Controlling sound to make buildings more functional, productive and comfortable

CLICK ANYWHERE on THIS PAGE to RETURN to SOUNDPROOFING MATERIAL PROPERTIES at InspectApedia.com

Acoustical Assemblies

Acoustical design can be one of the most complex facets of architecture and construction. Depending on the purpose of a building or room, primary acoustical requirements could include sound control between spaces, sound control within a space, or listening efficiency in meeting rooms and auditoriums. Just as technical challenges can vary widely from space to space, so, too, do the choices of materials and design details that can meet them. Thoroughly exploring these options requires time and effort. However, this investment can yield important benefits – happier tenants, higher property values, reduced turnovers and vacancies, and greater productivity – that clients will value just as highly as they do the allure of your design.

Making Sound Choices

User's Guide

This brochure provides:

- Comprehensive information about strategies for enhancing acoustics and sound control
- Guidelines for selecting USG products and systems to meet acoustical needs in a range of applications
- Technical information and test data for featured products and systems

3 USG Acoustical Assemblies

Overview

Acoustics affect critical aspects of a building's function, from productivity in office settings and performance quality in theaters and auditoriums, to the price an apartment, condominium or single-family house can command. Understanding how to select a combination of building materials, system designs and construction technologies that will provide the most appropriate sound control is key to creating a successful acoustical design.

While the science behind sound is well understood, using that science to create the desired acoustical quality within a building or room is complex. No single acoustical "solution" can be universally applied to all designs. Each environment features unique parameters the architect and designer must consider when developing floor plans, selecting materials and designing assemblies. Virtually every material—from furniture and wall and floor coverings to computer equipment—will affect sound to some degree. However, designing wall partitions, ceiling systems and floor/ceiling assemblies for the distinct qualities of a space will achieve the most effective sound control.

Sound is defined as a vibration in an elastic medium, that is, any material (air, water, physical object) that returns to its normal state after being deflected by an outside force such as a sound vibration. The more elastic a substance, the better it can conduct sound. Lead, for instance, is very inelastic and therefore a poor sound conductor. Steel, on the other hand, is highly elastic, making it an excellent conductor of sound.

Sound travels not only in a straight path from its source but also bounces off partitions, bends around barriers and squeezes through small openings, all of which can allow noise to reach surprisingly far beyond its point of origin. Designers must consider the dynamics of sound when determining how they will control noise within a building.

Definitions

Pitch	The oscillation rate of a sound wave, which travels as a small pressure change alternating above and below the static
	(at rest) state of the conducting material. Each cycle of compression and re-expansion is a wave. The number of
	waves occurring per second is the frequency, which is measured as hertz (Hz); one Hz equals one cycle per second.
	A sound's pitch rises as its frequency increases. The human ear can discern sounds ranging from approximately
	20 Hz to 20,000 Hz. Human speech ranges between 125 Hz and 4,000 Hz.
Reflection	The bouncing of sound waves off any hard, smooth wall, ceiling or floor surface, making them audible beyond the
	immediate area of the source. The shape of surfaces also affects where sound may travel. Concave surfaces
	concentrate or focus sound, while convex surfaces can disperse sound in multiple directions.
Reverberation	Sound that persists in an enclosed space by reflecting off surfaces in the room.
Sound Masking	A carefully engineered sound spectrum similar to that of softly blowing air, which is amplified through speakers to raise
	the ambient sound level, "masking" conversations and background noise. In enclosed rooms, sound masking increases
	speech privacy by lowering the articulation index, preventing conversations from being overheard.
Sound Transmission Class (STC)	Measurement of the ability of a wall or floor assembly to isolate airborne sound and prevent it from passing from one side to the other.
Transmission	The passage of sound waves from its source, through a vibrating medium, and to a listener. "Airborne sound" passes
	through a space by vibrating the air. "Structure-borne sound" travels through wall partitions, ceilings and floor/ceiling assemblies.
Volume	The loudness of a sound—how much the amplitude of a sound wave exceeds the static pressure of the conducting medium as measured in desibels (d). The higher the desibel lovel the greater the volume. Noise from a jot plane
	medium—as measured in decibels (dB). The higher the decibel level, the greater the volume. Noise from a jet plane has an amplitude of 140 dB, while a human whisper is approximately 20 dB. Sound in a typical office environment reaches 40 dB to 60 dB. Volume doubles with each 10 dB increase in sound energy.

Components

	Acoustically-rated syst	ems have been comprehensively tested for sound			
	control. Substitution of	control. Substitution of any components is not recommended or			
	supported by USG. Re	efer to the material safety data sheet for each			
	product for complete 1	health and safety information.			
eilings	USG Acoustical Ceiling Panels				
	- Available with high NRC, CAC, and c	combination NRC/CAC ratings			
	 Provide stylish and effective sound hospitality, educational and office set 	control in a full range of commercial applications including retail, healthcare, ettings			
	 Combine top-rated acoustical perfore complement any décor 	mance with durability, high light reflectance and a range of textures to			
		- Many feature the <i>ClimaPlus</i> [™] Non-Sag Warranty			
		- Cast ceiling panels provide unparalleled strength and integral color to mask nicks and scratches for long service life

	Lencore [®] Spectra [®] Sound Masking				
	- Covers ambient noise in large spaces so potential distractions are less intrusive				
	- Enhances speech privacy in private offices by preventing conversations from being overheard outside				
	- Adds acoustical balance to exceptionally quiet environments				
	-Each unit is powered by 16/18 volts AC and includes a self-contained noise generator, audio amplifier, loudspeaker,				
	and power supply unit in an aluminum enclosure				
	- Supports an optional paging system				
	- Allows paging and masking volume to be adjusted independently, and additional central control capabilities				
	 Allows paging and masking volume 	to be aujusted independently, and additional central control capabilities			
	 Allows paging and masking volume are available 	to be adjusted independently, and additional central control capabilities			

Components

Walls and Partiti	ons
-------------------	-----

SHEETROCK[®] Brand Gypsum Panels

- Available in thicknesses of 1/4" to 3/4" for assembling interior partitions with one or more layers per side for effective sound control in any application
- Steel-framed resilient partition systems with sound attenuation fire blanket (SAFB) in the partition cavity can achieve up to 65 STC with multi-layer designs, up to 63 STC with double-layer designs, and up to 56 STC with single-layer designs
- Wood-framed resilient partition systems with SAFB can achieve up to 59 STC with double-layer designs and up to 50 STC with single-layer designs

SA933

- Have achieved up to 4-hr. fire-resistance ratings with 3/4" ULTRACODE® Core panels in steel-framed partition assemblies

Aesthetic Assemblies

For more information see the following brochures:

Moisture-Resistant Assemblies SA932 SHEETROCK Gypsum Panels Submittal Sheet WB1473

USG Area Separation Walls

- -Achieve up to 60 STC
- Offer 2-hr. and 3-hr. fire-resistance ratings; comply with fire-resistance requirements under evaluation reports of UL U336
- Weigh at least 50% less than masonry walls, allowing faster, easier installation

For more information see the following brochures:

Area Separation Wall Systems	Area Separation Wall Submittal Sheet
SA925	WB2129

SHEETROCK Shaft Wall Systems

- -Tested systems achieve up to 58 STC
- Have achieved up to 4-hr. fire-resistance ratings with multi-layer designs (UL U415)
- -Oscillation tested to 1 million cycles to ensure structural performance
- Feature panels with water-resistant facings and/or mold-resistant paper and a water-resistant core to help minimize the risk of moisture damage

For more information see the following brochures:

Shaft Wall Systems SA926 SHEETROCK Gypsum Liner Panels Submittal Sheet WB2278

Plaster Systems

- Veneer plaster partitions achieve up to 63 STC in steel-framed resilient systems and up to 52 STC in wood-framed resilient systems
- Have achieved 1- to 4-hr. fire-resistance ratings for veneer and conventional systems
- Can minimize or eliminate irregularities such as ridging, boarding and nail pops associated with standard drywall construction, plus lower lifecycle costs and greater sustainability
- Used in theaters and auditoriums to create reflective surfaces near the stage to reinforce sound

For more information see the following brochure:

Plaster Wall Systems SA920

SHEETROCK Acoustical Sealant

- Helps ensure that partition sound performance matches the promise of sound tests by sealing off spaces at partition perimeters and around cutouts
- Can increase the STC rating of a double-layer, steel-framed partition from 29 to 53 STC
- An integral part of high-performance USG partition designs for attenuation of low-frequency sound from machinery and music
- -Suitable for use at the perimeter of fire-rated wall assemblies

For more information see the following brochure:

SHEETROCK Acoustical Sealant Submittal Sheet J678

MICORE® Mineral Fiber Board

- A quality substrate or core for upholstered sound-absorbing wall panels, office dividers and baffles
- Available in thicknesses of 3/8" to 3/4", with 24-28 STC and .25-.35 NRC
- -Nearly 50% lighter than particle board for easy handling and lower freight rates
- Inorganic mineral fibers won't absorb moisture, preventing expansion and warping
- Class A flame spread ratings developed per ASTM E84; UL classification
- Provides very low VOC emissions, per ASTM D5116-97
- Meets requirements for classrooms, per Collaborative for High-Performance Schools (CHPS), Section 01350

For more information see the following brochures:

MICORE 300 Board Submittal Sheet

MICORE 160 Board Submittal Sheet IW944

Components

Floor/Ceiling Assemblies	Levelrock [®] Floor Underlayment				
	- Low-profile leveling gypsum concrete system increases IIC ratings by as much as 13 points when used with				
	LEVELROCK [™] SRB [™] sound reduction board or SRM-25 [™] sound reduction mat - Improves sound control in nominal wood-joist, engineered I-joist, open-web truss, and concrete floor systems - Provides 1- and 2-hr. fire-resistance ratings for wood-framed floor/ceiling assemblies, and 4-hr. ratings for precast concrete assemblies - Available in an unmatched range of compressive strengths from 2,500 to 8,000 psi For more information see the following brochures:				
	Floor Underlayment Systems SA305	High-Strength Flooring Solutions IG1503			
	SRM-25 Sound Reduction Mat				
	-Low 1/4" profile allows use of the full range of flooring finish materials including hardwood, ceramic tile, and marble				
	with smooth transitions between surfaces				
	- Elevated on small nodes so less than 5% of surface area makes direct contact with the subfloor				
	- Increases STC rating by 4-7 points and IIC rating by 8-13 points				
	For more information see the following brochure:				
	LEVELROCK SRM-25 Sound Reduction Mat Submittal Sheet IG1619				
	SRB Sound Reduction Board				
	- Smooth, coated finish resists abrasion and maintains tight tolerance				
	- Just 3/8" thick; allows flexibility in choosing flooring materials				
	- Increases STC rating by 2-3 points and IIC rating by 5-8 points				
	For more information see the following brochure:				
	LEVELROCK SRB Sound Reduction Board Submittal Sheet				
	IG1523				

Performance Testing

	Testing provide	es a measuren	nent of maxim	um performance potential		
	achieved under controlled laboratory conditions. The actual ability					
			•	nd in real-life applications,		
	however, depends on their design and the methods used to install them. Deviations from the detailing shown in this publication, substitution					
	of components	, or damage a	nd improper r	epair or maintenance could		
	severely reduce the acoustical performance of these installations.					
Testing Methods	All USG products and systems undergo exhaustive testing to ensure that they meet exacting standards. USG's products are Classified as to fire resistance and fire-hazard properties. As part of this protocol, Underwriters Laboratories (UL) periodically audits production of these materials to ensure compliance with necessary properties. UL is an independent, not-for-profit organization that has tested products for public safety for over a century. Products are manufactured and tested in accordance with recognized standards. ASTM International is one of the largest voluntary standards development organizations in the world, and is a trusted source for technical standards for materials, products, systems, and services.					
Testing Results	ASTM C423					
	Sound Absorption and Sound Absorption Coefficients by the Reverberation Room Method measures Noise Reduction					
	Coefficient (NRC). This rating represents the average of a given material's sound absorption coefficients at four					
	frequencies from 250 Hz to 2000 Hz.					
	ASTM E1414					
	Determination of Sound Transmission Class by the Two-Room Method measures Ceiling Attenuation Class (CAC), the					
	sound reduction in decibels provided between rooms with a shared ceiling and common plenum. This rating represents					
	the average of the sound attenuation at four frequencies from 250 Hz to 2000 Hz.					
Acoustical Ceilings	Panels	NRC	CAC	CAC with Lencore Sound Masking ^a

	Halcyon [™] <i>ClimaPlus</i>	.90	30	40		
	Mars [®] <i>ClimaPlus</i>	.70	35	45		

Performance Testing

ASTM E90

Standard Test Method for Laboratory Measurement of Airborne Sound Transmission Loss of Building Partitions and Elements measures Sound Transmission Class (STC), the acoustical isolation provided by a barrier material or partition assembly. This rating represents the average of the sound attenuation between two spaces at four frequencies from 250 Hz to 2000 Hz.

Notes

(a) LENCORE sound masking adds the equivalent of 10 points of CAC by increasing ambient background sound by 10 dB. (b) Includes SAFB in the partition cavity.

(c) Performance shown for perforated products.

ASTM E492

Standard Test Method for Laboratory Measurement of Impact Sound Transmission Through Floor-Ceiling Assemblies Using the Tapping Machine determines Impact Isolation Class (IIC), the ability of a floor/ceiling assembly to isolate noise from footsteps and other impact sources. This performance is tested using a tapping machine that impacts the floor of a "source" room and measuring the amount of sound that comes through the ceiling of a "receiving" room located directly below.

Good Design Practices

In most building design, the No. 1 acoustical goal is to specify wall partitions, ceiling systems and floor/ceiling assemblies that will minimize transmission of airborne and impact sound beyond their areas of origin. This performance can be achieved with a combination of materials, assembly designs and construction methods tested for acoustical performance on a variety of parameters. Here is an overview of design strategies for key components that can make spaces more pleasant, comfortable and productive.

Ceilings

Absorb Sound in Open Spaces

Select high-NRC ceiling panels for open areas to absorb a significant amount of the sound generated within these spaces. Acoustics are further improved with partitions having high STC values to help block sound and prevent transmission across large spaces.

Block Sound in Enclosed Spaces

Choose high-CAC ceiling panels for private offices, meeting rooms and other enclosed areas to block sound from traveling up into the plenum and out to adjacent spaces. This approach will reduce distractions for those outside and improve speech privacy for those within.

Cover Sound in All Areas

Sound masking covers noise that is not absorbed or blocked by introducing uniform, ambient, background sound into the space. Sound masking produces an electronic sound spectrum similar to that of softly blowing air; it is amplified through speakers above the suspended ceiling to unobtrusively raise the background sound level. Sound masking makes noise in open spaces less distracting, increases speech privacy in enclosed spaces and provides greater acoustical balance throughout.

Walls

Increase mass

As partition mass increases, sound waves lose more energy passing through the medium, reducing their ability to vibrate air on the other side. Relying on mass alone, however, poses limitations. Doubling the mass of a partition can reduce sound transmission by up to 5 dB. Thus, achieving a 60 dB reduction would require total mass of 320 pounds per square foot, the equivalent of approximately 3' of solid concrete, not a feasible solution for most building designs.

Enlarge air spaces

Isolating air space within a partition can increase STC performance. But like increasing mass, performance increases are limited. Doubling partition air space can reduce sound transmission by up to 5 dB, so achieving a 60 dB reduction would require an isolated air space 4' wide, hardly practical for most applications.

Add sound insulation

Adding a layer of fibrous sound-absorbing insulation material such as mineral wool into the partition cavity will dissipate sound by creating friction, which transforms a portion of sound wave energy into heat. However, sound attenuation blankets cannot completely counter the conductivity of the wood or steel studs in the framing assembly, which provide a path of least resistance for sound energy.

Decouple wall panels

Attaching the wall surface diaphragm (e.g. drywall panels) directly to framing members provides an uninterrupted path for sound travel. This route can be interrupted by mounting the surface diaphragm to resilient channels attached to the wall studs and placing sound insulation inside the partition cavity.

Seal flanking paths

Closing off gaps or penetrations in the wall assembly is critical to controlling noise. One of the most effective methods is to apply acoustical sealant at the intersection of the gypsum panel, floor system (wood or concrete), and the leg of the steel runner or wood sole plate; sealant should be applied at this location on both sides of the partition. A properly sealed wall assembly with one 5/8" gypsum panel on each side and a 1-1/2" thick sound attenuation blanket installed in the air cavity achieves an STC of 53. Without acoustical sealant, this assembly would produce an STC of only 29—a dramatic 45 percent reduction.

Increase isolation with steel studs

A single-layer partition with 5/8" gypsum panels and 3-5/8" stud achieves 40 STC with 25-ga. steel and 38 STC with 20-ga. steel. STC falls to 35 with a traditional 2' x 4' stud due to the greater stiffness of wood.

Floor/Ceiling Assemblies

Isolate sound

Whether constructed with joists, trusses or concrete slabs, floor systems can develop gaps or cracks, providing a flanking path for sound to travel between levels of a building. Even properly sealed assemblies can transmit noise from footsteps, falling objects, closing doors and other impacts. These acoustical problems can be significantly reduced with a flooring system that includes a layer of sound absorbing material topped with a poured cementitious underlayment. The poured underlayment finds and seals cracks and other sound channels, then hardens to form a solid barrier isolated from the structure below by the sound mat or board. This system can provide STC ratings as high as 66 and increase IIC by as much as 13 points, a significant improvement.

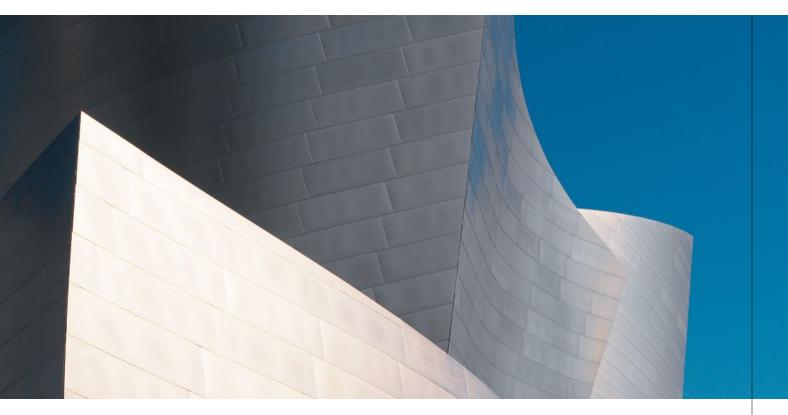

STC Guidelines

				STC

Note

(d) Current model building codes require a minimum STC (and IIC) separation of dwelling units. The 2003 International Building Code requires a minimum separation of 50 STC and 50 IIC for apartments, condominiums and townhouses. Local jurisdictions using the 2003 International Residential Code may require a minimum separation of 45 STC for townhouses.
