the total pressure nor by the added oxygen. FSO₃ NO₂ and NO₂F develop as sole products. The former occurs in the form of a white precipitation. The reaction speed is proportional to the concentrations of NO₂ and F₂SO₃. A bimolecular reaction between NO₂ and F₂SO₃ determines the reaction speed which follows the equations N₂O₄ yields 2NO₂ and the reverse: NO₂ + F₂SO₃ yields FSO₃ + NO₂F, and NO₂ + FSO₃ yields FSO₃ NO₂. The activation energy of the first reaction is 9.970 plus or minus 200 cal; its probability factor is 0.0036.

MOLECULAR ASSOCIATION IN HYDROGEN FLUORIDE

VAPOR. J. Chem. Phys., vol. 15:337, May 1947. 8 refs.

Ring structure in molecular association in hydrogen fluoride vapor was studied by measuring the dielectric constant of the vapor and calculating its polarization. Two curves were run for polarization as a function of pressure, one at 26.0 and the other at 38 C, temperatures at which association has been established. For pressures above 120 mm at 26.0 and 160 mm at 38.0, the polarization rose rapidly with increasing pressure. The large increase in polarization brought about by molecular association shows that ring structures, which would decrease the polarization, cannot predominate; the presence of more or less extended chains, which increase polarization due to their large dipole moments, is clearly indicated.

THERMOELECTRIC POWER OF SINGLE CRYSTALS OF

ICE CONTAINING HF OR HN₃. Phil. Mag., 16(141):495-504,

Sept. 1967. 12 refs.

The homogeneous thermoelectric power of single-crystalline ice containing hydrogen fluoride or ammonia was measured over a wide range of concentrations. The experimental values were of the order of a few millivolts per degree centigrade and varied in sign and magnitude with the type and concentration of impurity in agreement with the theory developed by Jaccard. A quantitative comparison with the theory enabled the calculation of several physical parameters relating to the electrical properties of ice. (Author abstract modified)

THE SOLUBILITY OF CERTAIN GASEOUS FLUORINE

COMPOUNDS IN WATER. J. Chem. Soc., no. 8:1793-1796,

1968. 22 refs. CFSTI, DDC: AD 678233

An apparatus designed for especially low solubilities was used to determine the solubilities of tetrafluoromethane, sulfur hexafluoride, and nitrogen trifluoride in water from 0 to 50 deg, while the changes in heat content and entropy were estimated

<xref image="2000WVHD.TIF|V3|2006:09:28:01:31:28.00|109824|0"> image: </xref>

from the temperature-dependence of the solubilities. The apparatus, sensitive to gas solubilities on the order of 10 to the minus 6th power mole fraction, differs from its predecessors in that it allows the bulk of gas measurement to be performed under 'dry' conditions, or in other words unsaturated with solvent vapor. An additional arm of the solubility vessel acts as a manometer, allowing the pressure to fall as the gas is dissolved, permitting equilibrium to be reached more rapidly. On the basis of observations and a review of the literature, it was concluded that the low solubilities of fluorinated gases are not due to specific anomalous factors that cause large negative entropies of solution, but the entropies appear to be related to the relatively larger size of the fluoride molecules in comparison with the inert gases, which are most frequently used as comparison standards.

Mueller, Robert F.
ENERGETICS OF HCL AND HF IN VOLCANIC EMANATIONS. Preprint, National Aeronautics and Space Administration, Greenbelt, Md., Goddard Space Flight Center, 32p., June 1969. 37 refs. (Paper NASA-TM-X-63608.) CFSTI: N69-32034
Thermochemical data were used to calculate the fugacities of HCl and HF in equilibrium with halogen salts and crystalline silicates. The calculated fugacities were compared with the abundances of HCl and HF in fumarolic gases. Good agreement between the calculated values and the results of hydrothermal experiments were obtained. In the case of fumaroles, the abundances of HCl and HF molecules can be explained by assuming some undersaturation of the systems in such crystalline components as NaCl, CaSiO₃, and Al₂SiO₅. Also, the fumarolic gases gave evidence that high temperature abundances of HCl and HF are quenched to much lower temperatures recorded at the fumarolic vents. Numerous determinations of Cl and F in igneous and crystalline rocks showed that on the whole, F is more abundant than Cl. Igneous rocks and minerals are quite distinct from volcanic emanations in terms of the F/Cl ratios. The relations between HCl and HF and the structure of the silicate melt were also discussed. Although heterogeneous equilibria may be established at high temperatures between the the halogen gases and crystalline phases of the wall rock, the ultimate source of most of the halogens is the silicate melt. Although the structure of such melts is not well known, it is reasonable that both the decrease in liquidus temperatures and viscosity are attributable to reactions in which the Si-O-Si bndges are destroyed by the reaction with water. Grahame, David C. and Barbara A. Soderberg
IONIC COMPONENTS OF CHARGE IN THE ELECTRICAL DOUBLE LAYER. J. Chem. Phys., 22(3):449-460, March, 1954. 17 refs.
The rate of change with concentration of the capacity of the electrical double layer on mercury has been measured. From this the excess of cations in the double layer and the excess of anions have been calculated. The latter has been subdivided into the excess of anions in the diffuse double layer, and the excess of anions in the inner part of the double layer. From these data it has also been possible to evaluate the potential of the outer Helmholtz plane. It is found that fluoride ion remains unadsorbed on mercury at all potentials investigated, including potentials anodic to the e.c.max. Other anions are strongly adsorbed (chemisorbed) when the mercury is positively charged, and sometimes even when it is negatively charged. The 'hump' in the capacity curves of salts of such anions as chloride, bromide, acetate, and nitrate, are found to be present in curves of the capacity attributable to anions alone. No chemisorption of monatomic cations could be detected. The kinetic theory of the diffuse double layer with constant dielectric constant is found to fit the experimental results within the

expected accuracy. This fit extends to electrolytes of the 1:2 and 2:1 types also. A new method of evaluating salt adsorption at the potential of the electrocapillary maximum (e.c.max.) is described and results are given. Likewise a new method of determining the capacity attributable to cations at the e.c.max. is described and used. (Author abstract)

HEAT CAPACITY OF GASES AT ELEVATED TEMPERATURES WITH ACCOUNT OF THEIR NONIDEALITY AND THERMAL DISSOCIATION (H₂O, CO₂, F₂, AIR, LITHIUM AND FUEL COMBUSTION PRODUCTS). *Teplo- Masopeneros*, vol. 7, 1968. 6 refs. Translated from Russian. Foreign Technology Div., Wright-Patterson AFB, Ohio, Translation Div., p. 152-157, Aug. 20, 1969.

A method of calculating the heat capacities C_p and C_v of chemically reacting gases is considered which takes into account their nonideality. Deviation from nonideality, when calculations are made of properties of pure components, equilibrium compositions, and compositions of mixtures, is allowed for by the second and third virial coefficients, which ensures adequate precision of results for the entire range of parameters investigated. Calculations of equilibrium compositions are carried out by solving a system of nonlinear algebraic equations, a specific form of which is determined in the individual case by the equations of the corresponding chemical reactions, equations of material valance of atoms, and the condition $\sum \xi_i = 1$. Since in the general form, solution of this system does not appear possible, equilibrium compositions were determined by the iterative method on an electronic digital computer at specified values of T and p . This method is applicable to the calculation of detailed tables of isobaric and isochoric heat capacities for water vapor, carbon dioxide, fluorine, air, lithium, and the combustion products of 13 organic fuels throughout the entire range of temperatures and pressures of practical importance (up to 6000 K and 0.1-1000 bar). An example is given for the isobars of the specific heat capacity C_p for one of the most complex systems of the groups under study (combustion products of a stoichiometric mixture of Saratov gas and air).

Warburg, Otto and Walter Christian
CHEMICAL MECHANISM OF THE FLUORIDE-INHIBITION OF FERMENTATION. (*Chemischer Mechanismus der Fluorid-Hemmung der Gärung*). *Kurze Originalmitteilungen*, vol. 39:194, 1941. Translated from German. Belov and Associates, Denver, Colo, 2p.

The chemical mechanism of inhibition of the ferment enolase by fluoride was investigated. Fluoride inhibition of three compounds was being determined: fluoride, magnesium salt, and phosphate. When the magnesium concentration was constant and the fluoride and phosphate varied, the equation phosphate times fluoride times remainder of effect/inhibition of effect equal constant was found. When the phosphate concentration was constant and the fluoride and magnesium salt varied, the equation magnesium salt times fluoride times remainder of effect/inhibition of effect equal constant was found. Since it is

<xref image="2000WVHE.TIF|V3|2006:09:28:01:31:32.00|124352|0"> image: </xref>

difficult to determine such a small phosphate concentration, the equation was not tested for large fluoride concentrations. However, both equations were tested and found to be valid for fluoride concentrations of 1/20,000 to 1/100. It was concluded that the effective compound for fluoride inhibition is a complex magnesium-fluoro-phosphate. This compound combines in proportion to its concentration with the ferment protein in a dissociating manner. The specific reversible inhibition is believed to be based on the displacement of the effective magnesium salt from the protein by the complex.

TERMINAL PROGRESS REPORT ON PUBLIC HEALTH SERVICE RESEARCH GRANT AP00349, 1/1/64 TO 12/31/68. Harvard Univ., Cambridge, Mass., 3p., May 15, 1969. 3 refs. Research for the period 1/1/64 to 12/31/68, financed by Public Health Service Grant AP00349, is summarized. Some of the research is described in papers published by scientific journals. Some unpublished work described in a Ph.D. thesis is presented. The photolysis of 2,2,2-trifluorodiazethane was carried out over a variety of conditions using standard photochemical techniques. Runs were also made with mixtures of carbon monoxide, nitrogen, and octafluorocyclobutane, and the reaction products were studied. Reaction mechanisms were postulated to explain butene/ethylene curves. Data on the reaction of methylene (generated photochemically from ketone) with iso-butane is discussed.

Posner, A. S. and E. D. Eanes

FLUORIDE IN BONE AND TEETH. Norelco Rep., 10(2):71-74, 80, April-June 1963. 27 refs.

Experiments are reported to investigate the inverse proportionality of fluoride concentration in human bones with bone citrate content and to determine whether fluoride in some way alters the specific surface of the bone crystal surfaces on which citrate is found. Post-mortem bone samples were obtained from 20 long-time residents of different areas with water supplies of 0.1-4.0 ppm fluoride content. In X-ray diffraction studies of the ashed samples, the degree of resolution of the four principal X-ray reflections of the bone apatite pattern was used as a measure of 'crystallinity' of each sample, when matched with one of a series of templates constructed to represent the apatite X-ray pattern with different broadening functions. An infrared study was also conducted on samples of human and rat dental enamel to investigate the possible existence of a calcium-deficient apatite as the major phase in hard tissue. It was found that, in general, the crystallinity of the bone apatite increases as the fluoride content of the bone ash increases. The data indicate that fluoride stabilizes bone (1) by increasing the crystal size and/or decreasing the crystal strain, and (2) by changing the stoichiometry to that of a more stable form of apatite. An effect of fluoride on the diminution of the crystal surface was not conclusively demonstrated, and both the role of citrate in bone and the mechanism which causes ingested fluoride to alter the crystal structure of bone apatite remain to be elucidated.

THE EFFECT OF SODIUM FLUORIDE AND OF MONOIODACETIC ACID ON THE ANAEROBIC AND AEROBIC DECOMPOSITION OF SOME SUBSTRATES BY PROPIONIBACTERIUM PENTOSACEUM. (Influence du

fluorure de sodium et de l'acide monoiodacetique sur les degradations anaerobique et aerobie de quelques substrats par Propionibacterium pentosaceum). Text in French. Enzymologia, 7(5-6):353-361, 1939. 21 refs.

The effect of different concentrations of sodium fluoride and

monoiodacetic acid on the anaerobic and aerobic metabolism of glucose, lactic, and pyruvic acid by *Propionibacterium pentosaceum* in a non-proliferating state was studied. At a concentration of 0.02 M, sodium fluoride completely inhibits the anaerobic decomposition of glucose and lactic acid but has only a weak effect on the anaerobic decomposition of pyruvic acid. At the same concentration the fluoride has practically no effect on the aerobic metabolism of the three substances other than to raise to one the respiratory quotient of glucose which in a phosphate medium is somewhat lower (0.85). Moniodacetic acid at a 0.0004 M concentration was found to completely inhibit glucose fermentation while its effect on the oxidation of the same substrate was relatively weak. The effect on the aerobic decomposition of lactic acid was practically nil even at a lactic acid concentration of 0.01 M.

THE THERMAL REACTION BETWEEN SF₅OF AND NO₂. J.

Inorg. Nucl. Chem., 33(8):2680-2682, Aug. 1971. 3 refs.

The reaction between SF₅OF and nitrogen dioxide was studied in nickel and aluminum vessels which were conditioned to fluorine and its compounds. In the nickel vessel, the reaction took place readily at room temperature, but in the aluminum vessel, the temperature had to be raised to about 80 C. The reaction was heterogeneous and was completed without change in the number of moles of gas. The products contained the expected quantity of SOF₄ and nitrosyl hypofluorite in place of nitryl fluoride. The ONOF had characteristic bands in the infrared at 1713, 1302, and 885/cm and could be isomerized to FNO₂.

NEW DIRECTIONS IN ION-SELECTIVE ELECTRODES.

Chem. Eng. News, 48(27):40-41, June 29, 1970.

Ion-selective membrane electrodes measure the activities of unassociated ions in solution with a sensitivity often less than one part/billion. The selectivity of the electrodes is such that they can be used in electrolyte solutions containing other species either present naturally or added to control the ionic strength and pH of the solution. There are now more than 20 electrodes available for more than 20 ions, including alkali and alkaline earth ions, heavy metal ions, and a wide variety of anions such as fluoride, nitrate, sulfide, and perchlorate. In recent work, ion-selective electrodes were used to measure formation constant in adenosine triphosphate complexes, complex formation of calcium, magnesium, and beryllium ions with biologically important ligands, and lead in urine samples.

ALUMINIUM PRODUCTION BY ELECTROLYSIS: A NOTE

ON THE MECHANISM OF THE REACTION. J. Inst. Metals,

17(1): 141-144, 1917. 3 refs. (Presented at the Institute of Metals, Annual Meeting, London, England, March 21, 1917.)

The conventional formula for the production of aluminum by electrolysis of a fused mixture of cryolite and alumina is

$A12O3 + 3C \text{ equals } 3CO + Al2$. Experiments in an electric furnace

indicate that this formula, which assumes a carbon consump-

<xref image="2000WVHF.TIF|V3|2006:09:28:01:31:34.00|116431|0"> image: </xref>

tion very near to theoretical, is not correct. A carbon consumption well below the theoretical was attained and the fact that carbon monoxide is not necessarily the sole gaseous product of the reaction was demonstrated. Whether oxygen, carbon dioxide, or carbon monoxide result from the reaction depends on such factors as temperature, current density, physical properties of the anode, and the rapidity with which the gases are removed from contact with the anode.

Badoz-Lambling, J., M. Herlem, A. Thiebault, and G. Adhami
THE REACTIONS OF SO₃ AND SBF₅ WITH FLUOROSULFURIC ACID. Anal. Letters, 5(5):305-307, 1972. 5 refs.
Fluorosulfuric acid is a good donor of sulfur trioxide, and as a result it reacts with antimony pentafluoride to give hydrogen antimony hexafluoride and SO₂. Solutions of SO₃ and SBF₅ in HSO₃F exhibit the same cathodic waves at platinum and platinized platinum electrodes. Electrochemical reductions at a potential corresponding to the plateau of these waves produces S sulfur dioxide and not hydrogen gas. This work confirms previous experimental evidence for the formation of SBF₆⁻ and SB₂F₁₁⁻ ions on the basis of 19F nonmagnetic radiation spectra of SbF₅-HSO₃F solutions. (Author abstract modified)

Shapiro, J. L.
TESTIMONY OF DR. J. L. SHAPIRO. CURRENT POWER GENERATION TECHNOLOGY. In: Problems of Electrical Power Production in the Southwest. Part 1. 92nd Congress (Senate), 1st Session, p. 531-605, 1971. 59 refs. (Hearings before the Committee on Interior and Insular Affairs, May 24, 1971.)
GPO

Current power generation technology is reviewed. Many new schemes have been proposed for central station power generation, including coal gasification or liquefaction, fluidized bed combustion, fusion reactors, geothermal, solar energy, tidal energy, and the use of magnetohydrodynamic generators. Condenser cooling technology, developed and employed within the U. S. for steam-electric generating plants during the past seven decades, includes once-through cooling systems and evaporative cooling tower systems. Cooling technology currently being developed includes once-through cooling systems with condenser by-pass dilution and once-through systems combined with evaporative cooling towers. Pollution control processes for the following pollutants are described: fly ash, sulfur dioxide, nitrogen oxides, and trace elements, especially fluorine and mercury. Cyclone, electrostatic precipitator, and wet scrubber collection systems and their efficiencies are described.

LASER-EXCITED VIBRATIONAL RELAXATION STUDIES OF HYDROGEN FLUORIDE. J. Chem. Phys., 56(5):2474-2475, March 1, 1972. 9 refs.

Room temperature rates of vibrational deactivation of hydrogen fluoride by HF, argon, nitrogen, deuterium, hydrogen, and carbon dioxide are reported. Laser-induced fluorescence experiments were carried out using a transverse electrode HF chemical laser as a pumping source. The fluorescence signals were monitored with goldgermanium and indium-antimony detectors, which, with the associated electronics, had time responses of 0.25 and 1.0 microsecond, respectively. The energy transfer properties of HF are of great importance in HF and HF-CO₂ (transfer) chemical lasers.

McCaldin, Roy O.
CONTROLLED ATMOSPHERES FOR AIR POLLUTION STUDIES. Florida Univ., Gainesville, Coll. of Engineering, Thesis (Ph.D.), Ann Arbor, Mich., Univ. Microfilms, Inc., June 1958, 162p. 79 refs.

Design and operation of a static chamber to contain atmospheric pollutants are described. A specific method of achieving known gas concentrations and the various means by which these concentrations become reduced within the chambers are described. The static chamber affords a simpler device because less instrumentation is required to achieve a test atmosphere, and once the atmosphere is achieved, it affords a uniform and relatively stable atmosphere with which to work. The hypodermic syringe with a needle was used to inject measured quantities of study gas into the chamber. The hypodermic syringe feed method was reasonably accurate for volumetric measurements. The adsorption of gas on the chamber walls was studied for sulfur dioxide, hydrogen sulfide, and hydrogen fluoride. Toxicological, bacteriological, physiological, and odor studies are reported. Calibration methods are mentioned.

Spicer, Chester William, Jr.

KINETIC STUDIES OF SOME REACTIONS OF SO₂, NO, AND NO₂. Pennsylvania State University, Dept. of Chemistry, Thesis (Ph.D.), Ann Arbor, Mich., Univ. Microfilms, Inc., Dec. 1971, 126p. 71 refs.

Reaction schemes, kinetic considerations, and mechanistic hypotheses are presented for the reaction of nitrogen dioxide with tetrafluoroethylene, the photolysis of sulfur dioxide in the presence of C₂F₄, and the reactions of methylperoxy radicals with nitric oxide and nitrogen dioxide. A low value corresponding to the Arrhenius preexponential factor for the acetyl fluoride (O₂NCF₂CO) in the first set of experiments runs contrary to other indications of homogeneity, and no definitive explanation for such a preexponential factor can be offered. The electronic states involved in chemical reaction when SO₂ is irradiated at 3130 Å in the second series of experiments are clearly different from the emitting states. The fact that addition of NO could not completely quench the chemical reaction indicates two such non-emitting states, one a singlet and one a triplet. The crucial feature of the last study is that the methylperoxy radical does not react with NO to produce a methoxy radical and NO₂ nor with NO₂ to produce the CH₃O radical.

TEST CHAMBER METHOD FOR DETECTION OF PHYTOTOXIC AIR POLLUTANTS. (Testkammerverfahren zum Nachweis phytotoxischer Inunissionskomponenten). Text in German. Environ. Pollut., 3(2):123-132, 1972. 12 refs.

Portable exposure chambers have been developed in which plants are exposed to filtered and unfiltered air for the purpose of identifying the presence of phytotoxicants in the air.

The chambers consist of a plexiglass cap covering the plants to be exposed and a box below containing an air filter, blower, and watering system; an experimental unit includes at least two such chambers. Ambient air is passed directly through the test chamber and is filtered before entering the control chamber in order to remove any phytotoxicants present. The effects of pollutants can be accurately identified by comparison of the plant reactions in both chambers. Individual pollutants can be identified by using special filtering systems and

<xref image="2000WVHG.TIF|V3|2006:09:28:01:31:38.00|113957|0"> image: </xref>

with combinations of indicator plants with differing resistance. A filter material coated with silver and silver oxide is used to remove the most important pollutants, sulfur dioxide, hydrogen fluoride, and hydrogen chloride. The filter material is also very effective in preventing leaf injuries to the tobacco variety BEL W3 which is very sensitive to oxidants. The exposure chambers may be used to conduct fumigation experiments both in the field and in climatic chambers as well as to test pesticides.

Crawford, V. A. and F. C. Tompkins

THE ADSORPTION OF GASES ON CALCIUM FLUORIDE.

Trans. Faraday Soc., vol. 46:504-514, 1950. 13 refs.

The adsorption of sulfur dioxide, nitrous oxide, and carbon dioxide on calcium fluoride crystals was measured at -28.8, 0.0, 19.4, and 35.5 C. Measurements were considered in terms of the nonuniformity of the adsorbent surfaces. Net heat of adsorption and distribution of adsorption sites were described by the Brunauer-Temkin, Freundlich, and De Boer-Bradley-Palmer isotherms. Analysis showed that SO₂ on CaF₂ will obey the De Boer-Bradley-Palmer equation over a wide range of pressures. The Freundlich equation is more satisfactory for the non-polar gases. Distribution of sites is affected by the nature of adsorbate-adsorbent forces, not by the nature of the non-uniformity of the solid adsorbent alone. Electrostatic forces predominate in the adsorption of a highly polar adsorbate. The edges and corners of the crystal will be low energy sites. Dispersion forces are important in the adsorption on non-polar gases. The edges and corners will be high energy sites.

Crawford, V. A. and F. C. Tompkins

THE ADSORPTION OF GASES SO₂, NH₃, CO₂ AND N₂OON BaF₂ CRYSTALS. Trans. Faraday Soc., vol. 44:698-708, 1948. 15 refs.

The adsorption of sulfur dioxide, carbon dioxide, ammonia, nitrous oxide on barium fluoride crystals was measured over the temperature range -78 to 119 C. The values obtained were corrected for adsorption on the glass walls of the apparatus used. The adsorption of the four gases was reversible and complete within 5 min at all temperatures. No correction was necessary for deviations from the perfect gas equation in the pressure range used. Heats of adsorption were calculated from the isotherms using the Clausius-Clapeyron equation and the H E T equation. There was no constant variation in heats of adsorption with temperature, but the variation decreased with increased adsorption for all the gases. The decrease of heats with coverage that was found experimentally was discussed and compared with those expected theoretically. Variation in adsorption potential over the crystal surfaces were calculated in an approximate manner, and the significance of these were discussed from the viewpoint of the applicability of the B.E.T. multilayer theory.

STRUCTURE OF FLUORINE SUPPORTED FLAMES. II.

CONCENTRATION PROFILES FOR FLAME OF THE

SYSTEMS: H₂-F₂, H₂-F₂-NH₃, NH₃-F₂, C₂H₂-F₂ AND C₂H₄-

F₂. Boston Coll., Chestnut Hill, Mass., Dept. of Chemistry, Office of Naval Research Contract N00014-69-A-0453, Task NR-92-536/4-25-69(473), FRK-117, 30p., May 1972. 13 refs. NTIS, DDC: AD 743501

Concentration profiles of reactants, stable products, and reactive intermediates were measured in low pressure flames of the following systems burning on a multi-diffusion burner: hydrogen-fluorine, hydrogen-fluorine-ammonia, acetylene-F₂, and ethylene-F₂. In the first system, preliminary results for

the H₂ and F-atom profiles were in good agreement with independent measurements of the elementary reaction F + H₂ yields hydrofluoric acid + H. In the H₂-F₂-NH₃ system, ammonia acts as an inhibitor in the H₂-F₂ flames due to the formation of solid ammonium fluoride. The main products of the C₂H₂-F₂ flame are HF and carbon fluoride (CF₂). The CF₂ recombines to C₂F₄ when the burned gas is cooled. The nature of the intermediates indicates that addition reactions of F and F₂ to unsaturated hydrocarbons and their radicals, respectively, are important. The formation of soot in this flame is compared to that in an acetylene-oxygen flame. Since a large amount of C₂H₄ is decomposed to C₂H₂ in primary reactions of the C₂H₄-F₂ system, the concentration profiles in this flame are very similar to those in a C₂H₂-F₂ flame. HANDBOOK OF INFRARED RADIATION FROM COMBUSTION GASES. National Aeronautics and Space Administration, Washington, D. C., Marshall Space Flight Center, 497p., 1973. 215 refs. NTIS: NASA SP-3080

Data is presented on radiative transfer in masses of combustion gases and flames. Radiant emission and absorption by combustion gases is reviewed. Typical applications include rocket combustion chambers and exhausts, turbojet engines and exhausts, and industrial furnaces. Some mention is made of radiant heat transfer problems in planetary atmospheres, in stellar atmospheres, and in reentry plasmas. Particular consideration is given to the temperature range from 500 to 3000 K and to the pressure range from 0.001 to 30 atmospheres. Strong emphasis is given to the combustion products of hydrocarbon fuels with oxygen, specifically to carbon dioxide, water vapor, and carbon monoxide. Species such as hydrogen fluoride, hydrogen chloride, cyanide, hydroxide, and nitric oxide are also discussed. A qualitative discussion is given of molecular radiators, molecular spectra, and radiative heat transfer in nongrey gases. The procedure for evaluating heat transfer from a given flow system is outlined, and guidelines for practical application of the handbook are given. Detailed discussions are presented on the properties of gaseous radiators and theoretical models for spectral emission from homogeneous and nonhomogeneous gases. Properties of the most commonly occurring molecules are tabulated, and specific computational models for these molecules are discussed. Emission from particle clouds and scattering effects in such clouds are discussed. (Author introduction modified)

late latex at 300, 600, and 850 C were studied by gas-liquid chromatography with flame-ionization detector. Carbon dioxide, carbon monoxide, as well as saturated and unsaturated hydrocarbons were consistently present in the reaction products. Both the CO and CO₂ contents increased with the temperature. Nitrogen oxides and ammonia were found in the oxidation products of synthetic rubber and nitrocellulose. The hydrochloric acid content of the combustion products of PVC was 54.7% at 300 C, 50% at 600 C, and 49.2% at 850 C. Perfluoroisobutylene and carbonyl fluoride were the most toxic products of fluorine-containing rubber. Aliphatic amines, benzene, toluene, n-xylene, divinyl methylmetacrylate, hydrofluoric acid, hydrogen sulfide, vinyl chloride, butylamine, formaldehyde, and phosphine were detected during the combustion of various polymers.

Chu, Chao-kang and Edgar Heckel
RADIATION INDUCED HYDROGEN FLUORIDE FORMATION IN FLUORINE CONTAINING ETHANES AND ETHENE. Preprint, East Carolina Univ., Greenville, N. C., Dept. of Chemistry, 18p., 1974. 32 refs.
Several fluorine containing ethanes and trifluoroethane formed hydrogen fluoride when irradiated with gamma rays in the gas phase at 25 C. Identical hydrogen fluoride yields were observed both in the absence and presence of molecular oxygen (except for monofluoroethane), indicating that hydrogen fluoride is formed by molecular elimination. A reduction in the radiation chemical yield (number of hydrogen fluoride molecules formed per 100 electron volts of energy absorbed by the sample gas) with increasing sample pressure indicated that collisional stabilization of excited fluoroethane molecules competes with the process of molecular hydrogen fluoride elimination. High radiation chemical yields for hydrogen fluoride and carbon dioxide in mixtures of trifluoroethane and oxygen indicated the occurrence of a chain reaction (Author abstract modified)

Clyne, M. A. A. and L. W. Townsend
RATE CONSTANT MEASUREMENTS FOR RAPID REACTIONS OF GROUND STATE SULPHUR 3P₄(3P_J) ATOMS. Intern. J. Chem. Kind., vol. 1975:73-84, 1975. 39 refs. (Presented at the Symposium on Chemical Kinetics Data for the Upper and Lower Atmosphere, 1st, Warrenton, Va., Sept. 15-18, 1974.)
Atomic resonance fluorescence was used to directly detect ground-state atomic sulfur (S(3P_J)) for the first time in a discharge flow system. Concentrations of S(3P_J) atoms between 1.0 times 10 to the 10/cu cm and 1.4 times 10 to the 12/cu cm were measured. The rate constants at 298 K for the bimolecular reactions of S(3P_J) with molecular oxygen, nitrogen dioxide, ozone, molecular fluorine, molecular chlorine, and molecular bromine were 1.5 + or - 0.3 times 10 to the -12, 6.2 + or - 1.4 times 10 to the -11, 1.2 + or - 0.3 times 10 to the -11, 2.9 + or - 0.8 times 10 to the -13, 1.1 times 10 to the -11, and 9.5 + or - 1.7 times 10 to the -11 cu cm/molecule/sec, respectively. The ground state sulfur atom appeared to be more reactive than the analogous ground state oxygen atom. (Author abstract modified)

Skolnik, Edward G., Stephen W. Veysey, Mahmooda G. Ahmed, and William E. Jones

RATE CONSTANTS FOR THE REACTION OF FLUORINE ATOMS WITH NITRIC OXIDE IN THE PRESENCE OF VARIOUS THIRD BODIES. Can. J. Chem., 53(21):3188-3193, Nov. 1, 1975. 20 refs.

The absolute rate constants for the reaction of fluorine atoms with nitric oxide in the presence of argon, helium, neon, nitrogen, nitric oxide, carbon dioxide, carbon tetrafluoride, and hexafluoroethane are reported. The reaction of F₂ atoms with NO in the presence of a third body produces nitrosyl fluoride in both ground and excited electronic states. The electronically excited FNO molecules decay to ground state FNO by both radiative and nonradiative processes. In addition to reaction with NO, F₂ atoms may be lost by a wall reaction. The values are compared to those found for reactions of chlorine, hydrogen, and oxygen with NO. (Author abstract modified)

THE VIBRATIONAL SPECTRA OF ANTIMONY PENTAFLUORIDE-SULFUR DIOXIDE (1/1). Inorg. Chem., 15(1):32-35, Jan. 1976. 20 refs.

Complete solid state Raman and infrared spectra are reported for the antimony pentafluoride-sulfur dioxide (1:1) complex, and assignments are made for the fundamental vibrations. Depolarization data are reported for the liquid-phase Raman spectra. The antimony-oxygen stretch in the complex is assigned to a band at 266/cm, this falls at a lower energy than does antimony-nitrogen for the analogous acetonitrile complex of antimony pentafluoride. The three fundamental vibrations ascribed to the sulfur dioxide moiety of the antimony pentafluoride-sulfur dioxide complex are assigned to Raman bands at around 1320, 1100, and 539/cm, these are shifted approximately -15, -45, and +15/cm from the values found for the equivalent modes in free sulfur dioxide. Qualitatively, other sulfur dioxide complexes show the same kind of shift, regardless of their mode of bonding. The difference between the two high frequency bands, however, appears to be symptomatic, if the difference is greater than 190/cm, the complex is oxygen bonded, whereas, if the difference is less than 190/cm, the complex is bonded through the sulfur (free sulfur dioxide liquid displays a difference between the two high frequency bands of approximately 190/cm) Author abstract modified)

M. Klemfeld

ACUTE PULMONARY EDEMA OF CHEMICAL ORIGIN.

Ind. Hyg. Rev. 7, (2) 1-10, Dec. 1965. (Reprinted from the Arch. Environ. Health 10, 942-6, June 1965.)

Six instances of pulmonary edema due to toxic exposure to ozone, nitrogen dioxide, cadmium oxide fumes, dimethyl sulfate, hydrogen sulfide and hydrogen fluoride are presented. The problems of diagnosis are discussed. In view of the unusual severity of these cases, the following points were stressed: (1) the need of the physician to be aware of the possible industrial origin in all instances where the cause of the pulmonary edema is obscure; (2) the importance of careful observation of the patient known to be exposed to an agent capable of producing a delayed pulmonary edema, even in the initial absence of any symptoms; (3) since certain of these agents, such as ozone and hydrogen sulfide, can act on the central nervous system to produce respiratory depression, it is contraindicated to administer morphine in these instances. Digitalis likewise has no place in the management of pulmonary edema caused by exposure to the chemicals mentioned. The effective treatment is primarily preventive, which calls for proper ventilation of the work environment and an adequate knowledge of the operational processes and procedures. The immediate treatment should include the following: (1) oxygen under controlled positive pressure to the inspiratory cycle, (2) nebulized bronchial dilators for the bronchial spasm, (3) steroids in the more severe cases, (4) broad-spectrum antibiotics for superimposed bacterial infection, (5) nebulized nonirritant bronchial detergents for increasing mucous secretion, and (6) tracheostomy as indicated. THE INHALATIONAL TOXICITY OF OXYGEN

DIFLUORIDE. Am. Ind. Hyg. Assoc. 26(6):562-7, Dec. 1965. (Presented at the American Industrial Hygiene Conference, Houston, Tex., May 6, 1965.)

The acute inhalational toxicity of oxygen difluoride in the albino rat has been determined at concentrations of 5 to 40 ppm for 5 to 15 minutes. A CT product (ppm-minutes) of about 100 results in 50% mortality. At the levels studied, gross and microscopic pulmonary damage develop 7 hours after termination of the exposure and if death does not intervene, repair begins after the third day. The extreme toxicity of oxygen difluoride and its insidious character make it imperative to exclude its inhalation by personnel. (Author abstract)

EXPOSURES OF BIOLOGICAL SYSTEMS TO INORGANIC FLUORIDE OXIDIZING AGENTS. VOLUME I. HANDLING

AND EXPOSURE TECHNIQUES. Oregon State Univ., Corvallis, Radiation Center (Rept. No. AMRL-TR-65-223-Vol. I) 25 pp. Dec. 1965. CFSTI.DDC: AD 631 483

A system adaptable for diluting and distributing various inorganic fluoride oxidizing agents has been developed. Known dilutions of these agents in nitrogen or air are generated on the basis of flow rate ratios between undiluted gas and various diluent gases, and confirmed chemically. Problems of materials compatibility, personnel protection, stability of the agents and exposure system design are discussed. (Author abstract)

SUBCELLULAR DISTRIBUTION OF FLUORIDE IN NAVEL

ORANGE LEAVES. Intern. J. Air Water Pollution (London), Vol. 9:6X5-691, Nov. 1965.

Navel orange leaves from trees grown in a fluoride contaminated atmosphere were analyzed for intracellular distribu-

tion of fluoride Leaf tissue was homogenized and fractionated by differential centrifugation in sucrose solution. The subcellular distribution of fluoride in particulates was, in decreasing order, cell wall, chloroplast, water soluble protein, and mitochondria. However, when consideration is made of the major cross-contamination of chloroplast and/or chloroplast fragments and protein, the fluoride accumulation was assumed to be, in decreasing order, chloroplast, cell wall, water soluble protein, and mitochondria. Almost 60 per cent of the total fluoride in the homogenate was in the supernatant fraction. Some fluoride was found to be associated with the water soluble prolem. Negligible amounts of fluoride were found in organic acids and sugars. (Author abstract)

J W. Clayton, Jr D. B Hood, M. S. Nick, and R. S Want/
INHALATION STUDIES ON CHLOROPEN-
TAFLUOROETHANE. Am. Ind. H>g. Assoc. J., Vol. 27:234-
238, June 1966.

Dogs, uits, mice, and rabbits were exposed to an atmosphere of \(\text{Yi}\) chloropentafluoroethane for 90 exposures of six houis each. Body weight and clinical condition of rodents were unaffected. Rat and dog blood, urine analyses, and urinary fluoride analyses revealed no significant changes. Dog weight gain, temperature, respiration, and pulse were normal, dross examination, histology, and organ weights of all species revealed no effects attributable to chloropentafluoroethane. An industrial hygiene standard of 1000 ppm as an eight-houi time-weighted average is suggested (Author abstract)

EFFECT OF ATMOSPHERIC FLUORIDES UPON CERT UN
METABOLIC PROCESSES IN VALENCIA ORANGE
LEAVES. Proc. Florida State Hort. Sue. 77, 9-15, 1964.
(Presented at the Florida State Horticultural Society. Miami,
Nov. 3-6, 1964.)

The removal of fluoride from the atmosphere around Valencia orange trees resulted in greater rates of photosynthesis. enhanced chlorophyll contents and lower rates of respiration
<xref image="2000WVHJ.TIF|V3|2006:09:28:01:31:48.00|87951|0"> image: </xref>

The degree of removal of fluoride was estimated by leaf analysis and by the degree of development of fluoride leaf scorch of gladiolus indicator plants. Preliminary procedures were tested for the removal and measurement of leaf-surface reacted fluorides. Time course measurements were made of the resistance of leaf-surface fluorides to removal by weathering outdoors. It was found that surface reacted fluoride from hydrofluoric acid solution dips remained on the leaves outdoors for nine days. Brief immersion (15 seconds) in dilute hydrofluoric acid solutions resulted in a depression in photosynthesis activity and in a significant closure of stomata. Needs for further research are discussed. (Author summary)

INHIBITION OF PHOSPHOGLUCOMUTASE ACTIVITY IN
OAT COLEOPTILES BY AIR POLLUTANTS. *Physiol. Plantarum* 18, 790-7, 1965.

A marked inhibition of cellulose and of glucan biosynthesis induced by the air pollutants fluoride, ozone and peroxyacetyl nitrate (PAN) was found in oat coleoptile sections. It was suggested that a common point of attack by these inhibitors might be phosphoglucomutase which catalyzes the interconversion of glucose-6-phosphate and glucose-1-phosphate. Glucose-1-phosphate is a probable precursor for glucan and cellulose biosynthesis. Fluoride is known to inhibit plant phosphoglucomutase in vitro more than the other enzymes involved in sucrose biosynthesis. Photooxidation producing inactivation has been carried out with pure phosphoglucomutase of animal origin. The influence of the air pollutant oxidants both in vivo and in vitro on this enzyme is unknown. The purpose of this report is to present results concerning the effect of these inhibitors on phosphoglucomutase activity in oat coleoptile tissue and the effects on enzyme prepared from this tissue.

AIR POLLUTION AND ALLERGY. *Acta Allergol.*
(Copenhagen) 18, 113-30, 1963

After describing some examples of acute air pollution episodes, the authors give a brief review of natural air pollution from the allergological point of view. Cultural air pollution is considered under two headings: indoor or local, and outdoor or general. The capacity of some chemical present in outdoor air-SO₂, H₂S, NH₃, Be and F-to provoke allergic diseases is discussed on the basis of the literature and personal investigations. Finally some figures and examples are given regarding the quality and degree of air pollution in the USA and in Finland. The authors stress the difficulty which arises in fixing the maximum allowable concentrations for general air pollution, owing to the wide variations in physiological response in general and in allergic reactivity in particular. (Author summary modified)

(INHALED NOXIOUS POLLUTANTS.) Pollutants nocifs inhalés. (Part of Chapter 1: Les pollutions et 'nuisances d'origine industrielle et urbaine. Tome 1. Leur prevention et les problemes scientifiques et techniques qu'elle pose en France.) Premier Ministre, Delegation generale a la recherche scientifique et technique. 13-7, June 1966.

This information on inhaled noxious pollutants, which is presented in brief semi-outline form, deals with, chronic and acute effects, influence of dusts on the lungs, influence of non-carcinogenic pollutants, influence of bacteria and viruses, and principal areas of concern in research. Pollutants must be considered both for their independent effect and for that which is conditioned by the state of health of the person such as that of persons with cardiovascular impairment or chronic bronchitis. Reactions from a number of pollutants, including ozone, nitrous vapors, and carbon monoxide, are of great concern. Research studies are being pursued with synthetic atmospheres in relation to synergistic actions, with studies of

the atmosphere in certain areas of Pans during a normal period and during a period of smog; with toxicological studies of certain chemical agents, particularly sulfur dioxide, carbon monoxide, and various fluonne compounds, with a view of fixing their limits of tolerance; with the carcinogenic potential of chemical agents as pollutants; and with consideration of the respiratory tree as influenced by inhaled chemical agents and studies of respiratory insufficiencies. This information is given in a section of Chapter 1 of this monograph.

EXPERIMENTAL STUDIES ON CHRONIC FLUORINE

POISONING. Effects of a Small Amount of Fluorine on a Living Body. Japan. J. Ind. Health (Tokyo) 1, (7-8) 683-90, Nov. 1959. Text in Japanese.

The following experiment is described: in 4 groups of rabbits, sodium fluoride (0.017, and 1.67 mg (kg body weight) was administered orally for 20 months. There were no striking changes in body weight, the blood picture, or the ECG. Mottled teeth and abrasion of the incisors were noted after 7 months. Symptoms of bone hardening such as swelling of the epithelium, increase of diameter, and increase in bending were observed. Swelling, turbidity, and vacuolation in liver and kidney, cells and slight myocardial fiber atrophy were observed, depending on the amount of fluorine administered. Pathohistological degeneration of the liver, kidney, heart, and spleen could be noted in the offspring of treated rabbits.

EFFECTS OF AIR POLLUTION ON ANIMALS. World Health

Organ. Monograph Ser. 46 (Air Pollution), 1961. pp. 221-31.

The report of animal morbidity and mortality which followed major air pollution episodes would be regarded critically. The investigations of these acute and intense exposures to air pollution have been done retrospectively. It is significant that the owners' reports of injury to animals could not be corroborated by professional observers at the Donora disaster. The high rate of animal mortality which allegedly occurred at Poza Rica is generally in contradiction to the information concerning the relative susceptibility to air pollutants of animal species which have been studied experimentally. The synergistic roles of physiological and of external environmental influences on reactions to air pollution indicate that the interactions of many factors may be necessary to produce critical situations. In contrast to the paucity of information concerning natural exposure to most air-borne pollutants, the effects of fluorides on animals have been defined well. Laboratory research has provided important information concerning the effects of specific pollutants on animals. Mice, rabbits, guinea-pigs, rats and monkeys have been utilized to demonstrate the toxic properties of such air pollutants as sulfur dioxide, sulfuric acid, hydrogen sulfide, ozone, nitrogen dioxide, organic compounds, and some dusts. Information which has been obtained by artificial exposure of animals is providing some indices of both human and animal effects to be expected from natural expo-

THE MECHANISM PRODUCING METAL FEVER IN THE PROCESS OF WELDING WITH LOW HYDROGEN-TYPE ELECTRODES. Japan J. Ind. Health (Tokyo) 3, (4) 237-48, Apr. 1967. Jap.

The causes of metal fume fever might be attributed to the high emission of MgO particles in the dusts from the low-hydrogen type electrodes during the welding process. Using 4 types of electrodes including low-hydrogen type electrodes, the mineralogical composition of coating materials was determined by microscopical examinations. CaF₂, ferrosilicon, a large amount of CaCO₃, MgCO₃ (in the form of dolomite), and water glass were found. After experimental welding was performed with different electrodes, one evidence of melting was found at the end of low-hydrogen type electrodes, while the end of another type showed the evidence of melting by the heat of the arc. By the thermobalance method the author measured the change in weight during continuous heating and examined the time-weight loss curve at different firing temperatures. The heating curves of the low-hydrogen type electrodes show a maximum decrease of weight at 600 C (as a result of the decomposition of carbonates), a marked increase of weight (as a result of oxidation) by heating above 600 C, the definite loss of weight as a result of a high porosity above 800 C, and a high sensitivity to the sudden change of temperature. Definite heat absorption at 500 C and 750 C and heat evolution at 600 C were observed in the differential thermal analysis of the low-hydrogen type electrodes, properties which are important as a cause of rapid destruction of the material. It was found that the porosity of the fired material after heating above 800 C shows a marked decrease in the number of MgCO₃ particles, signs of dehydration of the water glass, and production of new round crystalline formations from the ferrosilicon particles which had originally irregular contours. THE TOXIC EFFECT OF THE VARIOUS DUSTS ON THE INTRAPERITONEAL MONOCYTE IN RAT. Bull. Natl. Inst. Ind. Health (Kawasaki, Japan) 6, 10-27, 1961.

The toxic effect of various mineral dusts on the monocyte of the rat is described. In a study of the effect of particle size on cell toxicity, it was assumed that the toxicity was indicated by the inhibition of the dehydrogenase activity of the cultured monocytes. The cell toxicity increased with the decrease of particle size in leached quartz, but it did not correlate in such a manner in particle sizes under 2 microns in original quartz or sericite. In a study of toxic doses to the monocytes of various mineral dusts based on the tetrazolium reducing capacity, the toxicities of the dusts decreased in the following order: (1) Tridymite; (2) NaOH leached quartz, quartz ground by hand for 2 min, fused silica, and cristobalite; (3) Sericite (Hitachi); (4) Opal, pyrophyllite, talc, sericite (Yoji), and Kibushi-clay, (5) Topaz, fluorite, tourmaline, cyanite, diatomaceous earth, sericite (Nasu), halloysite and sphalerite; (6) Olivine and asbestos; and (7) Microcline chlorite, diposide, obsidian, albite beryl, pyrite, muscovite, and anthracite.

HISTOLOGICAL AND CHEMICAL STUDIES IN MAN ON EFFECTS OF FLUORIDE. Public Health Rept. 80, (6) 529-38, June 1965.

In this investigation, 127 human bodies were autopsied and studied for gross, histological, and chemical evidence of fluoride intoxication. Eighty-eight of these deceased persons came from geographic areas known to have had a elevated fluoride levels in the atmosphere and forage. Analyses for fluoride, calcium, phosphorus, and ash were made on the calvanum, sternum, rib, iliac crest, and lumbar vertebrae. Determinations for fluoride and dry matter were made on the brain, heart, lungs, thyroid, aorta, liver spleen, pancreas, and kidney. The highest fluoride levels were observed in older adults showing the end-stage kidney of bilateral pyelonephritis and polycystic disease. Average levels were found in subjects with unilateral pyelonephritis and in subjects with pyelonephritis with only slight to moderate disease. The highest fluoride levels found, in subjects with the most severe kidney disease, were within the normal range, and no disease associated with fluorides was evident. Because the number of cases of chronic renal disease in this series was limited, further studies seem advisable. (Author summary)

THE INFLUENCE OF METHEMOGLOBINEMIA ON THE LETHALITY OF SOME TOXIC ANIONS. I. Azide. Toxicol. Appl. Pharmacol. 6, (5) 576-83, Sept. 1964.

The time course and extent of the methemoglobinemia induced by intraperitoneal sodium nitrite and p-aminopropiophenone (PAPP) have been characterized in female mice. The peak methemoglobin formation (34%) from sodium nitrite (75 mg/kg) is achieved in about 40 minutes. Comparable levels from PAPP (15 mg/kg) are achieved more quickly (between 5 and 10 minutes) but decline more rapidly to normal. Both nitrite- and PAPP-induced methemoglobinemia afford a significant degree of protection against poisoning by sodium azide when administered in an appropriate time sequence. It was not possible under the same circumstances to protect mice against death from fluoride, cyanate, thiocyanate, selenate, or borate, although some prolongation of survival time was seen after fluoride. The formation of the azidemethemoglobin complex has been demonstrated within intact mouse red blood cells, and small amounts of the complex were identified in vivo in an antidotal situation. It is considered important that the protective action of methemoglobinemia has been demonstrated to date only against established inhibitors of cytochrome oxidase (Author summary)

E. J. Largent

EFFECTS OF FLUORIDES ON MAN AND ANIMALS. Proc. Natl. Air Pollution Symp., 1st, Pasadena, Calif., 1949. pp. 129-34.

Chronic fluorosis in livestock is the effect most frequently associated with the release of fluorides into the general atmosphere. A herd of cows, ranging in age from five to thirteen years, was examined on a farm adjacent to a factory in which rock phosphate was being processed. The length of time during which the cows had been pastured near this factory ranged from five to nine years. Most of the animals displayed symp-

<xref image="2000WVHL.TIF|V3|2006:09:28:01:31:56.00|114701|0"> image: </xref>

toms of chronic fluorosis. Analysis of tissues obtained from three of the affected cows indicates that the animals had considerable exposure to fluorides. Samples of elm leaves contained fluoride to the extent of nearly 7,000 ppm and samples of grass approximately 300 ppm. In a few instances samples of air collected on the farm had remarkably high fluoride concentrations. The gaseous portions of the samples always contained far less than 1 ppm, while the concentrations of particulate fluorides were sometimes much higher than the gaseous component, a factor which was important in the production of fluorosis. Information as the effects of human exposure to fluorides is separated on the basis of its relationship to the acute effects, and the chronic effects. The metabolic fluoride balance of an experimental subject during periods of normal and elevated intake are tabulated. It is concluded that the pollution of the atmosphere with fluorides, as the result of industrial operations, may contaminate near-by vegetation and induce chronic fluorosis among cattle grazing thereon. However, it seems unlikely that any human discomfort or impairment of human health will occur from present normal industrial operations.

THE EFFECTS OF AIR POLLUTION ON VEGETATION.

Proc. Clean Air Conf., Univ. New South Wales, Vol. 1, 22p., 1962, Paper 8.

Solid, liquid and gaseous pollutants are present in the atmosphere. Ash, grit and tars in smoke form mechanical barriers to the maximum use of solar energy by the plant. Dusts from chemical manufacture interfere with the plant's physiological processes and acid aerosols cause leaf spotting. Coal combustion releases sulphur dioxide and various industrial processes release gaseous fluorides. Extensive injury has resulted from the continuous emission of these gases in agricultural and pine forest areas. Other gaseous pollutants have been of less importance on a large scale. Sulphur dioxide is toxic to sensitive plants in parts per million of air and fluorides are toxic in part per thousand million. Plants vary widely in their sensitivity to either sulphur dioxide or fluorides and in their relative sensitivity to both gases. Environmental factors have a marked effect on sensitivity. Studies of meteorological data, air analyses, plant analysis and of the reaction of indicator plants have been of value in the determination of gaseous pollutant damage. A mathematical formula for the objective assessment of sulphur dioxide damage has been derived and losses in some crops have been calculated. Mathematical assessment of fluoride damage has not yet been possible. Any assessment of crop damage by air pollutants must call for a parallel evaluation of the reductions in yield which would result from unfavourable environmental influences, e.g. weather damage, from toxic materials in the soil, from nutrient deficiencies and from the depredations of insect pests or plant damage diseases. Goldsmith, John R.

AIR CONSERVATION - THE BIOLOGIST'S VIEW. Preprint, American Assoc. for the Advancement of Science, 13p., 1963.

(Presented at the American Association for the Advancement of Science Meeting, Cleveland, Ohio, Dec. 29, 1963.)

The effects of air pollution on the biosphere are reviewed in terms of the necessity for establishing a strategy of air conservation. Topics covered include: air pollution episodes associated with increased morbidity and mortality rates; epidemiologic studies investigating the association between air pollution and increased rates of respiratory disease and cancer; physiologic tests designed to determine the effects of sulfur dioxide and carbon monoxide on experimental animals and human volunteers; the irritating effects of irradiated motor vehicle exhaust on the respiratory tract and eye; the action of

ozone as an irritant and phytotoxicant; the effects of photochemical oxidants and fluorides on vegetation and animals feeding off of such vegetation; and the necessity for air conservation plans which take into account the air shed and dilution capacity of the environment.

ACUTE INHALATION TOXICITY OF

TETRAFLUOROHYDRAZINE. (Army Chemical Research and Development Labs., Edge wood Arsenal, Md., Toxicology Division.) (May 1963). 15 pp. (Rept. No. CRDLR 3174.)

Experiments were designed to study the effects of tetrafluorohydrazine resulting from single, short-exposure periods. Rats were exposed to various concentrations of N2F4 for single 15-, 60-, and 240-min periods, and the LC50'S were calculated. A 60-min LC50 for guinea pigs was also determined. In addition, rats and dogs were exposed to several concentrations below the 15- and 60-min rat LC50's. The criteria used to evaluate the toxicity of N2F4 were eye and nasal irritation, cyanosis, and hematologic and pathologic changes. Pathologic changes were the least effective measure for determining the toxicity of N2F4 in the short exposures. The other signs decreased in severity as the concentration was lowered. Rats showed signs of eye and nasal irritation at concentrations causing no such effects in dogs. At these concentrations, however, dogs had a greater increase in methemoglobin than did the rats. Based on the responses of rats and dogs, the threshold concentrations for the production of toxic effects were about 500 and 100 ppm of N2F4 for 15 and 60 min, respectively. (Author abstract)

FLUORIDE-BEARING DUSTS AND FUMES (INORGANIC).

Am. Ind. Hyg. Assoc. J. 26 (4), 426-30 (Aug. 1965).

Guidelines for industrial health considerations and procedures for those exposed to fluoride-bearing dusts and fumes (inorganic) are set forth. In general, these compounds are more neutral in comparison to gaseous and liquid fluoride compounds and all are soluble in inorganic acids. They may decompose and react with other compounds to give off HF and other irritating compounds. Hygienic Standards: (1) Recommended Maximal Atmospheric Concentrations (8 hrs): 2.5 mg (F ion)/cu m of air; (2) Short exposures may vary widely, the more soluble fluoride forms being the more toxic. Toxic Properties: (1) Inhalation - repeated exposures to excessive concentrations of fluorides in the air over a long period of time result in increased radiographic density of the bones and may be responsible for anatomical abnormalities; (2) Skin Contact - this may cause rash; Eye Contact - exposures to neutral dusts and fumes have not been considered serious; Ingestion: acute fluoride intoxication may result from ingestion of soluble fluorides, like NaF in amounts as low as 500 mg; chronic fluoride intoxication or fluorosis may result from daily intake of excessive amounts of fluoride over long periods of time. Evaluation of exposures: (1) Air sampling and analysis: A systematic air sampling program should be carried on to ascertain that the average concentration of fluorides in the air does not exceed recommended levels. (2) Biological sampling and analysis: A systematic program of urine analysis should be

<xref image="2000WVHM.TIF|V3|2006:09:28:01:31:58.00|121626|0"> image: </xref>

G. EFFECTS-HUMAN HEALTH

275

conducted for personnel exposed to fluorides; (3) Water sampling: The standard method of the American Society for Testing and Materials and the method listed in Standard Methods for the Examination of Water and Wastewater Including Bottom Sediments and Sludges are recommended. (4) Hazards and their Recommended Control: The principal problem from industrial exposures to the fluorides other than the highly corrosive forms is fluorosis caused by inhalation or ingestion.

FLUORIDE EXPOSURE AND WORKER HEALTH (THE
HEALTH STATUS OF WORKERS IN A FERTILIZER
MANUFACTURING PLANT IN RELATION TO FLUORIDE
EXPOSURE). Arch. Environ. Health 6(4), 503-11 (Apr. 1963).
Clinical and laboratory studies were conducted to assess the health of a group of workers exposed to fluorides as compared with a group of workers equivalent in age, race, and living standards without industrial exposure to fluorides. No disability attributed to fluoride exposure was encountered in any of the individuals in this study. Minimal or questionable degrees of increased bone density were found in 23% of the fluoride-exposed group. Abnormal findings related to the gastrointestinal and cardiovascular systems occurred in the two groups with approximately equal frequency. The distribution of findings suggestive of not-normal genitourinary conditions was approximately the same for the fluoride-exposed group and the control group except for the incidence of albuminuria which was found to be higher in the exposed group. This finding and its distribution in the sub-groups suggest the possibility of a relationship between fluoride exposure and increased excretion of albumin in the urine. The fluoride excretion level of 4 mg. of fluoride per liter in urine samples collected at the end of the work shift has been found to serve as a useful reference level for evaluating atmospheric fluoride exposure where industrial environmental concentrations vary widely and in determining the probability of incurring increased bone density. Z. Ya. Lmdberg
EFFECT OF SUPERPHOSPHATE PRODUCTION
DISCHARGES ON CHILDREN'S HEALTH . U.S.S.R. Literature on Air Pollution and Related Occupational Diseases, Vol. 7, 284-8, 1962. (Gigiena i Sanit.,) 25 (5), 89-96 (1960). Russ. (Tr.) CFSTI: 62-11103
In order to assess the possible health effects of emissions from a superphosphate plant, the frequency of upper respiratory illness was studied in 2053 children. Of this total, 1375 children lived in the vicinity of the plant and 678 were controls. Air samples were taken in the inhabited zones around the plant at distances of 500 and 3000 meters. The concentrations in excess of allowable limits are given for SO₂, H₂SO₄, F, and NO_x. Most of the children involved in the study were given either x-ray or fluoroscopic chest examinations. The results of these examinations were correlated with tuberculin skin tests. The data indicated that children residing in the area of the superphosphate plant had a higher frequency of both upper respiratory ailments and tuberculosis.

THE PULMONARY RESPONSE OF RATS TO FLUORSPAR
DUST AND RADIATION. Proc. Intern. Symp. Inhaled Particles
Vapours, II, Cambridge, England, 1965. p. 135-140, 1967.
An attempt was made to study separately the biological effects of fluorspar and radiation and the possible effect of radiation per se on the clearance of dust from the pulmonary tissues. Dust was, injected six weeks after irradiation (external radia-

tion). This time interval was determined by a pilot study and coincided with a maximum early recovery from acute radiation injury. In these experiments, calcium fluoride (fluorspar) injected intratracheally in adequate dosage caused no significant pulmonary fibrosis and behaved as a so-called inert dust. X-irradiation of the chest in rats at the dosages used in this investigation produced relatively slight collagenization of alveolar walls, several mouse-type adenomata and an adenocarcinoma within one year following irradiation. No inhibition of alveolar clearance was observed when lung dust burden was imposed six weeks following the irradiation. The failure of the X-irradiation to affect the alveolar clearance mechanism is attributed to the timing of the dust-burden imposition, a time when the alveolar lining had recovered from the radiation effects. A greater degree of alveolar fibrosis in the radiation-plus-dust animals than in the other groups was observed. Additive or adjuvant factors require further study. A high incidence of endemic chronic broncho-pulmonary disease was observed among dusted animals whereas none was found in stock controls or in animals exposed to radiation only.

AIR POLLUTION AND ALLERGY. (Work Environ. Health
(Helsinki),) Vol. 1, p. 2-15, Oct. 1962.

The authors current knowledge regarding the problem of air pollution and allergy is reviewed and observations made in Finland are presented. Air pollution is divided into natural and cultural the former deriving from wind pollinated plants and the latter from industrial sources. Emphasis is on cultural pollution and major pollutants such as SO₂, beryllium, and fluorine are treated individually. It is pointed out that there is a disparity between maximum allowable concentrations, as commonly set, and concentrations tolerated by allergic individuals.

PULMONARY SCLERODERMA AND ASSOCIATED FLUOR
SPAR SILICOSIS- RELATION BETWEEN SCLERODERMA
AND SILICOSIS. ((Sclerodermie Pulmonaire et Silicose du
Spath Fluor Associee Rapports Entre Sclerodermie et Silicose.))
Text in French. J. Franc. Med. Chir. Thorac. (Paris), 20(6):603-
618, Sept.-Oct. 1966. 43 refs.

A case is reported of a fluor spar miner in whom was found scleroderma of the sclerodactylic type with subacute myositis, complex endocrine disorders, gynecomastia, and dysoric retinopathy. A pulmonary biopsy showed Sclerodermie diffuse interstitial fibrosis and nodular silicotic lesions. Photomicrographs are shown of muscular, skin, and pulmonary biopsy specimens as well as chest plates. There are a number of problems associated with this case such as the effects of the fluor spar on the lung, the pulmonary effects of scleroderma, and the association of scleroderma and silicosis. Recent statistics show that the association is not uncommon, but as yet no specific anatomic or radiological characteristics have been determined. The incidence of scleroderma in miners is high and the question of pathogenic relation between scleroderma and pneumoconiosis has not been answered.

Keplinger, M. L.

FLUORINE TOXICITY STUDIES. Miami Univ., Fla., School of
Medicine, Grant NASA-NGR-10-007-012, Up., bSdec. 1, 1966.

(Status Progress Report.) NASA: N67-28013

Studies to determine the toxic effects of fluorine are being continued. The results summarized in this report generally are preliminary. The concentrations which cause irritation in man were determined. When rats and mice survive for six months after exposures which damage the kidneys, regeneration of the tissue is essentially complete. Repeated, intermittent exposures to fluorine appeared to cause lesser effects than a single exposure at the same concentration. Animals exposed to low concentrations of fluorine appear to be less susceptible to the effects caused by exposure to high concentrations of fluorine than animals which have not been exposed previously. The formation of edema following exposure to fluorine was shown. Succinic dehydrogenase may be increased in the lung after inhalation of fluorine. Very young and rather old mice apparently are no more susceptible to fluorine than the young adult animal. (Author's summary)

DeVilliers, A. J.

CANCER OF THE LUNG IN A GROUP OF FLUORSPAR

MINERS. Can. Cancer Conf. (Ontario), Vol. 6, p. 460-474,

1964. 13 refs.

A study of the community of St. Lawrence, Newfoundland including the entire physical environment of the people was undertaken because of the statistically significant number of deaths due to lung cancer and tuberculosis. All of the deaths due to lung cancer involved individuals who were born in St. Lawrence and who had worked in the fluorspar mining industry at some period. An analysis of underground dust samples from the mines showed concentrations of SiO₂ and CaF₂ which, though high, were not considered alarming. The unusual factor proved to be radon daughters in the atmosphere, from the mine ground water. Ventilation was installed in the mines. Ratios of actual fatalities to statistically expectable mortalities for the area gave figures in a range of 12.56-146.34. The increasing incidence with increasing duration of underground exposure indicated an occupational hazard. Smoking was also mentioned as a contributing factor but heredity was inconclusive. Tuberculosis and malignancies of the buccal system and digestive system were also found with increased exposure. Full statistics on atmospheric findings and tables of death statistics for the population of the mines are included.

EXPOSURES OF BIOLOGICAL SYSTEMS TO INORGANIC

FLUORIDE OXIDIZING AGENTS. VOLUME II. FLUORIDE

ANALYSIS BY CHEMICAL METHODS. Oregon State Univ.,

Corvallis, Radiation Center, Contract AF 33 (615) - 1799, Proj.

6302, Task 630202, AMRL-TR-65223-VoI II, 20p., Dec. 1965. 19

refs. CFSTI, DDC: AD 630593

Methods are described for assaying the fluoride content of ashed samples of plant and animal tissues. Using the Hall method, submicrogram quantities of fluoride were measured and a new procedure was devised to measure fluoride in a 1 to 8 microgram range. Modification of the Weinstein procedure, in which an AutoAnalyzer is used, permitted rapid and semiautomated analysis samples containing 2.5 to 100 micrograms of fluoride. (Authors' abstract)

FLUORINE TOXICITY STUDIES AT THE UNIVERSITY OF

MIAMI. (SEMI-ANNUAL PROGRESS REPORT.) Miami Univ.,

Fla., Research and Teaching Center of Toxicology, Grant NGR-

10-008-012, CR-69992, 6p., Nov. 30 1965. CFSTI: N68-18861

Animals were exposed to fluorine in a specially developed exposure chamber. Signs of intoxication from high concentrations of fluorine in air were marked irritation of the mucous membranes of the eyes and respiratory tract. The skin of the animals showed very little irritation at the concentrations used. The LC50 (concentration calculated to kill 50% of the animals) was determined for 5, 15, 30 and 60 minutes of exposure in both rats and mice. The LC50 for guinea pigs was determined for 15 and 60 minutes of exposure, while the LC50 in rabbits was determined after 5 and 30 minutes of exposure. There appeared to be very little difference between the LC50's of the different species. At lower concentrations there were fewer signs of intoxication. Dyspnea, lethargy, red nose and swollen eyes were observed at concentrations equivalent to 50% of the LC50's. At concentrations which were 25% of the LC50's there were only mild signs of intoxication, manifested by slight dyspnea and closed eyes. At lower concentrations there were no gross signs of intoxication. Complete blood counts of these animals showed no significant changes, however it is interesting that the clotting time appeared to be affected. Although this phenomenon was not tested (but probably should be) the blood did not seem to clot as rapidly as normal. Gross pathology found in animals, which succumbed from exposure or were sacrificed following exposure near the LC50's, was congestion, hemorrhage and atelectasis in the lungs and some congestion and/or mottling in the liver. Survivors which were sacrificed up to 45 days after such exposures had congestion in the lungs and occasional congestion in the liver. There was some discoloration of the kidneys in animals which were sacrificed 8 to 14 days after exposure. This appeared to be more prevalent in mice than in other animals. Gross changes in the lungs were found after sacrifice of animals which showed no signs of intoxication. The information at date indicates that concentrations of about 10 to 15% of the LC50's cause little or no gross pathology in the lungs.

Derradenko, N. M.

THE EFFECT OF MIXED INDUSTRIAL DUST ON THE ORGANISM-Gigiena i Sanit., No. 11:26-29, 1954. 13 refs. Translated from Russian by B. S. Levine, U. S. S. R. Literature on Air Pollution and Related Occupational Diseases, Vol. 4, p. 243-247, Aug. 1960. CFSTI: TT 60-21913

Knowledge of the combined action of mixed dust is essential for the determination of hygienic limits of allowable dust concentration in the air, and for the rational selection of means for the protection of sanitary working conditions in mixed dust generating industries. Mixed dust containing quartz and hematite (ferric oxide), quartz and fluorite, quartz and coal, and quartz and chalk were investigated. Chalk dust used as bulk material in the preparation of mixed dust samples of uniform component ratios. Each dust mixture consisted of 50 percent quartz and 50 percent admixture. The dust mixtures were introduced intratracheally in 4 series of tests using white rats. Animals were kept under observation 6 - 8 months then sacrificed and their internal organs were fixed in 10 percent formalin. It was shown that: a) dust mixtures containing 50 percent silicon dioxide and 50 percent coal or hematite had a less pronounced pathogenic effect than the same percentage of silicon dioxide alone; b) fluorite admixture did not lower the effect of silicon dioxide but changed its character; this may be

<xref image="2000WVHO.TIF|V3|2006:09:28:01:32:04.00|121898|0"> image: </xref>

G. EFFECTS-HUMAN HEALTH

277

regarded as due to an added increase in pathogenic effect of such a mixture of dusts. Differences in the chemical nature of the dust components may necessitate a change in the limit of allowable dust concentration arrived at on the basis of the primary component alone.

AN EPIDEMIC OF POLYMER-FUME FEVER. J. Am. Med.

Assoc., 191(5): 103-106, Feb. 1, 1965. 18 refs.

An 'epidemic' of Polymer-fume fever involved 36 of 61 employees in one industry over a 90-day period. All of those involved demonstrated the classic history of an influenza-like syndrome, with fever and chills occurring several hours after exposure to the products of pyrolysis of polytetrafluoroethylene (Teflon). The majority of cases resulted from this material. A study of pulmonary function of all workers involved demonstrated changes that could be accounted for only on the basis of smoking habits. Three persons experienced changes in pulmonary function consistent with mild obstruction of airways, in association with the onset of symptoms. While no serious consequences were observed, the effect of these illnesses upon the health and productivity of the group could have been prevented. (Author Abstract)

DETERMINATION OF FLUORIDE IN BONE WITH THE

FLUORIDE ELECTRODE. Anal. Chem. (U.S.), 40(3):613-614,

March 1968. 8 refs.

Electrodes made from single-crystal sections of rare earth fluoride have been developed to measure fluoride ion activity in solution. A simple direct method for determination of fluoride in bone with the use of a fluoride ion electrode and a conventional potassium chloride electrode is rapid and accurate. Factors such as pH, ionic strength, temperature, and some other ions must be rigorously controlled in both standard and unknown solutions to obtain meaningful results. The method is applicable also to fluoride in the ash of other normal and pathological calcifications.

DEFINITION ANALYSIS OF THE HEALTH OF CHILDREN LIVING

IN THE VICINITY OF ALUMINUM WORKS. (Hlbkovy

rozbor zdravotneho stavu deti v sidlis-kac z okolia zavodu na vyrobu hlinika.) Translated from Slovak. Cesk. Hyg., 5(10):573-579, 1960. 20 refs.

Children living in a village in the vicinity of an aluminum plant and in a control village were examined for hemoglobin percentage, erythrocyte and leucocyte counts, differentiation of the blood count amount of fluorides eliminated in urine, and general state of health. In the case of the children of the affected village radiographs we also taken of the bones, and the children's teeth were examined. In the affected village the average percentage of hemoglobin was 62.85 in the 6-8-year-old group and 69.55 in the 9-11-year-old group as compared to 70.95 and 72.25 respectively in the control village. The average erythrocyte count in children of the affected village was 3,958,000 in the 6-8-year-old group and 4,208,000 in the 9-11-year old group as compared to 3,741,000 and 3,783,000 respectively in the control village. No substantial differences were found in the value of segmented and unsegmented neutrophils, eosinophiles, basophiles and the lymphocyte and monocyte counts between children of the affected village and the control village. The average level of fluorides eliminated in urine was 0.91 mg/1 in children of the affected village as compared to 0.48 mg/1 in those of the control village. Evaluation of subjective complaints and objective symptom shows no perceptible differences between children of the affected village and those

of the control village. Radiographs of bones for children of the affected village showed no changes which could be suggestive of pathological and significant fluorosis. The teeth of the children from the affected village also showed no traces of fluorosis as yet. (Authors' summary)

BEHAVIOUR OF RADIOACTIVE CERIUM FLOURIDE (144 Ce F3) IN THE LUNGS INTRODUCED INTRATRACHEALLY

((Povedenie v legkikh radioaktivnogo ftoristogo tserija (144 Ce F3) pri vrutritrakheal'nom vvedemi.)) Text in Russian. Med. Radiol. (Moscow), 5(7):65-69, 1965. 10 refs.

A colloidal solution of cerium fluoride (144 Ce F3) was introduced into the trachea of 60 chinchilla rabbits. Each rabbit, weighing about 3 kg, was administered 0.5 ml of solution transcutaneously. The solution had a radioactivity of 25 me (specific radioactivity 50 me/ml). Scanograms of the lungs were taken 15 minutes after the introduction of cerium and 4, 8, 16, 32, 60, 120 and 420 days later. Autopsies were performed at intervals and pathological and radiometric tests were made. Scanograms show that the substance gradually concentrates in the periradical zone of the lungs, with two phases of redistribution and elimination. During the 30-day, initial phase, biological lung clearing processes prevailed, while during the second phase, a certain balance between the elimination of Ce144 from the lungs and its radioactive decay was established.

EXPERIMENTAL EVALUATION OF CONCENTRATIONS OF HYDROGEN FLUORIDE DETECTED IN THE AMBIENT

AIR. ((Zksperimentalnaya otsenka kontsentratsii ftorictogo vodoroda, obnaruzhivaemkh v atmosferenom vozdukhe.)) Text in Russian. Vrachebnoe Delo No. 1:89-91, Jan. 1967. 4 refs.

The aluminum, cryolite, superphosphate and other industries which use fluorine compounds all emit NF, NaF, AIF₃, and Na₃AIF₆ into the air. Air containing fluoroine levels of 0.20, 0.10 or even 0.03 mg/cu m has a noxious effect, particularly on children, and raises their general susceptibility to illnesses, attacks their breathing system, and destroys tooth enamel. White male mice, two months old, were exposed to different levels of hydrogen fluoride around the clock for five months, except for a four-week recess. Concentrations of the 0.10, 0.03 and 0.01 mg/cu m level were administered to three groups of animals. The 0.10 concentration was found to produce a profound, generally toxic, effect Less intense but still clearly defined, were damages caused by the 0.03 concentration. The 0.01 concentration had no detrimental effect. Data from these experiments are thought to be conclusive as to the dangers to children who reside within industrial pollution zones.

FLUORINE INTAKE INCREASED IN MAN BY FOOD PRODUCTS OK ANIMAL ORIGIN. Med. Ernaehr., 6(2):30-3S, 1965. 29 refs. Translated from German by H. Warfield. National Institutes of Health, Bethesda, Md., Translating Unit, 16p., 1965.

The metabolism of fluorine is reviewed, including the tolerance of the human organism for this element. Resorption, tissue accumulation, elimination, and the pathogenetic mechanism of fluorine are included. Since fluorine-containing mineral phosphates are added to the feed given farm animals, consideration is given to whether its long-range administration can increase the fluorine concentrations of such foods as meat, milk, and eggs. Even when the fluorine doses given the animals are chronically toxic, fluorine supplements are found to be harmless to man. Toxic tolerances are mentioned.

INFRASTRUCTURE OF THE LUNGS OF DOGS EXPOSED TO BERYLLIUM-CONTAINING DUSTS. Arch. Environ. Health, 17(2): 193-203, Aug. 1968.

Two beagle dogs were exposed by the natural respiratory route to rocket exhaust fumes containing beryllium oxide, beryllium fluoride, and beryllium chloride. The lung tissue was examined electron microscopically after a three-year post-exposure period. Beryllium particles and small agglomerates less than 1 micron in size were deposited in lysosomes in the cytoplasm of histiocytes in the interstitium of the septa. They were closely associated with collagen bundles several microns wide and with increases in numbers of septal capillaries. The lesions were more typical of the classical reaction to a foreign-body than immunologic in character and represented an early form of chronic beryllium disease. (Authors' abstract)

Antonelli, G.

EFFECTS OF FLUORINE IN THE REGIONS CLOSE TO THE INDUSTRIES THAT PRODUCE IT AND ITS TOXICITY IN PROPHYLACTIC AND THERAPEUTIC USES. ((Effetti del fluoro nelle regioni prossime ad industrie die sua produzione e (ossivila di esso anche negli usi profilattici e terapeutici.)) Translated from Italian. Rass. Trimestrale di Odoontoiatria, 35(2):05-122, April-June 1954. 7 refs.

The effects of fluorine compounds on vegetation, cattle, workmen, and students in the vicinity of a fluorine processing plant were investigated. The techniques and methods used at the plant are described indicating the sources of emission. The entire vegetation found in the surrounding territory-plants and trees-were struck and damaged by the toxic gases. Varying degrees of serious effects and certain evidence of pathological disorders were observed - ranging from types of chlorosis to complete dryness due to a third degree scorching. The crop most affected was Indian corn, Cattle showed signs of organic decline with symptoms of anemia of a chronic character and irritation of the bronchial mucosae and of the main respiratory

tracts. None of the workers examined displayed signs of fluorosis. The front teeth of the workers and part of the premolars display, dark yellow-green stains. In approximately one-half of the cases the gingival mucosae showed whitish, opaque aspects with some spots slightly reddened, a moderate tumefaction and readily bleeding gums. Caries is absent in most of the subjects with eight years of exposure, and extremely rare in others. The percentage of caries was substantially lower in children in the vicinity of the plant than those of the same age group outside the district. The properties of fluorine, its pharmacology, toxicology, water toxicity, therapy, and prophylaxis are reviewed.

Miessner, H.

DAMAGE TO ANIMALS CAUSED BY INDUSTRY AND TECHNOLOGY. ((Schadigung der Tierwelt durch Industrie und Technik.)) Translated from German. Deut. Tieraerztl. Wochschr., 39, p. 340-345, 1931. 26 refs.

Pollution of the air and damage to feed plants, and the resulting diseases of humans and animals, are extremely frequent in regions where ore-processing metallurgical plants are located. The fumes being produced during roasting and melting of the ore are usually bonded to sulfur and arsenic; consequently the smoke contains considerable quantities of SO₂ and As₂O₃. This smoke most affects cattle. Acute arsenic intoxication becomes manifest in the form of vomiting and diarrhea, caustic injuries to the gastric mucosa, and fatty degeneration of the liver. In chronic cases, increasing cachexia, eczema and weakening resembling paralysis are observed. The metallic elements in the fly dust, moreover, can lead to harmful indigestion. During acute lead poisoning, stomach distress is observed, as well as spastic movements. Chronic lead intoxication leads to a general malaise combined with abortion, lead colic, muscular pain, epilepsy, and paralysis. The red blood corpuscles show a partial basophilic granulation. Hydrofluoric acid fumes from foundries and plants producing artificial fertilizers dissolve the calcium in the bones, and chronic calcium degradation and softening of the bones are the consequences. As a result of an air pollution episode in Luttich, damage by foundry smoke in fog caused hundreds of persons to fall ill and 63 to die, mostly within 1 to 2 days. Hardest hit were asthmatic and heart patients, and persons suffering from bronchitis. Copper intoxication was observed in sheep and cattle as a result of spraying orchards with lime and copper.

Babayants, R. A.

INFLUENCE OF URBAN AIR POLLUTION ON THE HEALTH OF INHABITANTS. Vestn. Akad. Nauk SSSR, 14(12):3-12, 1959. 15 refs. Translated from Russian. 15p.

A survey of the influence of air pollution in general and of several air pollutants (carbon monoxide, sulfur dioxide, fluorides, aerosols) on the health of humans in the U.S.S.R., is given. The first study dates back to 1933 and has become important primarily for the method used. The first broad study was conducted in 1948-1949 where relationship between the incidence of lung, throat and tonsil pathology and air pollution was established as 1.5 to 8.1 times higher in the polluted area than in the control area. Subsequently, a clear relationship

<xref image="2000VHQ.TIF|V3|2006:09:28:01:32:10.00|113471|0"> image: </xref>

between eye disease and air pollution could be established. A study of school children in polluted and non-polluted areas revealed that changes of the lung image were five times as common among the children in the polluted area. In later studies, catarrhs, tonsillitis, influenza and bronchitis were related to air pollution. A regional investigation conducted in Baku in 1955 revealed a correlation between bronchitis and laryngotracheitis and air pollution by aerosols. Similar results were obtained in a study in 1954-1955 in the Ukraine. A study of the influence of CO on traffic officers revealed that 68% of the officers exposed to concentrations of 25 mg CO/cu m had a carboxyhemoglobin of 11%. Tests in gas-heated apartments revealed a similar high incidence of CO intoxication. An investigation of the effects of SO₂ on animals revealed that respiratory disturbances began to develop at 2 mg/cu m. The increase of lung cancer is attributed to carcinogenic pollutants such as 3,4-benzpyrene. A higher number of persons with mottled teeth from the effects of fluorine emissions were found close to the source than at more remote distances from the source.

Demole, V., T von Fellenberg, A. J. Held, and H. Schmid
 FLUORINE, DENTAL CARIES, AND THE THYROID
 GLAND. Bull. Schweiz. Akad. Med. Wiss. vol. 7:440-462, 1951.
 8 refs. Translated from French. 31p.

Analyses of the soil, water, and plants and examinations of several groups of children between the ages of 7 and 15 with the same ethnological background in different parts of Wallis (Switzerland) showed a relationship between the environmental fluorine content and the fluorization of the hard dental tissues and their resistance to caries. In the Sembrancher area, where the drinking water contains 1.4 mg of fluorine/l, the resistance to dental caries is much higher than in children living in the vicinity of Le Chable where the fluorine content of the water is only 0.05 mg/l. Some white stains on the enamel of the children's teeth were observed in Sembrancher, but no definite relationship could be established between the high fluorine content of the water in this village. The development of the thyroid gland in children was about the same, whether they came from areas with fluorine-rich or fluorine-poor water. In the area richest in fluorine (Sembrancher), no goiters were observed in 15-year-old boys and girls who were native to the area and had drunk the water since birth. These facts permit confirmation of the existence of a biological iodine-fluorine antagonism.

Sadilova, M S.
 STUDIES IN THE STANDARDIZATION OF MAXIMUM ALLOWABLE
 HYDROGEN FLUORIDE CONCENTRATIONS IN
 THE AIR OF INHABITED AREAS. In: The Biological Effects
 and Hygienic Importance of Atmospheric Pollutants, Book 10.
 Translated from Russian by B. S. Levine, U.S.S.R. Literature on
 Air Pollution and Related Occupational Diseases, Vol. 17, pp.
 118-128, 1968. CFSTI: PB 180522T

An investigation of the levels of atmospheric fluorine found near aluminum and cryolite plants, accompanied by a survey of the health of children who live in these areas has shown that the establishment of the maximum allowable concentration of fluorine is imperative, series of tests made on human subjects and animals exposed to hydrogen fluoride yielded the following information: The odor perception threshold and the threshold of reflex action of HF in the human organism are both 0.03 mg/cu m. Five-month experimental inhalation of HF in concentrations of 0.10 and 0.03 mg/cu m produce many changes in warm-blooded animals: (a) inhibition in the central nervous system, the higher concentration leading to irreversible destructive changes in the nerve cells; (b) a change in calcium phosphate metabolism; (c) F accumulation in the bones;

and (d) histomorphological changes in teeth, bones, and internal organs. I was found that the extent of the changes varied with the HF concentration in the inhaled air. An HF concentration of 0.01 mg/cu m produced no changes in the experimental animals. Finally, the investigation showed that: (a) an HF concentration of 0.15 mg/cu m cannot be regarded as threshold of odor perceptive concentrations; (b) an HF concentration of 0.03 mg/cu m cannot be taken for the maximum allowable single-exposure concentration; (c) the maximum single-exposure concentration of HF must not exceed 0.02 mg/cu m.

METABOLISM AND PHARMACOLOGY OF INORGANIC AND FLUORINE CONTAINING COMPOUNDS. Oregon State Univ., Corvallis, Radiation Center, Contract AF 33(615)-1799, Proj. 6302, Task 630202, AMRL-TR-67-224, 91p., Aug. 1968. 47 refs. CFSTI, DDC: AD 681161

Studies were made on rats of the toxicology and chemistry of several compounds considered for deployment as oxidizers in missile propulsion: nitrogen trifluoride, tetrafluorohydrazine, chlorine trifluoride, bromine pentafluoride, and oxygen difluoride. The lethality of each agent by inhalation was determined, using an exposure chamber, as well as estimates of lethality after intraperitoneal administration. Experimental evidence suggests that the lethal effect of interhalogens is by corrosive local destruction of pulmonary surfaces, resulting in failure of gas exchange. Oxygen difluoride is thought to pass intact into the pulmonary cells where it reacts with biochemical reducing systems to ultimately cause cell death and structural failure. This agent is considered one of the most lethal of all chemicals and the development of an antidote is considered of critical importance. The nitrogen fluorides both cause intrinsically lethal levels of methemoglobin formation, but other pharmacologic activity by these compounds or their derivatives may also contribute to their toxic activity. (Author abstract modified)

Gudjonsson, S. V.

((CRYOLITE POISONING.)) Kryolitherkrankung. Text in German. *Arztliche Sachverständigen Zeitung*, 41(12):15S-1S7, Jun. 1935.

A new disease was discovered in Copenhagen, Denmark, through X-ray examinations of the workers in the cryolite plant. Cryolite is a fluorine containing mineral which is presently only mined in Greenland. Only two factories in the entire world (in Canada and Denmark) process this mineral. It is used in the production of enamel and opal glass. In aluminum fabrication it serves as catalytic agent. In an examination of 80 workers occupied with the grinding of the material it turned out that they all felt pains in their limbs and complained about lack of appetite, nausea and fatigue. They all walked with a stiff back. The X-rays showed serious deformations of the skeleton. The lungs had the appearance of those of silicosis patients. But silicic acid, the cause for silicosis, is hardly a major component of cryolite. The cause for the disease was found in the fluorine contents of the cryolite. This assumption can be verified by laboratory experiments conducted with rats, dogs, calves, pigs, and sheep. Another in-

<xref image="2000WVHR.TIF|V3|2006:09:28:01:32:14.00|118149|0"> image: </xref>

interesting observation has been made. During a volcanic eruption about 150 years ago - numerous animals and humans died. Examinations of the bones of animals which died at that time showed that they suffered from serious fluorosis. Thus not only cryolite plants but also volcanic areas can be hazardous in this respect, not to speak of aluminum and other plants.

Craste, C.

FLUORIC POISONING. (CONTINUED.) (L'intoxication fluoree.) Text in French. Rev Med Veterinaire, 103:214-221. 1952.

The toxicity of milk produced by animals struck with fluorosis or fluoridosis is difficult to ascertain. This was shown in the experiments on rats by the Wisconsin (U.S.A.) Agricultural Station (1934). Work by Thieberox on young French children in the vicinity of aluminum factories fails to determine whether their absorption of fluorine is due to their drinking of milk from affected cows or their inhalation of polluted air. Radical prophylaxy of fluorosis and fluoridosis could be achieved by suppressing the toxic emanations from the aluminum factories. These emanations pollute the neighboring agricultural establishments. Cattle struck by 'factory disease' were found as far as 25 km from five factories in the Maurienne and Gard areas. Public authorities and electrometallurgical companies are involved in the solution of the problem. Their reluctance to act may lead the public to resignation, were it not for the fact that one factory in the Alps has successfully prevented the disease in its area. But it keeps its method secret, and only the public authorities may, some day, force its disclosure. Fluoric poisoning can be cured only when caught early. The best treatment is to eliminate all toxic fodder from the animals' diet, since the origin of the 'factory disease' is exclusively of a digestive nature. To do this, the flock is moved to some unpolluted area. This treatment will result in permanent cure. Medical treatment can be considered only as complementary.

12549

Craste, C.

FLUORIDE POISONING. ((L'intoxication fluoree.)) Text in French. Rev Med Veterinaire, 103:142-148, 1952. 9 refs. Subacute and chronic forms of poisoning are, clinically and anatomopathologically, closer to each other than has been claimed. Bone lesions (marmoration, narrowing of marrow channels) cause brittleness and fractures. Dental lesions (mottled enamel of permanent teeth) are found in North America, Brazil, Argentina, North Africa. Tooth decay and gingivitis made chewing difficult, the animal wastes away and loses its value in the rural economy. Fluoridosis (sodium fluoride poisoning through water intake and calcium fluoride poisoning through vegetable intake) appears slowly in factory workers handling natural phosphates. Fluorosis, caused by hydrofluoric acid, appears suddenly in plants and animals downwind from the factory. In cryolite factories, lumbar ankylosis and muscular calcification may appear, and even kidney and liver lesions, emaciation, and cachexy. All farm animals may be subject to fluorosis. Goats and cattle are highly sensitive, horses quite resistant; poultry may also be affected. Speed of evolution depends on food toxicity, the richness and variety of the diet, and on the activity of the infection generating centers and factories. Pathology: Fluorine acts on the parenchyma, the general metabolism, and calcium metabolism. Depending on the dose of the compound, the action may be acute (toxic action with sudden decalcification) or subacute (on the parenchyma and general metabolism) or chronic (on phosphocalcium metabolism). Fluorosilicates are highly toxic. Sodium fluoride decalcifies and marmorizes the bones.

Cristiani, H. and R. Gautier

FLUORINE FROM THE VIEWPOINT OF INDUSTRIAL HYGIENE: ACTION OF FLUORINE ON ANIMALS. ((Le fluor au point de vue de ('hygiene industrielle: action du fluor sur les animaux.)) Text in French. Ann. Hygiene Publ. (n.s.), 3:210-233, 1925. 50 ret

Acute poisoning by sodium fluoride may be produced by intestinal absorption of 0.5 gr per kg of animal or by veinous absorption of 0.1 to 0.15 gr per kg of animal. Chronic cases by absorption of smaller doses also set forth. The toxicity of fluorsilicic acid seems due to its low dissociation power and high content of HF molecules. The relation between emanations from aluminum factories and the endemic sickness prevailing in the surrounding area, as described in the literature, is confirmed by the authors' experiments on a particular installation: (1) plants were damaged soon after the factory began operating; characteristic foliage lesions appeared on vine and fruit trees, and reduction of the crops coincided with the factory activity. (2) Cattle showed stiffening of the legs, loss of weight, bone fracture, cachexy, and death. Tabulated data and maps support these observations. (3) On humans, no positive conclusions are yet available. They are less affected than animals, since the latter are poisoned by feeding on damaged plants, whereas the former clean and prepare these plants before consuming them; and poisoning of humans through toxic gases is minimized by the conditions (temperature, distributioQ existing within the factory.

Firket, J.

COMPARATIVE PATHOLOGY AND AIR POLLUTION.

((Pathologic comparee et pollutions atmospheriques.)) Text in French. Congr. Intern Pathol. Com., 7th Lausanne, 26-31st May 1955. 7(2):57-80.

Air pollution factors include the chemical action of gases and vapors, the physical action of particle suspensions (aerosols), and the reaction of certain pollutants turning harmless gases into toxic ones. This report stresses the pathological aspects of air-pollution poisoning as evidenced by the fatal accidents in Belgium (1932), Donora, Pa. (1948), and London (1952), where geographical and meteorological factors helped in the formation of a fog umbrella and critical pollutant concentrations over the area. Physiological effects of certain gases and vapors in industrial atmospheres are shown in Table I. The penetration of dusts into the lungs depends upon their sizes (micronic, submicronic, submicroscopic) and on the presence of fog. The pathogenic action begins with an irritation of the respiratory mucous membranes, slow paroxystic expiration, followed by vascular collapsus, low blood pressure. Postmortem toxicological tests were negative. Fog induced asthma and emphysema have affected Belgian cattle since 1911. Goats, sheep and cattle have contracted fluorosis from fluorine and fluorine dusts discharged into the air by industry. Sheep in the vicinity of a fluorine processing plant developed dental and osseous lesions. Other aspects of 'civilization sicknesses' arise from our changing environment, the use of insecticides on vegetation, the presence of smokes, gases, fluorine in the air. The relation of air pollution to primary lung cancers is considered for certain trades and professions. Statistics seem to indicate tobacco smoke (in cigarettes) to predispose to lung cancer, without, however, determining it.

Moese, J. R., H. Brantner, and G. Fischer
AIR POLLUTION STUDIES IN THE GRAZ AREA. 3. INVESTIGATIONS OF THE CORRELATION AND MEANING OF FLUORIDE EMISSION AND FLUORIDE EXCRETION IN THE KIDNEY. (Studien über die Luftverunreinigung im Raum Graz. 3. Mitt.: Untersuchungen über Zusammenhang und Bedeutung von Fluorimmissionen und Fluorausscheidung in Harn). Text in German. Arch. Hyg., 153(2):114-118, April 1969. 7 refs. Fluoride excretion in the urine was determined in population groups living in various industrial areas of the city of Graz, Austria. A total of five groups was selected. The first group consisted of workers in a brickyard outside the residential area of Graz. The workers resided in the immediate vicinity of the brickyard. The second group included workers in this brickyard who lived in the country. The third group (control group) lived and worked outside the region of the brickyard. The fourth group included members of a shoe factory in the industrial center of Graz. The last group consisted of persons living in a nearby resort remote from any industries. The highest amount of fluoride was found in the first group, the lowest in the group from the resort town of St. Radegund. Thus, a marked correlation between fluoride excretion and the degree of air pollution could be found. The concentrations found in the fourth group were markedly higher than those in the third group, due to industrial emissions and domestic heating. In none of the groups did the concentration reach the level of acute intoxication. Nevertheless, such groups should receive special attention in such programs as caries prevention by distribution of fluoride-containing tablets.

Colombini, M., C. Mauri, R. Olivo, and G. Vivoli
EXPERIMENTS ON RABBITS FED FORAGE GROWN NEAR AN ALUMINUM FACTORY. Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 2(1):49-54, Jan. 1969. 2 refs. Skin lesions resembling bruises were exhibited by individuals living near an aluminum factory in Chizzola, Italy. To study the etiology and pathogenesis of this phenomenon, male albino rabbits were fed forage grown near the factory and forage artificially contaminated by substances collected from the factory's purification system. At regular intervals, serum alkaline phosphatase, serum calcium, serum phosphate, leucocyte alkaline phosphatase, and nonspecific esterases were determined. After about five months, the animals were killed and fragments of their tibia were analyzed for fluoride. The serum alkaline phosphatase, calcium, and phosphorous levels did not show any significant changes in the treated animals. A decrease in the leucocyte alkaline phosphatase activity of positive cells was observed. Nonspecific esterases were present in very small quantities in pseudo-eosinophils, in traces in lymphocytes, and in slightly greater amounts in monocytes. The fluoride content of the bones of treated rabbits was almost twice as high as that of control rabbits, who received forage from uncontaminated areas. (Author summary modified)

Balazova, G., P. Macuch, and A. Rippel
EFFECTS OF FLUORINE EMISSIONS ON THE LIVING ORGANISM. Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 2(1):33-36, Jan. 1969. Health parameters were measured in children living in an area near an aluminum factory. In the area near the factory, excessively high F levels were found in the air and in dust. This fact was reflected in high F levels of agricultural products. High F levels were noted in urine, hair, nails, and teeth in the child population residing in the immediate vicinity of the factory. In children living in the exposed area since birth, hemoglobin values were lower and erythrocyte values were higher than in

a control area. The average daily total F intake was calculated at 2.15 mg for the exposed children as compared with about 1 mg in the controls. (Author summary modified)

A STUDY OF THE HEALTH CONDITIONS OF THE PEOPLE LIVING AROUND AN ALUMINUM FACTORY. (Studio sulle condizioni di salute della popolazione abitante nelle vicinanze di una fabbrica di alluminio). Text in Italian. Med. Lavoro (Milan), 59(5):376-380, 1968. 4 refs.

The physical condition of children living in the area of an aluminum factory was studied. Ambient air around the factory was heavily polluted by fluorine and high concentrations of fluorine were present in the agricultural products of the region. In the children examined, absorption of fluorine by digestive and respiratory systems was approximately 2.15 mg/day. In contrast to children living considerable distances from the factory, these children showed marked increases in the fluorine content of their teeth, nails, hair, and urine. Clinical and laboratory studies indicated a moderate decrease of hemoglobin values and a slight increase of red blood cells among the affected children

Macuch, P., J. Kortus, G. Balazova, and J. Mayer
EFFECTS OF SODIUM AND HYDROGEN FLUORIDES ON THE METABOLISM OF FLUORINE, CALCIUM, AND PHOSPHORUS IN RATS. Brit. J. Ind. Med. (London), 25(2):131-135, April 1968. 23 refs.

The effects of oral sodium fluoride and inhaled hydrogen fluoride on calcium and phosphorus retention are presented. Rats given 4 mg fluoride/kg/day for eight days excreted more calcium and phosphorus and retained less than the control group. In bone ash from rats given different fluoride doses for 40 days, the calcium and phosphorus were maximal after a total dose of about 250 micrograms of fluoride/rat but fell to subnormal levels after higher doses. The calcium and phosphorus levels in bone ash from rats given 750 micrograms of fluoride/day fell with the duration of treatment. Rats exposed to 9.4 to 11.7 micrograms of hydrogen fluoride/liter air absorbed fluoride rapidly, as shown by increased urinary excretion, by changes in the tooth enamel, and by rising fluoride levels in the teeth and bones. Radiological examination, however, showed no gross changes. It was evident that fluoride under different conditions affected the metabolism of calcium and phosphorus differently and also that some calcium compounds reduce the toxicity of a high fluoride intake. Fluoride caused the same changes whether given by inhalation or in the diet. The analyses for fluorides in the first samples of urine after an exposure of only three days showed raised levels. Although in the experiment, the concentration of fluoride in the urine in different specimens were variable, the mean concentrations from the series of tests showed as increased excretion with the increased duration of exposure.

POLLUTANTS. Med. Lavoro (Milan), 60(4):267-273, 1969. 12 refs.

Bluish skin-spots occurring in women and children living in the vicinity of a fluorine-emitting aluminum factory have been attributed to a poorly understood capillary-damaging effect of fluorine. To clarify this phenomenon, a study was carried out on rats born of mothers which were injected subcutaneously for the whole pregnancy period with NaF and an extract of dust emitted from the aluminum factory at a dose of 2 mg fluorine per day. The total dose of fluorine given was 40-52 mg. No cutaneous lesions, or even an increased capillary fragility of the skin, as proved with the suction cup test were observed. In a second experiment, newborn rats were injected subcutaneously with NaF and the dust extract at a dose of 0.2 mg fluorine per day in the first 10 days of life. Again no cutaneous lesions or increased capillary fragility of the skin were observed. Studies on subacute toxicity were carried out in female mice injected subcutaneously with NaF and with the dust extract in a dose of 0.2 mg fluorine per day for 24 days. No cutaneous lesions or capillary alterations as studied in histologic preparations of the mesentery were observed. (Author summary modified)

Moese, J. R., G. Fischer, and H. Brantner
STUDIES ON AIR POLLUTION IN THE GRAZ AREA. IV.
ON THE MEANING OF INCREASED FLUORINE EXCRETION
IN THE KIDNEY AS A MEASURE OF THE
FLUORINE BURDEN OF A LARGE CITY POPULATION.

(Studien ueber die Luftverunreinigung im Raume Graz. IV. Mitt.: Ueber die Bedeutung der erhoehten Fluorausscheidung im Ham als Massstah fuer die Belastung der Grosstadtbevoelkerung durch Fluorimmissionen). Text in German. Arch. Hyg. Bakteriol. (Munich), 153(3):234-238, 1969. 4 refs.

Since fluorine discharge in the urine has been found to be a good relative measure of the fluorine concentration in the atmosphere, various selected groups of the population in and around Graz were used for continuation of earlier studies. Of the four groups, one was made up of residents of the moderately populated suburbs, one of residents of an industrial section of the city, and one of residents of a densely populated residential area. The fourth group was used as control group with its members coming from a resort town located 400 to 500 m above sea level in a forested area. The highest fluorine concentrations in the urine were found in the groups from the industrial and densely populated residential areas. Average concentrations of 0.85 plus or minus 0.015, 0.91 plus or minus 0.007 and 0.63 plus or minus 0.014 mg F ions per 1000 ml urine were found in the former group and 0.85, 0.86 and 0.81 mg F ions per 1000 ml urine in the latter group. It is striking that the values of the two groups are almost the same. This can be explained by the fact that mostly coal-fired domestic heaters were used in the residential area under study. The normal value for fluorine discharge in the urine of 1 mg per 1500 ml urine per day was exceeded slightly by the majority of persons in these two groups. Although there is no danger of acute or chronic fluorine intoxication among the population in these two areas, there is clearly a higher fluorine intake from the air. This fact should be considered in the distribution of fluorine tablets or fluorine-containing toothpaste.

Agate, John N., G. H. Bell, G. F. Boddie, R. G. Bowler, Monamy Buckell, E. A. Cheeseman, T. H. J. Douglas, H. A. Druett, Jessie Garrad, Donald Hunter, K. M. A. Perry, J. D. Richardson, and J. B. de V. Weir
INDUSTRIAL FLUOROSIS: A STUDY OF THE HAZARD TO
MAN AND ANIMALS NEAR FORT WILLIAM, SCOTLAND.
Med. Res. Council Memo. 22(1949), 131p. 192 refs.
The effects on health of fluorine escaping from an aluminum factory were studied. Fluorine concentrations in the factory

room were as high as 3.60 mg/cu m and outside the factory varied from 3-15% of the average factory room concentration, depending on the distance from the factory. It was established that chronic endemic dental fluorosis affecting both cattle and sheep occurs in the area near the aluminum factory. A substantial measure of osteodystrophia occurs in cattle grazing in this vicinity, and dental lesions are confined to animals reared on contaminated pastures. Cases of osteomalacia due to chronic fluorine intoxication was also found. Loss of milk in affected animals was severe. Volunteers from factory workers and from adults and schoolchildren living in the neighborhood were examined. The factory workers were divided into two groups; those working in the furnace room and those from other departments. The examinations covered full occupational and medical histories, complete physical examination, X-rays, and for selected individuals, a full blood count and an estimation of blood fluorine and urinary fluorine concentrations. The excretion of fluorine in the furnace-room workers ran parallel to the intensity of exposure. Some of the older workers, exposed for a number of years, showed bone changes recognized as fluorosis. Despite the bone changes, none of the workers were found to suffer clinical disability. Some degree of mottling was found in the teeth of schoolchildren, but mottling was also found in schoolchildren in an area which was far removed from the aluminum factory. Clinical examination of a number of resident in the neighborhood of the factory showed no injury to health. It was concluded that while direct exposure to fluorine does not impair the health of man and animals, fluorine emissions from the factory should be reduced. (Author summary modified)

'NEIGHBORHOOD' FLUOROSIS. Fluoride Quarterly, J. Intern. Soc. Fluoride Res., 2(4):206-213, Oct. 1969. 9 refs. Data obtained from medical examinations or medical histories established the presence of the nonskeletal phase of fluorosis 32 individuals living in areas near fertilizer factories and an iron foundry and where fluoride damage to vegetation, livestock, and to materials had been determined. The symptomatology of the disease is identical with that of the nonskeletal phase of fluorosis recorded by others in industrial fluorosis, neighborhood fluorosis, hydro fluorosis, and fluoride intoxication from long-term administration of fluoride tablets. The musculoskeletal, gastrointestinal, and respiratory systems were principally involved. Fluoride assays of hay, flydust, human tissue, and urine are presented. Ten individuals exhibited the skin lesions designated as Chozzola Maculae which were recently described in population exposed to fluoride emanations near aluminum factories in Italy. It was concluded that fluoride emissions from the factories were the source of the illness. (Author summary modified)

G. EFFECTS-HUMAN HEALTH

283

Four groups of five rats each were subjected to a diet of bread and milk for 6 months. The rats in the first group were fed 50 mg/kg sodium fluoride per day; the second group, 2 mg sodium iodide per animal; the third group, fluoride and iodide at the same time; and the fourth group received neither of these substances. The growth of rats receiving fluorine was better than that of the control group for 3 months, then slackened, and on the sixth month was less. The hair was less silky and blood marks appeared at the nostrils and on the vagina. The rats that were iodized and fluoridized had the same symptoms, but more accentuated. Iodide given alone favored growth. The teeth of fluoridized rats had uniform whiteness and marked elongation of superior incisors. The enamel presented undulated prisms and numerous Retzius brown streaks; superficial pigmentation was completely lacking. In the group receiving fluoride and iodide, the alterations were less marked; the teeth were more compact. Bones and organs were also studied, but noted modifications were not substantial.

POLLUTED AIR. ORIGIN, MEDICAL SIGNIFICANCE AND COMBATING OF POLLUTED OUTSIDE AIR. (Verontreinigde Lucht. Ontstaan, medische betekenis en bestrijding van verontreinigde buitenlucht). Assen, Van Gorcum, 1966, 214p., 339 refs. Translated from Dutch. Franklin Inst. Research Labs., Philadelphia, Pa., Science Info. Services, 27Sp., July 29, 1969. Factors affecting emissions are considered, together with trends in emissions in the Netherlands and Rotterdam. The qualitative and quantitative significance of air pollutants as potential disease agents in Rotterdam is evaluated. The maximum sulfur dioxide concentration so far recorded in Rotterdam is 1600 micron cu m; the maximum smoke concentration, 500 micron/cu m. No epidemiological significance is attributed to measured concentrations of fluorides, nitrogen dioxide, carbon monoxide, or lead. Concern is shown for the role of benzpyrene and other carcinogens in the etiology of lung cancer. Distinctions are made between acute, sub-acute, and chronic air pollution. During acute air pollution, SO₂ and smoke concentrations in Rotterdam show five-fold increases. Sub-acute pollution occurs when wind speeds drop below 2 m/sec. Chronic air pollution is present on all other days, especially in winter. Though the effects of pollution can also be categorized as chronic, acute, and sub-acute, the level of air pollution is still too weak to cause illness. Methodologies employed in determining the relationship between air pollution and human mortality and morbidity are reviewed, and hypotheses developed to describe the effects of pollution on illness and death in Rotterdam. Refinements in analytical methods are urged so that the factors influencing increased chronic non-specific lung disease mortality and lung cancer mortality can be identified. It is also suggested that emission standards be supplemented by regulations making it possible to restrict emissions when meteorological data and monitoring station readings point to certain dangers.

'NEIGHBORHOOD' FLUOROSIS. Fluoride Quart. Repts., 2(4):206-213, Oct. 1969. 9 refs.

In 32 individuals residing near fluoride-emitting fertilizer factories and an iron foundry where fluoride damage to vegetation, livestock and to materials was established, evidence of the non-skeletal phase of fluorosis is presented. The symptomatology is identical with that of the non-skeletal phase of fluorosis recorded by others in industrial fluorosis, in 'neighborhood' fluorosis, in hydrofluorosis and in fluoride intoxication from long-term administration of fluoride tablets. Principally involved are musculoskeletal, gastro-intestinal and respiratory systems. Fluoride assays of hay, flydust, food,

human tissue and urine are presented. Ten individuals exhibited the skin lesions designated as 'Chizzola Maculae' which have been described recently in populations exposed to fluoride emanations near aluminum factories in Italy. (Author's Summary)

Alpaugh, E. L., K. A. Phillippo, and H. C. Pulsifer
VENTILATION REQUIREMENTS FOR GAS-METAL-ARC
WELDING VERSUS COVERED-ELECTRODE WELDING.
Am. Ind. Hyg. Assoc. J., 29(6):551-557, Nov.-Dec. 1968. 6 refs.
Comparative tests were undertaken of the amounts of particulate and gaseous byproducts generated by gas-metal-arc welding and covered-electrode welding processes to determine if the same ventilation requirements apply to both processes. Solenoid values set for inhalation and exhalation times observed in the normal adult male were used to stimulate breathing by a plaster dummy head mounted on a movable welding head carriage. Air samples were taken concurrently inside and outside the welding helmet worn by the dummy. Samples were analyzed for iron oxide, nitrogen dioxide, ozone, fluorides, and carbon monoxide. The gas-metal-arc welding process was represented by five wire electrodes, three of which were flux-cored, and five shielding gases. A standard covered electrode was used for comparison purposes. Contaminant levels generated by the two processes were comparable, and it is concluded that more stringent regulations for either process would be unreasonable. In addition, the study offers evidence that the welding helmet is an effective barrier against the particulate and gaseous byproducts. Consequently, air samples taken adjacent to the helmet yield exaggerated exposure results in welding surveys. Contaminant concentrations are tabulated.

Schrenk, H. H.
CAUSES, CONSTITUENTS AND PHYSICAL EFFECTS OF
SMOG INVOLVED IN SPECIFIC DRAMATIC EPISODES.
Arch. Ind. Hyg. Occupational Med., 1950:189-194, 1950.
(Presented at the American Medical Association, Annual Meeting, 98th, Atlantic City, N. J., June 8, 1949.)
The Meuse Valley and Donora, Pa. air pollution episodes are discussed. A primary factor in both incidents was the unique weather conditions. In the Meuse Valley a temperature inversion and anticyclonic conditions lasted from Dec. 1 to 5, 1930, and in Donora, from Oct. 27 to 31, 1948. These prolonged periods of static air conditions allowed the accumulation of atmospheric pollutants. About 30 atmospheric constituents in the Meuse Valley were identified indirectly by visiting the plants in the area and obtaining information concerning raw materials, intermediates, gases, and fumes. The investigations showed that those particularly affected by the fog were elderly persons and asthmatic or cardiac patients. Sulfur dioxide and its oxidation products produced the injurious effects. In Donora, physicians, nurses, dentists, veterinarians, statisticians, engineers, chemists, sanitary engineers, housing experts, and meteorologists collected data pertaining to the incident. Stack gases and the general atmosphere were sampled for sulfur dioxide, chlorides, fluorides, nitrogen oxides, arsine, stibine, carbon monoxide, carbon dioxide, and oxygen. Particulate matter and soot-fall were also collected. The analysis of the information and data obtained and the correlation of clinical, environmental, and meteorologic findings are in progress.

THE BIOLOGICAL EFFECT OF RARE EARTHS. (Die biologische Wirkung von Seltenen Erden). Text in German. Zentr. Arbeitsmed. Arbeitsschutz, 16(6): 168-172, 1966. 11 refs. Photo-reproduction workers were tested with x-rays. They had been exposed to the fumes of electric arc light carbons in their jobs. Changes were found on their lungs resembling the silicosis pattern, but mostly without any clinical symptoms. Since the deposits on the lungs were essentially cerite fluorides, experiments were made with guinea pigs, who were given intratracheal injections of rare earth preparations containing cerite fluorides and alternatively cerite oxides. The animals lungs showed either nests of dust accumulation, or more diffused dust deposits, causing structural changes in the fibers locally surrounding the dust material. The type of change also depended on the duration of the experiments, some of which extended over nine months or longer. The overall conclusion was that, compared with the effects of silica dust, this rare earth dust is practically inert.

Laidlaw, S. I. A.

THE EFFECTS OF SMOKE POLLUTION ON HEALTH. J.

Inst. Fuel, vol. 36:96-99, Feb. 1954. (Presented at the Institute of Fuel, Scottish Section, Glasgow, Scotland, Oct. 15, 1953.)

The health effects of several air pollutants are discussed. One effect of a polluted atmosphere is a diminution of sunlight. This may lead to lowered vitality and lowered resistance to infection. A lack of sunlight can also cause a reduction in vitamin D production, and thus lead to rickets and carious teeth. The panaculate pollutants discussed include dust, soot, and fog. Dust has an aggravating effect on respiratory tract infections and causes certain forms of dermatitis and inflammatory conditions of the eyes and ears. It can also cause fibrosis, silicosis, and anthracosis. The long-term accumulation of soot deposit in the respiratory tract is a contributory factor to certain diseases, such as catarrh, sinusitis, and bronchitis. It may also contain traces of carcinogens such as arsenic and benzopyrene. Dust and soot are more harmful when they form nuclei for droplets of moisture and form fog. In the London fog of 1952, the death rates from bronchitis, pulmonary tuberculosis, and heart and circulatory disorders rose markedly. Several gaseous pollutants are discussed, including sulfur dioxide, fluorine, carbon monoxide, and beryllium compounds. Sulfur dioxide affects humans, animals, vegetation, and materials. Fluorine causes changes in bone structure, known as fluorosis. The effect of CO on the body is to cause anoxia. Acute and chronic lung disease and skin lesions have resulted from exposure to beryllium compounds. The possibility that air pollution may be one cause of bronchial carcinomas is also discussed.

Wallace, A. S.

MORTALITY FROM ASTHMA AND BRONCHITIS IN THE

AUCKLAND FUMES AREA. New Zealand Med. J., 56(313):242-249, June 1957. 1 ret.

Onehunga and Otahuhu lie in a part of Auckland, New Zealand, where there is heavy industry, adjacent to the heavily polluted Mangere Inlet. Residents have complained of choking or malodorous fumes. In late summer and autumn paint-staining episodes have occurred during temperature inversions, suggestive of hydrogen sulfide concentrations of about 1 ppm. The atmosphere may also contain detectable concentrations of sulfur dioxide, nitrogen dioxide, sulfuric acid mists, fluorine-containing acid mists, lead fume, and various organic compounds at any season of the year. The death rates from asthma and bronchitis for the years 1951-1955 inclusive in Onehunga and Otahuhu are compared with those from Mt. Albert, a predominantly residential area. There were more deaths

from asthma and bronchitis per 100,000 population in Onehunga and Otahuhu than in Mt Albert. The actual deaths in the fumes area exceeded those of the control area in each year separately except 1953. However, the actual numbers involved are too small for the application of tests of significance or to warrant drawing any firm conclusions. The acute paint-staining fume attacks were not associated with any apparent immediate increase in mortality from asthma or bronchitis. (Author summary modified)

Marier, J. R.

FLUORIDE RESEARCH. Science, vol. 159:1494-1495, March 29, 1968.

At the first meeting of the International Society for Fluoride Research, 32 papers dealing with dental, skeletal, cytological, diagnostic, analytical, and related factors in fluoride research were presented. Various mechanisms that may explain the anticarcinogenic effect of fluoride were discussed. It was concluded that this is due to a fluoride-induced reduction in the solubility of surface enamel apatite. Fluoride can inhibit streptococcus-induced osteolysis of alveolar bone in dental infections of pulpal origin. Chronic ingestion of alcohol may aggravate skeletal fluorosis. Crippling fluorosis has been related to the fluoride content of drinking water. The effects of aluminum lactate and aluminum sulfate in alleviating symptoms of fluorosis were studied. A daily dose of 24 mg/kg aluminum lactate reduced skeletal fluoride storage by 50%. Fluoride also caused skin lesions in the extremities and lumbosacral region. These lesions may serve as diagnostic criteria in subjects exposed to industrial fluoride emissions. Discoloration and disfiguring of vegetables were also caused by fluoride. Children in an industrial area where fluoride is emitted had decreased hemoglobin and increased erythrocyte level, with two to three times more fluoride in their teeth, fingernails, hair, and urine than children in a control area. It is recommended that research in this area continue.

Feldstein, Milton

TOXICITY OF AIR POLLUTANTS. Bay Area Air Pollution Control District, San Francisco, Calif., 20p., 1963. 70 refs. 'Oxidizing' air pollution, resulting from photochemical processes which occur in the atmosphere, is distinguished from 'classical' air pollution, the predominating features of which are the presence of sulfur dioxide, industrial dusts, and soot. The processes leading to the formation of photochemical smog are summarized, as are the meteorological, topographic, and solar energy factors influencing the intensity of photochemical smog episodes. Classical and photochemical air pollution may coexist. The principle effects of photochemical air pollution are eye irritation, vegetation damage, and visibility reduction. Other possible effects are also pointed out on health of acute or chronic exposure to photochemical smog and one or more of its specific components. The components include carbon monoxide, ozone, nitrogen oxides, lead, sulfur oxides, fluoride, beryllium, hydrogen sulfide, polynuclear hydrocarbons, and particulates.

Tsunoda, Humio

THE INFLUENCE OF AIR POLLUTION BY FLUORIDE ON

THE HUMAN HEALTH. (PART 1). (Fukkabutsu nlyoru

taikiosen to ningen no kenko (sono 1)). Text in Japanese. Kogai

To Taisaku (J. Pollution Control), 6(7):504-508, July 15, 1970.

Air pollution by fluorides has two main aspects: the fluorides are extremely toxic for plants, parts per billion being critical for most plants, and the fluorides are accumulated in plants.

Livestock feeding on them develop chronic fluorosis. To survey the air and environmental pollution caused by fluorides

around the large aluminum plant in Fukushima Prefecture, a

high volume air sampler was used. Within 1 km from the fac-

tory, 5.2-14.0 mg of fluorine per 1 cu m air was observed.

Secondly, a relative measurement by lime treated filter paper

technique was employed. The fluorine concentration in the

factory was 100 times that of the adjacent villages. A method

of airborne particulates was used to monitor the fluorine con-

centration. In the factory premises, the particulate concentra-

tion was 20 times as dense as that in villages. The fluoride pol-

lution of the soil and subterranean water was also monitored.

Among vegetables and cereals cropped in the area, some of

the green vegetables showed 10 times more fluoride content

than in plants from other areas. The inhabitants of the area

take in 4.2 mg fluorine daily, which is above the daily limit of

3.5 mg of an average Japanese. After the physical check-up of

the inhabitants, dental fluorosis, skeletal fluorosis, and crip-

pling fluorosis were found.

Balazova, G. and A. Rippel

A STUDY OF HEALTH CONDITIONS OF THE POPULA-

TION LIVING IN THE VICINITY OF AN ALUMINUM FAC-

TORY. (Studio sulle condizioni di salute della popolazione abi-

tante nelle vicinanze di una fabbrica di alluminio). Med. Lavoro

(Milan), 59(S):376-380, 1968. 4 refs. Translated from Italian.

Belov and Associates, Denver, Colo., 6p., Jan. 27, 1970.

The health conditions of children living near an aluminum fac-

tory were studied. The ambient pollution from fluorine emitted

by the factory was very high. High fluorine values were found

in the agricultural products of the areas near the factory. In

the children examined, the absorption of fluorine by the

digestive and respiratory systems was approximately 2.15

mg/day. The children showed a marked increase in the fluorine

content in their teeth, hair, nails, and urine when compared

with children living in a non-polluted area. Clinical and labora-

tory studies revealed a moderate decrease in hemoglobin

values and an increase in the red blood cell count in children

exposed to a high absorption of fluorine. When some of the

children were transferred to a non-polluted zone, the urinary

excretion of fluorine decreased by 40% after one month. It

may, therefore, be assumed that the accumulation of fluorine

is reversible. (Author summary modified)

Keplinger, M. L.

EFFECTS FROM REPEATED SHORT-TERM INHALATION

OF FLUORINE. Toxicol. Appl. Pharmacol., vol. 14:192-200,

1969. 10 refs. (Presented at the Soc. of Toxicology, 7th Annu.

Meet., Washington, D. C., 1968.)

Mice, rats, and rabbits were exposed to fluorine for 5, 15, 30,

or 60 minutes at intervals ranging from 24 hours to one week;

animals were sacrificed immediately after the last exposure, or

at 7, 14, 21, or 45 days after the last exposure. A single expo-

sure caused marked changes in the lungs and some changes in

the liver and kidneys. After four exposures to the same con-

centration, the lungs had slight changes; livers were normal.

Kidneys showed slight changes at 7 and 14 days, but were nor-

mal at 21 and 45 days. Therefore, four exposures to fluorine

caused no more damage than a single exposure to the same

concentration. Repeated exposures were made with different concentrations during each exposure. A low, apparently harmless level was used first; then 4, 24, and 96 hours later, the LC50 of fluorine was determined. The LC50's of pre-exposed animals were higher and there was less lung damage than in control animals. Exposures to a low concentration were also repeated every third day. At 1, 3, and 7 days after the last exposure the LC50's were determined. Even at 7 days the pre-exposed animals had higher LC50's and showed less lung edema than animals that were not pretreated by previous fluorine exposure. There may be some type of tolerance or protection developed by exposures to low fluorine concentrations. (Author abstract modified)

Hodge, Harold C.

EFFECT OF FLUORIDES ON MAN. J. Air Pollution Control Assoc., 20(9):615-616, Sept. 1970. 3 refs.

The transcript of a court case involving ingestion and inhalation of fluorine compounds from an aluminum factory is quoted to illustrate symptoms of subacute fluorosis. The symptoms reported include dyspepsia and thyroid enlargement. Subacute fluorosis, as described in the transcript, has recently been equated with the nonskeletal phase of fluorosis, which is characterized by symptoms relating to musculoskeletal, respiratory, and gastrointestinal symptoms. Typical of the disease is increasing general malaise and exhaustion leading to complete disability. As determined by other investigators, a relation appears to exist between the disease and fluoride exposure in patients living near a fertilizer factory and an iron foundry.

22628

Cecilioni, Victor A.

EFFECTS OF FLUORIDES ON MAN. J. Air Pollution Control Assoc., 20(9):614-615, Sept. 1970.

Issue is taken with a recent report indicating the relative immunity of man to even high levels of fluoride air pollution. Among the misleading conclusions of the articles are the contention that, with few exceptions, the health of persons living near installations emitting fluoride dusts and fumes is not adversely affected and that 10 ppm of airborne fluorides will not damage vegetation. The fact is that some persons, like some species of vegetation, are more susceptible than others to elevate atmospheric fluoride levels. Considering that many species of plants are even more susceptible than man to the effects of fluorides, other countries have suggested that the maximum allowable fluoride air level be 1 ppb or less. There can be no doubt about the cumulative nature of fluoride effects in man or animals. While true osteosclerotic changes and even crippling fluorosis require many years exposure, 'neighborhood' fluorosis is known to produce early symptoms of fluorosis involving the musculoskeletal, gastrointestinal, and respiratory systems. The hazards of occupational exposure to fluoride are well documented, as evinced by a study of a fluorspar mine, where the average dust and fluorine concentrations were about 1 ppb. Among 53 deaths over a 10-yr period, 23 were due to pulmonary cancer, 29 times the average rate.

Waldbott, George L.

EFFECTS OF FLUORIDES ON MAN. J. Air Pollution Control Assoc., 20(9):614, Sept. 1970. 12 refs.

The validity of recent air quality criteria for fluorides is questioned because the criteria were derived from standard epidemiological procedures rather than a careful evaluation of clinical data available on individual cases. It is emphasized that the adverse effects of air pollutants on man cannot be determined by epidemiological surveys. Disputed conclusions of the fluoride survey are that fluoride can be stored in soft tissue in high magnitudes and that urinary fluoride excretion is a reliable index of fluoride intake. With respect to the former, information is not yet available on the extent of functional damage to organs that have stored high values. With respect to the latter, urinary fluoride excretion varies widely from patient to patient. Other shortcomings of the survey were its failure to consider total fluoride intake and its exclusion of patients with chronic diseases and diseases known to affect the bone structure. Lastly, the authors ignored the evidence that the Meuse Valley incident was due in large part to airborne fluoride.

Tsunoda, Fumio

THE INFLUENCE OF AIR POLLUTION BY FLUORIDE ON HUMAN HEALTH. (Fukkabutsu ni yoru taiki osen to ningen no kenko). Text in Japanese. Kogai to Taisaku (J. Pollution Control), 6(8):577-582, Aug. 15, 1970. 25 refs.

The health condition of employees under the influence of atmospheric fluoride in an aluminum refinery and the health condition of neighboring residents under the influence of contaminated air from the refinery were surveyed from the viewpoint of epidemiology and clinical toxicology. The people living in the fluoride-bearing atmosphere did not have clear subjective symptoms as to skin and mucous troubles when the fluoride level was between 1.0 and 1.9 ppm. This is quite contrary to the effects of other stimulative gaseous substances like SO₂ which is particularly irritating to olfactory organs and skin. Fluoride concentration between 1.0 and 1.9 ppm may cause light obstructive trouble to the pulmonary function but not seriously. The investigation of atmospheric Ht variation and of both tooth spot trouble and osteomalacia, which are representative of chronic fluoride poisoning, has indicated that daily exposure to fluoride-bearing air did not provide any conclusive evidence as to its effect on health as long as the concentration remains between 1.0 and 1.9 ppm. Some dubious aspect in view of clinical toxicology are presented, however. As in the case of the influence of excessive fluoride intake through agricultural products, the direct effect of atmospheric fluoride on respiratory organs is a subject still to be studied.

Cumpston, A. G. and B. D. Dinman

A MODIFIED DIFFUSION METHOD FOR THE DETERMINATION OF URINARY FLUORIDE. Am. Ind. Hyg. Assoc. J., 26(5):461-464, Sept.-Oct. 1965. 7 refs.

A modified diffusion method for the determination of urinary fluoride is described. Forty-eight samples, each with a volume of 0.5 ml, were taken from the same specimen of urine, and increasing quantities of sodium fluoride were added. Twenty-four distilled water blanks were also prepared. Silver perchlorate-perchloric acid solution was added to the urine samples and the distilled water blanks. Diffusion was commenced and allowed to continue for 20 hours at 50 C. After diffusion, measured amounts of sodium fluoride were added to the aqueous extracts of the filter papers from the sample blanks, and absorbances were read on the Beckman DU spectrophotometer, using 1-cm cells. The plot of the absorbance readings was linear for values between 1 and 6 micrograms of added fluoride. Since these represent recoveries from 0.5 ml of urine, they are equivalent to values of 2 to 12 micrograms/ml,

a range that would fully meet the requirements of fluoride exposure screening in industry.

Foster, Lloyd L.
EFFECTS OF NITROGEN TRIFLUORIDE ON CARDIOVASCULAR SYSTEM OF RATS. School of Aerospace Medicine, Brooks AFB, Tex., Aerospace Medical Div., Proj. 7753, Task 7753 07, SAM-TR-70-8, 6p., Feb. 1970. 6 refs. CF-STI, DDC: AD 705045

The specific toxicologic action of nitrogen trifluoride, a potential rocket propellant on the cardiovascular system was studied by exposing rats for one minute to tracheal inhalation of the gas. These rats had a definite decrease in diastolic pressure, systolic pressure, and heart rate. Similarly, rats that prebreathe oxygen for 5 minutes before exposure had the same changes in the cardiovascular system as those breathing only NF₃. However, animals which inhaled oxygen for 5 minutes immediately after exposure to NF₃ showed a temporary increase in diastolic pressure, systolic pressure, and heart rate. It is concluded that NF₃ significantly affects the blood pressure and heart rate, and that oxygen alters some of its effects. These effects of NF₃ could possibly be attributed to the formation of methemoglobin and myocardial degeneration. Studies by other investigators suggest that contact with NF₃ may not only cause anoxemia and damage to the lungs, but harm to the erythrocytes as well. (Author abstract modified)

Call, R. A., D. A. Greenwood, and J. L. Shupe
EFFECT OF ATMOSPHERIC FLUORIDES ON MAN. (FINAL REPORT). Utah State Univ., Logan, Utah Valley Hospital, Provo, Utah State Hospital Provo, NTH, Grants S-83, S-83(C1), and S-83(C2), 71p., 1961 (?). 23 refs.

A report is presented which represents findings from studies designed to obtain information relating to the concentration of fluorides and total particulate matter in the atmosphere under known meteorological conditions in selected industrial and non-industrial areas in Utah, and to determine whether man, living in these areas, has been affected by the fluorides. Average yearly values for fluoride in impinger air samples are reported, and total particulate matter values are also given. Of the 127 human cases studied, 90 came from geographic areas known to have had elevated fluoride levels in the atmosphere and forage. Long-term ingestion of the latter produced changes characteristic of fluorosis in some animals. Analyses for fluoride, calcium, phosphorus, ash, and dry matter were made on various parts of the body. The studies indicate that the levels of fluoride to which Utah residents in these areas had been exposed are not responsible for gross or histologic changes in soft tissue or bone. Chemical and meteorological studies relating to the concentration of fluorides in the atmosphere are described. The medical studies were done on patients ranging in age from infant to 88 years old; their residence in the industrial areas ranged from 0 to 83 years. (Author summary modified)

Collings, Gilbeart H., Jr., Richard B. L. Fleming, and Roy
May

ABSORPTION AND EXCRETION OF INHALED

FLUORIDES. Arch. Ind. Hyg. Occupational Med., vol. 4:585-590, 1951. 24 refs. (Presented at the American Industrial Hygiene Association, Atlantic City, April 24-26, 1951.)

A study was undertaken to determine the response to inhaled fluorides on the part of two human subjects who had had no previous exposure to significant amounts of fluoride, and who were shown to have normal rates of fluoride excretion in the urine during periods in which they were not subjected to such exposure. As determined by the analysis of serial urine specimens, exposure to atmospheres containing either gaseous fluorides or particulate fluorides produced the same changes in the rate of the urinary excretion of fluorides over a period of time. A single exposure of eight-hour duration to approximately 3.3 mg of gaseous fluorides per cu m of air resulted in an elevation of the rate of urinary excretion of fluorides to approximately 8.1 mg per day; a similar exposure to approximately 5.0 mg of 'insoluble' fluoride dust per cu m of air resulted in an elevation to about 8.9 mg per day. In proportion to the respective atmospheric concentration, the total amount of fluoride excreted after exposure to gaseous fluorides was slightly greater than was the amount excreted after exposure to fluoride dust, but the equal rapidity of urinary changes occasioned by these two types of exposure would indicate that the two forms of fluoride are equally well absorbed by the lungs. Under conditions of usual industrial work in which 8 hours of exposure are followed by 16 hours of freedom from exposure, it is to be expected that the elevation of the rate of urinary fluoride excretion occasioned by the exposure during one work shift will have returned to normal before the next shift begins. (Author conclusions modified)

Autian, John

TOXICOLOGIC ASPECTS OF FLAMMABILITY AND COMBUSTION OF POLYMERIC MATERIALS. J. Fire Flammability, vol. 1:239-268, July 1970. 28 refs. (Presented at Polymer Conference Series, 'Introduction to Flammability and Characteristics of Polymer Materials,' University of Utah College of Engineering, June 15-20, 1970.)

The toxicity problems which may result from the burning or heating of manmade polymeric materials (plastics, elastomers, and textiles) are reviewed at length. After a general discussion of the burning of manmade materials and of toxicology in real fire situations, the effects of some of the more important thermal degradation products are summarized, including carbon monoxide; sulfur dioxide, hydrogen sulfide, hydrogen fluoride, chloride, and cyanide; aliphatic hydrocarbons, aromatic hydrocarbons, nitrogen compounds, and epoxy compounds. Toxic effects from polymer 'fumes' and from smoke are also considered. The literature on laboratory experiments on the toxicity of these products is reviewed, and the need for the development of standardized toxicity testing procedures is stressed. Three levels of toxicity testing are proposed: level I deals with 'life and death' possibilities, level II with toxic effects at sub-lethal concentrations in animals, and level III with ultimate prediction of toxicity on the basis of pertinent data about the degradation products. It is emphasized that, besides the prime attention traditionally accorded to acute toxicity, toxicity consideration must be extended to include possible health effects from lower concentrations of the gases and exposures over longer time periods now that new materials are being used for all types of items, including housing units, and with increasing air pollution from industrial process or from municipal trash incineration. An extensive introduction to toxicology is included as an appendix.

THE INFLUENCE OF INDUSTRIAL POLLUTION ON ANIMAL COMMUNITIES AND THE USE OF ANIMALS AS

BIO-INDICATORS. (Influence des pollutions industrielles sur les communautés animales et utilisation des animaux comme bioindicateurs). Air Pollution. Proc. First European Congr. Influence Air Pollution Plants Animals, Wageningen, Netherlands, 1968, p. 41-48. 9 refs. Translated from French. Belov and Associates, Denver, Colo., lip., Sept. 15, 1970.

Analyses made on blood samples from hares shot during the fall hunting season confirmed the possibility of using hares as indicators of industrial air pollution and of the presence of certain pesticides. The distribution of harmful emissions can be estimated by analyzing some elements of the erythrocytes (hemoglobin, hematocrit, and eventually globular saturation). In general, the blood values decrease with increased pollution, except in a few cases of very high SO₂ emissions. The pH of the urine varies: in cement-producing areas, it is over 7.0; in SO₂ areas, it is below 7.0. A good practical criterion is the multiplication coefficient calculated from the number of young and full-grown hares killed. For hares in an area of mixed ash and sulfur dioxide pollution, the multiplication coefficient was 30% lower than for controls. In contrast, the coefficient was higher by 35% in an area rich in cement dust. The present investigations, which covered mainly the influence of gaseous SO₂ and hydrogen fluoride, point to a decrease in the number of insects (without an actual decrease in the number of species) with increasing pollution. The differences in the taxonomic groups are not pronounced: the decrease in number is almost uniform in all categories. However, a slight increase was noted in the Phytophaga in the most polluted zone and in the Zoophaga in a less polluted zone.

Hagen, Arne R.

NEW VIEWPOINTS ON THE PHYSIOLOGY AND TOXICOLOGY OF FLUORIDES. Nor. Tannlaegeforen Tidsskr., vol. 77:469-486, 1967. 52 refs. Translated from Norwegian. National Institutes of Health, Bethesda Md., Translating Unit, 20p., Oct. 9, 1969.

The change in attitude toward fluorides with respect to their effect on human health is traced over a period of thirty years. From a point where the maximum daily dose of fluorides was established by law at 0.5 mg, medical knowledge concerning the toxicity and physiological reactions of fluorides has progressed to where therapeutic doses of up to 100 mg daily for periods of years can be administered without fear of adverse consequences. In 1963 it was reported (without confirmation) that fluorides in drinking water should increase the frequency of mongoloid births. In 1960, fluorides were reputed to have a serious effect on hormone production. In 1952 they were responsible for loss of hair and lefthandedness. Today they are used in the treatment of osteoporosis and osteogenesis imperfecta. There is mounting evidence indicating they may inhibit calcination of the aorta. The supply of fluorides, especially in childhood years, is an established necessity. Optimum quantities of fluorides create desirable conditions in the bone tissue, and from that point of view, fluoride supply is indicated for adults as well.

FLUORINE GASES IN ATMOSPHERE AS INDUSTRIAL WASTE BLAMED FOR DEATH AND CHRONIC POISONING OF DONORA AND WEBSTER, PA., INHABITANTS. Chem. Eng. News, 26(50):3692, Dec. 1948.

Circumstantial and actual proof was found of acute fluorine poisoning by the smog in the Monongahela River Valley to persons who already had chronic fluorine intoxication according to the official report of investigations of the causes of the death of 17 people in Donora, Pa., and of 3 in Webster. Besides being saturated with soot, the fog blanket also contained sulfur dioxide, carbon monoxide, and hydrofluoric acid. Analysis of blood of deceased and hospitalized victims showed 12 to 25 times the normal quantity of fluorine. Corn crops, very sensitive to fluorine, were severely damaged, and all of the vegetation north of the town was killed.

Linde, Harry W.

ESTIMATION OF SMALL AMOUNTS OF FLUORIDE IN BODY FLUIDS. Anal. Chem., 31(12):2092-2094, Dec. 1959. 10 refs.

The current use of fluorinated organic compounds in medicine makes it desirable to have a method to determine the possible formation of fluoride ion within the body from these compounds. Submicrogram amounts of fluoride ion may be estimated directly in body fluids or water by measuring their inhibitory effect on the enzymatic hydrolysis of ethyl butyrate. In blood or urine, the sensitivity is about 0.1 gamma per ml and in water about 0.1 gamma per 100 ml. The reproducibility is about 0.1 to 0.2 gamma. The procedure is useful for determining fluoride ion in the presence of compounds containing fluorine in nonlabile organic combination, as it does not require sample ashing, which might decompose these compounds. Substances which interfere with enzyme activity or which are excessively buffered will interfere with the method. (Author abstract modified)

Mohamed, Aly H.

INDUCED RECESSIVE LETHALS IN SECOND CHROMOSOMES OF DROSOPHILA MELANOGASTER BY HYDROGEN FLUORIDE. Preprint, International Union of Air Pollution Prevention Associations, lip., 1970. 13 refs. (Presented at the International Clean Air Congress, 2nd, Washington, D. C., Dec. 6-11, 1970, Paper MB-4F.)

Drosophila melanogaster, the fruit fly, males of the genotype plus b/dp plus were fumigated with hydrogen fluoride in population cages. The source of HF was a 2.5% concentration of hydrofluoric acid. The fumigation period was for a total of 12 hr, with the first treatment being for 6 hr, followed by increments of 3 hr, giving a total of three treatment durations. Control runs were always made simultaneously with treatment periods. Double distilled water was substituted for the hydrofluoric acid in the control. After each treatment period, the fumigated males, as well as the control males, were mated singly with virgin females of the tester stock Cy/Pm dp b (chromosome 2). The offspring from the crosses Pm dp plus/Pm dp plus or Pm plus b/Pm plus b were classified to determine the presence of lethal second chromosomes. The data indicated that HF was able to reduce the viability of homozygotes for all the treatments. The average viability was 26.16% while the expected normal should have been 33.3%. The differences among the three treatments indicated that HF has a cumulative effect. There was a trend toward a higher frequency of lethal and semilethal chromosomes (drastics) with an increase in treatment duration. It can be concluded that HF is a mutagenic agent. (Author abstract)

Waldbott, G. L.

CHRONIC FLUORIDE INTOXICATION DUE TO AIR POLLUTION. Preprint, International Union of Pollution Prevention Associations, 20p., 1970. 13 refs. (Presented at the International Clean Air Congress, 2nd, Washington, D. C., Dec. 6-11, 1970, Paper MB-4D.)

In view of the sparsity of data on neighborhood fluorosis, clinical observations are presented on 32 individuals afflicted with 'neighborhood' fluorosis in the pre-skeletal phase. Twenty-eight had been residing within three miles of an Ontario fertilizer factory, 3 near two Iowa fertilizer factories, and one in the vicinity of a Michigan iron foundry. In all cases characteristic fluoride damage to plants, livestock, and materials was established. General malaise and exhaustion leading to complete disability characterizes the disease. All except two boys reported pain and stiffness in the lumbar and cervical spine, with restriction of spinal movements and arthritis in other joints. Myalgia and paresthesia were complained of, as well as impaired muscular power. Bilateral migraine-like headaches were encountered in 20 of the patients, while 10 patients complained of visual disturbances. Eighteen individuals had gastrointestinal disturbances and 10 had skin lesions. Nasal and conjunctival irritation was common, and 6 patients had a history of frequent epistaxis. In the hospitalized cases, the spinal x-rays showed changes indicative of osteoarthritis. Hypercalcemia, hyperuricemia, polyuria, a rise in alkaline phosphatase, and a slight impairment of liver function were noted but were not sufficiently consistent to be attributed to chronic fluoride intoxication. A typical case report is included.

THE EFFECTS OF THE ABSORPTION OF FLUORIDE. V.

THE CHEMICAL DETERMINATION OF FLUORIDE IN HUMAN SOFT TISSUES FOLLOWING PROLONGED INGESTION OF FLUORIDE AT VARIOUS LEVELS. A.M.A.

Arch. Ind. Health, 21(4):330-332, April 1960. 2 refs.

Fluoride levels were determined in human heart, liver, lung, kidney, spleen, and aorta taken from 23 autopsies. With the exception of the aorta, no tissue had accumulated fluoride to any degree, and there was no indication of fluoride increasing with increasing concentration of fluoride in water. The levels of concentration of fluoride in the aorta correlated well with age; the concentration increased with increasing age. The increase of fluoride in the aorta with age may be associated with the increase in calcification in this tissue with advancing age.

TASKS AND PROBLEMS OF INDUSTRIAL TOXICOLOGY

FROM THE VIEWPOINT OF TECHNICAL CHEMISTRY.

(Aufgaben und Probleme der Industrietoxikologie aus der Sicht der technischen Chemie). Text in German. Chem. Tech. (Berlin), 17(1):38-41, Jan. 1, 1965.

Industrial toxicology faces two complexes of problems. The first are problems arising from the manufacture and processing of toxic raw, intermediary, and primary materials; the second

<xref image="2000WVI0.TIF|V3|2006:09:28:01:32:42.00|113727|0"> image: </xref>

complex encompasses problems which the manufacturing process poses for the biosphere. Hydrocyanic acid, tetraethyl lead, and some very toxic insecticides (organic derivatives of phosphoric acid) are examples of the first category. While industrial analytical instruments working on the principle of chemical reactions or their physical manifestations have an accuracy of around 0.1 ppm, some lexicologically dangerous chemicals require a detection accuracy of the order of 0.001 ppm which requires biochemical and biophysical detection methods. Another problem are the periodic clinical checkups of employees because in some cases toxic manifestations have appeared in the form of secondary manifestation without acute symptoms. Lack of knowledge and information complicates the setting up and enforcement of hygienic norms. Toxic emissions posing problems are industrial dusts, ash and smoke oxides of sulfur and of nitrogen, hydrocarbons, aldehydes, acids, ammonia, tars, ketones, peroxides, nitroolefines, and carbon monoxide. Catastrophies caused by smog are known from Europe as well as from North America when aerosol concentrations reached levels exceeding 2 mg/cu m as against the 100 microg/cu m level of normal industrial pollution. The London smog is as a result of high humidity characterized by a high content of sulfur trioxide in addition to sulfur dioxide, a highly irritating combination. The most toxic component of photochemical smog resulting from the action of ultraviolet irradiation on smog is peroxyacetyl nitrate which is highly toxic to humans and plants at very low concentrations. Other problems are exemplified by fluoride dusts and emanations from the manufacture of polyethylene.

Largent, Edward J.

THE METABOLISM OF FLUORIDES IN MAN. A.M.A. Arch.

Ind. Health, 21(4):318-323, April 1960. 8 refs.

The balance between the intake and output of fluoride was investigated with three healthy adults. Fluoride absorption from the alimentary tract was remarkably effective, while roughly half of the fluoride salts were excreted in the urine. Approximate balance between the intake and output of fluoride was achieved at levels ranging from 0.4 to 0.8 mg per day. When the skeleton approaches saturation with fluoride at a given level of absorption, the rate of accumulation therein diminishes progressively as the absorption at the rate continues. Excretion of fluoride in sweat was a highly significant feature of the fluoride metabolism in hot weather. In another experiment, those subjects whose intake of fluoride in drinking water had been high for long periods of time, had accumulated abnormal quantities of fluoride in their tissues. Subjects who were subjected to the inhalation of air containing hydrogen fluoride experienced a slight stinging sensation in the skin of the face and in the eyes, as well as some slight irritation of the nasal passages. A much greater excretion of fluoride in the urine was observed, but an explanation was not found for the unexpected increase in fecal elimination.

McCann, H. G.

THE EFFECTS OF THE ABSORPTION OF FLUORIDE. VH.

COMPARISON OF THE PHYSIOLOGIC AND PATHOLOGIC CHARACTERISTICS AND OF THE FLUORIDE CONTENT OF THE SKELETAL TISSUES OF TWO PERSONS OF SIMILAR EXPERIENCE, EXCEPT FOR EXPOSURE TO FLUORIDE: PART 2. THE FLUORIDE CONTENT OF THE SKELETAL TISSUES. A.M.A. Arch. Ind. Health, 21(4):336-337, April 1960.

The fluoride content was determined in selected dry, fat-free identical specimens of bone from the bodies of two human females. One of the two persons had been a continuous resident of Washington, D. C. for 25 years, during which time the fluoride content of the water had been 0.2 ppm; the other

had been a resident of Bartlett, Texas continuously for 34 years, during which time the fluoride content of the water was 8 ppm. The quantities of ash, calcium, phosphorus, magnesium, and carbon dioxide were also determined, to throw some light on the effect of the deposition of fluoride on those constituents of bone particularly concerned with calcification. The average percentage of ash in the bones of subject B was 64.91, as compared to 57.71 in those of Subject A. The calcium of subject B was elevated to 24.16% as compared to 21.72%, and the phosphorus in the same sequence was 10.55% as compared to 9.74%. Some increased calcification evidently has occurred in the skeletal tissues of subject B in association with her relatively high intake of fluoride in water. The histological, x-ray, historical, and clinical data obtained prior to death from the examination of subject B failed to reveal any skeletal abnormalities or systemic conditions of consequence to health or well-being that could be attributed to the absorption of fluoride, in spite of the fact that at autopsy the skeletal tissues showed a remarkably high fluoride content.

Tsunoda, Fumio

NEW ASPECTS OF AIR POLLUTION PROBLEMS: SPECIAL REFERENCE TO FLUORIDES. (Taiki osen mondai no arata naich: kyokumen - fukkabutsu ni yoru baai o rei ni). Text in Japanese. Igaku No Ayumi (Progr. Med.), 70(13):621-623, Sept. 1969. 2 refs.

Fluorine in air pollution mainly originates from aluminum refineries, phosphate fertilizer factories, and ceramic industries. Fluorides have a strong toxicity against plants and tend to become accumulated in them. For example, in the western mountain areas of Fukushima Prefecture, silk production has been destroyed due to damages to mulberry trees since the establishment of an aluminum refinery plant in the area. The process involves the use of $3\text{NaF}-\text{AlF}_3$. An epidemiological investigation was conducted on pollution by fluorides, and the subjects chosen for this purpose were 35 to 54-year old farm workers exposed for a long time to high concentrations of fluorides in air. The items examined were the determination of fluorine in urine, pulmonary function, existence of effects on teeth, and hardening of bones. Although it will take a long time to get any results from the investigation, it is also necessary to evaluate the effects of fluoride pollution in water, soil, and food.

Farrah, George H.

DIFFUSION METHOD FOR DETERMINATION OF URINARY FLUORIDE: RECENT DEVELOPMENTS. Am. Ind. Hyg. Assoc. J., 25(1):55-58, Jan.-Feb. 1964 13 refs. (Presented at the American Industrial Hygiene Association Annual Meeting, Cincinnati, Ohio, May 9, 1963.)

The determination of urinary fluoride, as an indication of fluoride exposure, has been greatly simplified by the microdiffusion-colorimetric technique. Problems that have been reported in the use of this method generally involve either high blanks or low recovery from standards and spiked samples.

Where highest accuracy is needed, cleaning of each diffusion dish with hot acid solution, followed by a distilled water rinse may be helpful. Random low recovery is apparently associated with poor distribution of dried caustic on the lid of the diffusion

<xref image="2000WV11.TIF|V3|2006:09:28:01:32:46.00|121296|0"> image: </xref>

sion dish, and the most satisfactory remedy has been an increase in alcoholic concentration to about 80%, and doubling of the caustic concentration to 1 N. Experience in diffusion of several duplicate sets of urine samples with sulfuric acid and with perchloric acid has shown slightly higher recoveries with the latter. However, some may prefer to use sulfuric acid because of the safety precautions generally required for the storage and handling of perchloric acid. Where maximum accuracy and precision are necessary for determinations of low microgram or fractional microgram quantities of fluoride, the lanthanum chelate of alizarin complexone is the reagent of choice. For industrial hygiene work, the zirconiumeriochrome cyanine R reagent is preferred.

Stokinger, Herbert E.

EFFECTS OF AIR POLLUTION ON ANIMALS. In: Air Pollution. Arthur C. Stern (ed.), Vol. 1, New York, Academic Press, 1962, Chapt. 9, p. 282-334. 122 refs.

Experimental investigations designed specifically to determine the effects of air pollutants on animals have been undertaken only recently, whereas field studies have been made sporadically for many years. The goal of the field studies has been to find the etiologic agent of some local affection in domestic or wild animals while the aim of the laboratory studies has been to determine whether a health hazard exists for man. Air pollution episodes and the acute effects on domestic animals and animals in captivity are discussed, as well as the chronic poisoning of livestock and wild animals. Chronic effects are confined to arsenic, lead, molybdenum and fluoride. Laboratory studies are cited on the effects of engine exhausts, the bactericidal action of oxidant smog, simulated oxidant smogs, and ultraviolet irradiated gasoline-nitrogen oxide mixtures. The acute toxicity of ozone is reviewed, including the effects of age, intermittent exposure, disease, exercise, temperature, reducing agents and drugs. Development of a tolerance to ozone is indicated. Subchronic toxicity is mentioned, as well as the characterization of ozone injury, chronic fibrosis of the lung, and ozone as a lung tumor accelerator. The effects of nitrogen dioxide, nitric oxide, and nitrogen pentoxide are discussed. Information on the toxicological effects of sulfur dioxide, ammonia, and carbon monoxide is also presented. Sulfur trioxide and sulfuric acid mists are considered, as well as oil mists. Organic vapors which are discussed include formaldehyde and its homologues, ketones, ketenes, organic hydroperoxides and peroxides, organic sulfur compounds from petroleum, and the conjugated nitro olefins. The study of toxicological interactions among various air pollutants has also demonstrated important instances of both synergism and antagonism. Effects of mixtures of particulate with gas or vapor are reviewed, as well as oil mists and oxidant gases, and beryllium sulfate mist and hydrogen fluoride vapor. Mixtures of gases and vapors which are considered include ozone and hydrogen peroxide, ozone and 100% oxygen, ozone and carbon dioxide, ozone and nitrogen dioxide, carbon monoxide and gaseous synergists, and sulfur compounds and oxidant gases.

Talvitie, N. A. and Lial W. Brewer

SEPARATION OF FLUORIDE BY ION EXCHANGE: APPLICATION TO URINE ANALYSIS. Am. Ind. Hyg. Assoc., J., 21(4):287-295, Aug. 1960. 15 refs. (Presented at the American Industrial Hygiene Assoc. Annual Meeting, 21st, Rochester, N. Y., April 25-28, 1960.)

Two ion-exchange procedures are described which provide simple, low-cost alternatives to the distillation process for the separation of fluoride from urine. The first procedure involves the elution of fluoride from hydroxide resin with hydroxide ion, the second the elution of fluoride from acetate resin with beryllium ion. The results obtained with the first procedure are

i close agreement with those obtained by distillation, while the results obtained with the second procedure are consistently higher than those for distillation. Both methods permit the simultaneous processing of a large number of samples and the attainment of an over-all rapidity of analysis. Because the second procedure has a low level of background interference, it is particularly suitable for evaluating control measures for protecting industrial populations in which the fluoride excretion level at times exceeds tenfold the normal.

Rowley, R. J. and G. H. Farrah
DIFFUSION METHOD FOR DETERMINATION OF URINARY FLUORIDE. Am. Ind. Hyg. Assoc., J., 23(4):314-318, July-Aug. 1962. 8 refs. (Presented at the Pittsburgh Conference on Analytical Chemistry and Applied Spectroscopy, Pittsburgh, Pa., March 5, 1962.)

A modified diffusion procedure is presented for analyzing urinary fluoride. No preliminary treatment is required and operator time is greatly reduced since samples can be conveniently processed in large groups. A 1 ml portion of specimen is placed in a plastic Petri dish containing a chloride fixative. The sample is acidified and the dish closed with a cover coated on the inner surface with sodium hydroxide. After diffusion for 20 hrs at 50 C, fluoride in the caustic film is colorimetrically measured by the Thorium-Alizarin Red S method or the Zirconium-Eriochrome Cyanine R method. Absorbance of fluoride against water is then determined spectrophotometrically at a wave length of 525 micrometers. Conversion to micrograms of fluoride is made by means of a corresponding calibration curve. Within the range 0-25 micrograms F/ml the precision and accuracy of this method are comparable to those of the distillation procedure. (Author abstract modified)

Boysen, John E.
HEALTH HAZARDS OF SELECTED ROCKET PROPELLANTS. Arch. Environ. Health, vol. 7:71-75, July 1963. 2 refs. Many of the present day propellants and oxidizers present unusual problems because of their high order of toxicity and the huge quantities used. The current 'concept of concurrency' also creates additional problems because design and procedural decisions must be made before the development of adequate toxicological and clinical data. Design of toxicological experiments is discussed, including the basis for threshold limit values. During the course of experimentation and clinical observation, efforts are made to determine the mechanisms of toxic stress as well as to find the early indicators of response to toxic agents. Indicators of physiological or pathological change are mentioned. Evaluation of the operational risk which is involved in the transport, storage, and firing of rocket propellants is a problem of considerable magnitude. The design of a medical program involving the use of propellants must also include periodic examinations and the treatment of casualties. Symptoms are mentioned due to exposure to unsymmetrical dimethylhydrazine, pentaborane, nitrogen tetroxide, chlorine trifluoride, perchloryl fluoride, and n-propyl nitrate.

Rosenzweig, Kurt A. and I. Abkewitz
PREVALENCE OF ENDEMIC FLUOROSIS IN ISRAEL AT
MEDIUM FLUORIDE CONCENTRATION. Public Health
Rept. (U. S.), 78(1):77-80, Jan. 1963. IS refs.
Examination of 262 children in Qiryat Haiyim, a suburb of
Haifa, Israel, revealed the presence of endemic fluorosis.
Local water contains about 0.75 ppm fluoride, the optimum
level according to the formula of Galagan and Vermillion.
Fluorosis was less prevalent and caries experience slightly but
consistently higher in both sexes and at all ages in children
who had been absent from Qiryat Haiyim for a continuous
period of at least one month, but the mean decayed, missing,
and filled teeth (DMF) of all age groups was within the limits
observed in the major cities of the country. Climatic condi-
tions which increase intake of water, as well as fluorides in
seafood and tea, may be the cause of the endemic fluorosis.
The slightly increased protection against caries does not justify
the observed amount of fluorosis. (Author conclusions
modified)

Maner, J. R., Dyson Rose, and M. Boulet
ACCUMULATION OF SKELETAL FLUORIDE AND ITS IM-
PLICATIONS. Arch. Environ. Health, 6(5):664-671, May 1963.
71 refs.
Absorption of fluoride and various effects of its accumulation
are discussed. When inorganic fluoride is ingested at any con-
centration, a portion of it is deposited in the skeletal structure
of animals or man. The amount deposited has been found to
be a fairly consistent function of the amount absorbed from
the digestive tract; however, the rate of fluoride deposition in
bone tends to decrease gradually with time. The concomitant
ingestion of multivalent cations, especially in the presence of
phosphate, promotes formation of insoluble fluoride ag-
gregates in the digestive tract, favoring fecal excretion of in-
gested fluoride. Deposition of fluoride in bones and teeth
probably occurs by means of an exchange of fluoride for
hydroxyl and bicarbonate ions at the crystal surface of bone
mineral. Incorporation of fluoride is discussed, including sur-
face exchange. Fluoride deposition occurs most intensely in
skeletal areas of high metabolic activity or great vascularity so
that cancellous bone tends to accumulate more fluoride than
does cortical bone. Incorporation of even small amounts of
fluoride into bone and tooth minerals causes a substantial
reduction in solubility, the effect is proportional to the degree
of fluoride incorporation, i.e., it is dependent on the propor-
tion of hydroxyapatite converted to the less soluble
fluoroapatite. Pathological changes in bone associated with
fluoride accumulation are discussed. Fluoride is incorporated
into teeth by the same ion-exchange mechanism involved in
bone, although the rate of migration of fluoride from the
crystal surface to the interior of the enamel is much slower.
Recommendations are presented for further research.

Carpenter, Frank G.
ANESTHETIC ACTION OF INERT AND UNREACTIVE
GASES ON INTACT ANIMALS AND ISOLATED TISSUES.
Am. JPhysiol., vol. 178:505-509, Sept. 1954. 22 refs.
To measure the depressant effect of inert gases relative to one
another, the pressure required of each to protect 50% of a
group of mice from electroshock convulsions was determined.
Twenty to thirty animals were tested at five different pres-
sures of each gas and the results plotted with respect to the
percentage protection afforded on logarithmic probability
paper. The gases included cyclopropane,
dichlorodifluoromethane, ethylene, xenon, nitrous oxide, kryp-
ton, sulfur hexafluoride, methane, argon, nitrogen, and helium.
Sciatic nerves from adult albino rats weighing 300-400 grams

were dissected, and the effect of these gases was measured by the decrease in excitability, blockade of fiber conduction, and alteration in the polarized state of the constituent fiber membrane. At consistently higher pressures six out of seven of the gases tested diminished excitability, blocked conduction, and produced significant depolarization of isolated rat peripheral nerve. The depressant action of these substances is fundamentally related to the facility with which they dissolve in olive oil or a non-polar liquid to produce a critical concentration of molecules at their site of action. The relative solubility of a gas in olive oil or a non-polar liquid is inversely proportional to its standard state fugacity. For two gases of very high molecular weight, smaller amounts were dissolved than would be predicted by this rule and the relation between the depressant action of a gas and its fugacity is not so clear. (Author summary modified)

Mangold, C. A. and R. R. Beckett
COMBINED OCCUPATIONAL EXPOSURE OF SILVER
BRAZERS TO CADMIUM OXIDE, NITROGEN DIOXIDE
AND FLUORIDES AT A NAVAL SHIPYARD. Am. Ind. Hyg.
Assoc. J., 32(2):115-118, Feb. 1971. 15 refs. (Presented at the
American Industrial Hygiene Association, Annual Meeting, Bre-
merton, Wash., Oct. 2-3, 1969.)

Silver brazers at the Puget Sound Naval Shipyard are chroni-
cally exposed to cadmium oxide fume, nitrogen dioxide gas,
and fluorides during the assembly of copper, or copper alloy
piping aboard ships under construction and repair, and in the
pipe shop. Physiological effects of exposures to the toxic
gases and fumes produced by silver brazing are cited. While
the intermittent peak exposures occurring during the heating
cycle often are above the current Threshold Limit Values, the
time-weighted average exposure do not exceed the combined
threshold limits calculated on the basis of additive effects. The
combined occupational exposures to CdO, NO₂, and fluorides
may occur during an acute exposure, but most likely the ef-
fects are due to nitrogen dioxide, since most of the solders in
use do not contain cadmium. Since both cadmium oxide fume
and nitrogen dioxide gas produce a delayed pulmonary
response, acute inhalation cases involving silver brazers might
be attributed to cadmium oxide fume, when nitrogen dioxide is
the cause. (Author abstract modified)

Stokinger, H E.
TOXICOLOGY OF CHEMICAL AIR POLLUTANTS. Chem.
Can., 5(1):23-26, 36, 44, Jan. 1953. 37 refs.
A brief summary of available semi-quantitative information on
the major group constituents of industrial atmospheres, con-
centration of metallic elements in urban atmospheres, and con-
centrations of elements by type of urban district is presented
in table form. Distinct seasonal variations are noted. Bodily in-
take of solid particles (and possibly of oil droplets as well) is
affected primarily by particle size, especially for insoluble par-
ticles, whereas solubility governs the amount of gases and
vapors retained in the body. The volume of air inhaled is af-
fected by type of physical activity. Once inhaled, the behavior
of inorganic substances in the body depends on whether the
metal salts remain in solution in ionic dimensions, or whether
they precipitate to colloidal forms. The former are distributed
<xref image="2000WVI3.TIF|V3|2006:09:28:01:32:50.00|119420|0"> image: </xref>

uniformly to all body tissues and then are uniformly deposited in bone; the latter are entrained to certain organs (e.g., liver, spleen) or deposited in bone in spotty distribution. The toxicologic effects of certain chemical air pollutants are reviewed sulfur dioxide, sulfur trioxide, hydrogen fluoride, and sulfuric acid mist; arsenic and arsine; smog ingredients; beryllium; cadmium; and fluorine and its compounds.

Stokinger, Herbert E.

AIR POLLUTION AND THE PARTICLE SIZE-TOXICITY

PROBLEM--1. Nucleonics, 5(6):50-62, Dec. 1949. 15 refs.

Industrial air pollution problems are discussed in the context of community air pollution and in-plant pollution. Special attention is given to airborne beryllium concentrations producing clinical disease within a 1/4 mi radius of a beryllium plant, to recent developments in identifying toxic agents in plants, and to particle characteristics responsible for toxic hazards. Cases of beryllium poisoning, some fatal, were caused by environmental beryllium concentrations as low as 0.1-0.01 microgram/cu m air. The toxicity of various grades of beryllium oxides increases with increased surface area, which is associated with increased solubility but not necessarily with particle size. Industrial beryllium poisoning is enhanced by hydrogen fluoride and physical exercise though, unlike silicosis, not by tuberculosis. Two major sites of possible radiation injury from long-term inhalation of uranium dust in very low concentrations are the lungs, from accumulation of insoluble uranium compounds, and bones, chiefly through accumulation of soluble uranium compounds. Lung retention of the insoluble dusts is greatly influenced by particle size.

FLUORIDES AND HUMAN HEALTH. (Fluoride und menschliche Gesundheit). Text in German. Oeffentl. Gesundheitswesen (Stuttgart), 33(3):173-182, 1971. 3 refs.

Fluorides present in atmospheric dust and gases are an important health hazard, since fluoride ions are almost completely retained in the lung. The world consumption of calcium fluoride (for steel production and other purposes) amounts to more than 2 million tons per year. Several times 200,000 tons of CaF₂ are produced in the United States alone. Since long-term exposure to high fluorine concentrations is harmful, elimination by the body is of importance. Fluorides are eliminated by the feces, urine, sweat, and in small quantities by skin. Most of the fluorine is discharged with the urine. A long-term intake of more than 2 to 8 mg/day fluoride causes abnormal density of bones.

AN EPIDEMIOLOGICAL SURVEY ON THE HUMAN EFFECTS OF FLUORIDE AIR POLLUTION IN KITAKATA, FUKUSHIMA PREF. IN JAPAN. (Fukkabutsu ni yoru taiki

osen no seitai ni oyobosu eikyo ni tsuite no ekigaku chosa. Kitakata-shi no baai). Text in Japanese. Taiki Osen Kenkyu (J. Japan Soc. Air Pollution), 5(1): 145, 1970. (Proceedings of the Japan Society of Air Pollution, Annual Meeting, 11th, 1970.)

An epidemiological study was conducted on the relationship between contamination of air by fluorides emitted from an aluminum refining factory and the health of adults permanently residing in the area. The subjects were residents, aged 35-64 yrs, in the polluted village and of a control village. Subjective

symptoms of fluoride poisoning, bone x-rays, cardiac and pulmonary functions, blood characteristics, and fluoride content of urine were studied. 'Discomfort' was obviously more frequent among men and women of the polluted area, but there was little difference between the two villages with respect to irritation of skin and eyes and pain in the joints. Results of pulmonary and cardiac function tests were also similar. Bone x-rays showed that osteosclerosis was relatively more frequent in the polluted area only for knee joints. As far as blood characteristics were concerned, there were no abnormal findings in either village. Urine fluoride levels were higher among men in the polluted area, but the concentrations were ion concentrations and the measurements were made only over a short period. Thus no conclusive statements could be made as to the effects of fluorine on the urine of the residents.

Osaka Prefecture (Japan), Suitd Public Health Center
REPORT ON THE SURVEY ON EFFECTS OF POLLUTION
OF LIVING ENVIRONMENT- SURVEY OF POLLUTION
FROM MORITA CHEMICAL CO., LTD. IN SOUTHERN
SUITA CITY. (Seikatsu kankyo osen eikyo chosa hokoku -
minami fukitu chiku ni okeru morita kagaku kogyo kabushiki
kaishi kogai ni kansuru jintai eikyo chosa). Text in Japanese.
48p, July 1970.

On Aug. 27, 1969, a newspaper reported that about 18 hectares of paddy field rice died because of the effect of hydrogen fluoride in the neighborhood of a chemical company. An investigation revealed that large amounts of HF were emitted during a power failure on the night of July 3, 1969. The chemical company's major products are hydrofluoric acid and aluminum fluoride. Damage to farm land, agricultural products, trees, and tin-plated iron sheet roofing from HF was repeated yearly despite the expansion of production at the factory and their efforts to improve the situation. Between September 1960 and October 1967 there were 15 disputed cases between the residents and the factory. The maximum fluorine concentration detected was 0.059 mg/cu m and the average concentration was 0.016 mg/cu m in the plot next to the factory. A medical survey showed symptoms such as cough, phlegm, nausea, and throat irritation in people who stayed home. The same sort of respiratory disturbances were observed in the other similar areas. Fifty-nine percent of the people were over 40 years old. No clear-cut effects were observed ophthalmologically and otorlaryngologically. Among infants, a high ratio of reddish pharynx and an abnormal respiratory sound were observed. It was contended that at present concentrations there are no immediate and serious effects anticipated, but since the pollution is expected to continue in the future, immediate steps should be taken.

G. EFFECTS-HUMAN HEALTH

293

average values in the air were 1186.2 micrograms of fluoride in A area and 39.7 in B area. Tests were carried out on the existence of subjective symptoms. The medical history of fractures, mottled enamel, and swelling of the thyroid gland, bone radiography, electrocardiogram, lung ventilative function, the determinations of serum transaminase alkaline phosphatase, calcium, inorganic phosphorus, hematocrit value and the quantity of hemoglobin, urinary protein, urobilinogen, sugar, and the quantity of fluorine in urine. These results were studied by area, sex, the number of years of residence, profession, and the lexicological effects. Excess intake of fluoride was not found to cause harm either in groups or in individuals. But the averages of the quantity of fluorine in urine were 0.88 ppm (male) and 0.70 ppm (female) in A area; both males and females were 0.47 ppm, in B area; this is the only point which differed for the two areas. X-ray investigation showed fair numbers of osteosclerosis, but these were not certified to have resulted from fluorine.

American Industrial Hygiene Assoc., Detroit Mich.,
Biochemical Assay Committee

BIOLOGICAL MONITORING GUIDES. FLUORIDES. Am.

Ind. Hyg. Assoc. J., 32(4):274-279, April 1971. 26 refs.

The nature of industrial exposures to fluorides is indicated and the metabolic fate of fluoride absorbed by the worker is briefly reviewed. Industrial exposure to these compounds may be assessed by measurement of the urinary excretion of fluoride, and urinary levels encountered in personnel in several fluoride-using industries are reported. Such data can be of use in arriving at approximations of the magnitude of exposure of a work force, and to indicate whether or not deleterious effects may be produced. The long term hazard to be protected against in the course of industrial exposure to fluorides is the development of crippling fluorosis. If early osteosclerosis as evidenced by increased density to x-rays can be avoided, crippling fluorosis will not be seen. Urinary fluoride concentrations not exceeding 5 mg/liter in before-shift, spot samples taken after two days off work are not associated with osteosclerosis, and such changes are unlikely at urinary levels of 5 to 8 mg/liter. STUDIES OF THE INHALATION TOXICITY OF THE
FLUORINE DERIVATIVES OF THE METHANE, ETHANE

AND CYCLOBUTANE. (Untersuchungen ueber die Inhalationstoxizitaet von Fluorderivaten des Methan, Aethan und Cyclobutan). Text in German. Zbl. Arbeitsmed., 21(5): 149-156, 1971. 10 refs.

Acute and chronic inhalation tests were performed on rats, guinea pigs, cats, and beagles with chlorotrifluoromethane (CClF₃), chlorodifluoromethane (CHClF₂), bromochlorodifluoromethane (CBrClF₂), 1-chloro-1, 1-2,2,2-pentafluoroethane (CClF₂-CF₃), carbon fluoride (C₄F₈), and dichlorofluoromethane (CHCl₂F). The acute inhalation tests (one exposure for two hours) on rats and guinea pigs showed that CClF₃, CClF₂-CF₃, and C₄F₈ caused no injuries even when a dose of 60% by volume was inhaled. Chlorodifluoromethane caused no injuries in rats to a concentration of 2.5% by volume and in guinea pigs to five percent. The limit concentration for CBrClF₂ was five percent by volume for rats and 10% for guinea pigs. For CHCl₂F, the limit concentration was one percent by volume. In the chronic experiments, the animals were exposed to the fluorine derivative/air mixture five days a week for three and one half hours per day. The experiments lasted four weeks. The total inhalation time was 70 hours. The concentrations ranged from 20% by volume for CClF₃, CClF₂-CF₃, and C₄F₈ to between 2.5 and 7.5% by volume for CBrClF₂. With the exception of

CHCl₂F and CBrClF₂, no injuries were caused by the fluorine derivatives. None of the derivatives attacked the respiratory tract.

THE INFLUENCES OF ATMOSPHERIC FLUORIC FLUORIDE POLLUTION UPON THE SKELETAL DEVELOPMENT OF SCHOOL CHILDREN. (Fukkabutsu no yoru

taikiosen ga gakudo no kotsu seijuku ni oyobosu eikyo). Text in Japanese. Fukushima Igaku Zasshi (Fukushima Med. J.), 18(5-6): 185-189, Dec. 1968. 16 refs.

In K city, Fukushima Prefecture, the skeletal development of 506 boys and girls in the 5th, 6th, 8th, and 9th grades was examined by x-rays of their right arms. A region within two km from the aluminum refinery, polluted with fluoride (three to five ppb fluoride and 100 to 230 kg/sq km/month fluorine per atmospheric dust fall), and a town only slightly polluted by fluoride located six km away from the refinery were studied. The x-rays were classified according to the standard of the skeletal development determined by Greulich and Pyle. Comparative studies on region, sex, and school year were also done. Children in the polluted area were found a little behind in the development of carpal bones in the 5th and 6th grade and metacarpal and digital phalanx bones in the 6th grade. Low levels of fluorine in the air promote the skeletal development of 8 - 12 year old school children; however, in this study, such a tendency was not found. Such a tendency was found however, in the girls in the 8th and 9th grade in the junior high school in the polluted area. Thus, if fluorine had an influence upon the skeletal development, the influence is greater upon the smaller children, and varies according to the individual child. There was only a slight difference between the polluted area and non-polluted area. Therefore, pollution in this area does not have a serious influence upon the skeletal development of children.

Gerdes, Raymond A., James D. Smith, and Howard G. Applegate

THE EFFECTS OF ATMOSPHERIC HYDROGEN FLUORIDE UPON DROSOPHILA MELANOGASTER - H. FECUNDITY, HATCHABILITY, AND FERTILITY. Atmos. Environ. (London), 5(3):117-122, March 1971. 2 refs.

Two strains of *Drosophila melanogaster* were treated with sub-lethal levels of gaseous hydrogen fluoride for six weeks. Egg samples were collected at various times for hatchability determinations. Adults reared from these samples were evaluated for fecundity and fertility. Treatment with HF caused a marked reduction in hatchability and fecundity in the more sensitive strain. Male fertility was depressed, but female fertility remained stable over the test period. The reduction of these parameters in the offspring of populations subjected to low levels of atmospheric HF pollution for prolonged periods suggests that HF causes genetic damage. THE EFFECTS OF ATMOSPHERIC HYDROGEN FLUORIDE
UPON DROSOPHILA MELANOGASTER -1. DIFFERENTIAL
GENOTYPIC RESPONSE. Atmos. Environ. (London), S(3):113-
116, March 1971. 4 refs.

Four inbred lines of *Drosophila melanogaster* were exposed to various concentrations of gaseous hydrogen fluoride for a period of six weeks. At all treatment levels the populations responded similarly during the first 12 hours with few deaths occurring. However, during the second 12 hours it was apparent that the 5.5 ppm HF level was harmful. By the end of the third day all flies subjected to this treatment were dead. At 4.2 ppm a definite difference in the response of the different strains existed. A different mechanism is involved with the three reduced concentrations than that displayed at 5.5 ppm. At the higher concentration a directly deleterious effect is noted, while at the reduced levels a genetic effect is indicated by the different genotypic responses. The effects on viability were predominantly linear with respect to fluoride concentration over the ranges tested. The differential responses of the inbred lines were interpreted to mean that tolerance to fluoride contamination is influenced by genotype. (Author abstract modified)

Fournier, P.

AIR POLLUTION AND ITS ROLE IN RESPIRATORY
PATHOLOGY. (Les pollutions atmospheriques et leur role en
pathologic respiratoire). Text in French. Sem. Then, 47(4):395-
398, April 1971.

The sources of air pollution are manifold: fumes from domestic and industrial combustion, industrial residues, exhaust gases from automotive vehicles, dust generated by road traffic, and the always present dust particles created by erosion and disintegration of animal and vegetable organic matter. It is estimated that in the city area of Paris, 50% of air pollutants emanate from home heating, 25% from industrial waste, and 25% from automobile exhaust gases. Chemically, the most analyzed pollutants are mineral and organic dust varieties, gases and vapors, particularly sulfur dioxide, nitric oxide, fluorine compounds, ozone, and aromatic hydrocarbons. Also mentioned should be, from the point of view of noxiousness, atmospheric allergens, bacteria, viruses, and fungi, all of which can affect the human broncho-pulmonary system. Symptoms of the effect of inhaling gaseous pollutants in substantial concentration can be, in the lung area, edemata, hemorrhages, distention and rupture of alveoli; in the bronchial area, erosion of the epithelium, edema, and hemorrhage. Prolonged inhalation of air containing gaseous pollutants in lesser concentrations can induce progressive sclerosis of the alveolic walls and ensuing development of emphysema, bronchial lesions causing dilatation or spasms, and hypersecretion of mucus. The effect of the weather in the Meuse valley in 1930, and in Donora, U.S.A., in 1948 is mentioned; both are industrial areas located in valleys where, due to a temperature inversion with extended absence of wind, extremely high concentrations of pollutants, particularly sulfur dioxide, accumulated. Forty-three percent of the population of Donora was afflicted by respiratory troubles; in the Meuse valley, the number of deaths attributed to this occurrence was ten times the statistical average of the preceding years.

TOXIC HAZARDS RESEARCH UNIT ANNUAL TECHNICAL
REPORT: 1970. SysteMed Corp., Dayton, Ohio, AF Contract
F33615-70-C-1046, Proj. 6302, Task 01, Rept. AMRL-TR-70-77,
SysteMed Rept. W-70005, 87p., Aug. 1970. 51 refs. NTIS, DDC:
AD 714694

The activities of the Toxic Hazards Research Unit for the

period of June 1969 through May 1970 are reviewed. Modifications of the animal exposure facilities are discussed including the installation of an automatic weighing system in each Thomas Dome. Acute toxicity experiments were conducted on beta cloth glass fiber dust, chlorinetrifluoride (ClF3), oxygen difluoride, and hydrogen fluoride. There was no evidence of irritation from the beta cloth dust; histopathologic examination of the nasal passages and respiratory airways failed to show any differences between the exposed and the control animals. Lacrimation, salivation, dyspnea, and rhinorrhea were the common symptoms seen in rats and mice exposed to ClF3. Lethal concentrations produced massive alveolar and interstitial hemorrhage. Animals exposed to near lethal concentrations showed congestion, edema, hemorrhage, and emphysema. The signs of HF toxicity were similar to those seen in ClF3 exposures. Massive lung hemorrhage and edema were the characteristic findings in those animals that died during exposure to HF. Respiratory distress was seen in rodents exposed to OF2; in dogs and monkeys, gagging and emesis occurred. All animals that died had lung congestion, edema, and hemorrhage. Subacute toxicity studies were conducted on Freon 113 and methylisobutylketone. The changes observed in animals exposed to Freon 113 were all minimal; there were no signs of toxic response to methylisobutylketone. The interim results of chronic toxicity experiments on monomethylhydrazine are also discussed.

Brantner, H.

THE PROBLEM OF CARIES PROPHYLAXIS IN AREAS OF HIGHER FLUORINE EMISSIONS. (Zur Problematik der Kariesprophylaxe in Gebieten mit erhoehten Fluorimmissionen). Text in German. Oeffentl. Gesundheitswesen (Stuttgart), 33(6):360-363, June, 1971. 24 refs.

The fluorine excretion with the urine of persons exposed to higher fluorine emissions was determined and compared to a control group living in a non-industrial section of the city of Graz. The fluorine excretion/1000 ml urine was used as relative value. The fluorine contents were first determined by spectrophotometry and later with an ion specific electrode. Since fluorine is not only emitted by industrial coal-fired furnaces, but also by domestic heaters, the residential areas were later included in the study. The fluorine excretion with the urine was proportional to the fluorine concentration of the atmosphere. In heavily polluted areas the excretion was significantly higher than in the control group. Therefore, it seems advisable for future caries prevention programs to consider the fluoride content of the air as well as that of the water.

HEALTH PERILS DUE TO AIR POLLUTION. (Gesundheit-sgefaehrdung durch Verunreinigung der Luft). Text in German. Atomwirtschaft, 16(6):288-293, June 1971. (Presented at the Reaktortagung Kern technischen Gesellschaft in Deutschen atomforum, Bonn, West Germany, March 30-April 2, 1971.)

<xref image="2000WVI6.TIF|V3|2006:09:28:01:33:02.00|114891|0"> image: </xref>

Health risks through air pollution are discussed by means of specific examples. Emissions emanating from large industries are of limited importance only, since they effect merely the closer vicinity of the source of emission. Furthermore, the typical composition of pollutants is known for each of these industries, and their health risks can be evaluated and combated individually. More reason for concern are emissions originating ubiquitously from all processes of incineration. Domestic heating, automobile engines, and a multiplicity of smaller industries produce a variety of air pollutants such as carbon monoxide, soot, polycyclic hydrocarbons, sulfur dioxide, lead compounds, and gaseous hydrochloric acid which arises in the incineration of polyvinyl compounds. Lead from automobile exhausts and fluorine compounds from aluminum works can be absorbed by food plants, and thus indirectly cause damage to the human organism. Sulfur dioxide and some hydrocarbons can attack the human respiratory tract and the lung. Dust in the air absorbs part of the ultraviolet radiation from the sun which is vital for some biological functions, for instance, the body development of children. Rickets, and affliction of the growing bone structure, and retardation in the growth of children can be ascribed to a lack of ultraviolet radiation. Carbon monoxide, when inhaled, combines with the hemoglobin of the blood to which it has a 200 time greater affinity than oxygen, and thus impedes the function of the blood in transporting oxygen.

EFFECTS OF THE PRESENCE OF FLUORINE IN AREAS IN THE VICINITY OF PLANTS WHERE IT IS PRODUCED, AND ITS TOXICITY WHEN USED FOR PROPHYLAXIS AND MEDICAL TREATMENT. (Effetti del fluoro nelle region!

prossime ad Industrie di sua produzione e tossicita di esso anche negli usi profilattici a terapeutici). Text in Italian. *Rass. Trimestrale di Odontoiatria*, 35(2):95-123, April-June, 1954. 7 refs.

With a view to investigating the effects of fluorine exposure on the development of caries in teeth, a study was made of a hydrofluoric acid plant which uses a reaction between fluor spar and sulfuric acid. The tests conducted consisted of measuring the fluorine content and pH of watercourses in the area, toxic action on plant and animal life, effect on caries formation with plant employees and area school children, and occupational illnesses traceable to fluorine. Suggestions are given for the treatment and prophylaxis of fluorine poisoning and the proper pharmacological use of fluorine products, especially in the topical application of sodium fluoride as a means of preventing dental caries. The normal fluorine content of the teeth is 0.6%, as compared with 0.1% for the bones. The normal topical application of sodium fluoride, which consists of two cc of a two percent solution of the salt, can be considered to have negligible toxicologic effects, since even the entire maximum dosage per treatment of 40 mg NaF, assuming it were at diluted by saliva and mouth rinsings, would be insufficient to cause damage to the tissues.

ANALYSIS OF ANIMAL EXPERIMENTS ON THE RETENTION AND ELIMINATION OF CALCIUM FLUORIDE IN THE LUNG (CONTRIBUTION TO FLUORSPAR PNEUMOCOCONIOSIS). (Tierexperimentelle Untersuchungen an der Lunge zur Frage der Retention und Elimination von Calciumfluorid (Beitrag zur Pneumokoniose der Flussspatarbeiter)). Text in German. *Beitr. Silikose-Forsch. (Pneumokoniose)*, 22(4):193-235, 1970. 112 refs.

Experiments were conducted to give quantitative values of calcium fluoride lymph transport from the lung. According to its cytopathogenic effect in pattern experiments, CaF₂ was expected to show an increased evacuation effect on the

lymphatics. The results of fluoranalysis showed no direct influence of CaF₂ on the acute course of fluorspar pneumoconiosis. During the phase of CaF₂ inhalation, analysis indicated a marked decrease of retention and, histologically, an interstitial pneumonia and lymphadenitis. When another inhalation followed CaF₂ inhalation, elimination of CaF₂ increased and evacuation of quartz particles in the lymphatics was limited. The inflammation of the lung tissue caused by CaF₂ increased the effect of quartz. Quartz increased the penetration of CaF₂ into the pulmonary interstitium, where mixed dust granulomas were formed. The evacuation of quartz particles by the lymphatics was diminished by CaF₂. Silicon dioxide could then develop its damaging effects since it was only eliminated from the lung by the bronchial tree to an insignificant degree; this was an especially decisive point in acute fluorspar pneumoconiosis.
